Dlk1/Pref-1 (delta like1/preadipocte factor-1) is an imprinted gene encoding a transmembrane protein that belongs to EGF-like repeats protein family. We have recently identified Dlk1/Pref-1 as negative regulator for differentiation of human mesenchymal stem cells into osteoblasts and adipocytes (Abdallah BM, et. al., JBMR, May,19(5):841-852, 2004). To further investigate the in vivo effect of Dlk1/Pref-1 on bone, we generated mice expressing high serum levels of FA1 (biological soluble form of Dlk1) using the hydrodynamic-based gene transfer procedure. Full length of mouse Pref-1 cDNA was subcloned under human ubiquitin promoter and rapidly injected via tail vein into BALB/cA male mice (16 weeks old, n =15) every 2 weeks over a period of 2 months. DNA, mRNA analysis, immunohistology and ELISA for FA1 were assayed to identify the expression of the transgene. Bone mass and structure were determined by PIXImus (Lunar^R) and micro-CT (Scanco^R) respectively. We could only localize the plasmid in the liver and no complications were detected due to transgene expression. Serum levels of FA1 in Dlk1 injected mice (Dlk1$^+$mice) was elevated by more than 15 folds compared to control saline injected mice (control) (198.0 ± 74.3 ng/ml vs 13.4 ± 1.1 ng/ml, $p<0.001$, respectively). Dlk1$^+$mice displayed lowered body weight and reduced total fat mass (13.5%, $p< 0.05$ and 17.8%, $p< 0.05$ respectively). Interestingly, Dlk1$^+$mice displayed (16.6 %, $p<0.005$) lowered total bone mineral density (BMD) compared to controls and BMD was negatively correlated with the circulating levels of FA1. Micro-CT analysis revealed significantly decreased micro-architectural parameters of trabecular bone in the distal femur and proximal tibia of the Dlk1$^+$mice compared to controls (see table).

Naked DNA delivery by hydrodynamic injection is a simple and safe procedure for evaluating the effect of genes on bone phenotype in vivo. Our data suggest that Dlk1/Pref-1 is a novel regulator of bone mass.

Evaluation of Quality of Life Criteria According to the Severity of Vertebral Osteoporosis: The Act'Os Study. J. Fechtenbaum[1], C. Cropet*[2], R. Said*[1], S. Kolta[1], O. Madi*[3], P. Orcel[4], C. Roux[1]. [1]Rheumatology, Cochin hospital, Paris, France, [2]MAPI - CRO, Lyon, France, [3]Aventis, Paris, France, [4]Rheumatology, Lariboisière hospital, Paris, France.

Introduction: osteoporotic vertebral fractures are responsible for back pain and for the reduction of mobility and functions. These different factors are determining of quality of life, and a specific questionnaire concerning osteoporosis has been validated (QUALEFFO).

Aim of the study: to evaluate de quality of life of women having vertebral fractures according to the severity of the disease.

Patients and methods: 629 menopausal osteoporotic patients having at least one vertebral fracture according to the investigator have been included.The QUALEFFO 41 questionnaire that covers 5 aspects (pain, physical activity, social activity, perception of general health and mental health) and has a total score, has been used in the study. Spine X-rays have been done in standardized conditions and analyzed centrally. Fracture analysis was done according to the semi-quantitative method (in 4 grades).

Results: analysis was done on 588 patients (in 41 patients, diagnosis was not possible due to the presence of some non legible or missing vertebrae with the remaining vertebrae considered as non fractured). The diagnosis of fractured patients was confirmed in 548 cases. Patients having at least one vertebral fracture had QUALEFFO scores greater than other patients (i.e. a worse quality of life) in two aspects: physical activity ($p = 0.055$) and social activity ($p = 0.027$). The scores were worse with increasing number of fractures for 3 aspects: physical activity ($p = 0.001$), social activity ($p = 0.002$) and total score ($p = 0.027$). The same results were obtained when the severity of the disease was defined as the sum of the grades of fractures or by an index calculated by the sum of the grades and the number of fractures.

The variation of pain and mental health scores was never significant.

Conclusion: the quality of life evaluated by a specific questionnaire is altered in menopausal patients having vertebral osteoporotic fractures compared to patients of the same age without fracture. A pain score was not significantly different in this evaluation. The quality of life is significantly worse with the severity of the disease. This is important to be considered in order to start treating women as soon as the first fracture is diagnosed.

Collagen Bundle Distribution along the Radial Direction of Human Secondary Osteons. M. Ascenzi, A. Lomovtsev*. Orthopaedic Surgery, UCLA, Los Angeles, CA, USA.

Collagen orientation distribution within so-called bright and extinct lamellae, secondary osteons' building blocks, is observed along the previously unexplored osteon radial direction.

70±3µm thick cross-sections were cut from femoral mid-shafts, aged 19-40, pathology-free. 22 fully-calcified lamellar specimens, 11 per type identified as bright or extinct on transverse section under circularly polarized light, were then isolated and gently flattened (Ascenzi M-G et al., J. Struct. Biol. 141: 22, 2003). A Leica TCS-SP confocal microscope (krypton laser, 63x Planapochromat lens) scanned wet specimens each 0.5µm through thickness. Natural fluorescence shows as green pseudo-color. Images were observed at 1575x and 3000x magnification with Image-I. Collagen bundles appear as bright elements on dark background of mucopolysaccharides and glycoproteins. Long portions of canaliculae appear to follow local collagen orientation. Domains were identified as 3D regions whose collagen bundle orientation varies up to ±7.5° within and across adjacent scans.

Collagen orientation within domain was measured relative to original osteon axis.
Bright lamellae show characteristic collagen distribution somewhat transverse to the original osteon axis within the middle thickness (Fig. a) becoming gradually oblique towards approximately ±45º with respect to the osteon axis. Extinct lamellae show characteristic collagen distribution whose orientation makes up to approximately ±22.5º angle relative to original osteon longitudinal axis (Fig. b).
Results conform to findings by different methods (Ascenzi M-G et al., J. Struct. Biol. 141: 22, 2003), mechanical significance of bone shaft collagen orientations (Ascenzi A, J. Biomech. Eng. 110: 357, 1988), and skeletal adaptation to mechanical function (Frost, Calc. Tissue Int. 45: 145, 1987). Results are integrated in high-accuracy hierarchical bone models (Ascenzi M-G, Scanning, 26: 25, 2004) which use the super-computer capability to test hip prostheses virtually.

Localisation of Beta Catenin in Regenerating Bone Supports a Role for the Canonical Wnt Pathway in Regulating Progenitor Cell Function, Intramembranous Ossification and an Interrelationship with PTHrP. J. G. G. Mount*, S. P. Allen*, M. Muzylak*, T. Althnaian, J. S. Price. Basic Sciences, Royal veterinary college, London, United Kingdom.

Mutations in Lrp5 reveal a critical role for the Wnt pathway in the acquisition of bone mass and Lrp5 is known to signal through β-catenin, a component of the canonical Wnt pathway that regulates osteoblast differentiation. In this study we used the deer antler to explore the hypothesis that the Wnt signalling pathway will be recapitulated when bone regenerates in an adult. Antlers elongate at an unparalleled rate by an endochondral process from an extensive 'growth zone' of multi-potential progenitors and increase in diameter by intamembranous ossification. Immunocytochemistry was used to localise the dephosphorylated, activated form of β-catenin (^{a}βCAT) in antler tissues and this was related to the localisation of PTHrP, which is widely expressed in antlers and is known to interact with the Wnt pathway in some developing systems. Compared to PTHrP, ^{a}βCAT staining had a restricted localisation; staining was associated with proliferating cells in hair follicles and in sebaceous glands but no immunoreactivity was seen in the epidermis, dermis, perichondrium, in hypertrophic chondrocytes or in osteoblasts at sites of endochondral bone formation. However, ^{a}βCAT was localised in cellular periosteum and in osteoblasts in intramembranous bone. Of particular note was intense ^{a}βCAT staining in progenitor cells in the antler's growth zone; these cells are not highly differentiated and have a high rate of division (21.7±5.5% of cells) and apoptosis (63.9±9.2% cells). Con-focal microscopy revealed that PTHrP and ^{a}βCAT co-localise in these progenitor cells. To identify the functional role of the Wnt pathway, cells from the growth zone were cultured with LiCl, which activates β-CAT, and EGCG, which inhibits Tcf transcription. LiCl inhibited ($p<0.001$) whereas EGCG increased alkaline phosphatase activity ($p<0.05$). LiCl and PTHrP had no effect on cell growth, whereas both EGCG and PTHrP induced apoptosis. However, Western blot analysis showed that PTHrP did not regulate ^{a}βCAT expression.
In conclusion, this study provides evidence that the canonical Wnt signalling pathway regulates progenitor cell differentiation and survival in regenerating bone. Results also suggest that there is an interaction between the PTHrP and Wnt pathways in controlling progenitor cell function, although PTHrP does not appear to signal through β-catenin. This study also shows that β-catenin's role in regulating osteoblast differentiation may be site specific.

Human Osteoblast Proteomics: Implications for Drug Discovery. K. J. MacLeod*[1], K. Shopbell*[1], B. L. Allen*[2], M. R. Pisano*[2], M. W. Long[1]. [1]Velcura Therapeutics, Inc., Ann Arbor, MI, USA, [2]Proteomic Research Services, Ann Arbor, MI, USA.

We hypothesized that a proteomics drug discovery platform utilizing primary human osteoblasts would produce physiologically relevant information important to the therapy of bone diseases such as osteoporosis. To develop such a platform, we postulated that 2-dimensional gel electrophoresis (2-DGE) analyses of osteoblast protein expression, averaged over a number of bone-cell donors, would identify specific protein expression patterns (i.e., protein maps). We utilized osteogenic growth-factors (OGFs) to model whether human osteoblast protein maps would be indicative of osteoblast responsiveness. Such maps are representative of induced "cellular activation states" and potentially useful in the identification of drug candidates that stimulate bone formation. We report that protein mapping using primary human osteoblasts distinguishes specific protein patterns for individual OGFs, or synergistic combinations thereof. The 2-D gels for TGF-β1 (100 pM), BMP2 (50 pM), or PTH (200 pM; cells cultured in serum-free, chemically defined media) were compared to control gels to identify differentially modulated proteins. Composite 2-DGE profiles, averaged across all donors (n = 8), were then generated showing differentially modulated protein patterns, or maps, that are unique to the effects of each cytokine. We also analyzed human osteoblasts nuclear phosphorylation and identified specific patterns in which several new phosphoproteins appear in the nucleus, reflecting either newly phosphorylated proteins, or phosphoproteins translocated to the nucleus. Finally, we utilized mass spectrometry (MALDI-TOF or LC/MS/MS) to identify 110 proteins from the OGF-composite protein maps. These include proteins relevant to bone formation such as annexin, and type I collagen, as well as several proteins (alpha tubulin, vimentin, actin) indicative of cytoskeletal rearrangement in differentiating osteoblasts. As well, concordant modulation of these proteins is seen among sub-cellular fractions. For example, we detected up-regulation of annexin V in membrane fractions and a coordinate increase in the cytoplasm of a calcium binding protein known to be critical for annexin-membrane association. We conclude that these results constitute an important proof of concept that proteomic analysis can distinguish specific patterns of responsive proteins in human osteoblasts. The use of such "cellular activation state" maps in drug discovery has important implications in developing bone disease therapies.

The Effect of Rosiglitazone, an Anti-diabetic PPAR-γ Agonist, on Bone Mass and Architecture in Growing, Adult, and Aged Mice. B. Lecka-Czernik[1], O. P. Lazarenko*[1], S. O. Rzonca*[1], K. Teng*[1], L. J. Suva[2]. [1]Geriatrics, UAMS, Little Rock, AR, USA, [2]Orthopedic Surgery, UAMS, Little Rock, AR, USA.

Rosiglitazone represents an oral anti-diabetic agent that is FDA-approved for the treatment of type 2 diabetes; a disease which affects individuals of all ages. Mechanistically, rosiglitazone sensitizes cells to insulin *via* the specific activation of PPAR-γ. PPAR-γ activated with rosiglitazone acts as a dominant inhibitor of osteoblast differentiation and phenotype. *In vivo,* PPAR-γ activation induces bone loss whereas PPAR-γ insufficiency leads to increased bone formation. Since bone and bone progenitor status changes with normal aging, we investigated the effect of rosiglitazone on bone of young, adult and aged mice. C57BL/6 mice (young - 1 mo, adult - 6 mo, aged - 24 mo old) were fed a rosiglitazone (young: 15 μg/g body weight/day; adult and aged: 20 μg/g body weight/day) supplemented diet for 8 weeks. Bone mineral density (BMD) and bone mineral content (BMC) were measured at the beginning and end of the experiment, and the tibiae were analyzed by microCT and histomorphometry. Administration of rosiglitazone to adult and aged mice produced a significant decrease in global BMD and BMC, with the expected changes in bone microarchitecture. Histomorphometric analysis revealed that rosiglitazone administration to adult mice simultaneously decreased osteoblast number and activity by 3-fold and increased osteoclast number and their activity by 4-fold. Surprisingly, in aged animals rosiglitazone did not appear to affect any osteoblast parameters but increased osteoclast parameters similarly as in adults. These changes were accompanied by increased serum levels of C-telopeptide. In contrast, rosiglitazone administration to 1-mo old growing mice did not affect global BMD, but it decreased global BMC, however serum markers of bone formation and resorption remained unchanged. These results demonstrate that the skeletal response to rosiglitazone differs with aging and may reflect the status of the osteoblast and osteoclast progenitors targeted by this drug. If confirmed in humans these data suggest that anti-diabetic rosiglitazone therapy should be accompanied by therapies specifically designed for patient age that would target either the prevention of bone resorption or the stimulation of bone formation, or both.

Delayed Fracture Healing in iNOS Knockout Mice. F. F. Safadi[1], T. A. Freeman*[2], J. L. Castaneda*[1], I. Arango*[1], S. N. Popoff[1], J. M. Daly*[2], P. P. Stapleton*[3]. [1]Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, [2]Microbiology and Immunology, Temple University School of Medicine, Philadelphia, PA, USA, [3]Surgery, Temple University School of Medicine, Philadelphia, PA, USA.

Inducible nitric oxide synthase (iNOS) is expressed in osteoblasts and is detected in the initial stages of fracture healing with expression localized to cells within the intra-membranous region of the fracture callus. In this study, we examined fracture healing in iNOS knockout (KO) and wild type (WT) mice with injury consisting of an open femur fracture. iNOS KO and WT mice (n=10/group) were subjected to femur fracture under anesthesia. Histological and x-ray analyses as well as expression of osteoblast-related genes, such as osteoactivin, type I collagen and osteocalcin were performed using RT-PCR analysis. Histological analysis of normal, non-fractured femurs from WT and iNOS mice showed an increase in trabecular bone volume in iNOS KO compared with WT littermates. At one and three weeks-post fracture, x-ray analysis showed a marked delay in fracture callus formation in iNOS KO compared with WT mice. These results were confirmed by histological analysis. In non-fractured femurs, osteoactivin, type I collagen and osteocalcin were over-expressed in iNOS KO compared with WT mice. In fractured femurs, osteoactivin, type I collagen, and osteocalcin expression were highly up-regulated in WT but not in iNOS KO mice. These data suggest that increased bone formation occurs after fracture in iNOS KO mice and furthermore, that iNOS regulates osteoblast development and function. These data suggest that iNOS might play an important role in fracture healing and mediate ostoeblast differentiation and function.

Impaired Cartilage Regeneration with Aging in the MRL Mouse Regeneration Model: Evidence for Blunted Growth Factor Expression. G. L. Masinde*, S. Mohan, H. Klamut*, M. Covarubias*, D. J. Baylink. Mdc, J.L. Pettis VAMC, Loma Linda, CA, USA.

The MRL strain of mouse has the unique capacity to regenerate completely an earhole punch. Because cartilage is a major component in the ear tissue, this model provides a means to characterize the molecular mechanisms involved in cartilage regeneration. We sought to test the hypothesis that during aging, the healing of an earhole punch, even in the MRL mouse, would decline. A 2 mm through and through hole was punched in the ear of 14 week and 1 year old mice and the rate of cartilage regeneration measured by the extent of ear healing as a function of time (up to 28 days) after ear punch. The rate of cartilage regeneration was 15% per week in the 1 year old MRL mouse compared to 23% per week in the 14 week old MRL mouse ($P<0.01$). To identify the molecular mechanism that contribute to impaired cartilage regeneration in the old mice compared to the young MRL mice, we performed microarray analysis of over 5,000 genes using RNA extracted from healing ear tissue at 4 hours (inflammatory stage), 14 days (proliferation stage) and 28 days (remodeling stage). Microarray analysis was performed using RNA from three replicate pools (RNA pooled from 3-5 mice for each pool) and data analyzed using GeneSpring software. We found that 318, 356 and 252 numbers of genes were differentially expressed in the ear tissue of 14 week old mice compared to 1 year old mice up to 28 days respectively. Of 30 ontological gene categories, the largest differences in gene expression between the young and old MRL mice were in cell growth and maintenance, signal transduction and inflammation for each category ($P<0.001$)(see table). Conclusions: 1) The impairment of healing in the older MRL mouse is associated with down regulation of several growth factor genes.

Growth factors upregulated in the young MRL mouse as compared to 1 year old MRL mouse

Histological Evaluation of a Calcium Sulfate-Carboxymethylcellulose Bone Graft Binder in a Critical Size Defect Model. M. A. Reynolds[1], J. D. Kassolis*[1], M. E. Aichelmann-Reidy*[1], H. S. Prasad*[2], M. D. Rohrer*[2]. [1]Periodontics, University of Maryland, Baltimore, MD, USA, [2]Oral Pathology, University of Minnesota, Minneapolis, MN, USA.

Carboxymethylcellulose (CMC) has been recently shown to enhance the handling properties medical grade calcium sulfate (CS) when used as a binder for particulate bone grafts. Few controlled studies, however, have examined the potential influence of CMC on bone regeneration. The purpose of this study, therefore, was to examine the osseous healing of critical size calvarial defects in rats grafted with demineralized bone allograft in combination with a CS:CMC (9:1 wt.) binder. Using a paired design, two separate 5 mm critical size defects were created using a trephine in the calvarium of 24 Wistar rats (350 g). Defects in each animal were randomly assigned to treatment with rat demineralized bone matrix (DBM) in combination with CS or CS:CMC binder, together with a CS barrier. The ostoinductive activity of the DBM was verified using a nude mouse model. Six animals each were sacrificed at 7, 14, 21 and 28 days. Calvarial specimens were dehydrated, infiltrated, and embedded in resin for undecalcified sectioning, staining, and blinded histomorphometric analysis using computer assisted image analysis. Statistical analysis was made using an analysis of variance. Histological findings consistent with a brisk cellular response were observed in essentially all specimens, with all defects demonstrating significant new bone formation, often in close apposition to recalcifying DBM. Evidence of inflammatory wound healing was evident in specimens, consistent with the post-surgical period; however, the lymphocytic and plasmacytic response was minimal. At 28 days post-grafting, differences between defects (CS and CS:CMC, respectively) were insignificant with respect to the proportion (%) of new bone (31.7 ± 9.5 versus 33.7 ± 12.9), fibrous tissue/marrow (54.2 ± 8.3 versus 53.0 ± 10.8), and residual DBM particles (8.3 ± 6.8 versus 10.1 ± 6.3). Comparable levels of residual binder were found in the CS and CS:CMC treated defects at 28 days (5.5 ± 4.6 versus 3.7 ± 3.5, respectively; $p \geq 0.05$). The results of this critical size defect model indicate that CMC and CS, when combined with particulate DBM graft, support osseous healing similar to that obtained with CS and allograft alone.

Role Of Architecture And Collagen Cross-linking on Trabecular Bone Mechanical Properties. T. M. Keaveny[1], E. K. Wong*[1], S. M. Daugherty*[1], S. Majumdar*[2], A. Burghardt*[2], N. Sakkee*[3], F. van der Ham*[3], J. deGroot*[3]. [1]Mechenical Engineering, University of California at Berkeley, Berkeley, CA, USA, [2]Radiology, University of California at San Francisco, San Francisco, CA, USA, [3]Gaubius Laboratory, TNO Hospital, Leiden, Netherlands.

While bone density plays a dominant role in the strength and stiffness properties of trabecular bone, it is widely believed that trabecular "bone quality" _ such as measures of cross-linking and architecture _ may also be an important aspect of bone integrity. The goal of this study was report on the combined role of architecture and collagen cross-linking, including non-enzymatic glycation, on the mechanical properties of aged human vertebral trabecular bone. Twenty-nine cylindrical specimens from the thoracolumbar spine were obtained from 29 radiographically normal cadaver spines (age 54-94; mean ± SD = 75.4 ± 11.7; 16F, 13 M). Specimens were imaged using micro-computed tomography and from the architecture was quantified. Mechanical tests were used to measure tensile strength. After testing, sections of the specimen were removed and both enzymatic and non-enzymatic cross-links were measured using reversed-phase HPLC. Results indicated that in terms of strength and stiffness, volume fraction dominated the behavior, architecture had some independent effects, and cross-linking had no effects. Multiple regression on ultimate strength showed effects of BV/TV, Tb.Th.SD, Conn-Dens, and DA, in that order of importance (adjusted R2=0.90, n=29). Regarding ultimate strain, only Tb.Th and Tb.Th.SD had any effect ($p<0.008$ both cases), and were negatively correlated with ultimate strain. While collagen cross-linking had no effect of any of these mechanical properties, it did have an effect on yield strain: Hyl was positively correlated with yield strain ($r=0.45$, $p=0.025$) whereas pentosidine was negatively correlated ($r=-0.44$, $p=0.027$). None of the collagen parameters were correlated with age. We conclude that while collagen cross-linking may have subtle effects on the mechanical behavior of trabecular bone, vertebral bone strength and stiffness are dominated by bone volume fraction and architecture.

Measurement of the Oxemic Status of the Intervertebral Disc Using a 2-Nitroimidizole Derivative. D. C. Lee*[1], S. M. Evans*[2], C. J. Koch*[2], I. M. Shapiro[1], T. J. Albert*[1], C. S. Adams[1]. [1]Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA, [2]Radiation Oncology, University of Pennsylvania, Philadelphia, PA, USA.

Previous work suggests that cells of the intervertebral disc have a limited vascular supply. As a result, it has been assumed that the pO_2 in the nucleus pulposus is low and the cells are in a hypoxic state. To test the hypothesis that the cells are hypoxic, we utilized a non-invasive technique to monitor the disc's oxemic status. Eight-week old (200 g) rats were injected with EF5, a 2-nitroimidazole derivative. This agent is metabolized by oxygen-sensitive nitroreductases that cleave EF5; these adducts can then be detected in tissues using monoclonal antibody techniques. We assayed the cleaved adducts by immunohistochemistry in both longitudinal and transverse sections of lumbar intervertebral discs. In addition, we used HPLC to measure both metabolized and unmetabolized drug in tissue extracts. We noted that there was a low level of EF5 staining in the nucleus pulposus suggesting that the pO_2 was insufficient to inhibit nitroreductase activity. Pharmacological distribution of the drug was similar to that of glucose and was approximately 50% of the serum concentration. As the level of drug binding to the nucleus pulposus was low the results suggested that there was minimal nitroreductase activity. Thus, to assess enzyme activity we artificially inducing hypoxia in vivo. Accordingly, discs were collected from a hypoxic animal following injection of EF5 and the oxemic status again determined. Since cells in these discs bound and metabolized EF5, it was clear that this enzyme system was active in the nucleus pulposus. This finding confirms the pharmacological analyses indicated above and indicates that the cells of the intervertebral disc contain an active nitroreductase system that metabolizes EF5. Since there was minimal EF5 binding in vivo, it is concluded that while the vascular supply is limited, the cells are adapted to a low pO_2 and do not exhibit signs of hypoxia.

Hyperparathyroidism Secondary to Vitamin D Depletion Stimulates Phex Expression in Rat Tibiae Independently of Serum Phosphate Concentrations. N. Dion[1], G. Mailhot*[1], M. Gascon-Barré[1], V. Lascau-Coman*[1], A. C. Karaplis[2], L. G. Ste-Marie[1]. [1]Hôpital Saint-Luc, CHUM Research Centre, Université de Montréal, Montréal, PQ, Canada, [2]Department of Medicine, McGill University, Montréal, PQ, Canada.

Mutations of the PHEX/Phex gene (phosphate-regulating gene with homologies to endopeptidases on the X-chromosome) in humans and mice are responsible for X-linked hypophosphatemic rickets, a renal phosphate-wasting disorder associated with defective bone mineralization. Recently, H.S. Tenenhouse's group showed that Phex expression in bone obtained from rats with chronic renal insufficiency is positively correlated with serum parathyroid hormone (PTH) levels (Brewer AJ et al., Am J Renal Physiol 286:F739-F748, 2004). Previously, our group used a non-rachitogenic rat model [low calcium (Ca)-vitamin D (D) depleted (Ca-D-) diet] to study bone mineralization and endochondral ossification defects. These rats had high serum parathyroid hormone (HPTH) concentration secondary to hypocalcemia and D depletion with increased serum levels and urine excretion phosphate (P). To better dissect the relationship between Phex expression and serum PTH, Ca and P, Ca-D- rats were repleted for 14 days with diets presenting various Ca/P ratios. Five groups were studied with Ca/P ratios of: 1.11/1 (Ca-D-); 4/1.5 (P+); 4/3 (P++); 2.25/1 (Ca+) and the same 2.25/1 ratio but repleted with D (Ca+D+). Rats paired for age and fed a regular rat chow diet served as controls. Compared to Ca-D-, P+ and P++ remained HPTH and hypocalcemic but normalized their serum P. However, Ca+ normalized both their serum Ca and P but remained HPTH. Ca+D+ normalized their serum Ca, P and PTH. Immunohistochemistry technique (IHC) was used to localize Phex protein on proximal tibiae sections. In all groups with HPTH, Phex was highly expressed in fibrosis surrounding trabecular bone at the primary and secondary spongiosa. Strong staining for Phex was also detected in osteoblasts, osteocytes and in some bone marrow cells. In Ca+D+, expression of Phex was decreased to a level similar to that of the controls. It was restricted to some osteoblasts, lining cells, osteocytes and few bone marrow cells. No major between-group difference was observed for the IHC of NEP which belongs to the same metallopeptidase family as Phex. Taken together, these results support the hypothesis that PTH or/and D is/are involved in the regulation of Phex expression in bone independently of serum phosphate concentrations. At present, the precise functions of Phex are not known and its potential role as an enzyme controlling the local action of PTH in bone or of still yet other unidentified anabolic factor(s) will require additional investigations.

Synergistic Catabolic Effects of TNFα and RANKL in Articular Chondrocytes. L. Ma*[1], P. Li*[1], E. P. Paschalis*[2], A. L. Boskey[2], R. J. O'Keefe[1], E. M. Schwarz[1], H. Drissi[1]. [1]Orthopeadics, University of Rochester, Rochester, NY, USA, [2]The Hospital for Special Surgery, New York, NY, USA.

Extensive research on RANK-RANKL in inflammatory arthritis has clearly defined its critical role in erosive pathology and its lack of involvement in inflammation. However, the role of RANK signaling in osteoclast-independent cartilage catabolism remains controversial base on several studies, which showed that the articular surface of inflamed joints are protected from degradation and proteoglycan loss as a result of RANK blockade. Here we tested the hypothesis that TNF and RANK signals in articular chondrocytes synergize to exacerbate cartilage catabolism. First we performed immunohistochemistry on surgically retrieved tissues to formally demonstrate that RANK expression is up-regulated in chondrocytes at sites of articular cartilage erosion, suggesting a potential role in catabolism. Next, we performed histomorphometry on toluidine blue stained knee sections from wild-type, TNF-transgenic mice (TNF-Tg), TNF-Tg treated with RANK:Fc and TNF-Tg x RANK-/- mice. The results showed that both biologic and genetic disruption of RANK signaling completely prevents proteoglycan loss in TNF-induced arthritis. We further quantified this chondroprotective effect in mice with collagen induced arthritis treated with placebo or RANK:Fc. Infrared microscopy showed that RANK:Fc sustained the [pyr/dHLNL] and [proteoglycan/collagen] ratios in articular cartilage. To investigate the downstream mechanisms of these effects, we compared the gene expression profiles of primary murine articular chondrocytes before and after treatment with TNFα or RANKL alone or in combination. Microarray analysis showed that of all the MMPs and TIMPs, MMP3 and MMP13 are significantly induced, and TIMP3 expression is dramatically decreased, by TNFα in comparison to untreated controls. While RANKL alone had no effects, its addition significantly enhanced the TNFα effects. Validation real time RT-PCR studies confirmed that RANKL alone has no effects, but synergies with TNFα to potently induce MMP3, 13 expression and TIMP3 down regulation. Taken together, our results indicate that TNFα and RANKL have a synergistic effect on articular cartilage catabolism and provide a novel explanation for the chondroprotective effects of RANK blockade in inflammatory arthritis.

Inhibition of Osteoblastic Matrix Metalloproteinases (MMPs) Positively Affects Anabolic Action of Parathyroid Hormone (PTH) In Vivo. V. Geoffroy*, D. Merciris*, N. Legoupil*, C. Marty*, M. C. de Vernejoul. Hôpital Lariboisière, INSERM U606, Paris Cedex 10, France.

Our aim was to evaluate whether inhibition of osteoblastic MMPs can affect the anabolic action of PTH using transgenic mice over expressing the TIMP-1 (tissue inhibitor of MMPs) specifically in osteoblastic cells. We have shown previously that these mice present an increase in bone mineral density and bone mass resulting from an overall decreased bone turnover reminiscent of the changes induced by pharmaceutical agents such as bisphosphonates. In this study, 10-week-old wild-type (WT) and transgenic (TG) females were treated with PTH at 40 µg/kg/day for 1.5 months. DEXA analysis was performed before and after treatment and histomorphometric and molecular analysis at the end of the experiment.

The densitometric analysis showed an increase in bone mineral density (BMD) and bone mineral content (BMC) in PTH-treated animals at the femur and the vertebrae. Only measurements of BMD and BMC at the femurs showed a significative positive interaction between genotype and treatment.

The histomorphometric analysis indicated that anabolic PTH treatment induced an increase of bone volume and trabecular thickness (Tr.Th.) in both genotypes. Only Tr. Th. was further increased in TG compared to WT mice. WT mice presented an increase in mineralizing surfaces and bone formation rate under PTH treatment. In contrast, matrix apposition rate (MAR) appears to be increased only in TG mice. Resorption parameters in cancellous bone (osteoclastic surfaces and trabecular separation) remain unchanged under PTH treatment. Interestingly, an increase of cortical thickness due to the expansion of the external perimeter was observed in TG mice. We observed an increase in intracortical osteoclastic surfaces and cortical porosity that was identical in WT and TG mice.

Molecular analysis performed on long bones indicated that expression of MMP-13, collagene type I and TRAP was increased by the PTH treatment. Only osteocalcin expression was shown to be affected in the WT bones but not in TG bones. This result corroborate the increase in MS and BFR observed only in WT mice. In conclusion, the interaction between transgene and treatment observed when measuring BMD and BMC at cortical sites is in accordance with the measurement of cortical thickness by histomorphometry. Furthermore, we showed that treatment of TG mice with PTH leads to an increase in MAR and therefore in trabecular thickness without affecting osteoblastic number as illustrated by osteocalcin expression. Our data suggest that in vivo inhibition of MMPs that induces a low bone turnover can potentiate the anabolic effect of low dose of PTH both at trabecular and cortical sites.

Extracellular Matrix Remodeling by MMP13 in the Developing Mouse Bone. D. J. Behonick*, D. Stickens*, Z. Werb*. Anatomy, University of California, San Francisco, San Francisco, CA, USA.

This study asked whether extracellular matrix (ECM) remodeling by the protease MMP13 (collagenase-3) is criticial for endochondral ossification. Generation of transgenic mice, including MMP13-null and cell type-specific MMP13-null animals, and histological and cellular analyses of tissues from these animals identified two significant yet transient phenotypes in the developing endochondral bones. MMP13-null mice show reduced type II collagen cleavage and an expanded hypertrophic cartilage zone, as well as reduced type I collagen cleavage and increased trabecular bone density. These phenotypes are ameliorated by as yet unidentified processes after 5 weeks of age. Preliminary studies in cell-type specific null mice generated by Cre/Lox-mediated gene ablation suggest that MMP13 - which is expressed and secreted by hypertrophic chondrocytes in the growth plate and osteoblasts in the trabecular bone - acts locally, and create new opportunities for further investigation of this vital remodeling process during endochondral ossification. We conclude that MMP13 activity is critical for proper endochondral ossification; however, it is also clear that other ECM remodeling enzymes (possibly other MMPs) are active in this process.

Pretreatment with Cathepsin K Inhibitor but not Alendronate Demonstrated Further Increases in Bone Mineral Density in Ovariectomized Rats Followed by Add-on Treatment with Parathyroid Hormone. Y. Ochi*, N. Kawada*, H. Yamada*, H. Mori*, R. Kayasuga*, M. Tanaka*, A. Hatayama*, K. Ohmoto*, K. Kawabata*. Minase Research Institute, ONO Pharmaceutical Co., Ltd., Osaka, Japan.

Cathepsin K, a cystein protease highly expressed in osteoclasts, is capable of degrading bone type I collagen. Recently, cathepsin K inhibitors have drawn much attention as novel therapeutic agents for treatment of impaired bone turnover including osteoporosis. However, the therapeutic potential of these inhibitors has not been fully elucidated, especially when used in combination with other treatments such as anabolic parathyroid hormone (PTH). A thorough evaluation of combination treatments for osteoporosis is essential, since bisphosphonates fail to demonstrate additive or synergistic effects with PTH in human clinical trials (Path study). In this study, we examined the effects of an α-amino acid derivative of cathepsin K inhibitor, given alone or in combination with PTH, on bone mineral density (BMD) in ovariectomized rats, and compared them to those of alendronate, a powerful bone anti-resorptive bisphosphonate, also given alone or in combination with PTH. In vitro studies showed that this compound potently inhibited human and rat cathepsin K with Ki values of 1.1 and 3.1 nM, respectively. In addition, this compound concentration-dependently inhibited the release of C-terminal telopeptide of type I collagen (CTX) from bovine bone slices incubated with rabbit bone cells. In ovariectomized rat model of osteoporosis, this inhibitor, given orally for 3 months, increased BMD, in a way dependent on its inhibition of CTX release, without affecting the level of osteocalcin. Furthermore, when ovariectomized rats were orally treated with this inhibitor for 2 month followed by a combination with PTH for 1 month, a further increase in BMD was observed. This increase in BMD was higher than that induced by the inhibitor or PTH alone, and most importantly, was not observed following combination therapy with alendronate and PTH. These results suggest that cathepsin K inhibitors have therapeutic potential not only by themselves alone but also in combination with anabolic agents in osteoporosis, and that the beneficial effects of this combination therapy are not reproducible with a combination of alendronate and PTH.

Maspin, a Serine Protease Inhibitor, Regulates the Bone Matrix Maturation by Enhancing the Accumulation of Latent TGF-beta. R. Tokuyama*, K. Satomura, E. Maeda*, E. Kitaoka*, K. Kume*, M. Nagayama*. Department of Oral and Maxillofacial Surgery, Graduate School of Health Biosciences, The University of Tokushima, Tokushima, Japan.

Maspin, a 42-kDa serine protease inhibitor originally isolated from mammary carcinomas, has been considered to have tumor suppressive and antiangiogenic activities. Despite of the huge amount of data concerning the expression pattern of maspin and its relevance to the biological properties of human breast and prostate cancer cells, little is known on maspin expression in skeletal tissues. This study was performed to elucidate a possible role of maspin in bone formation. First, the expression of maspin in endochondral ossification of tibiae of 1-week-old rats was immunohistochemically investigated. Gene and protein expression of maspin in ROS 17/2.8 and rat primary osteoblasts isolated from femora of 4-week-old rats were analyzed by reverse transcription-polymerase chain reaction (RT-PCR), immunocytochemistry and Western blotting. Besides, to elucidate the biological role of maspin in bone matrix formation and maturation in the cultures of ROS 17/2.8, the gene expression of bone matrix proteins such as type I collagen, bone sialoprotein and osteocalcin was examined by RT-PCR in the presence or absence of anti-maspin antibody. TGF-beta content in extracellular matrix was also examined by ELISA in the same culture condition. Moreover, the effect of maspin on the TGF-beta accumulation into extracellular matrix and serine protease activity of ROS 17/2.8 was analyzed by transfecting maspin expression vector or by repressing maspin mRNA using gene silencing methods with siRNA or antisense RNA. As a result, immunohistochemistry revealed that active osteoblasts in primary spongiosa beneath the growth plate of tibiae strongly expressed maspin. Moreover, RT-PCR, immunocytochemistry and Western blotting showed that ROS 17/2.8 expressed maspin in mRNA and protein levels. In addition, latent TGF-beta content in extracellular matrix decreased in the presence of anti-maspin antibody and under the condition in which maspin mRNA was repressed. In contrast, latent TGF-beta content in extracellular matrix was noted to increase in the culture of ROS 17/2.8 which overexpressed maspin. Moreover, serine protease activity decreased in ROS 17/2.8 which overexpressed maspin, while the activity increased in ROS 17/2.8 in which maspin mRNA expression was repressed. These findings suggest that maspin expressed in active osteoblasts was considered to play an important physiological role in bone matrix maturation, particularly in the accumulation of latent TGF-beta into the extracellular matrix.

Endothelin-1 Promotes Extracellular Matrix Degradation via Matrix Metalloprotease Induction in Human Osteosarcoma Cells. M. Felx*[1], F. Shipkolye*[1], M. Isler*[2], J. Doyon*[3], R. Turcotte*[4], A. Moreau[1], F. Moldovan*[1]. [1]Dentistry Medecine, Ste-Justine Hospital Research Center, Montreal, PQ, Canada, [2]Surgery, Maisonneuve-Rosemont Hospital, Montreal, PQ, Canada, [3]Pathology, Maisoneeuve-Rosemont Hospital, Montreal, PQ, Canada, [4]Surgery, McGill University, Montreal, PQ, Canada.

Degradation of extra cellular matrix (ECM) in many tumours including osteosarcoma is an essential step to promote cell invasion and malignancy. Matrix metalloproteases (MMPs) and endothelin-1 (ET-1) are among the factors contributing to ECM destruction and they are potential target in cancer therapy. This study investigates the effect of ET-1 and its precursor, Big ET-1, on MMP-2 and MMP-9 synthesis and activity in osteosarcoma (MG63) and chondrosarcoma (SW1353) cell using Western Blot, zymography, RT-PCR and Northern Blot. First, we showed that ET-1 and its two receptors (ETA and ETB) are constitutively expressed in osteosarcoma and chondrosarcoma cells. Then, we demonstrated that both ET-1 and Big ET-1 markedly induce synthesis and enzymatic activity of MMP-2 and that enzymatic activity is significantly increased when compared to MMP-9. Furthermore, inhibition of NF-κB activation (by PDTC) blocked MMP-2 production and activity indicating the involvement of NF-κB, a ubiquitous trancription factor playing a central role in the differentiation, proliferation and malign transformation processes. Similarly, inhibition of Big ET-1 maturation by the furin convertase inhibitor, abrogated MMP-2 synthesis and enzymatic activity. These findings demonstrate that ET-1 acts as an autocrine mediator through the induction of MMP-2 and MMP-9 synthesis and activity and could contribute to the tumour cells growth promotion and malignancy.

Interaction of MMP-13 and its Specific Receptor with Low Density Lipoprotein Receptor Related Protein-1. I. Choudhury*, S. Williams*, N. C. Partridge. Physiology and Biophysics, Robert Wood Johnson Medical School - UMDNJ, Piscataway, NJ, USA.

An endocytotic receptor mechanism for matrix metalloproteinase-13 (MMP-13) removal in osteoblastic cells, fibroblasts and chondrocytes has been identified previously. MMP-13 internalization and subsequent inactivation in these cells proceeds through a dual receptor mechanism, involving high affinity binding to a specific MMP-13 receptor followed by interaction with the low-density lipoprotein receptor related protein-1 (LRP1). In the present study, the specific MMP-13 receptor purified from rat primary osteoblastic cells and LRP1 purified from rat liver and rat primary osteoblastic cells were used in solid phase binding assays. The available ligand binding sites in the specific receptor are higher than that in LRP1. However, mMMP-13 binding to the specific receptor is augmented in the presence of LRP1. The MMP-13 specific receptor associates with LRP1 independent of MMP-13. There is no competition of binding of MMP-13 and LRP1 with the MMP-13 specific receptor, suggesting that different domains of MMP-13 bind to each of these. To identify the binding domain in LRP1 for MMP-13, the receptor associated protein (RAP) and α2 macroglobulin (α2M) were used as competitors. In the solid phase binding assay, RAP does not compete with MMP-13 for binding sites on LRP1, but α2M competes for binding in a dose dependent manner. RAP binds to three different clusters (II, III and IV) of ligand binding repeats in LRP1, α2M binds mainly in cluster I and possibly cluster II of LRP1. Binding and internalization of MMP-13 apparently requires co-operative participation of the specific receptor and LRP1. Soluble mini receptors representing each of the putative ligand binding domains (I, II, III and IV) of LRP1 as well as the transmembrane domain and cytoplasmic tail, termed mLRP1, mLRP2, mLRP3 and mLRP4 respectively, were stably expressed in CHO cells that lack endogenous LRP1. These cells were used for MMP-13 binding and internalization studies. MMP-13 binds to all of these cells but internalizes primarily in mLRP2 cells. The results suggest that i) MMP-13 binds to both specific receptor and LRP1 independently, ii) the recognition site in LRP1 for MMP-13 is localized in cluster I and /or II and iii) the recognition site on LRP1 for MMP-13 is different from that for the specific receptor.

Acidic Microenvironment Created by Osteoclasts Causes Bone Pain Associated with Tumor Colonization. M. Nagae*, T. Hiraga, T. Yoneda. Biochemistry, Osaka University Graduate School of Dentistry, Osaka, Japan.

Bone pain is one of the most common and devastating complications in cancer patients with bone metastases. Although the mechanism of cancer-induced bone pain is poorly understood, previous results that inhibitors of osteoclastic bone resorption such as bisphosphonates (BPs) reduce bone pain in cancer patients indicate a critical role of osteoclasts that are increased in number and activated in bone metastases. These osteoclasts destroy bone to facilitate tumor colonization by secreting protons, thereby making adjacent microenvironment acidic. Since acidosis is a well-known cause of pain, it is plausible that an acidic microenvironment created by osteoclasts may cause bone pain associated with cancer colonization in bone. To test this notion, we studied an animal model in which inoculation of the MRMT-1 rat breast cancer cells into the tibial bone marrow cavity in female rats induced hyperalgesia. Radiographical analyses demonstrated that MRMT-1 cells caused aggressive bone destruction and histological observations revealed numerous TRAP-positive osteoclasts in the lesions. Behavioral analyses including the plantar, foot stamp and force grip test showed that rats exhibited hyperalgesia in tumor-inoculated legs as tumor grew, while non-tumor-inoculated legs had no hyperalgesia. Subcutaneous injections of the BP zoledronic acid (ZOL) (250 μg/kg/day) significantly reduced the cancer-

induced hyperalgesia and bone destruction. To investigate a role of acidosis, mRNA expression of acid-sensing receptors including the acid-sensing ion channels (ASICs) and the transient receptor potential channel-vanilloid subfamily member 1 (TRPV1) in the dorsal root ganglions (DRGs) was determined by RT-PCR. The expression of ASIC1a and ASIC1b mRNA was increased in the ipsi-lateral DRGs, whereas TRPV1 expression was not changed. Of note, ZOL reduced the expression of ASIC1a and ASIC1b in the DRGs. In addition, immunohistochemical examinations revealed that the expression of c-Fos, which is a widely-used marker of neural activity in response to noxious stimuli of primary sensory neurons, in the ipsi-, but not contra-lateral, lamina I-II and V-VI neurons in spinal cord was increased in association with hyperalgesia. ZOL decreased these c-Fos-positive neurons. In conclusion, our data suggest that an acidic microenvironment created by proton release by osteoclasts, at least in part, contributes to the induction of hyperalgesia through up-regulating ASICs expression. Our results also suggest BPs reduce cancer-induced bone pain through preventing the development of acidic microenvironment by inhibiting osteoclasts, which in turn down-regulates ASICs and c-Fos expression.

2-Methoxyestradiol-mediated Cell Death Is Dependent on Protein Kinase PKR in Osteosarcoma Cells. A. Maran, K. L. Shogren*, R. T. Turner. Orthopedics, Mayo Clinic, Rochester, MN, USA.

Osteosarcoma is the most common primary bone tumor and most frequently develops during adolescence. 2-Methoxyestradiol (2-ME), a naturally occurring mammalian metabolite of 17β-estradiol induces interferon gene expression, cell cycle arrest, and cell death by apoptosis in human osteosarcoma cells. PKR is an interferon-inducible serine-threonine protein kinase that plays a role in regulation of cell growth, differentiation and apoptosis and mediates the anti-proliferative and anti-cancer activities of interferon. To test a cause and effect relationship we determined the effect of 2-ME and protein kinase inhibitors on PKR protein and cell death in MG63 human osteosarcoma cells. Western blot analysis showed that PKR protein level was increased by 2 fold in 2-ME (10 μM) treated cells, whereas 17β-estradiol, 4-hydroxy- and 16-hydroxyestradiol, estrogens which do not induce cell death, had no effect on PKR protein levels. Flow cytometric analysis of 2-ME treated cells showed an increase in PKR staining compared to the vehicle control. SB203580, a general serine-threonine kinase inhibitor and 2-aminopurine, a specific PKR inhibitor blocked 2-ME-mediated cell death in MG 63 cells. These results suggest that 2-ME-mediated activation of interferon signaling is transduced by PKR protein, resulting in anti-growth and apoptosis in osteosarcoma cells.

Osterix Inhibits RANKL and IL-1α in Osteosarcoma Cells Resulting in Decreased Bone Destruction and Tumor Growth. Y. Cao*, Z. Zhou*, E. S. Kleinerman*. Pediatrics, UT MD Anderson Cancer Center, Houston, TX, USA.

Osteosarcoma is a malignant tumor that originates and grows within bone resulting in bone destruction. This destruction is thought to be mediated by osteoclasts. Osterix (osx) is a new zinc finger-containing transcription factor required for osteoblast differentiation and bone formation. We previously demonstrated that osx expression was absent in mouse K7M2 osteosarcoma cells. In addition, osx expression was low or absent in TC71 human Ewing's sarcoma cells, PC3-MM2 human prostate cancer cells and RBM1 human renal cancer cells all of which cause osteolytic bone lesions when injected *in vivo*. Replacement of osx in K7M2 cells inhibited tumor incidence following bone injection and decreased osteolysis. The purpose of these studies was to investigate possible mechanisms by which K7M2 cells cause bone destruction and how osx inhibits osteolysis. Osteolytic bone lesions (detected radiographically) developed 35 days following intraosseous injection of K7M2 cells. Histologic examination demonstrated TRAP+ multinucleated giant osteoclasts in the interface between tumor cells and bone cortex. Using an *in vitro* osteoclast formation assay, we found that K7M2 cells stimulated significant osteoclasts formation in the presence of stromal osteoblasts. K7M2 cells co-cultured with normal MC3T3 mouse osteoblasts for 5 days resulted in increased RANKL (Receptor activator of NF-κB ligand) expression as quantified by RT-PCR. By contrast, osteoprotegerin (OPG) expression was unchanged. Two stable osx-transfected K7M2 cell lines (K7M2-osx1 and K7M2-osx2) and a control transfected cell line (K7M2-neo) were generated to determine the effect of osx on tumor development, growth and morphology. Intraosseous injection of K7M2-osx1 and K7M2-osx2 cells resulted in a lower tumor incidence. Tumors that did develop were significantly less osteolytic as judged by x-ray, histology and TRAP staining. Co-culturing K7M2-osx1 or K7M2-osx2 cells with MC3T3 cells did not stimulate RANKL expression as seen when MC3T3 cells were co-cultured with either K7M2 or K7M2-neo control cells. In addition, IL-1α expression was significantly decreased in both K7M2-osx transfected cells. We demonstrated that IL-1α protein increased MC3T3 RANKL expression. These data indicate that the suppression of RANKL by osx may be mediated by an effect on IL-1α. Our results also indicate that K7M2 cells disrupt the RANK/OPG balance in normal osteoblasts leading to increased RANKL expression and bone destruction. We, therefore, conclude that osx inhibits IL-1α leading to a reduction in RANKL, which subsequently inhibits osteolysis and invasion of the tumor cells into the bone cortex thereby reducing tumor growth.

Zoledronic Acid and Calcitriol in Malignancies with Bone Involvement - A Pilot Trial. G. M. A. Palmieri, L. S. Schwartzberg*, R. E. Imseis*. The West Clinic, P.C., Memphis, TN, USA.

Calcitriol has anticancer effects by stimulating cell differentiation and inhibiting proliferation and angiogenesis. Its major drawback is stimulation of osteoclasts with liberation of cancer growth factors from bone and hypercalcemia. Aminobisphosphonates inhibit osteoclasts and correct hypercalcemia of malignancies. We reported bone healing with calcitriol + pamidronate in 2 multiple myeloma patients (pts) (AmJMedSci, 1999). We are reporting ongoing findings from a 12 month (m) pilot trial with zoledronic acid (Z) + calcitriol (C) in 11 pts (5 women, 6 men), with bone metastases from various tumors (4 breast, 5 prostate, 2 myeloma). Patients on cancer therapy received Z, 4 mg i.v./m + C (Calcijex), 1 μg i.v., 2/week x 2 weeks, followed by C (Rocaltrol) 0.25 μg po/tid + Ca 1,500 mg/d. Chemistries, calciotropic factors, bone turnover markers, skeletal MRI and bone mineral density (BMD) by DEXA were determined at 1 - 3 m. Of 11 pts so far recruited, 2 died of cancer in the first 2 m, 4 are in the study and 5 have completed the 12 m of the pilot trial. So far Z and C were well tolerated. One patient developed transient hypercalcemia (11.6 mg/dl) and hypercalciuria that responded to temporary reduction of the dose of C. In the 5 pts who completed this trial we observed stable skeletal MRI at 3 m intervals in 3 pts and new lesions in 2 pts; serum PTH fell by 64% in 4 of 5 pts; serum C remained within the normal range in most pts; variable results were observed in bone alkaline phosphatase; urinary NTX fell in 4 or 5 pts by 62% and BMD, measured every 3 m for 1 year, increased in 5 of 5 pts (total hip 11%, lumbar spine 15%, whole body 6%). The ongoing data suggest: 1. Z + C were well tolerated. 2. Skeletal metastases did not progress in some pts. 3. PTH and NTX fell by 60%. 4. Bone density increased in multiple sites. These results are encouraging and support the continuation and completion of this study.

Reciprocal Regulation of Osteoclast and Dendritic Cell Differentiation from Monocytes by Myeloma Cells: A Role for MIP-1. T. Hashimoto*, M. Abe, Y. Tanaka*, E. Sekimoto*, T. Oshima*, H. Shibata*, S. Ozaki*, S. Kido, D. Inoue, T. Matsumoto. Department of Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medicine, Tokushima, Japan.

Multiple myeloma (MM), a malignancy of plasma cells, generates a devastating bone destruction by osteoclasts (OCs). We and others reported that macrophage inflammatory protein (MIP)-1alpha and beta are among major OC activating factors secreted by MM cells. In contrast to OCs, dendritic cells (DCs) decrease in number and their function is defective in MM, leading to tumor escape and susceptibility to infection. Because OCs and myeloid DCs are derived from the same monocytic precursor cells, we hypothesized that differentiation into the two cell lineages are reciprocally regulated and that MM cells modulate the lineage determination process. In this study, we examined roles for MIP-1 as well as MM cells in OC and DC induction from human peripheral blood monocytes. OCs were formed from monocytes spontaneously or by exogenous M-CSF and soluble RANKL. Interestingly, addition of anti-MIP-1alpha and beta antibodies in combination inhibited OC formation with a concomitant increase of RANK-negative macrophages. Culture supernatants of thus formed OCs revealed MIP-1alpha and beta immunoreactivity, suggesting an autocrine action of MIP-1 in the OC induction. We next investigated a role for MM cell-derived MIP-1 in OC induction from monocytes. When the MIP-1- and RANKL-expressing MM cell line TSPC-1 was co-cultured with adherent populations of monocytes on dentine slices, formation of TRAP-positive multinucleated cells as well as pits were enhanced. Again, anti-MIP-1alpha and beta in combination abrogated these enhancement, suggesting a critical role for MM cell-derived MIP-1 in enhancement of monocyte-derived OC formation and function. In sharp contrast to the OC induction, non-adhesive co-cultures with MIP-1-producing MM cell lines as well as primary MM cells inhibited the induction of CD83+ mature DCs from monocytes in the presence of GM-CSF plus IL-4, followed by TNF-alpha. However, the DC maturation impaired by MM cells was not restored by addition of anti-MIP-1alpha and beta in combination, suggesting that soluble factors other than MIP-1 may be responsible for inhibition of DC maturation. These results suggest that MIP-1 may play a critical role in the commitment of OC lineage as well as OC maturation and activation and that MM cells may affect the reciprocal regulation of differentiation into OC and DC lineages, thereby enhancing bone resorption and concomitantly inhibiting antigen-presenting capacity of DCs.

5T2MM Murine Myeloma Cells and CD138+ve Human Myeloma Cells Promote Osteoclastic Activity Rather Than Osteoclast Formation *In Vitro*. G. S. Mueller*[1], K. Vanderkerken*[2], R. G. G. Russell[1], P. I. Croucher[3]. [1]Botnar Research Centre, Nuffield Department of Orthopaedic Surgery, Oxford University, Oxford, United Kingdom, [2]Department of Hematology and Immunology, Free University Brussels, Brussels, Belgium, [3]Division of Clinical Sciences, University of Sheffield School of Medicine, Sheffield, United Kingdom.

A major clinical feature in multiple myeloma (MM) is the development of osteolytic bone disease. Increased osteoclastic bone resorption is responsible for bone disease; however, it is unclear whether this is mediated by increased osteoclast recruitment and differentiation, or increased osteoclastic activity, or both. The aim of the present study was to determine whether 5T2MM murine myeloma cells or human myeloma cells isolated from patients with myeloma could promote osteoclast formation and osteoclastic bone resorption, in vitro, in a stromal cell independent manner.

5T2MM murine myeloma cells were injected intravenously into C57BL/KaLwRij mice. All mice developed a serum paraprotein and the growth of 5T2MM cells in the bone marrow (BM). Radiographic and histological analysis demonstrated the presence of lytic bone lesions and an increase in the number of TRAP+ve osteoclasts cells lining bone surfaces. 5T2MM murine myeloma were purified by density gradient centrifugation and incubated with murine peripheral blood mononuclear cells in the presence or absence of soluble RANKL (sRANKL). 5T2MM caused a significant reduction in the formation of TRAP+ve cells when compared to control. However, when cultured on dentine slices, those osteoclasts that formed, created large resorption 'trails', rather than the smaller pits seen in the absence of 5T2MM cells suggesting that resorption activity was increased. In contrast, 5T33MM cells, which in vivo do not promote osteoclastic resorption, inhibited osteoclast formation and resorption of dentine slices. To determine whether this was specific to the 5T2MM murine cells, human myeloma cells were isolated from the bone marrow of patients with MM by density gradient centrifugation and purified by immunomagnetic separation using an antibody to CD138 to identify the myeloma cells. CD138+ve human myeloma cells did not affect TRAP+ve osteoclast formation when cultured with human peripheral blood mononuclear cells, but did promote an increase in the proportion of dentine slices undergoing resorption and induced the formation of resorption 'trails' rather than the pits seen in the absence of myeloma cells. In all cases, sRANKL was required to induce osteoclastic bone resorption. These data are consistent with 5T2MM murine myeloma cells and CD138+ve human MM cells promoting osteoclast activity and/or survival rather than osteoclast formation.

Clinical Study Using Urine NTX in Patients with Metastatic Spine Tumors. S. Ichimura[1], T. Miyamoto*[1], H. Maruno*[1], T. Asazuma*[2], J. Ogawa*[1], K. Satomi*[1]. [1]Orthopaedic Surgery, Kyorin University, Tokyo, Japan, [2]Orthopaedic Surgery, National Defense Medical College, Tokorozawa, Japan.

We investigated the utility of bone resorption marker (NTX) for metastatic spine tumors. This study included 101 patients (male: 45, female: 56) with various malignancies who ranged in age from 42 years to 87 years (mean 64). Twenty-four patients had breast cancer, 14 had prostate cancer, 13 had lung cancer, 11 had gastric cancer, 7 had renal cancer, 6 had colon cancer, and 26 had various other malignancies. Of the 53 patients with spine metastasis, 49 had not been treated and 4 treated with radiation therapy or spine surgery for spine metastasis. Forty-eight patients had no spine and bone metastasis. We classified bone metastasis into 3 Grades. Grade - had no bone and spine metastasis (n:48), and Grade + had only one spine metastasis (n:10), and Grade ++ had multiple spine and bone metastasis (n:43). Urinary NTX was measured by second-void urine samples. Urinary NTX level in patients with Grade ++ was greater than in patients with Grade + and - (129 nM BCE/mM Cr vs. 58 nM BCE/mM Cr and 53 nM BCE/mM Cr; $p < 0.01$), and no significant difference was observed in urinary NTX level between Grade + and -. We were able to follow the clinical course in 13 patients with conservative treatment (mean: 11.4 months) and in 15 patients with spine surgical treatment (mean: 7.8 months). There was a temporary reduction of urinary NTX level by mean 33% after Radiation therapy. However, the levels of urinary NTX were gradually increased and the prognosis was poor in patients with Grade ++ in both treatment groups. On the other hand, in patients with Grade + in both groups, the levels of urinary NTX were not changed and there was no death during observation period. The measurement of urine NTX appeared to be more useful to monitor the clinical course in patients with spine metastasis than to diagnose spine metastasis.

Heparanase Supports Tumor Metastasis to Bone. Y. Yang*, M. Bendre, Y. Huang*, L. Joseph*, V. Macleod*, A. M. Theus*, T. Kelly*, R. Sanderson*, L. J. Suva. Orthopaedic Surgery, Pathology and Arkansas Cancer Research Center, UAMS, Little Rock, AR, USA.

Bone is a common site for cancer metastasis. Skeletal metastases connote a dramatic change in the prognosis for the patient and significantly increase the morbidity associated with disease. Relatively little is known regarding the mechanisms that control myeloma metastasis, although widespread skeletal dissemination is an important step in disease progression. Understanding the complex interactions contributing to the metastatic behavior of cancer cells is essential for the development of effective therapies. The myeloma microenvironment is replete with heparan sulfate, an important component of the extracellular matrix and vascular basement membrane, where it can serve as a physical barrier to tumor cell metastasis and interaction with normal tissue. In addition, heparan sulfates on the cell surfaces and within the extracellular matrix bind to, and regulate the activity of, numerous factors that control myeloma growth and angiogenesis (e.g., IL-8, HGF, FGF-2). In the present study, the enhanced expression of human heparanase-1 (HPSE1) *in vivo* dramatically upregulates spontaneous metastasis of myeloma cells to bone. HPSE1 is the primary mammalian enzyme responsible for cleaving heparan sulfate chains into 10-20 residue fragments that are biologically active. Promotion of metastasis by HPSE1 is an early event, occurring before primary tumors reach a large size. In addition, HPSE1: (i) greatly enhances whole body tumor burden compared to controls, and (ii) has a dramatic impact on both the number and size of microvessels within the primary tumor, suggesting an important role for heparanase in myeloma tumor angiogenesis. Similarly, preliminary studies indicate that breast cancer cells expressing HPSE1 growing in the mammary fat pad are more capable of dissemination to bone than non-HSPE1 expressing cancer cells. The process correlates with a dramatic increase in serum C-telopeptide collagen cross-links, demonstrating increased bone resorption. These data, from two distinct tumor types, indicate that HPSE1 is an important determinant of cancer dissemination in bone. In addition, these studies reveal a novel experimental animal model for examining the spontaneous metastasis of bone-homing tumors. This novel model of bone metastasis provides a unique opportunity to study the entire metastatic cascade *in vivo*, and may provide insight into new therapeutic modalities.

Regulation of PTH-rP Expression and Osteolysis by Human Breast Cancer Cells by Gli2 and Gli 3. J. A. Sterling, B. O. Oyajobi, M. Zhao, A. Gupta*, M. Banerjee*, B. Grubbs*, G. R. Mundy. Cellular and Structural Biology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Osteolysis associated with breast cancer is due to the tumor peptide parathyroid hormone-related peptide (PTH-rP). The molecular mechanisms responsible for PTH-rP expression by breast cancer cells are clearly important, since PTH-rP is the causative factor in osteolysis, inhibition of PTH-rP transcription by small molecules reduces bone lesions and tumor burden (Gallwitz et al., 2002), and there is evidence for differential expression of PTH-rP by breast cancer cells in different organ sites. However, the mechanisms responsible for increased PTH-rP expression by breast cancer cells are unknown. We hypothesize that the Gli family of transcriptional regulators is responsible for regulating PTH-rP transcription in breast cancer. The rationale for this concept is that PTH-rP expression in the growth plate is controlled physiologically by hedgehog signaling, and the Gli family mediates hedgehog signaling in vertebrate cells. Furthermore, Gli2 is overexpressed in some human carcinomas. To investigate this hypothesis, we transfected breast cancer cells with PTH-rP promoter luciferase constructs and expression vectors for the Gli family. We found that Gli2 specifically increased PTH-rP promoter activity by greater than 2-fold, while Gli3 and Gli1 did not significantly affect basal promoter activity. We and others have shown that Gli3 is processed in the proteasome to a truncated form (trGli3). This proteasomally processed form of Gli3 suppressed the Gli2 stimulated-PTH-rP transcription in human MDA-MB-231 breast cancer cells. Furthermore, when MDA-MB-231 human breast cancer cells stably overexpressing Gli2 were inoculated into the left cardiac ventricle of athymic nude mice, enhanced osteolysis was observed when compared with mice injected with the empty vector control. We examined the relationship between expression of Gli2 in human and murine breast cancer cells and PTH-rP expression and osteolysis, and found Gli2 was expressed in cells that also express PTH-rP (MDA-MB-231, RWGT2, PC-3, and 4T1), but not in cells that do not (MCF-7, ZR-75, and T47D). Taken together, these data indicate that the Gli family of transcriptional factors regulates PTH-rP expression and subsequent tumor-induced osteolysis. The activities are distinct and uncoupled, with Gli2 acting as a stimulator and truncated Gli3 as a repressor of PTH-rP transcription. This family represents possible targets for drug development to retard osteolytic bone metastases associated with breast cancer.

Bone-Specific Microenvironment and Epithelial-Mesenchymal Transition Contribute to the Increased Bone Metastatic Potential of Human Prostate Cancer Cells. V. A. Odero-Marah*[1], J. Xu*[1], Y. Cui*[1], M. N. Weitzmann[2], L. W. K. Chung*[1], H. Y. E. Zhau*[1]. [1]Urology, Emory University School of Medicine, Atlanta, GA, USA, [2]Division of Endocrinology & Metabolism & Lipids, Emory University School of Medicine, Atlanta, GA, USA.

The propensity of human prostate cancer to metastasize to the skeleton and elicit osteoblastic and osteolytic reactions has been the subject of intense investigation. In our laboratory, we proposed that acquisition of osteomimetic properties by human prostate cancer cells is essential for human prostate cancer growth, survival, and invasion in bone. In addition, the epithelial-mesenchymal transition (EMT) whereby epithelial cancers undergo morphological changes to become more mesenchymal and migratory has a known role in cancer invasiveness and metastatic potential. In this study, we developed a novel ARCaP human prostate cancer bone metastasis model to evaluate the role of osteomimicry and EMT in experimental bone metastasis. The ARCaP cell line was derived from a patient with highly metastatic prostate cancer. When injected into athymic mice, it mimics clinical behaviors as seen in patients, including the development of bone metastasis, formation of ascites fluid, expression of neuroendocrine factors, androgen receptor and prostate-specific antigen. We further derived two morphologically and behaviorally stable and distinct ARCaP subclones, 1A8 and 1F11, which share a common genetic background. We have evaluated a wide range of genes expressed by these subclones using RT-PCR, IHC, and western blots and tested their tumorigenicity and metastatic potential in athymic mice using an intracardiac injection protocol. The results of

these studies showed that 1A8, a cell line with spindle-like morphology, expressed mesenchymal markers and was more aggressive than 1F11, which exhibited a cobblestone morphology and expressed epithelial markers. The data suggests that 1A8 could be the mesenchymal derivative of 1F11 through the process of EMT. Secondly, skeletal metastatic variants from 1A8 and 1F11 subclones gained highly aggressive bone metastatic potential with higher incidences and shorter latency periods after intracardiac administration, compared to their respective parental subclones. Thirdly, 1A8 and 1F11 cells that metastasized to bone generated both osteoblastic and osteolytic lesions. We observed a marked elevation of osteomimicry-related genes, osteopontin and osteocalcin, but not RANKL in bone metastatic tissue specimens, compared to these same variants grown subcutaneously. Thus, our data suggest an important role for EMT in the acquisition of tumor aggressiveness and the inductive role of the bone microenvironment for prostate cancer homing to bone.

An Immune-Intact Murine Model of Bone Metastasis for Prostate Cancer. M. T. Moser*, X. Wang*, B. A. Foster. Pharmacology & Therapeutics, Roswell Park Cancer Institute, Buffalo, NY, USA.

Prostate cancer is the most commonly diagnosed cancer in men in the United States and is second only to lung cancer as the leading cause of death from cancer in men. The terminal stages of prostate cancer frequently metastasize to bone resulting in osteoblastic lesions. In men who died of prostate cancer greater than 70% had bone metastases. However, relatively little is understood about the underlying molecular mechanism of prostate cancer initiation, progression, as well as, why prostate cancer preferentially metastasizes to bone and elicits an osteoblastic response. This is in part due to the lack of animal models that recapitulate the full spectrum of the human disease. Recent studies suggest that species-specific factors may limit the ability of human cancers to colonize rodent bone. This may be one explanation for the scarcity of human prostate cancer cell lines that metastasized to bone in severe combined immunodeficient (SCID) mice.

We have established cell lines from a spontaneously occurring boney metastasis in the transgenic adenocarcinoma of mouse prostate (TRAMP) model of prostate cancer. A C57/FVB (50:50) TRAMP animal presented with hind leg paralysis. Upon examination a large tumor mass was observed engulfing the spine. Histological analysis indicated that the spinal cord contained poorly differentiated prostate cancer with both osteolytic and osteoblastic features. Three plates of cells were established from this tumor tissue, designated TRAMP-BC1, -BC2 and -BC3. RT-PCR analysis indicates the TRAMP-BC cell lines express bone markers such as cbfa1/RUNX, bone alkaline phosphatase, osteopontin, osteocalcin, bone sialoprotein II and procollagen type I. The tumorigenicity of the parental TRAMP-BC cells has been characterized by injection of cells into immune-intact, syngeneic hosts. Three routes of injection have been investigated; 1) subcutaneous; 2) intrafemoral and 3) intracardiac. TRAMP-BC cells were tumorigenic and metastatic by all three routes of injection. Radiographic analysis of the femurs showed thickening of the bone consistent with an osteoblastic response. Furthermore, TRAMP-BC cells have be reisolated from the femurs of host animals following intracardiac injection, indicating TRAMP-BC cells can home to bone and induce an osteoblastic response.

These cell lines can be used to further our understanding of prostate cancer-bone interactions leading to better treatment and prevention of bone metastasis in the clinical disease. These cell lines can also be used as a preclinical model to test new therapies for bone metastases in prostate cancer, including immune-based therapies.

Protein Profiling of Highly Osteolytic MDA-231 Breast Cancer Expressing High Gelatinase Activity versus Poorly Osteolytic MDA-231 Breast Cancer with Low Gelatinase Activity. P. A. Veno*[1], J. Guthrie*[2], J. Zhao*[1], M. R. Dallas*[1], J. Bonewald*[1], D. Dinakarpandian*[1], N. Gopathi*[1], L. F. Bonewald[1], S. L. Dallas[1]. [1]Univ. of Missouri, Kansas City, MO, USA, [2]Midwest Research Institute, Kansas City, MO, USA.

Breast cancer frequently metastasizes to bone, causing bone destruction with complications of hypercalcemia, fracture and nerve compression. Although breast cancer metastasis to bone is often associated with formation of osteolytic lesions, osteoblastic lesions can also occur. While comparing a panel of human breast cancer cell lines that either cause osteolytic or osteoblastic lesions in nude mice, we noted that osteolytic cell lines showed higher expression of the gelatinases (matrix metalloproteinases 2 and 9) compared to osteoblastic lines. To test the hypothesis that gelatinases may be a determinant for osteolytic bone metastasis, parental MDA-MB-231 cells were cloned by limiting dilution and screened for high or low gelatinase expression by zymography. Individual clones maintained their gelatinase expression phenotype for a minimum of 3 months in culture and also when cultured on bone extracellular matrix. High and low MMP9 expressing clones were evaluated in a mouse model of bone metastasis. X-ray analysis showed significantly higher osteolytic lesion area in the high MMP9 expressing clone compared to the low expressing clone in long bones of both fore and hind limbs. Histomorphometric analysis confirmed significantly higher tumor volume and lower bone volume with the high MMP9 expressing clone. To identify proteins causing or associated with the osteolytic phenotype, protein profiles were obtained from whole cell lysates of high and low MMP9 expressing clones using 2D gel electrophoresis, peptide mass mapping (MS) and selected peptide sequencing (MS/MS). Approximately 700 protein spots were detected, of which 34 were assigned to the MDA-231 proteome. 8 protein spots were identified that are differentially expressed in high versus low MMP9 clones, several of which have been shown to be associated with cancer. To identify activated signaling pathways, 2D gels were stained for phosphorylated proteins. 171 positively stained spots were detected, of which three have been identified. The differentially expressed phosphorylated proteins are currently being identified. An informational database cataloging the proteome of parental and high vs low MMP9 expressing MDA-231 clones has been created to help identify new protein targets that may be involved in breast cancer metastasis to bone. These studies will provide important insights into the role of gelatinases in bone metastatic breast cancer and may highlight novel targets for treatment of osteolytic bone disease.

Osteoporosis and Spinal Fractures in Men with Prostate Cancer: Risk Factors and the Effects of Androgen Deprivation Therapy. T. H. Diamond[1], J. Bucci*[2], J. H. Kersley*[2], P. Aslan*[3], C. Bryant*[4]. [1]Endocrinology, St George Hospital Campus and University of New South Wales, Sydney, NSW, Australia, [2]Radiation Oncology, St George Hospital Campus, Sydney, NSW, Australia, [3]Urology, St George Hospital Campus, Sydney, NSW, Australia, [4]Radiology, St George Hospital Campus, Sydney, NSW, Australia.

To determine the risk factors for osteoporosis and spinal fractures in men with prostate cancer receiving androgen deprivation therapy.

We performed a retrospective analysis of 87 consecutive men with prostate cancer receiving androgen deprivation therapy and who were referred for evaluation of osteoporosis. Data comprised of lateral thoraco-lumbar radiographs, bone densitometry, serum biochemistry and a detailed assessment of osteoporotic risk factors. Multivariate regression analysis was used to determine the major risk factors for osteoporosis and spinal fractures.

There were 38 (44%) men aged 74.5 years who had radiographic evidence of spinal fractures. They had an initial mean PSA value of 52.8 ng/mL and had received androgen deprivation therapy for a mean of 39.6 months (95% confidence interval, 28.7 to 50.4 months). Their mean spinal (quantitative computed tomography t-score = -4.2) and femoral neck bone mineral densities (dual energy x-ray absorptiometry t-score = -2.1) were significantly lower than men without spinal fractures ($P<0.001$ for all measurements). In the regression analysis, the duration of androgen deprivation therapy ($P=0.002$), serum 25 hydroxyvitamin D levels ($P=0.003$), and a history of alcohol excess (defined as more than 4 standard drinks per day) ($P=0.04$) were the main determinants of spinal fractures.

Prolonged androgen deprivation therapy, low serum 25 hydroxyvitamin D levels and a history of alcohol excess are important risk factors for osteoporosis and spinal fractures in men with prostate cancer.

Methylation of Urokinase (uPA) Promoter Results in Blocking Prostate Cancer Cells Invasion, Growth and Metastases *in Vitro* and *in Vivo*. N. Shukeir*, P. Pakneshan*, M. Szyf*, S. A. Rabbani. Departments of Medicine, Oncology and Pharmacology, McGill University, Montreal, PQ, Canada.

Prostatic adenocarcinoma is among the leading hormone-dependent cancers with a high propensity to develop skeletal metastases. Urokinase, a member of the serine protease family, has been implicated in the progression of several malignancies including prostatic cancer. uPA mRNA is undetectable in normal (PrEC) and low invasive (LNCAP) human prostate cancer cells. In contrast uPA mRNA is abundantly expressed by highly invasive prostate cancer cells PC-3 due to the demethylation of the uPA promoter. This epigenetic mechanism regulating gene transcription is controlled by balanced activity of DNA methyltransferase and demethylase (MBD2).

In order to evaluate the role of uPA promoter methylation in prostate cancer, PC-3 cells were treated with the universal methylating agent S-adenosylmethionine (SAM) and an anti-sense oligonucleotide directed against MBD2 (AS). Scrambled oligonucleotide was included as a control (S). Both SAM and MBD2-AS resulted in a dose and time dependent inhibition in uPA production and tumor cell invasive capacity as determined by Matrigel invasion assay. For *in vivo* studies male Balbc nu/nu mice were inoculated with control and experimental cells into the right flank. Animals inoculated with control cells exhibited tumors of progressively increasing size as compared to animals inoculated with PC-3 cells treated with SAM (500μM for 6 days) or MBD2-AS (200nM for 3 days). To determine the effect of SAM treatment on the development of skeletal metastases, male Fox-Chase SCID mice were inoculated directly into the tibia with control and SAM (500μM) treated PC-3 cells. Large lesions were observed in the tibia of mice inoculated with control PC-3 cells upon X-ray analysis using Faxitron. Majority (90%) of experimental animals inoculated with PC-3 cells pretreated with SAM failed to develop any radiological evidence of skeletal metastases. In 10% of remaining animals these lesion were of markedly smaller area. Bone histomorphometric analysis of tibia where no radiological lesions were observed showed the presence of microscopic tumor cells in the tibia of animals inoculated with SAM treated PC-3 cells. Control and experimental tibias are being evaluated by immunohistochemical analysis to determine the levels of uPA production and markers of bone turnover. The results obtained from these studies will establish the role of uPA methylation status in prostate cancer in promoting tumor growth and metastasis. Additionally these studies will provide valuable insight into developing novel therapeutic strategies against this common disease, which target the demethylation machinery.

The Relationship between Bone Mineral Density and Breast Cancer in Hispanic and Non-Hispanic White Postmenopausal Women - An Ancillary Study of the Women's Health Initiative. L. Arendell*, D. Deshpande*, R. Bruhn*, T. Bassford*, M. Maricic, Z. Chen. University of Arizona, Tucson, AZ, USA.

Previous studies among primarily non-Hispanic white populations have found that women with higher bone density are more likely to develop breast cancer. The purpose of this study was to investigate the association between bone mineral density (BMD) and breast cancer in both Hispanic and non-Hispanic white postmenopausal women. We hypothesize that our study will confirm this association among both ethnic groups.

This is a matched case-control study. Seventy-two newly diagnosed breast cancer cases (56% Hispanic) were recruited from physician's offices in Southern Arizona. We selected 288 age and ethnicity matched women from the Women's Health Initiative Observational Study as controls. BMD was measured using dual energy x-ray absorptiometry (DXA). Conditional logistic regressions were used to compute odds ratios (OR) for univariate and multivariate analyses and to test for an interaction of ethnicity and BMD.

Cases and controls did not differ significantly on age at menarche, pregnancy status, Hormone Therapy (HT) use, or family history of breast cancer. Cases were significantly heavier. In the unadjusted models, the OR of breast cancer among those in the highest tertile of whole body BMD compared to the lowest tertile was 2.7 (95% CI: 1.4, 5.3) and the OR of breast cancer for those in the highest tertile of hip BMD compared to the lowest tertile was 2.1 (1.1, 4.2). Interactions of ethnicity and BMD were indicated in these models, so analyses stratified by ethnicity were conducted. The ORs of breast cancer for those in the highest versus lowest tertile of whole body BMD were 1.2 (0.5, 2.9) among Hispanic women and 7.7 (2.4, 24.8) among the non-Hispanic white women. The ORs of breast cancer for those in the highest versus lowest tertile of Hip BMD were 1.2 (0.5, 2.9) and 4.8 (1.5, 14.8) among the Hispanic and non-Hispanic white women, respectively. Additional analyses support these findings after adjustment for potential confounders, including age at menarche, BMI, HT use, family history of breast cancer and pregnancy.

These data support an association between BMD and breast cancer. In this small sample the association between BMD and breast cancer appears to differ in the two ethnic groups. Since the groups were not population-based samples representative of the two ethnic groups, conclusions cannot be made about the ethnic differences; however, these data suggest that further studies of the relation between BMD and breast cancer are needed in Hispanic women.

BMP-7 in Prostate Cancer Bone Metastases. L. G. Brown*, T. E. Pitts*, A. M. Odman*, R. L. Vessella*, E. Corey. Urology, University of Washington, Seattle, WA, USA.

Metastases of prostate cancer result in osteoblastic reactions in bone. Mechanisms that are involved in the increased bone formation under these conditions are not fully understood at present. Understanding of mechanisms responsible for development of the osteoblastic reaction might lead to identification of potential treatment targets. Bone morphogenetic proteins (BMPs) regulate many developmental processes and are involved in bone formation. BMP-7 has been reported to be upregulated in prostate cancer bone metastases. The objective of this study was to evaluate effects of over-expression of BMP-7 in C4-2 cells *in vitro* and on the character of bone metastases *in vivo.*

Treatment with recombinant BMP-7 inhibited proliferation of LNCaP cells *in vitro* (35.6%, p=0.0029) while androgen-independent prostate cancer cells C4-2 and C4-2B were not affected, suggesting alteration of BMP signaling accompanying development of androgen independence. To evaluate effects of BMP-7 expression on C4-2, androgen-independent prostate cancer cells, the ORF of BMP-7 was amplified, cloned into pcDNA3.1, and used to transfect C4-2 cells using the AMAXA system. BMP-7-transfected cells express ~30 times higher levels of BMP-7 mRNA than pcDNA3.1-transfected C4-2 cells, as determined by real-time PCR. BMP-7 protein was detected in conditioned media of BMP-7-C4-2 cells but not in the conditioned media of pcDNA3.1-C4-2 cells. BMP-7-transfected cells secreted 4.8 ng BMP-7/ml/10^6 cells in a 3-day period. Real-time PCR analysis of transfected cells revealed altered expression of various transcription factors involved in BMP signaling, including SMAD-1, znf-8, and smurf-2. To determine effects of BMP-7 overexpression on C4-2 CaP tumors *in vivo* the BMP-7- and pcDNA3.1-transfected C4-2 cells were injected subcutaneously and intratibially in SCID male mice. *In vivo* studies are underway.

Further investigation of the effects of BMPs on CaP cells are warranted to delineate the signal transduction pathways activated in CaP cells and to elucidate more fully the role of BMPs in CaP bone metastases.

Effect of 17 Beta-estradiol on the Metastasis-related Gene Transcription in Estrogen Receptor-positive Human MCF7 Breast Cancer Cells. S. Kim*, H. Chung*, J. Byoun*, R. Hwang*, J. An*, S. Jun*, Y. Rhee, S. Lim. Brain Korea 21 Project of Medical Science, Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea.

While hormone replacement therapy (HRT) has proven to be effective in relieving many of the uncomfortable symptoms of menopause such as osteoporosis, its use remains highly controversial. Recently, numerous studies have demonstrated the potential health risks surrounding HRT. Of foremost concern is the possibility that women on HRT are particularly susceptible to blood clots, heart attack, stroke, gallbladder disease and breast cancer. Therefore, in this study, we evaluated the effect of 17beta-estradiol on the metastasis-related gene transcription in estrogen receptor (ER)-positive human MCF7 breast cancer cells with poor metastatic potential. MCF7 cells were cultured until 70% confluency in alpha-Minimum Essential Medium (MEM) containing 10% Fetal Bovine Serum (FBS) and then rendered quiescent by incubating cells in alpha-MEM medium containing 0.1% FBS for 24h. After the starvation, cells were treated by 17beta-estradiol for 4 days. Total RNAs were isolated for semi-quantiative RT-PCR and total proteins were prepared for Western blotting. Cell culture media were collected, filtrated and concentrated for the analysis of metalloproteinases (MMPs). 17beta-estradiol (10 nM) significantly induced the proliferation of MCF7 cells, and induced the mRNA expression levels of angiogenesis-related gene, vascular epithelial growth factor (VEGF) and invasion-related gene, MMP-1, in a dose-dependent manner. The induced mRNA expression levels of MMP-9 and tissue inhibitor of metalloproteinase (TIMP)-2 by the treatment of 17beta-estradiol were also observed, but these were not in a dose-dependent manner. Several metastasis-related genes such as angiopoietin-2, tumor growth factor-beta, cyclin E, and TIMP-1 were also evaluated, but not induced by 17beta-estradiol. In addition, MMP-2 activity and the protein expression of ER were evaluated by gelatin zymography and Western blotting, respectively, but both were not changed by 17beta-estradiol. Considering that 17 beta-estradiol highly induced the mRNA expression levels of both VEGF and MMP-1, which have been well known to be related with the metastasis process, in human MCF7 breast cancer cells, it could increase the metastatic potential of breast cancer cells via the selective induction of the metastasis-related gene transcription.

Bisphosphonates Decrease Telomerase Expression in Prostate Cancer Cells In Vitro. M. Valenti*[1], L. Dalle Carbonare*[1], G. Azzarello*[2], E. Balducci*[2], A. Fracalossi*[1], S. Zenari*[1], O. Vinante*[2], F. Bertoldo*[1], V. Lo Cascio[1]. [1]Dpt. of Biomedical and Surgical Sciences, Medicina Interna D, Verona, Italy, [2]Dpt. of Oncology and Hematologic Oncology, Noale Hospital, Noale, Italy.

Telomerase is a cellular ribonucleoprotein reverse transcriptase responsible for elongation of the telomere that prevents the loss of sequence from chromosome ends to avoid replicative senescence. Telomerase expression is increased in many cancers. Bisphosphonates play an important role in the management of tumors with a secondary involvement of bone. Recent findings have suggested an effect of these drugs on primary tumor burden, too.

We studied the direct effects of alendronate at different concentrations (from 10^{-6} M to 10^{-4} M) on PC-3 human hormone-resistant prostate cancer cell line. In particular, we investigated the effect on viability, and on quantitative telomerase expression. We used real-time reverse transcriptase-polymerase chain reaction to quantify mRNA expression of the catalytic subunit of telomerase (hTERT gene) vs the housekeeping gene GAPDH with gene specific, dual labeled fluorescence probes.

Alendronate induced a dose-dependent inhibition of viability of prostate cancer cells (-27% and -32% vs controls at concentration of 10^{-5} and 10^{-4} M, respectively; $p<0.0001$) as expressed by XTT-test. In addition, treatment with alendronate showed a significant decrease in telomerase expression with respect to control group in PC-3 cells as analyzed through the real-time RT-PCR by two tube comparative Ct method. In conclusion: our preliminary data on alendronate showed that bisphosphonates are able to inhibit PC-3 prostate cancer cell growth. In addition, they reduce the telomerase expression. This is a new finding that suggests an alternative explanation of the direct effect of bisphosphonates on prostate tumor cells.

The RalGEF Pathway Promotes Prostate Cancer Metastasis to Bone. J. Yin, M. D. Oberst*, M. K. Chock*, Y. Ward*, K. Kelly*. NIH/NCI, Bethesda, MD, USA.

Although conflicting results have been reported regarding the involvement of oncogenic mutation of Ras in prostate cancer carcinogenesis, functional activation of Ras has been shown to correlate with prostate cancer progression and metastases. Ras is a multi-effector signaling molecule that activates the Raf/MEK/MAPK, PI3 kinase, and RalGDS pathways. Previous work done in this lab has shown that the Ras effector pathway mediated by the Ras(12V,37G) mutant increased the invasiveness of both epithelial cells and fibroblasts by activating the RalGEF pathway. To determine if RalGEF pathway activation is essential for prostate cancer-related bone metastasis, Ras(12V,37G) was expressed in the DU145 prostate cell line. We then studied the metastatic capacity using a mouse bone metastasis model. Vector-transfected DU145 cells (DU145/EV) were only weakly metastatic, whereas cells expressing Ras (12V,37G) induced multiple metastases in long bones and vertebral bodies 6-8 weeks after injection. Ras (12V,37G) bearing mice had decreased survival compared with DU145/EV control. Interestingly, DU145/Ras (12V,37G) caused cortical bone metastases in which tumor cells grew between periosteal and cortical bone.

These metastases destroyed cortical bone before invading the bone marrow cavity. Cortical bone metastases are mostly seen in bronchogenic carcinoma, and have also been reported in other cancers. To investigate the mechanism responsible for the increased metastastic property, we compared the gene expression profiles of DU145/EV and DU145/ Ras(12V,37G) cells using oligonucleotide arrays. DU145/Ras(12V,37G) expresses a distinct set of genes including 3 upregulated genes (CD24, CTGF and HAS3) and 2 down-regulated genes (E-cadherin and Hsp 27) that may determine the metastastic property of these cells. Since TGFβ has been shown to promote bone metastasis, the growth rate and gene expression in response to TGFβ (2ng/ml) treatment were also compared between these two cell lines. DU145/EV cells were growth inhibited by TGFβ, while DU145/ Ras(12V,37G) cells were not. 13 genes were up-regulated in DU145/ Ras(12V,37G) after TGFβ treatment. Several genes such as angiopoietin-like 4, PDGFB, and CTGF encode angiogenic factors and growth factors that may promote tumor invasion and metastasis. We are currently validating these gene expression changes using real-time RT-PCR and Western blotting, and will charaterize the biological significance of these changes using the *in vivo* bone metastasis model. Prostate cancer bone metastasis is a multifactor process, and our results indicate that Ral-GDS pathway activation may be important in promoting the development and progression of bone metastasis.

Induction of PTHrP mRNA Expression in Human Lung Carcinoma at Sites of Bone Metastasis in Nude Mice. X. Deng*, S. Tannehill-Gregg*, P. Nadella*, E. He*, A. Levine*, T. Rosol. Veterinary Biosciences, Ohio State University, Columbus, OH, USA.

PURPOSE AND BACKGROUND: Parathyroid hormone-related protein (PTHrP) plays an important role in inducing bone resorption at sites of bone metastases. However, it is still unclear how the expression of PTHrP messenger RNA is regulated during the process of bone metastasis. We hypothesized that various isoforms of PTHrP would be regulated differentially in bone metastases compared to subcutaneous neoplasms. METHODS: Human lung squamous cell carcinoma HARA cells (1 x 10^5) were injected into the left ventricle (intracardiacally, IC) or subcutaneously (SQ) into nude mice (8 for IC and 5 for SQ). In addition, in vitro experiments with MDA-231 human breast cancer cells were performed. MDA-231 cells were cultured overnight in the presence of medium conditioned with neonatal mouse calvaria. Total RNA were prepared from mouse bone metastases and SQ tumors or cultured cells. Quantitative real-time RT-PCR was performed to measure the expression of the various isoforms of human PTHrP (139, 141 and 173) mRNA. Human GAPDH mRNA expression served as the normalization control.

RESULTS: Intracardiac injection of HARA cells resulted in bone metastases in the femurs, tibias, and humeri 6 - 8 weeks after inoculation; whereas subcutaneous tumors formed in the SQ-injected mice. Bone metastases were confirmed by radiography and histological examination. PTHrP (139), PTHrP (141), and PTHrP (173) mRNA expression were increased 4-, 14-, and 7-fold, respectively, in bone metastases compared to the subcutaneous tumors ($P < 0.05$). In vitro co-culture of MDA-231 cells with mouse calvaria-conditioned medium resulted in a 3.6-fold increase in PTHrP (139) mRNA expression.

CONCLUSIONS: All three isoforms of human PTHrP messenger RNA were induced in bone metastases in vivo, but the effect was greatest for PTHrP (141). PTHrP (139) was induced in MDA-231 cells co-cultured with mouse calvaria-conditioned medium. PTHrP induction may be an important step in the pathogenesis of bone metastasis by some human cancers.

Type I Collagen Receptor ($\alpha_2\beta_1$) Signaling Promotes the Growth of Human Prostate Cancer Cells within the Bone. C. L. Hall*[1], J. Dai*[1], E. T. Keller[1], M. W. Long[2]. [1]Urology, University of Michigan, Ann Arbor, MI, USA, [2]Velcura Therapeutics, Inc., Ann Arbor, MI, USA.

Bone is the most frequent site of distant metastases in human prostate cancer (CaP). Selective binding to organ specific factors may facilitate organ specific metastasis of cancer cells. Therefore, we tested whether bone metastasis of CaP cells is mediated by binding to Type I collagen, a factor that comprises 90% of the total protein within the bone. To examine the role of collagen binding, human LNCaP cells, that routinely fail to bind to Type I collagen, were selected for collagen binding by serial passage on Type I collagen. These collagen-selected cells ($LNCaP_{col}$) were compared to parental LNCaP cells, and the highly metastatic, isogenic CaP variants LNCaP-LN3 and C4-2B. The data show that $LNCaP_{col}$ cells bound collagen equivalent to that of bone metastatic C4-2B cells (34 ± 2%, n=3). In sharp contrast, the non-metastatic parental LNCaP and lymph node metastatic LN3 cells were incapable of collagen binding. FACS analysis demonstrated that both C42B and $LNCaP_{col}$ express equivalent levels of the integrin $\alpha_2\beta_1$, a known collagen receptor. Antibodies to $\alpha_2\beta_1$ or GRGDTP peptide inhibited C42B and $LNCaP_{col}$ binding to collagen thus confirming that integrins mediate the attachment. Importantly, both $LNCaP_{col}$ and C4-2B cells had an increased ability to migrate towards collagen I compared to parental LNCaP cells and $\alpha_2\beta_1$ blocking antibodies prevented this migration. To directly test whether $\alpha_2\beta_1$ dependent collagen binding contributes to the bone metastatic phenotype, the ability of $LNCaP_{col}$ and parental LNCaP cells to grow within the bone was evaluated following intratibial injection into nude mice. After 9 weeks, 7 of 13 mice (53%) injected with $LNCaP_{col}$ had mixed lytic/blastic bone tumors; whereas, 0 of 8 mice injected with parental LNCaP cells had evidence of bony lesions. We conclude that binding type I collagen through $\alpha_2\beta_1$ induces motility programs in human CaP cells that promote growth within the bone and may explain the high prevalence of CaP metastasis to this site.

Assessment of Total Body Percent Fat from Regional Spine and Femur DXA Measurements. H. S. Barden, W. K. Wacker*, K. G. Faulkner. GE Healthcare, Madison, WI, USA.

Body composition studies usually rely on total body scans using full sized DXA (dual-energy x-ray absorptiometry) systems. Regional assessment of soft tissue composition, however, is a requirement for accurate DXA bone mineral measurements at the spine and femur. In this study, we determined whether regional body composition estimates from spine and femur DXA data could be used to predict total body fat percentage.

We evaluated the ability of soft tissue measurements (tissue %fat and thickness) available from spine and femur scans, along with height, weight and body mass index (BMI), to predict total body soft tissue %fat. We examined results from 161 female subjects (mean age 55;range 22-91 years) whose spine, femur, and total body were measured concurrently with the Lunar Prodigy densitometer (GE Healthcare). Percent fat and tissue thickness for spine and femur scans were available from scan printouts and were stored in the database. A best subset regression analysis fitting the residuals from an initial regression of total body %fat on BMI found that a regression equation using spine thickness, femur %fat, spine %fat, spine %fat x spine thickness, and height provided the best prediction of total body %fat ($R^2 = 0.85$, $r = 0.93$). Three subjects who fell more than 3 SEE from the regression line were excluded.

Regression of measured on predicted total body %fat gave a slope and intercept not significantly different from one and zero, respectively (Figure 1). The median absolute deviation was 1.6 %fat, with 62% of predicted values within 2 %fat of measured values. This regression might be improved with the addition of thin (<20%fat) and very heavy subjects. We conclude that data obtained from spine and femur scans, in combination with anthropometric information, provide a good estimate of total body fat and fat-free body composition. On systems that do not offer total body measurements, regional body composition information derived from spine and femur scans can be used to estimate total body fat percentage.

Comparison of Spine BMD Measurements from DXA With and Without Leg Elevation. C. Simonelli[1], L. Del Rio[2], N. Binkley[3]. [1]HealthEast Clinics, Woodbury, MN, USA, [2]CETIR Centre Medic, Barcelona, Spain, [3]UW Osteoporosis Clinical Center and Research Program, Madison, WI, USA.

Measurement of lumbar spine BMD using DXA traditionally requires hip flexion and elevation of the legs onto a positioning block. This flattens the lumbar curve with the intent of producing more accurate and precise BMD measurement. We determined if not elevating the legs affected BMD accuracy and precision.

Ninety-six women (54 ± 12 years, 70 ± 12 kg) had spine scans using Lunar Prodigy or Bravo (GE Medical) densitometers. One center[3] scanned 30 subjects with Prodigy, once using standard positioning (legs elevated on the manufacturer's spine positioner) and once without the spine positioner (legs flat on the table, feet secured with the dual-femur positioner). Two other centers[1,2] scanned 40 subjects with Prodigy and 26 with Bravo 3 times legs-up and 3 times legs-down. The RMS CV was determined for BMD values measured in triplicate. Single-scan results[3] were pooled with first-scan results from the other centers. L1-L4 BMD for both positions were compared using paired T-tests.

There were no obvious visual differences in disc spaces or vertebral bodies between the two positions. There was a small, but statistically significant, difference of 1.3% (0.014 g/cm^2) in measured L1-L4 BMD, with higher BMD in the legs-down position ($p<0.001$). Bland-Altman analysis showed no significant bias with mean BMD. Precision (~1% CV) was excellent in both positions. Linear regression analysis showed BMD was highly correlated (r = 0.99), with slope near unity (0.97), intercept near zero (0.02) and SEE=0.021 g/cm^2. Given the high correlation, a mathematical correction factor was derived to produce comparable T-scores between the two measurements. After adjustment, there was no significant difference (<0.01 T) in mean T-scores ($p=0.65$). We conclude that measured spine BMD differences with legs-down are small and there is no effect on precision. Adjusted T-scores for the legs-down position are equivalent to the legs-up position.

The Threshold of Vertebral Fracture Determined by Bone Mineral Density in Secondary Osteoporosis Caused by Glucocorticoid Treatment and Primary Hyperparathyroidism. M. Yamauchi, T. Sugimoto, T. Tobimatsu*, J. Naito, M. Iu*, R. Nomura*, Q. Chen*, H. Sowa, H. Kaji, K. Chihara*. Division of Endocrinology/Metabolism, Neurology and Hematology/Oncology, Kobe University Graduate School of Medicine, Kobe, Japan.

Although the vertebral fracture (VFx) risk has good relationship with bone mineral density (BMD) in primary osteoporosis, it remains uncertain whether the same relationship exists in secondary osteoporosis. Glucocorticoid(GC) excess as well as primary hyperparathyroidism (pHPT) are classically listed as important causes of secondary osteoporosis. Thus, we analyzed the cut-off values of BMD in the incidence of VFx in patients with GC treatment and pHPT, and compared these values with those in control subjects. One hundred and thirty-six female patients with GC treatment for more than 6 months (Mean: age 50yr; daily dose of predonisolone 10.1mg; treatment duration 7yr; VFr+ 34), 116 pHPT female patients (age 60yr; serum Ca 11.7 mg/dl; intact PTH 206 pg/ml; VFx+ 14) and 716 female controls (age 61yr; VFx 158) participated in this study. BMD measurement was performed by DXA at sites of lumbar spine, femoral neck and distal one third of radius. VFx was assessed on lateral radiographs of thoracic and lumbar spines. The cut-off values of BMD for the discrimination of VFx were obtained from ROC analysis, that is, the points where the sensitivity curve intersects the specificity curve, as the optimal VFx thresholds. As for comparison of BMD Z scores between VFx+ and VFx-, values at any site were significantly lower in VFx+ in controls. In contrast, values only at femoral neck were significantly lower in VFx+ in patients with GC treatment and no significant differences were found at any site in pHPT patients. At lumbar spine, the cut-off values of BMD (g/cm2) as well as their sensitivity/spefcificity (%) were 0.716; 71, 0.807; 67 and 0.676; 62 in controls, patients with GC treatment and pHPT patients, respectively. At femoral neck, they were 0.581; 75, 0.611; 71 and 0.556; 62, respectively. At radius, they were 0.477; 73, 0.592; 62 and 0.398; 60, respectively. Cut-off values of BMD at any site were higher and lower in patients with GC treatment and pHPT patients, respectively, compared with controls. Sensitivity/specificity was lower in both groups, compared with controls. In conclusion, the present findings suggest that GC excess and endogenous PTH excess induce more accelerated and less deteriorative vertebral fragility than that estimated from BMD, respectively. Although BMD is a good predictor of bone fragility in primary osteoporosis, it is rather difficult to assess bone fragility from BMD value in secondary osteoporosis.

Predicting the Risk of Fracture at Any Site in the Skeleton: Are All BMD Measurements Equally Effective? G. M. Blake[1], K. M. Knapp[1], T. D. Spector[2], I. Fogelman[1]. [1]Imaging Sciences, Guy's, King's and St Thomas' School of Medicine, London, United Kingdom, [2]Twin Research and Genetic Epidemiology Unit, St Thomas' Hospital, London, United Kingdom.

The ability to assess a patient's risk of fracture is fundamental to the clinical role of bone densitometry. Fracture discrimination is quantified by the relative risk (*RR*) defined as the increased risk of fracture for a 1 standard deviation decrease in bone mineral density (BMD). The larger the value of *RR*, the more effective measurements are at identifying patients at risk of fracture. The data available suggests that if the objective is to predict the risk of fracture at *any* skeletal site then all types of BMD measurement are equally effective. In this study we show theoretically that the observation that *RR* values for predicting the risk of any fracture are comparable for all types of measurement is a consequence of two other observations: (1) that fracture risk prediction at BMD sites distant from the fracture site is quantitatively explained by the correlation of the BMD measurements; (2) that the correlation coefficients between distant BMD sites are all comparable with values in the range $r = 0.55$-0.65. Although both these observations are only approximations, they nevertheless provide useful insight into the potential for improving the clinical effectiveness of bone densitometry. In particular, they point to the importance of the correlation coefficient between different types of measurement as a key index that is predictive of the ability of new types of measurement to discriminate fracture risk. It is the narrow range of values of the correlation coefficient between BMD measurements in the central and peripheral skeleton that leads to the conclusion that such measurements should all have comparable power to predict fracture risk. The ability of peripheral bone densitometry to predict fracture risk could be improved by the development of new techniques that correlate better with BMD measurements in the central skeleton, for example by reducing the accuracy errors due to variations in soft tissue composition. Conversely, those techniques that correlate poorly with central BMD, for example some types of ultrasound measurement, are likely to prove less effective at predicting fracture risk.

DXA and QUS Can Comparably Dicriminate Patients with Osteoporotic Hip Fractures from Matched Controls. P. Hadji, M. Gottschalk*, V. Ziller*, E. Mann*, G. Esser*, U. Wagner*. Endocrinology and Osteoporosis, Clinic of Gynokology and Obstretics of Philipps- University, Marburg, Germany, Marburg, Germany.

Introduction: The aim of this pilot study was to evaluate the ability to discriminate patients with hip fracture from healthy controls using DXA and QUS in postmenopausal women.

Material and Methods: We included 22 Patients mean age 76,5 ± 5,4 years with an incident osteoporotic hip fracture and 22 age and BMI matched controls. Women in the control group with a history of Osteoporosis or with a fracture or diseases or treatments known to effect bone metabolism were excluded from the study. BMD was measured by DXA (Prodigy, GE/Lunar) at the spine and hip. QUS was performed at the Os Calcaneus using the Achilles + device as well as the Insight device (GE/Lunar).

Results: DXA results of women with hip fractures at the femoral neck showed statistically significant lower T-score of -2.6 and Z-score of - 0.8 compared to T-score of -1.7 and a Z-score of 0.1 in healthy controls (p= 0,008 and p= 0,01). In women with hip fracture, DXA results of the Spine (L1-L4) showed an insignificant difference in T- and Z-score compared to age and BMI matched controls. In accordance to QUS results, measurement at the Os Calcaneus (Achilles + and Insight) showed significant differences between the groups. The T-score was -3.3 and -2.6 in women with hip fracture compared to a T-score of -2.3 and -1.6 (p= 0,01) in controls. The Z-score was -0.9 and -0.3 in women with hip fracture compared to 0.1 and 0.8 (p= 0.01 and p= 0.005) in controls.

Conclusion: The results of our pilot study confirm the capability of DXA and QUS to discriminate patients with prevalent hip fracture from healthy controls. This significant difference could be observed by DXA at the hip and both QUS devices measuring at the Os calcaneus but not for DXA of the spine. Further large scale longitudinal studies are needed to evaluate the diagnostical capabilitys of DXA and QUS.

Association between Current Bone Metabolism Parameters and the Progression of Vascular Calcification in Men and Women. M. Naves-Diaz*, J. B. Díaz-López*, C. Gómez, A. Rodríguez-Rebollar*, M. Rodríguez-García*, J. B. Cannata-Andía. Bone and Mineral Research Unit, Hospital Universitario Central de Asturias, Oviedo, Spain.

In the elderly population it has been found that low bone mass is associated with a higher prevalence of vascular calcification (VC). The aim of this study was to find out the association between bone metabolism parameters and the progression of aortic VC in men and women from a non-selected Spanish population.

A cohort of 156 men and 164 women participated in this study. Two lateral dorsal and lumbar radiographs and lumbar and hip bone densitometry were performed at baseline and again 4 years later. The progression of aortic VC was defined by an increase in the severity -with a semi quantitative scale- of the VC in the second radiograph compared with the radiograph performed at baseline. In addition, the presence of a new aortic VC was also determined. Bone metabolism parameters selected were analysed in a fast serum sample. All those subjects who had undergone any previous osteoporosis treatment were excluded from the analysis.

Progression of aortic VC was found in 56% of men and in 33% of women. The incidence of aortic VC was 26% in men and 15% in women. The univariate analysis showed that in men, those with VC progression showed a significant reduction in lumbar spine bone mineral density (BMD) compared with those without VC progression (-1.94±4.4% vs. 0.66±4.7% respectively, p=0.006). In addition, in men with VC progression, the serum calcium was significantly higher 9.5±0.3 mg/dl and the osteocalcin lower 5.0±1.5 ng/ml compared with those without VC progression, 9.3±0.3 mg/dl and 5.9±2.3 ng/ml respectively, p<0.05).
Women with VC progression showed also a significantly reduction in lumbar spine BMD compared with those without VC progression (-0.58±5.8% vs. 2.06±4.9%, p=0.035). Serum calcitriol was higher in women with new VC (43±15 vs. 37±11 pg/ml, p=0.047).
In men, using logistic regression adjusting by age and smoking, increments in serum calcium [RR=3.46; (95% CI)=1.17-10.20], increments in osteocalcin levels [0.75; (0.61-0.92)] and the rate of reduction in lumbar spine BMD [1.14; (1.03-1.25)] were independently associated with progression of VC.
In women, only serum calcitriol was positively associated with the incidence of VC [1.04; (1.00-1.09)]. The rate of change in BMD at lumbar spine was not independently associated, either with the progression or the incidence of VC.In summary, in men higher serum calcium and a reduction in lumbar spine BMD were independent risk factors for the aortic VC progression, whereas higher levels of osteocalcin were a protective factor. In women, higher serum calcitriol was the only risk factor associated with the appearance of a new aortic VC.

Wider Limits of Acceptable Change in Projected Vertebral Areas Between Serial Scans Still Renders Many Serial DXA Interpretations Invalid. G. Kline*, D. A. Hanley. Medicine, University of Calgary, Calgary, AB, Canada.

The ISCD recommends vertebral projected areas should differ by < 2% to avoid measurement error due to apparent change in bone size. This strict criterion is rarely achieved in clinical practice. We re-analyzed 103 consecutive pairs of DXA reports to determine the frequency and magnitude of serial differences in vertebral area.
Scans were performed at qualified community radiology sites and included if free from any technical errors, artifacts or rotation. We calculated the proportion of paired scans having at least 2 vertebrae differing in area by <2%, <3%, <4% or <5%. Using the differing sets of validity criteria, vertebrae not meeting the areal standard were removed from the analysis and the overall change in BMD recalculated. The new, recalculated BMD was compared to the original report to determine the frequency and magnitude by which the re-analysis would change the final report.
Of the paired scans, 5%, 16%, 27% and 35% had all 4 vertebrae differ in area by less than 2%, 3%, 4% and 5% respectively. When only 2 vertebrae were required to meet acceptability criteria, 51%, 73%, 85% and 89% of scans met the 2%, 3%, 4% and 5% difference criteria. 11% of scans were non-comparable by even the least stringent criteria of 2 vertebra differing by <5% between scans.
Re-analysis of BMD change in each group differed from the reported change by 0.012 to 0.015 g/cm2. However, this amount was sufficient to change a clinical report from "significant change" to " non-significant change" in 26%, 27%, 21% and 20% of scans in each of the four validity groups using a least significant change of 0.025 g/cm2. Between 11%-17% of scans differed in the recalculated BMD change by an amount greater than the least significant change of 0.025 g/cm2.
Fewer serial BMD results were classified as non-acceptable when using the broader validity criteria of <5% area difference, but when corrected for areal differences, a similar and large proportion of scans would have a major change in the clinical interpretation of BMD change. These results do not change the interpretation of population BMD change in randomized trials but highlight the need for more caution in data analysis of serial densitometry results when used to make individual patient management decisions.

Variation in the Location of the Ward's Triangle Region in the Norland Femur Study. J. M. Wang*[1], J. C. Liu*[2], T. V. Sanchez[3]. [1]Research and Development, Norland--a CooperSurgical Company, Beijing, China, [2]Department of Nuclear Medicine, PLA 304th Hospital, Beijing, China, [3]Research and Development, Norland--a CooperSurgical Company, Socorro, NM, USA.

Variations in distribution of femur head bone mineral have been reported as a major component to bone fragility by a number of investigators. In addition to other femur regions, DXA allows assessment of an area reported as the Ward's Triangle region. When using the Norland scanner to locate the Ward's region, the analysis program searches for a region with the lowest density along a fixed area located near the crosshair formed by the femur neck cursor and the trochanteric boundary cursor. While the Ward's region is usually located very near this crosshair region, on occasion the search program locates the lowest density region somewhere deeper into the femur neck region or the trochanteric region. This study examines these substantially "off-line set" Ward's regions in a population referred for DXA evaluation.
Femur studies using the Norland XR-36 were performed on an ambulatory population of 3,000 subjects referred for DXA to the Department of Nuclear Medicine at the PLA 304th Hospital. All studies were reviewed by a factory trained operator (JMW) to insure that all scans had been properly performed and analyzed. Of the 3,000 studies examined, 207 (6.9%) subjects showed "off-line set" Ward's regions--70 (2.3%) being off-line set in the femur neck region and 137 (4.6%) being off-line set in the trochanteric region. Examining those studies with the "off-line set" Ward's located in the femur neck area showed bone density was 84% that found in the normally located Ward's region. Similarly, bone density in the "off-line set" Ward's located in the trochanteric region was about 80% that in the normally located Ward's region.
The survey shows that, when compared to the bone density in the normally located Ward's region, a number of subjects show significantly lowered densities within the "off-line set" Ward's located deeply within the femur neck or trochanteric regions. Finding these significantly reduced bone densities within biomechanically stressed areas may serve to identify subjects especially prone to femoral neck or trochanteric fracture.

Finite Element Analysis of DXA Images (FEXI) for the Prediction of Osteoporotic Fractures - Experimental Validation. C. M. Langton*[1], J. A. Thorpe*[2], M. J. Fagan*[3]. [1]Centre for Metabolic Bone Disease, University of Hull, Hull, United Kingdom, [2]Centre for Metabolic Bone Disease, Hull & East Yorkshire Hospitals, Hull, United Kingdom, [3]Engineering, University of Hull, Hull, United Kingdom.

The preferred method of assessing the risk of an osteoporosis related fracture is currently a measure of bone mineral density (BMD) by dual energy X-ray absorptiometry (DXA). We know however that other factors contribute to the overall risk of fracture including anatomical geometry and the spatial distribution of bone. The purpose of this study was to compare the abilities of plane radiograph- and DXA-derived finite element analysis (FEXI), along with BMD, to predict experimentally derived mechanical stiffness and yield load of the porcine proximal femur.
The FEXI analysis procedure simulates a mechanical compression test, providing a measure of stiffness (N mm^{-1}), being inherently sensitive to the external shape and internal structure of a bone.
DXA scans and digital plane radiography were performed on 23 excised porcine femurs, with BMD recorded for the proximal third. Following addition of resin support platens over the greater trochanter and femoral head, compressive mechanical testing provided stiffness and yield load data. The DXA and plane radiograph images were converted into bitmap format (256 grey levels). Simulated support platens were manually added to the images. A bespoke computer program converted the images into a finite element model whereby the grey level of each image pixel was converted into a corresponding Young's modulus value. 2D plane stress finite element analysis was performed, from which the stiffness of the bone image was derived.
BMD showed a good correlation with both experimentally determined stiffness and yield load (R^2=0.65 and 0.71 respectively). FEXI stiffness derived from DXA images demonstrated higher correlation with stiffness and yield load (R^2=0.61 and 0.71 respectively) than did plane radiograph-derived FEXI (R^2=0.53 and 0.63 respectively). BMD correlated highly with DXA derived FEXI (R^2=0.83), but less so with plane radiograph FEXI (R^2=0.45). FEXI utilising the two X-ray modalities were highly correlated (R^2=0.65).
These findings confirm that both BMD and DXA-derived FEXI predict the stiffness and yield load of bone, the poorer performance of plane radiograph derived FEXI being attributed to variability in X-ray exposure. The porcine proximal femur exhibits a short and wide neck, a large greater trochanter, and lower variation in hip angle and hip axis length. It is therefore feasible that the ability of FEXI to predict mechanical integrity may be higher in human than porcine bones.

Assessment of Criteria for Lateral Morphometry in over 65 Year Olds Attending for Bone Densitometry. A. L. Dolan*, J. Wilkinson*, B. Coutinho*. Rheumatology, Queen Elizabeth Hospital, London, United Kingdom.

The presence of vertebral fractures increases the risk of subsequent fracture fourfold and supports the need for more potent treatments such as bisphosphonates or PTH, yet many are undetected clinically. Lateral vertebral morphometry is now widely available on modern densitometry machines an can identify such fractures. There is now a need to define those patients in whom the technique is most appropriate.
Patients were selected for lateral vertebral morphometry if they were over 65 years and satisfied one of the following criteria: previous low impact fracture, kyphosis, height loss > 2", height loss seen at DXA or BMD <-2.5 and non of above. Scans were performed on a Hologic 4500c DXA Bone Densitometer with an upgraded 'Discovery' software package and Instant vertebral assessment. Ethics committee consent was obtained.
268 patients (36 males, 232 females) satisfied one or more criteria and received lateral morphometry, out of 363 patients over 65 years of age (74%) referred to an open access bone densitometry service at Queen Elizabeth Hospital, Woolwich over a 4 month period. Of these 160 patients (60%) had satisfied criteria for morphometry because of low impact fracture, 77 (29%) had kyphosis, 84 (31%) showed height loss >2", 56 (21%) had height loss observed at DXA and 40 (15%) had solely low BMD values. 152 patients had one or more vertebral fractures (57%) identified. A total of 338 vertebral fractures were identified in these patients of which 79 (23%) were severe, 149 (44%) moderate and 110 (32%) mild according to Genant criteria. 76/152 patients (50%) with vertebral fracture were osteoporotic at either hip, spine or forearm (6 males, 70 females). 99/152(65%) patients were osteopenic (9 male, 90 female).
Lateral morphometry at DXA identified a significant number (57%) of patients with vertebral fracture when they were selected according to high risk criteria. This is an important intervention since it may imply need of more potent osteoporosis treatment. This is especially so for those with vertebral fracture but osteopenia 99/268 (37% of those receiving morphometry) where treatment should be upgraded following their morphometry results.

The Femoral Neck Is Ellipsoid: the Assumption of Circularity or Parallelepipedal Shape Introduces Errors in Volume and Volumetric Bone Mineral Density. R. M. Zebaze*[1], F. Welsh*[2], S. Iuliano-Burns[1], A. Evans*[1], E. Seeman[1]. [1]Endocrinology, Austin Health, Melbourne, Australia, [2]University of Aberdeen, Aberdeen, United Kingdom.

Comparisons of femoral neck dimensions, volumetric BMD and bone strength between sexes, races, patients with and without fractures use estimates derived from bone densitometry. Calculation of FN external volume, medullary diameter, cortical thickness, volumetric BMD, sectional modulus assume that the FN approximates a cylindrical structure in which 60% of the mineral is in the cortex, the rest is medullary in location, and that the tissue mineral content is constant with age (1.05 g/cc). These assumptions are untested. Volumetric BMD assumes the FN is a parallelepipedal structure and computed as BMC/ area2 (vBMDe1) or a cylinder computed as BMC/*(W/2)2*h (BMDe2), h being the height of the bone scan region. We used DXA in 26 Caucasian female cadavers mean age of 69.2 ± 3.2 years (range 29 to 85 years) and directly measured FN dimension using a caliper and Archimedes principle. FN diameter measured by DXA as an average FN 3.37 ± 0.4 or mid-FN value 3.37 ± 0.1 were no different from FN width measured in vitro 3.51 ± 0.13 cm. Femoral axis length and neck shaft angle measured by DXA and directly did not differ (9.61 ± 0.2 vs 9.65 ± 0.22 cm and 123.5 ± 0.21 vs 123.6 ± 0.19 degrees respectively). However, FN depth was always lower than the width by 25% (from 14 to 36%). Thus, DXA underestimated FN vBMD by 41% for BMADe1 (0.214 ± 0.02 vs 0.364 ± 0.03 g/cm3) to 20% for BMADe2 (0.272 ±0.01 vs 0.364 ± 0.03 g/cm3). Smaller bones were more circular, bigger bones were ellipsoid so the bigger the bone, the worse the vBMD under-estimate. Adjustments of the DXA estimates assuming that the FN was ellipsoidal (BMADe3) with the bigger axis being the FN width and the smaller axis being the depth (0.75 depth/width) result in no difference between BMADe3 (0.359 ± 0.02 vs BMAD 0.364 ± 0.03 g/cm3). We infer that DXA overestimates volume, and underestimates estimates FN vBMD and this may have an impact on fracture prediction. (ii) Estimates assuming a cuboidal structure should be abandoned in favour of an ellipsoidal structure.

Bone Mineral Density and the Risk of Peripheral Arterial Disease: Mr Os, Hong Kong. S. Y. S. Wong[1], E. M. C. Lau[2], H. Lynn[1], J. Woo*[1], P. C. Leung*[3]. [1]Department of Community and Family Medicine, Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China, [2]Jockey Club Centre for Osteoporosis Care and Control, Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China, [3]Department of Orthopedics and Traumatology, Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China.

Previous studies have demonstrated an association between peripheral vascular disease and bone mineral density in women but not in men. In a large prospective cohort of 2000 Chinese men aged 65 to 92 years of age in Hong Kong (Mr Os, Hong Kong), the association between peripheral vascular disease and bone mineral density was explored.

Demographic and lifestyle information were obtained from face to face interviews using standardized questionnaire. These include demographic information, medical history, smoking and alcohol history and physical activity. Physical examination measurements include anthropometry and tibial and brachial systolic blood pressures. The ratio of the posterior tibial and brachial systolic blood pressures, the ankle/arm index, was used as a measure of peripheral arteriosclerosis in the lower extremities. Bone mineral density at the total hip and spine (L_1 - L_4) was measured by Hologic QDR-4500W densitometers (Hologic, Inc., Waltham, MA).

In this cross-sectional analysis, the ankle brachial index was positively associated with BMD at the total hip but not the spine. A decrease in index of 2 standard deviations (SD) was associated with a decrease of 3.6 % in hip BMD. In multiple regression analysis, the effect size at the hip decreased from 3.6% to 1.4% when adjustment was made for smoking, body mass index, history of hypertension and diabetes, and physical activity (Table 1).

Table 1. Summary of multivariate analysis of bone mineral density (g/cm^2) at the total hip expressed as the percent difference (95% Confidence Interval) in BMD per unit change of the predictor variables (N=2000)

Variable	Mean (SD)/ prevalence	Unit (2SD)	Percent difference (95% CI)
Age	72.4(5)	10	**-2.4(-3.6, -1.2)**
BMI	23.4(3.1)	6	**13.2(12, 14.2)**
Current smoker	11.9%	Yes/no	-1.2(-2.9, 0.6)
Hypertension	41.8%	Yes/no	-0.2(-1.4, 1)
PASE score	97.3(50.3)	100	**1.2(0, 2.4)**
A history of diabetes mellitus	14.7%	Yes/no	**4(2.4, 5.7)**
Ankle-arm index	1.1(0.13)	0.26	**1.4(0.4, 2.6)**
			R^2=0.268

Bold numbers indicate statistical significance at the p<0.05 level.

Our study shows that in addition to women, peripheral arteriosclerosis in the lower extremities may also be associated with decreased bone mineral density in men. This shows that in addition to the previously suggested role of abrupt estrogen decrease in explaining the association between peripheral arterial disease and osteoporosis, other factors must also be involved.

Significant Malnutrition And Osteopenia In Gaucher Type I Patients Despite Enzyme Replacement Therapy. B. Oliveri, M. Parisi*, G. Goldstein*, A. Bagur. Sección Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina.

Gaucher patients (GP) have a deficit in Beta glucocerebrosidase activity, which in turn leads to accumulation of glucocerebroside in the macrophages of various organ systems (spleen, liver, lung, kidney, bone and bone marrow). Eighty % of Type I GP present skeletal involvement. In a previous cross-sectional study we reported that GP receiving enzyme replacement therapy (ERT) (ASBMR2003) had diminished bone mass associated with unbalanced bone metabolism due to higher resorption than formation. Hypermetabolism (higher resting energy expenditure) was described in GP, and found to improve partially and to varying extents with ERT. The aim of the present study was to evaluate whether GP patients receiving ERT presented alterations in body composition (BC) (fat and lean mass), and the relationship between body composition and bone mass. The study population comprised 10 patients (5 women, 5 men) aged (X± SD) 26.1± 7.0 years (range (r):19-43) with a BMI of 19.4.±1.7 kg/m2 (r:16.5-22.9). Six patients were splenectomized and 5 had hepatomegaly. All patients had been receiving ERT (imiglucerase) in a dose of 50.8±14.0 IU/kg/2weeks (r:30-71) during 4.9±3.7 years. Bone Mineral Density and Content (BMD and BMC) of Total Skeleton (TS) and fat and lean mass were measured by DXA (Lunar DPX-L) and compared with age/sex matched controls, to calculate Z score and percentage of diminution.

Age and height of GP were similar to controls but the following parameters were significantly diminished: weight, fat. and lean mass Zs were: -1.84 (p<0.05), -1.6 (p<0.001) and -1.13 (p<0.05) respectively and TS BMD, BMC and total calcium Zs were: -1.69 (p<0.001), -1.65 (p< 0.001) and -1.67 (p<0.001), respectively .When GP were grouped according to sex: both males and females had a high diminution in TS BMC (-19%,p<0.05) and fat mass (-40%,p<0.01) but only males showed a significant diminution in lean mass (-12%,p<0.05).

When divided according to ERT dose, the patients receiving <60IU/ kg/2w had lower: TS BMD: Zs -2.5 vs -1.1 (p<0.04), BMI 18 vs 20 (p<0.067), and fat mass Z: -2.0 vs -1.3 (p<0.067), than those receiving >60IU/kg/2w. No differences in BC were observed in patients with hepatomegaly or splenectomy. The only positive significant correlation was between Z of TS BMC and lean mass. CONCLUSION: GP present severe malnutrition (mainly due to diminished fat mass) and present significant osteopenia, which is probably due to multifactorial causes rather than to fat mass diminution. Although ERT was not sufficient to prevent body composition alterations, patients receiving higher ERT doses tended to present fewer alterations.

A Randomized Study to Evaluate Strategies to Improve Osteoporosis Detection and Treatment in Elderly Women. B. Muma*[1], J. Lafata*[1], B. McCarthy*[2], D. Kolk*[1], E. Peterson*[1], D. Rao[1], T. Weiss[3], Y. Chen*[3]. [1]Henry Ford Health System, Detroit, MI, USA, [2]Alina Medical Group, Minneapolis, MN, USA, [3]Merck & Co., Inc., West Point, PA, USA.

Current estimates are that only 20% women age 65 and older have received a bone mineral density (BMD) test, despite recommendations from the US Preventive Services Task Force and the National Osteoporosis Foundation. Thus, a large number of women are at risk of avoidable late-stage osteoporosis. We report preliminary findings of a randomized prospective study to evaluate strategies to enhance the quality of care for osteoporosis.

We identified women aged 65-89 that received primary care from 15 ambulatory care clinics of a large medical group in southeast Michigan between 4/1/2001 and 3/31/2003. The clinics were stratified by size and BMD availability, and randomized to one of 3 study arms: (1) usual care; (2) patient mailing (BMD reminder letters + educational material); and (3) patient mailing plus physician reminder prompts for BMD testing. Women that previously received a BMD test, a diagnosis for osteoporosis, or a prescription drug claim for an osteoporosis-specific therapy (alendronate, risedronate, raloxifene, or calcitonin) were excluded. A total of 10,565 eligible women were included in the study: 3,110 women in strategy (1) clinics; 3,368 in strategy (2) clinics; and 4,087 in strategy (3) clinics. Preliminary analysis of BMD testing rates were calculated for each study arm for a six-month window starting in August 2003. Differences between groups in BMD testing rates were evaluated using generalized estimating equations. To adjust for different intervention start times, we matched the usual care group to each of the intervention groups separately by starting time. Statistically significant differences in BMD testing rates between groups were evaluated using generalized estimating equation approaches.

Preliminary analysis adjusted for intervention start date indicate differences in BMD screening rates between the usual care and patient mailed reminders (2% vs. 13%); and the usual care and the patient mailing plus PCP prompt (5% vs. 27%).

Differences between usual care and patient mailing strategies were significant (p<.001). The use of a patient mailing plus physician prompts lead to significant improvements in BMD testing compared to both usual care and patient mailing alone (p<.001). Results did not change with adjustments for clinic, race, and age.

Preliminary results indicate that the use of mailed patient reminders alone or in combination with physician prompts can lead to significant increases in osteoporosis screening rates compared to usual care, with the combination intervention (patient mailing + PCP prompt) showing the greatest effect.

In-vivo and Phantom Bone Mineral and Body Composition Calibration of DXA. D. Pearson*[1], B. Horton*[1], D. J. Green*[1], C. G. Miller[2], S. A. Jackson[2]. [1]Nottingham City Hospital NHS Trust, Nottingham, United Kingdom, [2]Bio-Imaging Technologies Inc, Newtown, PA, USA.

The purpose of this study was to obtain in-vivo and phantom cross calibrations for bone mineral and body composition studies using DXA.

21 subjects (18F, 3M mean age 55, range 31-80) had whole body scans on GE Lunar Prodigy (P) and Hologic QDR2000 (H) scanners. The Bio-Imaging Variable Composition Phantom (VCP) is a lightweight DXA phantom for cross calibration for body composition. It consists of a stack of 4 rectangular plastic blocks 13cm thick, with an aluminium head to simulate the skull. Three different kinds of plastic sheet are used in different combinations to simulate low (10%), medium (24%) and high (48%) fat content, but it has no bone mineral content (BMC). The VCP has a simulated body weight of about 9.5kg and was scanned on both machines 4 times with each percentage fat (%fat) . The calibrations were calculated using a standardised principal components analysis. The BMC, fat mass (FM), lean body mass (LBM) and %fat were compared using a Bland & Altman plot to calculate the mean difference and limits of agreement (LA).

The mean weight of subjects was 65kg (range 43-92kg), providing a good range of body composition values for cross calibration. There was good correlation between FM, LBM and %fat measured on the two instruments (r=0.97). The mean difference in BMC was 364g (P - H) and the LA were 91g to 638g compared to a mean BMC of 1712g on the QDR2000 ($p<0.01$). For FM the difference was -1.5kg (-4.3kg to 1.3kg mean 26kg $p<0.01$). For LBM the difference was -0.6kg (-3.6kg to 2.6kg mean 39kg). For %fat difference was -1.3% (-5.5% to 2.8% mean 38.7% $p<0.01$). The mean differences in FM, LBM and %fat using the VCP were -0.4kg, 0.2kg and -3.3% respectively. Figure 1 shows the in-vivo and VCP calibrations for %fat. The in-vivo calibration equation for LBM is H = 1.034P - 709 g (± 1587g), for FM is H=1.038P+562 g (±.1364g), for BMC is H = 0.83P-11 g (±111g) and for %fat is H = 1.099P + 0.72 (±2.1).

There is a consistent difference in BMC, %fat, FM and LBM between the Prodigy and QDR2000. The VCP gives an adequate cross calibration for %fat, FM and LBM despite it being necessary to extrapolate to higher values of FM and LBM. The limits of agreement are acceptable for cross calibration in the context of a cross sectional study, but would not be acceptable in longitudinal measurements to allow individuals to transfer between DXA instruments.

Inter-observer Variation of Vertebral Morphometry Using Two Different DXA Methodologies: Expert vs Prodigy. D. Pearson*[1], B. Horton*[1], D. J. Green*[1], D. J. Hosking[1], A. Goodby*[2], S. A. Steel*[2]. [1]Nottingham City Hospital NHS Trust, Nottingham, United Kingdom, [2]Hull Royal Infirmary, Hull, United Kingdom.

The purpose of this study was to compare inter-observer variation and vertebral morphometry on a supine lateral DXA scanner (GE Lunar Expert) and decubitus lateral scanner (GE Lunar Prodigy).

25 patients (19F, 6M, mean age 68, range 50 to 84) were recruited. Morphometry was carried out on each machine. Patients completed a questionnaire on comfort during scanning. The scans from each machine were analysed by two operators. Both completed a questionnaire on image quality.

One patient had an unsatisfactory scan on the Prodigy because of the presence of pins and plates in the lumbar spine. There was no significant difference between the scanners in terms of patient comfort. 19/25 reported that comfort was very good or better on the Expert compared with 17/25 on the Prodigy. There was no significant difference between the scanners in perceived image quality or in the ability to identify osteophytes or aortic calcification. The image quality was significantly worse in the thoracic (median 4, range 1-6) compared to the lumbar spine (median 5, range 2-6, $p<0.001$). T4 was the highest vertebra assessed in 71% of cases on the Expert compared to 46% of cases on the Prodigy ($p=0.08$). Inter-observer coefficients of variation (CV) ranged from 4% in the lumbar region to 13% for the posterior height in the upper thoracic region. The limits of agreement on vertebral height were ±3.5mm. Posterior height CVs were higher than anterior or mid height CVs. In the inter-machine comparison, mid and posterior heights were significantly higher (0.5mm) on the Expert ($p<0.001$) and the limits of agreement were ±3mm. The Expert identified 10 wedge fractures, 3 in a patient not scanned on the Prodigy and 2 further not seen on the Prodigy. The Expert identified 7 biconcave fractures and the Prodigy identified 9, all at different sites.

There are no qualitative differences between the Expert and Prodigy in patient comfort or image quality. Whilst the mean difference between machines in vertebral height measurements, A/P ratio, M/P ratio and Z-scores were small, the limits of agreement were wide. The inter-observer limits of agreement were the same size as the inter-machine limits of agreement suggesting that this is representative of underlying precision of MXA rather than differences in patient positioning or scanner used. There was reasonable agreement between the two machines on the identification of wedge fractures, although the number of fractures identified was small. The number of biconcave fractures, and the lack of agreement between the two systems requires further study, although it is unsurprising given the limits of agreement.

M105

A Strategy for DXA Cross Calibration during Equipment Upgrade. D. Pearson*[1], B. Horton*[1], D. J. Green*[1], C. G. Miller[2], S. A. Jackson[2]. [1]Nottingham City Hospital NHS Trust, Nottingham, United Kingdom, [2]Bio-Imaging Technologies Inc, Newtown, PA, USA.

The purpose of this study was to develop a cross calibration strategy for replacing three old DXA scanners (GE Lunar DPXL, GE Lunar Expert, Hologic QDR2000) with two new GE Lunar Prodigy scanners.

Each of the old scanners was paired with one of the new scanners, e.g. patients scanned on the Expert or QDR2000 would be transferred to Prodigy 1 and only scanned on that machine in future. A cohort of patients was recalled for each old scanner, and up to 30 patients had lumbar spine and hip scans on the old scanner and the appropriate new scanner. An in-vitro calibration was carried out using a Bona Fide Phantom (BFP) scanned on each scanner on the days when calibration scans were carried out. Calibrations were fitted using a standardised principal components method. A Bland & Altman plot was used to calculate the mean difference and limits of agreement (LA) between scanners. Standardised BMD (sBMD) was calculated as an alternative method of calibration and compared with the in-vivo calibration.

A range of calibrations was generated, e.g. for Expert to Prodigy 23 patients (mean age 70, range 50-84) were scanned. There was a good range of lumbar spine BMD (mean 1.086g.cm^{-2} range 0.753-1.460 g.cm^{-2}). The calibration equation was P = 1.014 E -0.044 (see = 0.046 g.cm^{-2}) where P and E are Prodigy and Expert BMD respectively (Figure 1). Without calibration, the mean difference was 3% with LA of 0.063 to -0.122 g.cm^{-2}. Applying the calibration, the LA were ±0.047g.cm^{-2}. There was no significant difference between the in-vivo an in-vitro calibration. As expected, Prodigy BMD was about 15% higher than Hologic BMD. Following calibration the LA were ±0.064g.cm^{-2}. Using sBMD to calibrate gave a mean difference of 3% with LA of 0.115 to -0.045 g.cm^{-2}. There was good correlation at spine and hip for all pairs of scanner (r=0.95 to 0.98).

The LAs following calibration are clinically significant so it is not possible to apply a calibration to an individual patient for trending purposes, as the error is similar to the expected annual change in BMD. The calibrations can be used for group data in clinical trials. The in-vivo calibration gives better agreement than using sBMD to transfer patients between scanners. The BFP calibration was close to the in-vivo calibration. When introducing a new scanner, a new baseline BMD has to be obtained for each patient.

Regional Trabecular Bone Volume Ratio Predicts Failure of Thoracic Vertebrae under a Posteroanterior Load. M. M. Sran[1], K. M. Khan[1], D. M. Cooper*[2], S. K. Boyd[3], R. F. Zernicke[4], T. R. Oxland*[1]. [1]Division of Orthopaedic Engineering Research, Medicine, UBC, Vancouver, BC, Canada, [2]Archaeology, UofC, Calgary, AB, Canada, [3]Engineering, UofC, Calgary, AB, Canada, [4]Engineering, Medicine, UofC, Calgary, AB, Canada.

Failure load of thoracic cadaveric vertebrae under a posteroanterior (PA) load (where fracture occurred at the base or middle of the spinous process), and which may be linked to fracture during spinal mobilization, is not predicted by lateral or AP DXA or geometry of the spinous process or vertebral body.[1] We hypothesized that this may be due to BMD being an integrated measure of the entire vertebra, whereas these particular fractures occur in the largely cortical spinous process.[1] Thus the objective of this study was to: a) measure trabecular bone volume ratio (BV/TV) using µCT in four regions of thoracic vertebrae and to correlate those measures with PA failure load, and b) compare trabecular BV/TV of the spinous process base with the central lamina and middle spinous process regions, as a possible determinant of the fracture site.

We measured failure load and failure site in 11 T5-8 cadaveric spine segments (mean age 77 yr) when a PA load was applied at the spinous process of T6 using a servohydraulic material testing machine (Instron 8874), simulating a commonly used spinal mobilization technique. The T7 vertebra was dissected and sectioned to produce regional samples of the spinous process, the central lamina, and a central vertebral body core (8mm diameter). Each sample was scanned with µCT (Skyscan 1072, 15µm nominal isotropic resolution). We segmented four trabecular regions (spinous process base, spinous process middle, central lamina, and vertebral body centrum) and determined BV/TV in each region. We correlated PA failure load (N) with BV/TV for each region and compared BV/TV of the spinous process base with the middle spinous process and central lamina regions (paired t-test).

BV/TV at the base or middle of the T7 spinous process (fracture sites) showed a strong significant correlation with PA failure load of T6 (base: r=0.74, p=0.01; middle: r=0.73, p=0.01). The relations between BV/TV of the vertebral body centrum (r=0.44, p=0.1) or central lamina (r=0.57, p=0.07) and PA failure load were not significant. There was a significant difference between BV/TV in the spinous process base and the central lamina (p=0.03).

These novel data supported the findings of our previous study where AP and lateral BMD measures by DXA did not predict failure load of the spinous process.[1] However, BV/TV of the base and middle regions of the spinous process predicted failure at those sites, and lower BV/TV at the base (compared with the lamina) may have influenced the site of fracture.

Dual Femur Densitometry - Effect on Diagnosis and Treatment Decisions. R. E. Cole. Osteoporosis Testing Center, Brooklyn, MI, USA.

The proximal femur is the best site for predicting hip fracture risk; a decrease of 1 T-score in hip BMD corresponds to ~3-fold increase in hip fracture risk. Recent technology enhancements allow rapid scanning of both hips in one acquisition, eliminating time-consuming repositioning and providing BMD results for individual and combined hips. While significant right vs. left BMD asymmetry is not the norm, discordance does exist in some patients. Bilateral scanning improves patient management by avoiding a potential missed diagnosis from scanning only one of two discordant femora.

Dual femur results from 537 women (mean age 61.2 years; SD 10.5, range 32 to 90 years) were evaluated for right and left BMD discordance that caused a difference in diagnosis (Dx) or treatment (Tx) recommendation. Subjects were classified as osteoporotic (T ≤-2.5), osteopenic (-2.5< T≤-1.0), or normal (T >-1.0) using WHO guidelines. A threshold of T-score ≤-2.0 was used for Tx recommendation. Chi square tests determined the significance of discordance in Dx and Tx recommendations between women under and over 65 years old.

Average femur BMD was ~1% higher on the left vs. right; there was no relation to hand dominance. Dx (normal, osteopenia, osteoporosis) differed with right vs. left femora in 29% of subjects at one or more sites, and in 14%, 15% and 10% of subjects for neck, trochanter and total femur, respectively. About 1% of women below age 65 showed Dx discordance between osteopenia and osteoporosis at neck and total femur, but 5% to 6% showed discordance after age 65.

Disagreement between right and left femora (any site) in Tx recommendation occurred in 7% (37/537) of subjects. Most subjects with Tx discordance were over 65 years old: 4% (14/349) were under 65 and 12% (23/188) were over 65 ($p<0.01$). When Tx agreement was defined as agreement at each left and right site (neck, trochanter, and total) 14% (74/537) of subjects showed Tx disagreement, while 6% to 7% showed disagreement at any one site. In subjects with discrepancy at an individual site, Tx discordance was 9% (31/349) for subjects under 65 and 23% (43/188) for subjects over 65 years old ($p<0.001$). In conclusion, dual femur scans showed right vs. left diagnosis differences in 10-15% of subjects and treatment differences in 7% of subjects, with significantly greater discordance (12%) in women over 65 years. Dual femur scanning enhances accurate clinical decision-making, especially in women over age 65.

Age-related Percentage of Subjects with Left-Right Femur Discordance

	Neck			Trochanter			Total Femur		
	<65	>65	All	<65	>65	All	<65	>65	All
Normal vs. Osteopenic	12.3%	10.7%	11.7%	12.0%	10.7%	11.5%	8.0%	7.5%	7.8%
Normal vs. Osteoporotic	0.0%	0.5%	0.2%	0.3%	0.0%	0.2%	0.0%	0.0%	0.0%

TACT Study: Spinal Pain and Height Loss: Diagnostic Value for Screening of Osteoporotic Vertebral Fractures in Women over 65 Years of Age. J. Fechtenbaum[1], C. Roux[1], C. Benhamou[2], P. Ravaud*[3], S. Brin*[4], F. Coriat*[4], S. Horlait*[5]. [1]Rheumatology, Cochin Hospital, Paris, France, [2]Rheumatology, Porte Madeleine Hospital, Orléans, France, [3]Biostatistics and Clinical Epidemiology, Bichat Hospital, Paris, France, [4]Aventis, Paris, France, [5]Procter et Gamble, Neuilly sur Seine, France.

Introduction : Two thirds of osteoporotic vertebral fractures are thought to be asymptomatic. These fractures are associated with increased risk of future vertebral and non-vertebral fractures. Several treatments have demonstrated a clear benefit in postmenopausal women presenting with such fractures. Therefore, it is useful to specify the indications and usefulness of spinal x-rays in screening for vertebral fractures. The aim of this study was to evaluate the sensitivity and specificity of recent spinal pain and its location, on one hand, and height loss >3 cm, on the other hand, in ambulatory women over 65 years of age, for the diagnosis of osteoporotic vertebral fractures. Patients and methods : Female patients who consulted a rheumatologist in private practice regardless of the reason and who presented with an episode of thoracic or upper lumbar pain (TULP) or lower lumbar pain (LLP) within the previous six months were recruited. Female patients with documented fractures were excluded. Patients in the two groups (TULP and LLP) were matched for age. Standardized x-rays of the thoracic and lumbar spine were performed on each patient, with centralized reading. Patients' height was measured and compared to height reported at age 25 years. Results : 114 female patients (57 per group) 74 ± 5 years of age were enrolled. In this ambulatory patient population, at least one vertebral fracture was noted in 23.7 % of the patients. In the TULP group, 26.3 % presented with one vertebral fracture; this percentage was 21.1 % in the LLP group. Sensitivity and specificity of localization of pain were 56 % and 52 % respectively (Likelihood ratio 1:15 ; 95 % CI 0.77-1.72). Among the female patients who lost > 3 cm, 27.5 % had at least one vertebral fracture, versus 13.8 % in those whose height remained stable. The sensitivity of height loss was 85 % while the specificity was 30 % (LR 1 :21 ; 95% CI % 0.98-1.50). Conclusion : The prevalence of vertebral fractures in ambulatory women over 65 years of age, who presented with spinal pain within the previous six months, and who consulted a rheumatologist regardless of the reason was 23.7%. Localization of pain (thoracic or lumbar spine) has no diagnostic value. This study confirms the good sensitivity of height loss for screening of vertebral fractures in such a population.

The Number of Canadian Men and Women Needed to be Screened to Detect a Case of Osteoporosis: A Population-Based Study from the Canadian Multicentre Osteoporosis Study (CaMos). A. M. Sawka[1], L. Thabane*[2], A. Papaioannou[3], A. Gafni*[2], G. Ioannids[4], D. A. Hanley[5], E. Papadimitropoulos[6], L. Pickard[4], J. D. Adachi[4], C. Investigators*[7]. [1]Endocrinology, McMaster University, Hamilton, ON, Canada, [2]Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada, [3]Medicine, McMaster University, Hamilton, ON, Canada, [4]Rheumatology, McMaster University, Hamilton, ON, Canada, [5]Endocrinology, University of Calgary, Calgary, AB, Canada, [6]Eli Lilly, Toronto, ON, Canada, [7]Canadian Multicentre Osteoporosis Study, Hamilton, ON, Canada.

The Osteoporosis Society of Canada has recommended routine screening of men and women ≥65 years of age for osteoporosis by measurement of bone mineral density (BMD) at the spine and hip. However, the efficiency of routine population-based screening of Canadians of both genders is not known. Our goal was to determine the number of Canadian men and women age ≥65 years as well as those age 55-64 years needed to be screened by BMD in order to detect a case of osteoporosis, using prevalence estimates from CaMos. CaMos is prospective population-based cohort study involving 9 sites across Canada. Regional participants were randomly recruited (stratified by age and gender). 5883 participants ≥55 years of age (1645 men and 4238 women) who underwent standardized baseline measurements of BMD at the hip (trochanter and femoral neck) and lumbar spine (L1-L4) using DXA were included in this study. The diagnosis of osteoporosis was based on a T-score ≤ 2.5 at any site. Of the participants studied, 2143 people (36.4%) were age 55-64 years and 3740 (63.8%) people were ≥65 years of age). The prevalence of osteoporosis in men was as follows: age 55-64 years - 3.9% (95% confidence interval [CI], 2.6, 5.8) (24/612), age ≥65 years - 9.0% (95% CI, 7.4, 10.9) (93/1033). The prevalence of osteoporosis in women was as follows: age 55-64 years - 12.3% (95% CI, 10.7, 14.0) (188/1531), age ≥65 years - 25.9% (24.2, 27.5) (700/2707). The number of men needed to be screened by BMD measurement in order to detect one case is: age 55-64 years - 25 men (95% CI, 17, 38), age ≥65 years - 11 men (95% CI, 9, 14). The number of women needed to be screened in order to detect one case is: age 55-64 years - 8 women (95% CI, 7, 9), age ≥65 years - 4 women (95% CI, 4,4). In conclusion, screening of women ≥65 years by measurement of BMD of age is the most efficient. The efficiency of BMD screening of men age ≥65 years and women age 55-64 years is similar but inferior to screening of older women.

A Population-based Study of Osteoporosis Testing and Treatment Following Introduction of a New Bone Densitometry Service. W. D. Leslie[1], L. Lix*[2], L. MacWilliam*[2], G. Finlayson*[2], P. A. Caetano*[3]. [1]Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada, [2]Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, MB, Canada, [3]Faculty of Pharmacy, University of Manitoba, Winnipeg, MB, Canada.

Bone density measurement plays a key role in the initial diagnostic assessment of osteoporosis and for targeting pharmacologic therapies. However, the impact of access to dual x-ray absorptiometry (DXA) on physician prescribing habits remains unclear. The objective of this study was to directly evaluate the change in physician osteoporosis testing and prescribing following the introduction of a DXA testing service in a geographic region that previously had very limited access. Manitoba has a provincially-based bone density testing program and maintains a population-based bone density database that can be linked with other provincial health databases. Manitoba was geographically partitioned into the urban and rural health regions serviced by the new DXA (URBANnew and RURALnew) and compared to health regions which had relatively unchanged DXA access during this period (URBANcontrol and RURALcontrol). Regression models of DXA testing rates and osteoporosis prescription rates were created for all women over 50 years of age in these regions. There was a statistically significant increase in bone density testing and BMD-guided osteoporosis treatment in the URBANnew and RURALnew regions after introduction of the DXA testing service relative to the control regions. There were no significant changes in overall prescribing rates for any group. When analysis was limited to non-hormonal agents a significant reduction in preventive and empiric post-fracture treatment emerged in some subgroups of women. Access to bone density testing led to an increase in both testing and BMD-guided osteoporosis treatment initiation, with a decrease in the use of newer non-hormonal osteoporosis agents for preventive and empiric treatment in some subgroups. This would be expected to translate into more cost-effective targeting of treatment, particularly for newer, more expensive agents.

The Prevalence of Osteoporosis in Japan - A longitudinal Cohort Study in Tottori, Japan. H. Katagiri*[1], H. Hagino*[2], R. Teshima*[1]. [1]Orthopedic Surgery, Tottori University, Yonago, Tottori, Japan, [2]Rehabilitation Division, Tottori University, Yonago, Tottori, Japan.

As the elderly population increases, osteoporosis has become an increasingly serious problem. It is well known that age-related bone loss has a great influence on development of osteoporosis. Early diagnosis of bone loss is important to prevent osteoporosis and osteoporosis related fractures. However, there have been few longitudinal studies of bone mineral density (BMD) in Japan. This study investigated the change in bone mass with aging and predicted the magnitude of age-related bone loss and the prevalence of osteoporosis (defined as calcaneus BMD <70% of the young adult mean) in a sample of Japanese men and women.

We examined BMD and age-related bone loss of the calcaneus in a cohort of Japanese men and women living in Tottori, Japan. The longitudinal studies included 160 men aged from 30-85 and 385 women aged 29-83 who had two bone mass measurements during 3 years. The bone measurement was performed using single X-ray absorptiometry (SXA).

In men calcaneal bone loss rate remained essentially constant from the forties. The loss rate among women in their fifties were greater than those in their forties and sixties. The longitudinal reduction in calcaneus BMD among women in their forties and seventies was similar to the men's data.

The prevalence rates of osteoporosis increased progressively with age. Eleven of the 160 males were diagnosed with osteoporosis. As for females, 185 of the 385 subjects were diagnosed with osteoporosis.

The prevalence rate diagnosed at the calcaneus seemed to be higher in the present study than that diagnosed by the spine BMD. This study suggests that the different definitions of osteoporosis should be established for the different skeletal sites.

Prevalence of osteoporosis in Japan

	Men		**Women**	
Age group	N	%	N	%
40-49	0/4	0	0/24	0
50-59	0/22	0	14/80	17.5
60-69	3/68	4.4	86/162	53.1
70-79	4/45	8.9	79/98	80.6
total	11/160	6.9	185/385	48.1

Hip, Spine and Total Body BMD Measurements in Children Using the Lunar Prodigy. H. Fors*, D. Swolin Eide*, S. Valdimarsson*, I. Bosaeus*, K. Albertsson Wikland*. GP-GRC, Institute of the Health of Women and Children, Sahlgrenska Academy of Göteborg University, Göteborg, Sweden.

Measurement of bone mineralisation in children has become important in clinical endocrinology and endocrine research. At the Göteborg Pediatric Growth Research Center children and adolescents with growth hormone disorders and diabetes are frequently measured with a DXA (Dual-energy X-ray absorptiometry) system to monitor their bone density and body composition. Recently, we purchased a new bone densitometer, the Lunar Prodigy, together with a new pediatric software package that takes into account biological/developmental age of the child. In addition, the femur program automatically adjusts the size of the neck, trochanter and shaft regions of interest (ROI) depending on the child's height.

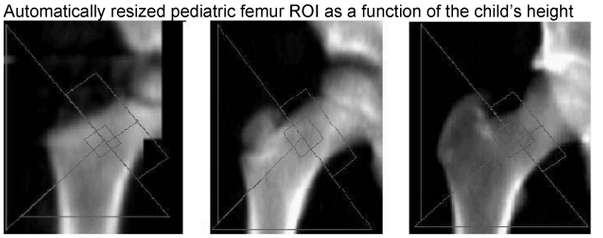
In this study we evaluated the performance of this new pediatric software and the accuracy of the new Lunar Prodigy in comparison to our previously used Lunar DPX-IQ.

Thirty nine children (29 boys and 10 girls) with ages ranging from 6 to 20 years had a AP-spine and total body BMD measurement with both the Lunar Prodigy and the Lunar DPX-IQ (GE Healthcare). Fifty children (37 boys and 13 girls) with ages ranging from 3 to 20 years had a femur scan with the Lunar Prodigy using the new pediatric femur software. Accuracy was determined with linear regression analysis to compare Prodigy vs. DPX-IQ results. Bland-Altman plots were used to detect any systematic differences between Prodigy and DPX-IQ measurements.

Very strong correlations were obtained for the BMD measurements with the Prodigy and the DPX-IQ at the spine and total body (r=0.99) with small SEE values (0.019 g/cm^2 and 0.015 g/cm^2 respectively). Bland Altman plots showed no significant biases with mean BMD. The automatic adjustment of the femur ROI with subject height performed well: e.g. the width of the neck ROI changes from 1.0 cm for subjects smaller than 91cm (3 feet) to 1.5 cm for subjects taller than 152 cm (5 feet, see figure). The three new graphs that report in centile the subject's height for age, BMC for bone area, and bone area for height are useful in identifying those children with potential developmental problems.

We conclude that the new pediatric software on the Prodigy performed well for measuring BMD at the hip, spine and total body in children with a wide range of ages.

Automatically resized pediatric femur ROI as a function of the child's height



Girl 88 cm tall
Width neck box =1.0 cm

Boy 125 cm tall
Width neck box =1.28 cm

Boy 174 cm tall
Width neck box =1.5cm

Screening Men 70 Years and Older for Osteoporosis: Are We Missing Osteoporosis in Younger Men? R. A. Adler[1], V. I. Petkov*[1], P. S. Via*[2], M. I. Williams*[3]. [1]Endocrinology, McGuire Veterans Affairs Medical Center/ Virginia Commonwealth University School of Medicine, Richmond, VA, USA, [2]Endocrinology, McGuire Veterans Affairs Medical Center, Richmond, VA, USA, [3]Endocrinology, McGuire Veterans Affairs Medical Center/ Virginia Commonwealth University School of Pharmacy, Richmond, VA, USA.

The International Society of Clinical Densitometry (ISCD) recommends that men 70 years and older should be routinely screened for osteoporosis by dual energy X-ray absorptiometry (DXA). The purpose of this study was to compare the prevalence of osteoporosis and osteopenia in men who were referred for bone density testing because of high or moderate osteoporosis risk as determined by the Osteoporosis Self Assessment Tool (OST). OST, calculated by the simple formula 0.2 X [age - weight (kg)], identifies subjects likely to have low bone mass. We compared using OST to using age $\geq$ 70 to screen asymptomatic men.

We analyzed data from an interventional trial on improving osteoporosis diagnosis in Primary Care Clinics at a Veterans Affairs Medical Center. Men (N = 410) who had a BMD test due to high (< -2) or moderate (-2 to 3) OST risk score were categorized by age (< 70 and $\geq$ 70 years). Proportions of osteoporotic and osteopenic patients were compared using two-sided Fisher's exact test.

The mean age was 61.5 (8.0) and 76.7 (11.3) years for the younger and older group. The younger group had significantly lower weight (73.7 vs. 77.6 kg). T-scores were similar in the hip, significantly higher at the lumbar spine in the older group (-0.4 vs. -0.8), but lower at the forearm (-1.4 vs. -1.0).

In both age groups, about 1/3 had osteoporosis and about 1/2 had osteopenia. Thus, using only age as a criterion for DXA referrals in men leads to substantial under-diagnosis. Adding weight by using the OST formula identifies both younger and older men with osteoporosis, particularly if forearm measurements are also considered.

Table. Osteoporosis classification in men by age group

	Age < 70 (N=132) %	*Age $\geq$ 70 (N=278) %*
TH, FN, Troch, or LS		
Osteoporosis (T-score $\leq$ -2.5)	27.7	24.1
Osteopenia (T-score -1 to -2.49	48.8	56.8
Normal (T-score > -1)	23.5	19.1
TH, FN, Troch, LS or FA*		
Osteoporosis	33.3	35.3
Osteopenia	45.5	51.0
Normal	21.2	13.7

* TH = total hip, FN = femoral neck, Troch = trochanter, LS = lumbar spine, FA = forearm

Comparison of BMD and %Fat in Adults and Children with the DPX-L and Prodigy Densitometers. P. Kooij*[1], F. Rivadeneira[2], M. Zillikens*[2], J. Sluimer*[1], E. Krenning*[1], H. Pols[2]. [1]Department of Nuclear Medicine, Erasmus MC, Rotterdam, Netherlands, [2]Departments of Internal Medicine and Epidemiology & Biostatistics, Erasmus MC, Rotterdam, Netherlands.

Replacing older densitometer systems with newer and better performing ones is a big obstacle for the assessment of bone mineral density (BMD) and body composition in both the clinical and research setting. At the Erasmus Medical Center, two older generation pencil-beam densitometers (Lunar DPX-L, GE Healthcare) have been used: one system (DPX1) for the study and evaluation of adult and pediatric patients and another (DPX2) used for research within the Rotterdam study (a population-based prospective study of disease and disability in elderly men and women age 55 years and over). Moreover, a large local pediatric reference database has been collected on the DPX1. Recently, both DPX-L systems have been replaced by Lunar Prodigy systems (a new generation narrow fan beam densitometer). Therefore, this study aimed to evaluate the cross-calibration of the Prodigy and DPX-L systems, in order to allow comparison of follow-up data across densitometers and to implement the pediatric reference database in the new system.

For the DPX1 and Prodigy1 systems, AP spine and femur scans were measured in 96 adults, and AP spine and total body scans were measured in 30 children. For the DPX2 and Prodigy2 cross-calibration, a random sample of 105 participants of the Rotterdam study had AP spine and femur scans measured on both systems. Cross-calibration methods included linear correlations and Bland-Altman comparisons.

Results correlated very well for all BMD sites in adults and children (table). In both comparisons, the highest correlation was observed at the lumbar spine. Femoral neck correlations were comparatively lower in the DPX2 - Prodigy2 than in the in the DPX1 - Prodigy1 comparison. Pediatric body composition (fat %) also observed a high correlation.

We conclude that BMD results from DPX-L and Prodigy systems can be cross-calibrated across pediatric, adult and elderly populations. Furthermore, based on this calibration the local Rotterdam pediatric reference database for BMD and fat% can be adapted for the Prodigy system.

	Scan site	Subjects F / M		Age (in years)	Pearson Correlation	Slope	Intercept
DPX1 vs. Prodigy1	AP-spine (29 children + 96 adults)	72	53	C: 9.1 (± 3.6) A: 50.1 (± 15.8)	0.991	0.987	-0.012
	Femur Neck (adults)	59	35	50.6 (±15.6)	0.972	0.976	0.040
	Total body BMD (children)	13	16	9.1 (± 3.6)	0.991	1.000	-0.018
	Total body % fat (children)	13	16	9.1 (± 3.6)	0.970	1.050	0.031**
DPX2 vs. Prodigy2	AP-spine	67	37	77 (± 6)	0.978	0.998	0.015
	Femur Neck	67	33		0.953	0.889 *	0.103**
	Femur Trochanter	67	34		0.956	0.939 *	0.002

Bone Mineral Density of Healthy Premenopausal Women of South India. U. Sriram*. Endocrinology, EV Kalyani medical center, Chennai, India.

Bone mineral density of apparently healthy south premenopausal women were studied. This study was undertaken to both establish the reference data for peak bone mass and to document the bone density in the pre and perimenopausal years. we rcruited women from the community between the ages of 20 and 49 with no prior history of metabolic bone disease and not on any treatmnet with bisphosphonates, selective estrogen receptor modulators, Teriparatide, Calcitonin or hormone replacement therapy. The women were recruited through corporate offices, the southern railways employee labor union and their relatives. Some were recruited by word of mouth.

BMD was measured in the spine, left hip and forearm using Hologic DXA. The results obtained are shown in a table. There were 249 women who were part of this study. The number of women between the ages of 20- 29 was 75, between 30-39 was 76 and between 40-49 was 98. The BMD of the peak adult bone mass group [20-29] was 0.93328 in the spine and 0.807213 in the hip. The BMD for the 30-39 group was 0.9614 in the spine and 0.879786 in the hip. The BMD for the 40-49 age group was 0.935112 in the spine and 0.7815 in the hip.

This study documents the normative data for healthy premenopausal women of South India.

BMD of premenopausal women

Age	Number	Spine BMD	Hip BMD
20-29	75	0.93328	0.80721
30-39	76	0.9614	0.8276
40-49	98	0.923487	0.7815

Bone Mineral Density of Healthy Men and Women of South India between the Ages of 20 and 50. U. Sriram*. Endocrinology, EV Kalyani medical center, Chennai, India.

Bone mineral density was studied in apparently healthy women of South India . This study was undertaken both to establish refence data base for peak bone mass and to study the effect of age on BMD. We recruited women from the community between the ages of 20 and 49 with no history of metabolic bone disease and not on any treatment with bisphosphonates, selective estrogen receptor modulators, teriparatide , calcitonin or hormone replacement therapy. The women were recrited through corporate offices, the Southern railways office labor union and their relatives and by word of mouth..

BMD was measured at the left hip, spine and forearm using Hologic DXA. The results obtained have been shown in a table. The total number of women studied were 259 . Between the ages of 20-29 there were 75 women, 76 between the ages of 30-39, 98 betwen the ages of 40-49. The BMD of the peak adult bone mass age group [20-29] was 0.93328 in the spine and 0.807213 in the hip. The BMD for the 30 -39 age group was 0.9614 in the spine and 0.879786 in the hip. The BMD for the 40-49 age group was 0.935112 in the spine and 0.7815 in the hip.

This study documented normative data for healthy premenopausal south Indian women.

BMD of women 20-49 years

Age	Number	Spine BMD	Hip BMD
20-29	75	0.93328	0.80721
30-39	75	0.9614	0.8276
40-49	98	0.923487	0.7815

Are Tissue Facsimile Bags Necessary for DXA Measurements? N. C. Grinnell*, T. M. DeFrancisco*, S. M. Strot*, L. Cole*, E. A. Mossman, M. R. McClung. Oregon Osteoporosis Center, Portland, OR, USA.

DXA of the hip and lumbar spine is commonly accepted as the standard technique for measuring bone mineral density to aid in the diagnosis of osteoporosis, help assess fracture risk, and monitor therapy. The analysis software used by DXA instruments distinguishes bone from the surrounding tissue using algorithms designed to detect the edges of the bone. In measurements of the hip where there is insufficient soft tissue surrounding the bone, air spaces, commonly referred to as air points, between the patient and the instrument can cause errors in these algorithms. In the past when such errors occurred, tissue facsimile bags (TFB) were placed under the hip to eliminate these spaces and the scan was repeated. The manufacturers of modern DXA instruments currently claim that air points appearing in the analysis in areas of tissue will be labeled as artifact in the instrument software, and that tissue facsimile bags are unnecessary. It is unclear what effect not using the tissue facsimile bags has on measured BMD values. This study was designed to determine if there is a systematic difference in measured BMD between simply allowing the air points to be labeled as artifact in the DXA software and re-scanning the hip using tissue bags.

We analyzed electronic records from patients referred to our clinic for DXA testing who had a hip DXA scan on a single Lunar Prodigy densitometer (GE Lunar, Madison, WI) repeated with tissue facsimile bags due to the presence of air points in the first hip image. A total of 31 women and 19 men were included in the analysis. Average age at the time of the scan was 65.8 years. Mean total hip (TH) BMD for the first scan in which the air points appeared and were labeled by the DXA software as artifact was 0.778 g/cm^2, and mean TH BMD for the second scan using tissue facsimile bags was 0.774 g/cm^2. These differences were not significant by paired t-test ($p=0.235$). However, when the results were analyzed by gender, the BMD values in men were significantly lower with tissue facsimile bags than without (mean difference 0.10 g/cm^2, $t=3.99$, $p<0.001$). The BMD values in women were not significantly affected by the use of the tissue bags ($p=0.479$). These results suggest that the use of tissue facsimile bags may be still be appropriate for some patients, even on newer densitometers.

Gene Expression Regulated by Physical Contact between Prostate Cancer Cells and Osteoblasts in a Heterotypic Co-culture System. J. Wang*, A. S. Levenson*, K. E. Thurn*, L. A. Simons*, R. L. Satcher. Department of orthopaedic surgery, Northwestern University, Chicago, IL, USA.

Bone is the most common target of prostate cancer metastasis. The molecular mechanisms of bone metastases involve in bi-directional interactions between prostate cancer cells and bone cells. In addition to interaction mediated by soluble factors, physical contact is an important step in metastasis formation and progression.

Several in vitro co-culture models were used to study the interaction between cancer cells and osteoblasts, such as cell culture with conditioned medium or co-culture with inserts (bi-compartmental culture system). These models can only detect the effects of soluble factors. In order to identify factors that are regulated in response to physical contact between cancer cells and osteoblasts, we established a heterotypic co-culture system containing prostate cancer cells PC-3 and primary osteoblasts derived from rat bone marrow. PC-3 cells were labeled with Vybrant CFDA SE fluorescent reagent before they were co-cultured with osteoblasts. Different ratios (1:100, 1:10, 1:1 and 10:1) between PC-3 cells and osteoblasts mimicked the different stages of metastasis development. The proportion of co-cultured cells was quantified with flow cytomytric analysis to explore the regulation of proliferation. In order to detect the effects of physical contact on gene expression, PC-3 cells and osteoblasts were co-cultured with inserts (bi-compartmental) or without inserts (heterotypic). The cells in heterotypic co-culture system were then re-separated with mag-

netic-activated cell sorting (MACS). Epithelial cell-derived PC-3 cells were positively selected by magnetic microbeads conjugated with antibody against human epithelial antigen (HEA). Differential gene expression in MACS-separated prostate cancer cells and osteoblasts was analyzed by Northern blot.
The results showed that proliferation of PC-3 cells in heterotypic co-culture was interrupted at ratios 1:100 and 1:10, which represented early stage of metastasis. Proliferation of BMSC was suppressed at ratio 10:1, which mimicked late stage of metastasis. The peak expression level of uPA in PC-3 cells was found at ratio 1:1. The expression of insulin growth factor binding protein-3 was down-regulated in bi-compartment co-culture, while it is much lower in heterotypic co-culture. In contrast, the expression of osteopontin and osteonectin in osteoblasts was not effected by physical contact. This heterotypic co-culture system set a fundamental to identify factors in response to physical contact.

Assessment of Vertebral Fractures in Post-Meopausal Women by Topological Analysis of High Resolution MRI of the Distal Radius in 2D and 3D Using Bone Mineral Density and Linear Texture Measures as a Standard of Reference. H. F. Boehm*[1], T. M. Link[2], R. A. Monetti*[3], D. Mueller*[1], E. J. Rummeny*[1], G. Morfill*[3], C. W. Raeth*[3]. [1]Radiology, TU-Munich, Munich, Germany, [2]Radiology, UCSF, San Francisco, CA, USA, [3]Institut fuer Extraterrestrische Physik, Max-Planck-Society, Garching, Germany.

Topological texture measures based on the Minkowski Functionals (MF) in 2D and 3D have successfully been employed to predict the mechanical competence of trabecular bone in-vitro.
In this in-vivo study, the MF in 2D and 3D are used to characterize the micro-structure of the distal radius in post-menopausal women as depicted by high-resolution magnetic resonance imaging (HRMRI) for identification of patients with vertebral fractures. Results are compared with bone mineral density (BMD) and standard texture measures in 2D, i.e. apparent trabecular separation (app.Tb.Sp) and apparent trabecular bone volume fraction (app.BV/TV).
HRMRI of the distal radius in 36 age-matched post-menopausal women (age 66 +/- 6 yrs) were obtained at 1.5 T using a 3D gradient-echo sequence with a spatial resolution of 195 x 195 x 500 µm. 23 of the women had vertebral fractures as diagnosed on lateral radiographs of the spine. BMD was measured by quantitative computed tomography in the lumbar spine.
From the image data, the MF in 2D {3D} corresponding to area, perimeter, and Euler-Number {volume, surface, mean integral curvature, and the Euler Number} were obtained as a function of gray-level threshold. In order to assign a scalar quantity to each image set, an optimised filtering procedure using two independently sliding windows of variable width was employed. As a standard of reference, linear texture measures in 2D were extracted from the image data.
The predictive potential of BMD, the linear and the topological texture measures was expressed using the receiver operator characteristic (ROC), validation of results was achieved by leave-one-out (LOO) analysis.
Mean values of BMD, linear and topological measures significantly differed for the fracture group and the controls ($p < .05$). When employing ROC-analysis for identification of fracture patients, an area-under-the-curve (AUC) of .73 was found for BMD, AUC for the linear measures ranged from .60 (app.BV/TV) to .65 (app.Tb.Sp), whereas the topological measures resulted in an AUC of .78 (2D) and .79 (3D).
In conclusion, topological descriptors are well suited to identify patients with vertebral fractures by texture analysis of HRMRI of the distal radius. Texture measures based on the MF in 2D and 3D are equally reliable. The diagnostic performance of topological analysis is superior to bone densitometry and linear texture measures.

Monitoring of Changes in Structural Cancellous Bone Parameters over Time with the Novel vivaCT40 in Anesthetized Rodents. J. A. Gasser[1], P. Ingold*[1], B. Koller*[2], G. Schett*[3]. [1]Musculoskeletal Research, Novartis Institutes for Biomedical Research, Basel, Switzerland, [2]Scanco Medical AG, Bassersdorf, Switzerland, [3]University of Vienna, Vienna, Austria.

Characterization of trabecular bone structures requires necropsy of animals followed by a labor intense histomorphometric or *ex vivo* microCT analysis. We tested the novel *in vivo* microCT vivaCT40 from SCANCO Medical AG (Bassersdorf, Switzerland), which allows to monitor such changes at a maximal resolution of 10µm and a total acquisition time of less than 15 minutes repeatedly in anaesthetized rats and mice. The scanner allows to accurately measure trabecular architecture with a reproducibility better than 0.2%.
Postmenopausal Osteoporosis: In 8 month old ovariectomized (OVX) rats, the vivaCT40 was capable to pick up the decrease in trabecular bone volume, the trabecular thinning as well as the decrease in the number of trabecular elements as a function of time at 0, 1, 2, 4, 8, 12, and 16 weeks post OVX. The bone anabolic effects of parathyroid hormone [hPTH(1-34)] as well as the bone protective effect of the two antiresorptive agents zoledronic acid and 17-α ethinylestradiol were detected correctly with the vivaCT40.
Imaging & Rheumatoid Arthritis: Imaging of subtle erosive lesions such as those occurring in subchondral bone and around the growth plate in the proximal tibia of TNFα-transgenic mice was easily possible. We were also able to detect trabecular bone loss caused by periarticular inflammation in a rat model of adjuvans arthritis and demonstrate the bone protective effect of dexamethasone on structural integrity.
Tumor Osteolysis: The vivaCT40 allowed monitoring of the osteolytic response caused by the local administration of 4T1luc2000 tumor cells into the tibia metaphysis of nude mice. The potent protective effect of zoledronic acid on tumor osteolysis was demonstrated. The new vivaCT40 is capable to monitor the effects of known agents and diseases such as osteoporosis, inflammatory arthritis and tumor invasion on 3D-trabecular microarchitecture accurately, repeatedly, reliably and quickly in more than 25 anaesthetized rats and mice per day. The scanner represents a breakthrough for large scale non-invasive imaging and 3D-structural measurements in anesthetized small rodents.

Modelling Trabecular Changes using Cellular Automata. C. Raeth[1], R. Monetti*[1], D. Mueller*[2], T. Link[3], H. Boehm*[2]. [1]Theory Division, CIPS/MPE, Garching, Germany, [2]Radiology, TU-Munich, Munich, Germany, [3]Radiology, UCSF, San Francisco, CA, USA.

Cellular automata (CA) have intensively been employed to model nonlinear phenomena by numerically solving differential equations governing the underlying (bio-)physical processes of the system. We propose a novel approach to simulate bone remodelling processes using probabilistic CAs. Bone remodelling processes including the effects of mechanical forces on the adaptation of form in trabecular bone can be described by nonlinear rate equations, which model the effects of osteoclasts and osteoblasts on the local change of the relative bone density (Huiskes et al., Nat., 405, 704). The differential equations can be solved numerically using CAs. CAs are discrete dynamical systems whose behaviour is specified in terms of local relations. Space is represented by a uniform grid and time advances in discrete steps. The physical laws expressed in the differential equations are transformed to local rules with which at each step each cell computes its new state from that of its close neighbours. A two-dimensional realization of a CA for bone remodelling processes is presented: Bone pixels are defined by applying a threshold to the bone density distribution. Within the bone pixels the loaded skeleton, i.e. the connected lines, which transfer the forces, is determined and the local strain is calculated. Bone resorption (spatially random) and bone formation (strain-dependent) at the bone surface is simulated. Various configurations (e.g. different direction of the external force) for the CA and the effects of (slight) changes in the control parameters (e.g. sensitivity of osteoblasts to local strain) are studied. We show that trabecular structures emerge from a uniform distribution whereby the alignment of the trabeculae follows the direction of the forces acting on the bone (Wolff's law). The configuration is stable with a mean relative bone density of mrbd=.42 (arbitrary units). Slightly decreasing the sensitivity of osteoblasts to local strain results in a new stable configuration with lower bone density (mrbd= .36) and rarefied trabecular structure. Recently introduced texture measures (e.g. scaling indices and Minkowski Functionals) can account for the structural changes. The variations of them are comparable to those observed in vitro and in vivo. Bone remodelling processes can well be described within the framework of CAs. They can account for trabecular changes induced by variation of control parameters. Therefore these models offer the possibility to investigate drug-effects 'in silicio' and to analyse systematically the sensitivity of texture measures to slight changes in the bone structures.

Three-dimensional Analysis of Trabecular Bone Structure of Human Vertebra in Vivo Using Image Data from Multi-detector Row Computed Tomography-correlation with Bone Mineral Density and Ability to Discriminate Women with Vertebral Fractures. M. Takada[1], K. Kikuchi*[2], S. Imai*[2], K. Murata*[1]. [1]Radiology, Shiga University of Medical Science, Otsu, Japan, [2]Orthopaedic Surgery, Shiga University of Medical Science, Otsu, Japan.

We developed a system to perform three-dimensional (3D) analysis of trabecular bone structure of human vertebra in vivo using image data from multi-detector row computed tomography (MDCT). The purpose of this study was to evaluate whether 3D structural parameters correlate with bone mineral density (BMD) of human vertebra, and whether they can discriminate women with vertebral fractures. We studied 20 women with no vertebral fractures (67±8 years old) and 27 women with vertebral fractures (74±7 years old). They underwent lumbar examinations by MDCT and dual x-ray absorptiometry (DXA). L3 was scanned using MDCT, Somatom Plus 4 Zoom (Siemens, Erlangen, Germany) at 140Kv and 170mAs by a slice thickness of 0.5mm and L2-4 BMD was assessed using Lunar DPX-L (General Electrics, Milwaukee, WI, USA). The CT images were reconstructed using a field of volume of 50mm x 50mm with 0.2mm interval, and were resulted in a spatial resolution of 0.097mm x 0.097mm on x-y axes with overlap of 0.3mm along z-axis. The CT image data was imported into software of 3D analysis for trabecular bone structure, TriBON (Ratoc System Engineering, Tokyo, Japan) and a 3D image was constructed. A cubic region of interest for analysis was extracted after the images containing the upper and lower endplates were excluded. The following 3D parameters were calculated; trabecular bone volume fraction (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), trabecular separation (Tb.Sp), trabecular bone pattern factor (TBPf), structure model index (SMI), and Fractal dimension (FD). L3 BMD was used for data analysis. Correlation between structural parameters and BMD was evaluated by linear regression analysis, and discrimination between women with and without vertebral fractures was evaluated by student t' test. A p-value of less than 0.05 was considered significant. The BMD was significantly correlated with the values of BV/TV, Tb.Sp, TBPf, SMI and FD with correlation coefficients of 0.30, 0.32, -0.46, -0.44 and 0.36, respectively. The values of TBPf, SMI and FD significantly differed between the two groups with t-values of 2.6, 3.2, and 2.4, respectively, but the L3 BMD did not differ. The results suggested that trabecular bone structure correlated with BMD and that the trabecular bone structural analysis could discriminate women with vertebral fracture better than lumbar DXA in this population. This technique appears to be useful for assessing osteoporosis in human vertebra in vivo.

A Model Based Anaysis to Study Mechanical Properties of Bone and to Identify Non-invasive Diagnostics for Bone Strength. G. H. Gunaratne[1], M. Liebschner*[2], S. Wimalawansa[3]. [1]Physics, University of Houston, Houston, TX, USA, [2]Bioengineering, Rice University, Houston, TX, USA, [3]Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Aging induces several types of architectural changes in trabecular bone including thinning, increased levels of anisotropy, and perforation. It has been determined, on the basis of analysis of mathematical models, that reduction in fracture load caused by perforation is significantly higher than those due to equivalent levels of thinning or anisotropy. This analysis has also provided an expression which relates the fractional reduction of strength to the fraction of elements that have been removed from a network. Further, it was proposed that the ratio of linear responses of a sample to uniform loading and high-frequency driving can be used as a surrogate for bone strength.

Unfortunately, experimental validation of these predictions requires following architectural changes in a given sample of trabecular bone; such a process cannot be implemented in human or animal studies with current technology. Instead, we use computer models constructed from digitized images of bone samples for the purpose. Images of healthy bone are subjected to successive levels of synthetic degradation via erosion of voxels that lie on the surface. Computer models constructed from these images are used to calculate their fracture load and other mechanical properties. Results from these computations validate predictions derived from the analysis of mathematical models.

Orientation of Load Force Influences Mechanical Stability in the Human Scaphoid: Implications for Traumatic Fractures. D. S. Perrien, R. R. Bindra*, L. J. Suva. Departments of Orthopaedic Surgery and Physiology and Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Fractures of the wrist occur most frequently in the scaphoid and account for approximately 70% of all carpal fractures. The scaphoid is composed of three anatomical regions: proximal pole, waist, and distal pole. Despite the high incidence of fracture in this bone, little information regarding the structural and mechanical properties of these three regions that may contribute to the differing fracture rates is known. The current study used microCT and finite element modeling (FEM) to investigate the hypothesis that inferior micro-architectural properties in the waist of the scaphoid were responsible for the high incidence of fracture in this region. Ten (10) intact scaphoids obtained from adult cadavers were scanned by microCT with a voxel size of 37 μm. Using 3-dimensional reconstructions of the whole bone, three 5-mm-thick regions of interest (ROIs) corresponding to the waist and proximal and distal poles were extracted from each specimen. In five of the bones, the ROI's were extracted perpendicular to the long axis of the bone and parallel to one another. For the other five bones, the ROIs were extracted at angles that were perpendicular to the natural curvature of the bone within the respective region. Standard three-dimensional morphometric analysis of the trabecular structure in all 30 ROI's demonstrated that BV/TV and trabecular number were highest in the proximal pole and lowest in the waist. To determine the mechanical integrity of each ROI, FEM was used to simulate a 'high-friction' compression test in which 500 N of compressive force was applied, and the displacement and tissue level strains were calculated. This analysis revealed that when the ROIs were taken at right angles to the natural curve of the bone, the waist consistently experienced the greatest displacement and tissue level strain during compression. In contrast, if the ROI's were taken at right angles to the long axis, the distal pole experienced the greatest displacement and strain. These results demonstrate that regardless of ROI orientation, the waist of the scaphoid consistently displays inferior micro-architectural properties. However, in spite of the poor architecture, mechanical insufficiency in the waist or distal pole appears to be dependent on the direction of the force applied. Hence, the mechanics of the trauma, in addition to microarchitecture, likely play an important role in determining the location of the scaphoid fracture. This analysis provides information critical for evaluating implant fixation, vascularity and mechanisms of fracture in the human scaphoid.

Changes In Sublesional Bone Mineral Density/ Bone Architecture Amongst Women With Spinal Cord Injury: A Twin Study. B. C. Craven*[1], L. Giangregorio*[2], C. E. Webber[3]. [1]Medicine Toronto Rehab, University of Toronto, Toronto, ON, Canada, [2]Kinesiology, McMaster University, Hamilton, ON, Canada, [3]Nuclear Medicine, Hamilton Health Sciences, Hamilton, ON, Canada.

This study measured changes in bone mineral density (BMD), bone geometry and muscle cross-sectional area (CSA) in two sets of homozygous female twins, where one of each twin pair had a spinal cord injury (SCI). Twin Pair 1 (TP1) was premenopausal and 32 years of age. Twin pair 2 (TP2) was postmenopausal and 47 years of age. The SCI twin (TP1) had C7 tetraplegia and was 7 years post injury. The SCI twin (TP2) had T6 paraplegia and was >20 years post injury. BMDs of the proximal femur, distal femur, proximal tibia, and spine were measured using dual-energy x-ray absorptiometry (DXA). Computed tomography was used to measure volumetric BMDs, bone geometries and muscle CSAs of the thigh (mid-femur) and calf (proximal-tibia). Dramatic differences were noted when the SCI twin and non-SCI twin were compared. For TP1, the SCI twin's BMD of the total proximal femur, distal femur, proximal tibia and spine BMDs were 59.5%, 46.6%, 53.1% and 93.3% of their non-SCI twin. For TP2, the corresponding values for the SCI twin were 36.2%, 35.9%, 39.2% and 62.2% of their non-SCI twin. Average thigh and calf muscle CSAs of the SCI twins were 31.2±2.3% and 31.0±6.1% of the values for their non-SCI twins, indicating that muscle CSAs were reduced by almost 70%. Amongst the SCI twins, average volumetric BMD at the mid-femur and tibias were 83% and 87% of the values of their non-SCI twins. Maximum moments of inertia (I_{max}) at the mid-femur site were reduced in the SCI twins; 73.8±1.5% of the values for their non-SCI twins. In TP1, tibia I_{max} values in the right and left legs of the SCI twin were 67.6% and 79.7% of the non-SCI twin. For TP2, the SCI twin tibia I_{max} values were 97.9% and 88.4% of the non-SCI twin. Similarly, bone cross-sectional areas at the mid-femur site of the SCI twin were 66.8±0.1% of their non-SCI twin, whereas at the tibia site the differences were larger in TP1 than in TP2. The bone areas in the right and left legs of the SCI twin of TP1 were 62.3% and 67.5% of those of their non-SCI twin. In TP2, the corresponding values were 88.1% and 83.7%. Similar observations were noted for minimum and polar moments of inertia. Muscle atrophy and declining BMD are common consequences of SCI. This study reveals that important changes in bone geometry occur after SCI. The magnitude of these changes may depend on patient-specific variables such as lesion level, age at injury, time post injury or bone site measured.

Advances in Mechanical Response Tissue Analysis of the Human Tibia. C. E. Callaghan*[1], C. R. Steele*[2], S. M. Nickols-Richardson[1], W. K. Ramp[3], D. F. Wootten*[1], L. E. Miller*[1], W. G. Herbert[1]. [1]Virginia Tech, Blacksburg, VA, USA, [2]Stanford University, Stanford, CA, USA, [3]Health Research Group, Blacksburg, VA, USA.

Mechanical response tissue analysis (MRTA) provides a noninvasive means for estimating the cross-sectional bending stiffness (EI) of long bones utilizing impedance response to low frequency (60-1600Hz) vibration. Cross-sectional bending stiffness of a long bone is predictive (R^2>0.9) of the maximum breaking strength of the bone [Roberts *et al. J Biomech* 1996 Jan; 29(1):91-8]; thus, in vivo measurement of EI can be used to assess bone quality. MRTA has demonstrated good reliability (coefficient of variation: CV = 3-5%) in laboratory settings for measurement of the human ulna and monkey tibia, but due to the more complex geometry of the human tibia, reliability of in vivo measurements has been problematic. The purpose of this study was to evaluate sources of variability in EI estimation for the human tibia and explore methods of controlling this variability. The current MRTA prototype supports the foot and thigh, allowing for measurement while both proximal and distal ends of the tibia are free to vibrate within the joints without external restraint. Computer algorithms fit prediction curves to the raw impedance response data of the tibia and use these curves to estimate EI. The algorithm rejects measurements if the root mean square error between the prediction curve and the raw data is > 9%, indicating that the measurement was inadequate for accurate prediction estimates. To identify sources of variability in EI, data from 110 females (age 20.2 ± 1.8 yr, height 163.3 ± 5.9 cm, weight 60.7 ± 9.3 kg) were evaluated. Nine sequential MRTA measurements from the right and left tibiae of each subject were taken without repositioning. The initial algorithm yielded a within-trial CV of 11.2%. Analysis of these results revealed that some measurements were acceptable, although the EI values were unrealistic and that repeated measurements without repositioning could yield a wide range of EI values. These errors are partially based upon variability in curve fitting due to noise in the raw data at the upper frequency range, which can send the iterative algorithm toward an unrealistic bone mass and resonant frequency. Based upon the lower frequency data, there are five possible prediction curves for the upper frequency range. Our refined algorithm now allows for iteration through all five possible upper frequency prediction curves and incorporates realistic estimates of mass and resonant frequency into the selection and rejection of these curves. These refinements have allowed for improvement in within-trial reliability of EI estimation to a CV of 3.7%.

Variability of pQCT Measurement at the Distal Forearm: Influence of Voxel size, Region of Interest and Analysis Software. M. Ashe*, K. M. Khan, N. White*, P. Guy*, H. A. McKay. Orthopaedics/Family Practice, University of British Columbia, Vancouver, BC, Canada.

Peripheral quantitative computed tomography (pQCT) is a safe and precise technique to differentiate cortical from trabecular bone and assess both bone geometry and density. Currently, pQCT data acquisition and analysis protocols are seldom reported and there are no universal standards. Smaller voxel size (and slower scan speed) enhances scan resolution but increases scan time, radiation exposure and movement. The default voxel size is .4mm and .5mm. However, in a compromised skeleton where cortices are thin, lower resolution scans may result in an inability to detect the outer edge and analysis failure. Thus, the purpose of this investigation was to: 1) determine the effect of voxel size (and scan speed) on the determination of bone structure at the distal radius (4%) and 2) to compare the difference between the two most common pQCT software programs (XCT 550 and Geanie 2.1 Bonalyse). We obtained ten fresh-frozen right female radial cadaveric specimens (mean age 79 ± 6 years). Specimens were sealed in a plastic tube with normal saline for scanning. Bone measurements were performed with the Norland/Stratec XCT 2000 pQCT. Three contiguous 2.5mm slices were obtained at the 4% site of the radius using .2mm, .3mm, .4mm and .5mm voxel sizes. Scan speeds were 10 mm/sec for .2mm voxel; 15mm/sec for .3mm; 20mm/sec for .4mm voxel and 25mm/sec for the .5mm voxel. Scans were analyzed using XCT 550 (with 2 different region of interest (ROI) techniques; rectangular and automatic) and Geanie 2.1 Bonalyse software analysis programs. We used ANOVA to compare total bone area across voxel sizes and between analysis software. We experienced a mean analysis failure rate of 43% of the scans at the 4% (distal radius) using the standard rectangular ROI. This significantly improved to 24% using a custom automatic ROI (chi-square p<.01). Table shows total bone area at the 4% site using XCT 550 and Geanie 2.1 Bonalyse software. The lower resolution (.5mm voxel) had significantly more failures overall. Dif-

ference between the two software programs was 23%, on average. There was a difference between the software programs across voxel sizes. There is a need to establish standard reporting procedures for pQCT data acquisition and analysis protocols as results vary significantly depending on the acquisition, ROI and software.

Total Bone Area 4% site (mm2)

Voxel Size	XCT 550 (Custom ROI)	Bonalyse
.2mm	310.74±103.25	241.30±84.69
.3mm	307.26±97.71	246.80±87.52
.4mm	303.63±103.02	250.60±95.83
.5mm	277.88±133.46	254.70±101.18

M128

Use of Micro-CT in Comparison with DEXA for Rat Osteoporosis. E. M. Johnson*[1], C. G. Ambrose[2], H. Hogan[3], D. D. Cody[1]. [1]Imaging Physics, M.D. Anderson Cancer Center, Houston, TX, USA, [2]Orthopaedics, UTHSC Medical School, Houston, TX, USA, [3]Mechanical Engineering, Texas A&M University, College Station, TX, USA.

The aim of this study was to determine if Micro-CT could significantly improve the DEXA analysis of the OVX rat osteoporosis model**,** by evaluating BMD distribution and trabecular structure.

16 female rats 9 months old were randomly divided into two groups: OVX (n=6) and SHAM control (n=8). The proximal and distal regions of the right femur of each animal were scanned *in-vivo* using DEXA at baseline and 8 weeks post-OVX just prior to sacrifice.

The right femurs were excised and scanned using a Micro-CT at 27 μm voxel size. Trabecular bone architecture parameters and BMD values were evaluated within distal and proximal cancellous 3D regions of interest. Mechanical tests included three-point bending, femoral neck shear test, and distal cancellous bone compression. A third set of femurs was used for correlation of conventional histomorphometry to Micro-CT architectural data (trabecular thickness [TbTh], bone volume fraction [BVF], and bone surface to bone volume ratio [BS/BV]).

No DEXA parameters separated the OVX group from the SHAM group; however, Micro-CT was able to detect differences in cancellous bone architecture that were not apparent from DEXA. Statistical differences were observed between the OVX and SHAM groups for isolated distal cancellous bone architecture and mechanical compression strength variables. Cortical bone-influenced mechanical tests were not significantly different between the SHAM and OVX groups. Significant correlations were found between the mechanical tests and DEXA and Micro-CT imaging parameters. Regression models to predict mechanical properties had more significant predictive value when both Micro-CT and DEXA variables were included, as opposed to DEXA parameters alone. There was no significant difference between histomorphometric and Micro-CT-derived average TbTh or BS/BV results. Although BVF was significantly different among the paired values, this difference was due to sampling issues. Despite small sample sizes, mature rats, and only 8 week period between OVX and sacrifice, the overall hypothesis of this study was proven. *Ex vivo* Micro-CT imaging improved the discrimination of the OVX and SHAM femur characteristics over *in-vivo* DEXA examination alone. Although the OVX femurs, based on DEXA and cortical-influenced mechanical test results, did not appear to become osteoporotic, the two groups were definitively separated by distal cancellous material and Micro-CT measures. This may indicate that the distal cancellous is sensitive to a hormone-deficient state and could serve as an early marker for developing osteoporosis in the OVX rat model.

Effect of Alendronate on Human Osteoporotic Spine Induced by Glucocorticoid -3D Microarchitectural Analyses in Vivo. T. Mawatari[1], H. Miura*[2], S. Hamai[2], T. Shuto*[2], Y. Nakashima*[2], R. L. Smith*[1], Y. Iwamoto*[2]. [1]Orthopaedics, Stanford University, Stanford, CA, USA, [2]Orthopaedics, Kyushu University, Fukuoka, Japan.

Disruptions of the cancellous bone architecture may be the earliest and most damaging skeletal lesions of osteoporosis and will produces a disproportionate loss of strength. The purpose of this study was to evaluate the effect of alendronate on 3D microarchitecuture of the human osteoporotic lumber spine in rheumatoid arthritis patients in vivo by using high-resolution computed tomography (HRCT). 18 postmenopausal rheumatoid arthritis (RA) patients (mean 61.8 years) who are receiving long-term glucocorticoid therapy (prednisone equivalent of >=5mg/day) and vertebral bone mineral density (BMD) T-score is below -1 measured by dual-energy x-ray absorptiometry were enrolled in this study and the whole body of the third lumber vertebra was scanned by HRCT at a spatial resolution of 351 x 351 x 500 micron. All the gray-value slice images were then noise-eliminated, segmented, and transformed to binary images. Preliminary experiments on the cadaveric human lumber spine were designed specifically to select the correct threshold value by using histologic sections. Finally, from the reconstructed 3D volume data, arbitrary-shaped volume which cover the whole trabecular space were extracted. A parametric analysis was carried out using bone-volume fractions (BV/TV, %), the fractal dimension (FD) as the measure of complexity calculated by the 3-D box-counting method, and the connectivity density (CD, the first Betti number / total volume (/mm3)) as determined by topological analysis. Randomly selected subjects (alendronate group; n=9) commenced 5mg of oral alendronate once daily and continued taking it for the duration of the study, while the rest of the patients were remain untreated (control; n=9). All patients were re-evaluated after 6 months or more and change rate per 6 months were calculated. HRCT provided satisfactory in vivo assessment of consecutive slice images, even though an effective resolution of 351 micron seems to be the lowest resolution level available for human trabecular bone. In control, BMD, the BV/TV, FD, and CD decreased significantly after six months. Alendronate significantly increased vertebral trabecular bone mass, however the effect on CD were not statistically significant. Once connectivity loss occurs, it seems more difficult to restore connectivity, and only possible to increase the thickness of the remaining trabeculae. Since deterioration of connectivity may limit the potential benefit to be derived from the agents that increase bone mass, appropriate therapeutic intervention should be initiated before the connectivity has been lost.

The Correlation with between Background Variables and Urine NTX Levels and Bone Mineral Density in Japanese Osteoporosis Patients. H. Matsuo*. Internal Medicine, Matsuo Hospital, Fukuoka, Japan.

In 397 patients diagnosed as having osteoporosis (348 females and 49 males), NTX level (a representative marker of bone metabolism) was measured, and its relationship to background variables (age, height, body weight, BMI, time of menopause and bone mineral density) was analyzed statistically. Furthermore, effects of Risedronate (Actonel®), a new bisphosphonate preparation, on NTX level were evaluated.

When the distribution of NTX in each range was analyzed for the 397 patients, its 50-percentile level (median) was 45.7 nmol BCE/mmol Cr. Its mean ± SD was 53.2 ± 30.91 nmol BCE/nmol Cr.

In the analysis of correlation of NTX level to background variables of the 397 patients (age, height, body weight, BMI, time of menopause and bone density), NTX level did not correlate with age ($R2 = 0.0000$) but it showed a negative correlation with height ($R2 = 0.0333$), body weight ($R2 = 0.0748$), BMI ($R2 = 0.0464$) and bone density ($R2 = 0.0898$). That is, NTX level tended to raise as height, body weight, BMI and bone density decreased. Furthermore, a weak positive correlation was noted between NTX level and time of menopause ($R2 = 0.0012$).

Of the 397 patients with osteoporosis, 36 were treated with Risedronate after the diagnosis of the disease. The time course of NTX level was followed in these 36 patients. The mean decrease in NTX level in the Risedronate treatment group (n = 36) was 40.5%. When analyzed for each category of individual background variables, the decrease in NTX level following Risedronate treatment was not large enough to be rated as statistically significant ($P < 0.10$) for the category "male" (n = 3) and the category "bone density over 70" (n = 6), but the decrease was statistically significant ($P < 0.05$) for the other categories of background variables.

Bone Turnover Markers Predict Changes Over Three Years in Pubertal, But Not Prepubertal Females. E. M. Laing[1], K. H. Yurman*[1], C. M. Modlesky[2], D. B. Hall*[3], A. R. Wilson*[4], R. D. Lewis[1]. [1]Foods and Nutrition, The University of Georgia, Athens, GA, USA, [2]Health, Nutrition and Exercise Sciences, The University of Delaware, Newark, DE, USA, [3]Statistics, The University of Georgia, Athens, GA, USA, [4]Campbell Soup Company, Camden, NJ, USA.

The purpose of this study was to examine the relationships of the bone turnover markers serum osteocalcin (OC), urinary pyridinoline (PYD) and deoxypyridinoline (DPD) with changes in bone area (BA), bone mineral content (BMC), and areal bone mineral density (aBMD) over three years in prepubertal females. Bone turnover markers, bone properties and sexual maturation (i.e., breast stage rated by a physician) were assessed annually in 32 prepubertal females, four to eight years of age. OC was determined using radioimmunoassay, PYD and DPD by high performance liquid chromatography and bone measures by dual-energy x-ray absorptiometry (DXA). By the end of three years, 13 participants progressed to breast stages 2/3 (early puberty), whereas 19 remained in breast stage 1 (prepuberty). Regression models with random subject effects were used to determine predictors of bone turnover markers. Canonical correlation and multiple regression analyses were employed to determine relationships between bone turnover markers and DXA measures of bone. OC, BA, BMC, and aBMD at all skeletal sites increased significantly over time ($p < 0.0001$). Significant predictors for annual increments in bone turnover markers were: annual increments of body weight for OC (slope = 0.305, p = 0.002), BMI and height for PYD (slope = 27.2, p = 0.002 and slope = 17.5, p = 0.046, respectively), and BMI for DPD (slope = 3.52, p = 0.019). Using canonical correlations, changes in all bone turnover markers were found to be more strongly correlated to changes in DXA measures of bone in those participants in breast stages 2/3 compared to those remaining in stage 1 ($R = 0.80$ vs. 0.38, total body; $R = 0.63$ vs. 0.39, lumbar spine; $R = 0.62$ vs. 0.38, proximal femur; $R = 0.82$ vs. 0.39, radius). The results suggest that OC, PYD and DPD may be useful in predicting changes in bone in early pubertal children. Assessment of additional bone turnover markers and bone properties may be necessary to elucidate relationships between markers and changes in bone in prepubertal females.

Disclosures: ***E.M. Laing****, None.*

Change of Biochemical Markers of Bone Turnover of General Residents in a Rural Japanese community, 1993-2003: The Taiji Study. N. Yoshimura[1], K. Nakatsuka[2]. [1]Department of Public Health, Wakayama Medical University School of Medicine, Wakayama, Japan, [2]The 2nd Department of Internal Medicine, Osaka City University Medical School, Osaka, Japan.

Biochemical markers of bone turnover were measured over a ten-year period in a cohort study in the town of Taiji, Wakayama Prefecture, Japan, to provide information on change of biochemical marker levels in the mature and elderly population. Four hundred subjects were selected by sex and age decade from the full list of residents born in 1913-1952 and aged 40-79 years at the end of 1992, with 50 men and 50 women in each age decade. Baseline BMD of the lumbar spine and the proximal femur was measured using dual energy X-ray absorptiometry (DXA) in 1993, 1996, 2000 and 2003. Blood samples of all participants were examined to obtain values for N-mid osteocalcin (NmidOC) as a bone formation marker, and C-telopeptide of type I collagen (CTX) as a bone resorption marker in 1993 and 2003.

The evaluation of changes in biochemical markers of bone turnover over ten years was completed for 322 of the 400 participants initially recruited (80.5%: 153 men, 169 women). There was no significant difference among age groups in the mean values of bone metabolic markers in men both at the first survey and 10 year-follow-up survey. In women, the mean values of NmidOC(ng/ml; SD) in 1993 and 2003, respectively, were 14.8(5.8) and 19.2(7.1) in their 40's, 28.1(8.9) and 23.7(9.5) in their 50's, 30.9(9.2) and 23.4(7.7) in their 60's, 29.3(10.8) and 23.0(10.1) in their 70's. The mean values of CTX(ng/ml; SD) in 1993 and 2003, respectively, were 0.10(0.07) and 0.20(0.11) in their 40's, 0.25(0.12) and 0.26(0.23) in their 50's, 0.29(0.13) and 0.27(0.14) in their 60's, 0.30(0.16) and 0.29(0.16) in their 70's. In women, there was a significant difference ($P<0.001$) of both serum NmidOC and CTX levels between in their 40s and in their 50s and older at the initial survey. The mean values of NmidOC and CTX in their 40's increased significantly over ten-year-period (NmidOC:$P<0.01$, CTX:$P<0.001$). In women in their 50's, 60's and 70's, NmidOC levels decreased significantly ($P<0.05$), while there was no significant difference of serum CTX levels during 10 years in their 50's, 60's and 70's. Furthermore, we found evidence of differences in biochemical marker levels for given age strata between birth cohorts. The mean values of NmidOC and CTX in women in the birth cohort of 1943-52, when they reached the age stratum 50-59, was significantly lower ($P<0.001$) than that of the older cohort born in 1933-42 when in the same age stratum.

Anabolic Index (Serum Osteocalcin/Urine NTX) Predicts Bone Mineral Density. O. S. Indridason*[1], L. Franzson*[2], G. Sigurdsson[1]. [1]Medicine, University Hospital, Reykjavik, Iceland, [2]Laboratory Medicine, University Hospital, Reykjavik, Iceland.

The usefulness of bone turnover markers in osteoporosis has been controversial. The aim of this study was to assess the association between BMD and bone turnover markers and examine if the ratio of a bone formation marker to a bone resorption marker might be useful.

This was a cross-sectional study of 70 year old Icelandic women who were invited for BMD measurement (DXA, Hologic QDR 2000+ scanner, Hologic, Waltham, MA, USA) at the hip, lumbar spine and total body. All subjects answered a thorough questionnaire on health and medication use. For the current analysis we excluded women with diseases or taking medications affecting mineral metabolism. Serum osteocalcin (OC) was measured using an immunoradiometric assay (Nichols Institute, San Juan Capistrano, CA, USA). Cross-linked N-telopeptides of type I collagen (U-NTx) was measured in urine with a competitive enzyme linked immunosorbent assay (Osteomark, Ostex International, Seattle, WA, USA) and expressed as a ratio to urinary creatinine concentration. Anabolic index (AI) was defined as the ratio of OC to U-NTx (OC/U-NTx). We used Spearman´s correlation coefficient and multivariable linear regression to assess the relationship between BMD, AI and other variables. Where needed, we used natural logarithm to obtain normal distribution for variables used in the regression analysis.

Of 418 women invited, 308 participated but after exclusion, 248 remained for analysis. There was a strong correlation between OC and U-NTx ($r=0.61$, $p<0.0001$). BMD at lumbar spine, hip and total body correlated negatively with OC ($r=-0.22$, $p<0.001$; $r=-0.24$, $p<0.001$; $r=-0.33$, $p<0.001$, respectively) and U-NTx ($r=-0.25$, $p<0.001$; $r=-0.26$, $p<0.001$; $r=-0.30$, $p<0.001$, respectively) but positively with AI ($r=0.18$, $p=0.006$; $r=0.18$, $p=0.01$; $r=0.17$, $p=0.01$, respectively). After adjusting for important covariates, including leanweight, fat-mass and serum iPTH, there remained a significant negative relationship between OC or U-NTx and BMD at all sites, whereas the relationship between the AI and BMD remained positive for all BMD sites (standardized beta coefficients: $r=0.14$, $p=0.03$; $r=0.18$, $p=0.002$; $r=0.12$, $p=0.05$, for lumbar spine, hip and whole body, respectively).

In contrast to OC, a marker of bone formation and Urinary-NTx, a marker of bone resorption, both of whom are negatively associated with BMD, the ratio between the two, the anabolic index, is positively associated with BMD in elderly women. Its usefulness in predicting BMD and changes in BMD should be evaluated in other studies.

Variation of Bone and Connective Tissue Turnover Markers with Age, Gender, BMI and Ethnicity in Elite Athletes. A. E. Nelson[1], M. J. Seibel[2], C. J. Howe*[3], T. V. Nguyen[4], J. de Winter*[2], K. Leung*[4], G. J. Trout*[3], R. C. Baxter*[5], D. J. Handelsman*[6], M. Irie*[7], R. Kazlauskas*[3], K. K. Ho*[1]. [1]Pituitary Research Unit, Garvan Institute of Medical Research, Sydney, Australia, [2]Bone Research Program, ANZAC Research Institute, Sydney, Australia, [3]Australian Sports Drug Testing Laboratory, Sydney, Australia, [4]Garvan Institute of Medical Research, Sydney, Australia, [5]Kolling Institute of Medical Research, Sydney, Australia, [6]ANZAC Research Institute, Sydney, Australia, [7]TOHO University, Tokyo, Japan.

The aim of this study was to determine the effect of the demographic factors age, gender, BMI and ethnicity on bone and connective tissue turnover markers in elite athletes, in order to establish reference ranges. As these markers are responsive to growth hormone (GH) and remain elevated following withdrawal of exogenous GH, they may be useful as indirect indices of GH doping. Reference ranges are essential to develop a test for GH doping based on these indirect markers.

Serum samples were obtained from 1087 elite athletes aged 22 ± 5 years from 14 countries, representing the following ethnic groups: Caucasian (53%), Asian (32%), African (10%) and Oceanian and other (5%). Bone and connective tissue markers were measured in duplicate by radioimmunoassay: N-terminal propeptide of type I procollagen (PINP), a marker of bone formation; N-terminal propeptide of type III procollagen (PIIINP), a marker of connective tissue collagen synthesis; C-terminal cross-linked telopeptide of type I collagen (ICTP), a marker of bone resorption. Statistical analysis was performed by random-effects analysis of variance.

There was a highly significant inverse relationship between all three markers with age. All three markers were significantly higher in males than in females, and were negatively correlated with BMI. Multiple regression analysis indicated that age, gender, BMI and ethnicity accounted for 32 - 48% of the total variability of serum PINP, ICTP and PIIINP. Age exerted the greatest effect (PINP: 27%, ICTP: 42%, PIIINP: 27% of the variability), then gender (PINP: 7.6%, ICTP: 4.6%, PIIINP: 2% of the variability). BMI (1.3%, 0.6% and 0.9% respectively) and ethnicity (0.7%, 0.01% and 2% respectively) both had modest contribution to the variability of PINP, ICTP and PIIINP.

In conclusion, reference ranges for the GH-sensitive bone and connective tissue markers PINP, ICTP and PIIINP should take into account demographic factors such as age and gender. For these markers, however, reference ranges can be established without needing to account for BMI and ethnicity.

M135

Does Impaired Renal Function in the Elderly Influence Serum Concentration of Bone Biochemical Markers? M. Healy*[1], M. Casey*[2], C. Walsh*[3], D. Coakley*[4], G. Cox*[1], C. Cunningham*[4], V. Crowley*[1], J. B. Walsh[4]. [1]Biochemistry Department, St James's Hospital, Dublin, Ireland, [2]Falls/ Osteoporosis Service, St James's Hospital, Dublin, Ireland, [3]Statistics Department, Trinity College, Dublin, Ireland, [4]Mercer's Institute for Research on Ageing, St James's Hospital, Dublin, Ireland.

The purpose of this study was to examine the effects of impaired renal function on the analysis of serum bone biochemical markers in an elderly population group.

245 patients referred from the St James's Hospital Care of the Elderly Service for DEXA bone scanning were recruited. All patients had calculated creatinine clearance (Cockcroft Gault), a marker of bone resorption (serum CTx), a marker of bone formation (serum osteocalcin), parathyroid hormone (PTH), and 25-hydroxyvitamin D (25OHD) assessed. The relationship between renal function and bone markers was examined. Bone markers and PTH were measured on a Roche 2010 analyser. 25OHD was analysed by radioimmunoassay (Diasorin Inc).

36 patients were male and 209 were female. Means and ranges for the variables are illustrated in the table. Statistics were calculated using Datadesk 6.1.

No correlation was found between creatinine clearance and CTx in the group as a whole and osteocalcin was only weakly correlated ($r = -0.183$). However, below a cut-off of 45 ml/min creatinine clearance an inverse relationship between renal function and markers became apparent (CTx v CrCl $r = -0.391$ $p < 0.0001$; OC v CrCl $r = -0.402$ $p < 0.0001$). This result indicates that declining renal function is associated with elevated marker concentrations.

In conclusion, care needs to be taken when interpreting biochemical markers of bone turnover in the elderly given the prevalence of renal impairment in this population. Creatinine clearance should be estimated to avoid misinterpretation

Table: Data for variables included in the study

N=245	Mean (+/- SE)	Range	Reference Intervals
CTx ng/ml	0.49 (0.02)	0.032-2.25	0.01-1.0
OC µg/ml	27.3 (1.3)	3.2-126	11-50
PTH ng/ml	41.7 (1.9)	4.9-181	10-65
25OHD ng/ml	23.9 (1.0)	2.5-67	>20
CrCl ml/min	47.5 (1.4	16-107	~1ml/min yearly decline after 3rd decade
Age years	78.8 (0.7)	50-97

Can Multiple Measurements or Pooled Measurements Reduce Within-subject Variability? J. A. Clowes, N. F. A. Peel, A. Blumsohn, F. Gossiel*, R. Eastell. Clinical Sciences (North), University of Sheffield, Sheffield, United Kingdom.

A decrease in bone turnover markers in response to therapy predicts fracture risk reduction; therefore monitoring may assist clinicians in determining an individual's therapeutic response. However, variability (noise) in the bone marker measurements frequently limits the ability to detect a statistically significant response (signal). We hypothesized that performing more then one measurement would reduce within-subject variance (SD_i) by the square route of the number of measurements performed. Thus if 4 measurements were made we might expect to reduce the SD_i by a factor of two (50%), since n=4 (calculated multiple sample approach). Increasing the number of measurements increases cost, therefore we examined whether a pooled sample obtained by taking a fixed volume aliquot from the 4 separate urines could reduce variance by a similar magnitude (pooled approach).

Twenty five postmenopausal women (age 50-80 years) were recruited as a control group for a randomized control study. Subjects attended at baseline, 1 and 24 weeks. At each visit subjects provided 4 urine samples, 3 from the preceding 3 mornings and 1 on the morning of the visit. Samples were stored at 4 ºC. Measurements of urine N telopeptide of type I collagen were performed in replicate in a batched analysis using an automated immunoassay (Vitros ECi). We calculated short term (1 week) and long term (24 weeks) analytical variability (CV_a) based on replicate assays and within-subject coefficient of variation (CV_i) after accounting for CV_a. Components of variance were assessed by nested ANOVA. We compared either 4 separate measurements (calculated multiple sample approach) or a pooled measurement (pooled approach) to a single measurement (global individual).

The calculation approach reduced the within-subject SD by between 27% and 35%. The pooled approach reduced the SD_i by between 20% and 61%. The calculation and pooled approach had a greater effect on short-term variance (35 to 61%) then long-term variance (20 to 27%). This may be because day-to-day variability is a significant part of short-term variance with additional sources of variability arising with long-term variance e.g. seasonal effect. In conclusion, multiple measurements and pooled samples reduce variance by up to 61%, which may be of benefit when monitoring response to therapy in an individual.

	Analytical SD_a	Analytical CV_a	Within-subject SD_i	Within-subject CV_i
Short-term, global individual	1.4	2.7	11.2	21.3
Short-term, pooled	2.2	4.4 (3.6-5.2)	4.4	12.1 (8.7-16.0)
Short-term calculated multiple	-	-	7.3	13.7 (8.9-19.0)
Long-term, global individual	1.9	3.6	9.9	18.8
Long-term, pooled	1.8	3.6 (2.9-38)	7.9	15.5 (0.0-18.2)
Long-term calculated multiple	-	-	7.2	13.6 (9.9-17.6)

The Degree of Isomerization of Collagen Type I C-telopeptide in Postmenopausal Women: A Potential Biochemical Index of Bone Quality. I. Byrjalsen*[1], P. A. Cloos*[1], P. Qvist[1], C. Christiansen[2]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Center for Clinical & Basic Research, Ballerup, Denmark.

The main protein component of the extracellular bone matrix is collagen type I of which the C-telopeptide motif of CTX is released during osteoclastic bone resorption. Newly synthesized bone matrix contains the α-form of CTX, but with aging the motif spontaneously isomerizes to the β-form. The α/β ratio has been reported to be high in trabecular bone and low in cortical bone (Cloos 2000), and it has been suggested to be an index of bone quality.

Purpose: To provide reference data in healthy pre- and postmenopausal women, and to investigate the effect of various antiresorptive therapies on the α/β ratio.

Methods: The native α-CTX, and the age-related isomerized β-CTX type I collagen C-telopeptide fragments were measured in fasting second void morning urine of healthy premenopausal (*n*=76; 40-50 years of age) and postmenopausal women (*n*=446). The postmenopausal women were from cohorts of women participating in placebo-controlled double-blind antiresorptive treatment studies, and samples were obtained at baseline, after 6, 12, and 24 months of therapy.

Results: Early postmenopausal women, mean age of 53 years and less than 5 years since menopause, had a significant ($p<0.0001$) two-fold increase in the bone resorption markers of urinary α-CTX and β-CTX as compared to premenopausal women. In contrast the ratio between the two markers were unaffected by change in menopausal status (geometric mean ratios of 0.202 and 0.213 for pre- and post, respectively, *p*-value=0.31). In postmenopausal women, the index of the α/β ratio showed a highly significant ($p<0.0001$) increase of 1.41% per menopausal year, and it was found that the index was independent of the rate of bone resorption as assessed by urinary β-CTX ($r=0.03$; $p=0.50$).

The antiresorptive therapies had different effects on the index of the α/β ratio with the time-averaged mean relative change from the baseline values during the two year study period of -35% (p<0.01), and -50% (p>0.0001) for two bisphosphonate treatments, -20% (p<0.01) for oral HRT, -10% (NS) for cutaneuos HRT, +12% (p<0.05) for nasal HRT, -11% (p<0.01) for SERM, and +1% (NS) for placebo.

Conclusion: The association between the increasing ratio of α- and β-CTX and the duration of the menopause, and the fact that the ratio in itself is independent on the rate of bone resorption, suggests that the α/β-ratio could provide information on the quality of the skeleton. The different responses of the index of the α/β-ratio caused by the various antiresorptive therapies may reflect different treatment effects between trabecular and cortical bone in the prevention of bone loss.

Bone Turnover Response to Feeding and infusion of Gut Hormones Peptide YY_{3-36}, Pancreatic Polypeptide and Oxyntomodulin. F. Gossiel*[1], C. W. Le Roux*[2], R. L. Batterham*[2], M. A. Cohen*[2], S. R. Bloom*[2], A. Blumsohn[1]. [1]Bone Metabolism Unit, University of Sheffield, Sheffield, United Kingdom, [2]Department of Metabolic Medicine, Imperial College, London, United Kingdom.

Mechanisms underlying the apparent change in bone turnover in response to feeding or in relation to time-of day in humans are uncertain, but may relate to a change in skeletal blood flow or a direct effect of a gastrointestinal peptide on the skeleton. Several peptides are secreted in the postprandial phase, and it is possible that one or more of these peptides could influence bone turnover. It is important to examine the response to these peptides at physiological dose.

Peptide YY_{3-36} (PYY_{3-36}), Pancreatic polypeptide (PP) and Oxyntomodulin (OXM) are secreted following meals, and infusion of these peptides reduces appetite and food intake in humans. The aim of this study was to investigate the effect of physiological-dose infusion of these peptides on bone turnover. Healthy volunteers were infused with placebo/PYY_{3-36} (0.8 pmol/kg/min, n=12), placebo/OXM (3.0 pmol/kg/min, n=13) or placebo/PP (10 pmol/kg/min, n=10) in a double blinded placebo crossover study for each peptide. Serum samples were collected at regular time points prior to peptide infusion, after cessation of peptide infusion and following a weighed buffet meal provided at t_{210} (PYY_{3-36} and PP infusion) and t_{75} (OXM infusion). We assessed the effect of peptide infusion and subsequent food ingestion on the serum concentration of the respective peptides, serum C-telopeptide of type I collagen (sβCTX), procollagen type 1 N-propeptide (P1NP), osteocalcin and parathyroid hormone (PTH). There was no significant effect of these peptides on bone turnover at physiological dose in comparison with saline infusion (all P>0.2, AUC analysis or repeated measures ANOVA). The decrease in sβCTX in response to subsequent food intake was 69±3%SEM (PYY study), 61±3 % (PP study) and 57±3% (OXM). There was no substantial effect of prior peptide infusion on the sβCTX response to feeding (although food intake was influenced by peptide infusion). Food intake resulted in increased serum PYY_{3-36} , OXM and PP of magnitude similar to that achieved with parenteral peptide. There was no significant effect of any peptide on serum PTH, PINP or OC versus placebo (all P > 0.05). In summary we were unable to establish an effect of any of these three food-stimulated peptide hormones on bone resorption when administered at physiological dose. Other peptides such as GLP-2 may be relevant.

Serum Markers of Bone Remodeling Following Total Knee or Hip Arthroplasty. R. L. Illgen*, L. M. Bauer*, T. M. Forsythe*, M. Hagenauer*, A. K. Franta*, T. R. Enright*, W. B. Valhmu*, J. P. Heiner*. Orthopedics and Rehabilitation, University of Wisconsin-Madison, Madison, WI, USA.

Pre-radiographic detection would be a valuable diagnostic of periprosthetic osteolysis, a major mode of failure after total hip (THA) and knee arthroplasty (TKA).[1] Osteolysis is often asymptomatic and radiologically undetectable until periprosthetic loosening or fracture occur. Serological markers of bone remodeling have been identified as a candidate approach.[2,3] This study defines the natural history of 2 serum markers following arthroplasty.

IRB approval and patient consent were obtained. Patients diagnosed with osteoarthritis or osteonecrosis scheduled for THA or TKA were recruited. Exclusion criteria included osteoporosis, rheumatoid arthritis, anti-resorptive agent prescriptions, or multiple joint arthroplasties within 1 year. Serum was collected at selected time points and stored at -80°C. Time points collected were at days 0 (preop and postop), 14, 28, 42; and 3, 6, 12, and 24 months. Serum was assayed using commercial enzyme-linked immunosorbent assay (ELISA) kits, measuring concentrations of the bone resorption marker, N-Telopeptide (NTx) (Ostex International, Seattle, WA) and bone formation marker, Bone-Specific Alkaline Phosphatase (BAP) (MetraBiosystems, Mountainview, CA). Multivariate analysis was performed using analysis of variance (ANOVA).

Sixty-nine patients were followed for 1 year after THA (N=32) or TKA (N=37). Of these, 33 were followed to 2 years (17 THA, 16 TKA). Pre-menopausal women were not analyzed due to small sample size (N=9).

ANOVA revealed significant serum elevations of NTx and BAP at 28 days (Fig. 1). NTx returned to preop levels, whereas BAP may have established a new baseline by 6 months. ANOVA for NTx and BAP didn't reveal effects ($\rho<0.05$) due to gender, THA versus TKA, surgeon, implant fixation (cemented or hybrid TKA), nor time from 6 months to 2 years.

These data suggest serum markers of bone remodeling change in predictable patterns after THA and TKA. This supports further investigation into whether patients developing periprosthetic osteolysis will display a significant deviation from these expected profiles prior to radiographic evidence of osteolysis.

Quantitative Ultrasound Bone Measurements in Healthy American Adolescents. K. J. Loud, H. A. Feldman*, K. C. DePeter*, A. A. Pettinato*, C. M. Gordon. Children's Hospital, Boston, MA, USA.

Quantitative ultrasound (QUS) bone measurements are appealing in young adolescents because of the absence of ionizing radiation. A limitation of their use in the United States is the lack of pediatric normative data. The purposes of this study were to develop reference distributions for speed of sound (SOS) measurements of the radius and tibia via QUS among American adolescents and to evaluate relationships between SOS and specific demographic and lifestyle variables.

Eighty-six (86) otherwise healthy adolescents and young adults aged 11-26 years were recruited during routine visits to an urban medical center adolescent clinic. The protocol was approved by the Committee on Clinical Investigation at Children's Hospital Boston. Participants completed a confidential semi-structured interview for demographic information and health history as well as self-administered, validated exercise and nutritional questionnaires. Weight, height, and sexual maturity ratings (SMR) were also recorded. The main outcomes, SOS at the distal third of the radius and mid-shaft of the tibia, were measured on the non-dominant limb using the Omnisense 7000P QUS (Sunlight Medical Ltd., Tel-Aviv, Israel).

The age of participants was 17.2 $\pm$ 2.5 years (mean $\pm$ SD). Forty-six (53%) were female. Self-reported ethnicities were 49% African-American, 24% Hispanic, 17% Caucasian, 6% Asian, and 3% other. Fifty-nine (69%) of the participants had achieved SMR 5; 96% of the females were post-menarcheal, with age at menarche of 12.4 $\pm$ 1.4 years. Daily dietary intakes of calcium and vitamin D were 1155 $\pm$ 710 mg and 242 $\pm$ 179 IU, respectively.

There were moderate correlations between age and SOS at the radius, with a correlation coefficient (r) of 0.59 ($p < 0.0001$), and at the tibia, $r = 0.58$ ($p < 0.0001$). Participants who had achieved SMR 5 had a significantly higher SOS than those who were less mature at both the radius ($p < 0.0001$) and tibia ($p = 0.002$). There were no significant relationships found between SOS and self-reported ethnicity, BMI, intake of calcium or vitamin D, age at menarche, or activity levels. In multiple linear regression controlling for these factors, age remained significantly associated with SOS at the distal radius ($p < 0.0001$) and mid-shaft tibia ($p < 0.0001$).

These findings suggest that skeletal QUS measurements follow similar age distribution patterns to bone mineral density (BMD) determinations by dual-emission x-ray absorptiometry (DXA) among healthy American adolescents. Youth in our sample did not, on average, meet the recommended daily allowances (RDA) for calcium or vitamin D. More data are needed to establish reference distributions in this population and to provide sufficient power to identify other modulating factors.

Ultrasound Bone Mineral Density of Os Calcis - Its Relationship with Bone Mineral Markers and 25(OH)D in Endemic Flurotic and Non-flurotic Villages. C. V. Harinarayan*, T. Ramalakshmi*, A. V. Hebbani*, U. V. Prasad*, E. G. T. Kumar*, D. Sudhakar*, D. Prasanna Kumar*, M. Suresh*. Endocrinology and Metabolism,, SVIMS, Tirupati, India.

OBJECTIVES: To study the relationship between the nutritional status, serum bone mineral markers, 25(OH)D levels and ultrasound bone mineral density of Os Calcis (USBMD) in endemic flurotic and non-flurotic villages.

METHODS: Sixty-four subjects from flurotic and 79 subjects from non-flurotic villages were studied for their dietary habits, biochemical parameters of bone mineral markers, 25(OH)D levels and correlated with stiffness index (SI) measured using USBMD (Achilles).

RESULTS: The results are depicted in table as mean $\pm$ SEM. (* $p< 0.001$; @ $p < 0.05$)

Table - 1 Dietary parameters

Parameter	Flurotic village	Non-flurotic village
Water fluoride(PPM)	> 1.5	<1
Age(yrs)	43$\pm$2	48$\pm$1
Energy(Kcal/day)	1763$\pm$46*	1398$\pm$10
Dietary Calcium(mg/day)	241$\pm$3	272$\pm$1.34*
Dietary Phosp(mg/day)	433$\pm$6	553$\pm$5*
Phytate/Calcium ratio	0.7$\pm$0.01	0.7$\pm$0.01
Dietary Proteins(mg/day)	26$\pm$0.28	37$\pm$0.54*

Table - 2 Biochemical parameters

Parameter	Flurotic village	Non-flurotic village
S. Calcium(mg/dl)	10$\pm$0.01	10.1$\pm$0.07
S. Phosphorus(mg/dl)	2.68$\pm$0.03	3.07$\pm$0.06*
S. Alk. Phos(IU/l)	65$\pm$2.4*	41.7$\pm$1.94
S. Protein(gm/dl)	6.5$\pm$0.04	6.76$\pm$0.03
25(OH)D(ng/ml)	20.3$\pm$0.94	22.6$\pm$0.71@
Serum fluoride(SF)(PPM)	0.13$\pm$0.005*	0.05$\pm$0.001
Young Adult(YA)(SI)	85.17$\pm$2.41@	76.44$\pm$2.58
Age Matched (AM)(SI)	94.78$\pm$2.74	88.81$\pm$1.58

Dietary calcium intake in both the villages is far below the recommended daily allowances (RDA) by Indian Council of Medical Research (ICMR), India for Indian population. 25(OH)D correlated positively with energy intake (r 0.7;p<0.001); dietary calcium(r 0.5;p<0.001); and negatively with phytate/calcium ratio(r 0.02;p<0.001), in the fluortic village. There was no similar correlation in non-flurotic village. For comparable levels of serum calcium, subjects in non-flurotic villages were more osteopenic than the flurotic counterparts. USBMD did not correlate with 25(OH)D in the flurotic and non-flurotic subjects.

CONCLUSIONS: Monitored food fortification program is required to correct the inadequate dietary calcium of both the populations. USBMD does not indicate the 25(OH)D status of an individual. Fluoride forms fluroappatite in the bone which is hyper dense and can fallaciously produce increased bone density. USBMD should not be used for screening osteoporosis in areas endemic for flurosis.

Heel Ultrasonometry as a Tool for Identifying Women at High and Low Risk for Osteoporosis. M. Gambacciani, B. Cappagli*, M. Ciaponi*, A. Genazzani*. Department of Obstetrics and Gynecology, University of Pisa, Pisa, Italy.

Not all people at high risk for future fracture have access to DXA bone density measurements. Inexpensive methods selecting high-risk patients could therefore improve healthcare delivery. Quantitative ultrasound of the os calcis is accepted as an effective, low-cost method to identify women likely to have osteoporosis at the hip or spine as measured by DXA. In this study, we wished to determine T-score cutpoints for the Achilles bone ultrasonometer to identify women at high and low risk for osteoporosis.

A total of 272 women aged 40 to 83 years (mean age 58 ± 7 years) had DXA measurements of the spine and hip using a Lunar DPX (GE Healthcare) and a heel ultrasound measurement using the Achilles InSight. The Achilles InSight is an imaging heel ultrasonometer with 8-10 second measurement time; the complete examination takes 3-5 minutes. Osteoporosis was diagnosed if the lowest DXA T-score at spine (L1-L4) or hip (total femur) was ≤ -2.5. Using the binormal fit to the ROC data, InSight T-score cutoffs for 90% sensitivity (patients at low risk) and 90% specificity (patients at high risk) were determined. For the different InSight T-score cutoffs the likelihood ratios for a positive test (LR+) and a negative test (LR-) at spine or hip were also calculated.

From the DXA results, 54 of 272 subjects were classified as osteoporotic. The InSight T-score cutoffs were found to be -0.8 and -2.3 for 90% sensitivity and 90% specificity, respectively. Women with InSight T-scores ≤ -2.3 are at high risk, and could be potential candidates for treatment and DXA monitoring measurements. Women with InSight T-scores ≥ -0.8 could be considered at low risk and scheduled for retesting in future depending on risk factors. Women with an InSight T-score between -2.3 and -0.8 should be referred for DXA assessment.

We conclude that the Achilles bone ultrasonometer can be used as a valid screening tool for identifying those patients who should be considered for spine and hip bone density assessment.

InSight T-score	Sensitivity	Specificity	LR+	LR-
-0.80	90%	41%	1.52	0.25
-2.34	45%	90%	4.51	0.61

The Usefulness of Quantitative Ultrasound at Calcaneus in the Detection of the Different Types of Non-traumatic Fracture in Chinese Men. S. K. AU*[1], E. M. C. Lau[1], D. T. K. Choy[1], S. Wong*[2], J. Leung*[1], F. W. K. Chan*[1], H. Lynn*[2], J. Woo*[2], P. C. Leung*[3]. [1]Jockey Club Centre For Osteoporosis Care & Control, The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [2]Department of Community & Family Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [3]Department of Orthopedics & Traumatology, The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

To determine the discrimating ability of QUS at calcaneus between individuals with and without non-traumatic fractures in elderly Chinese men.

A total of 1708 men, aged 65 years or above, have their heel QUS measured by Sahara Sonometer (Hologic) in our centre from Aug 2001 to Feb 2004. Subjects are either recruited by public announcements or from Orthopedics out-patient clinic, Prince of Wales Hospital. Details on history of fracture were obtained, and subjects were divided into controls without fractures (n=1456) and with non-traumatic prior fractures (n=252). The fractured group was divided into hip, vertebral and forearm fractures subgroup. Statistical significance of difference between Quantitative Ultrasound Index (QUI) of each group was assessed by ANOVA (adjusted for age, weight, height and BMI).

The clinical characteristics and QUS values of the participants are summarized in table below.

	Control	All	Hip	Vertebral	Forearm
N	1456	252	10	44	56
Age	72.7 (5.1)	73.8 (5.7)	78.5 (4.1)	74.8 (6.3)	75.1 (5.5)
Weight (Kg)	62.1 (9.3)	61.0 (10.3)	58.8 (12.2)	58.2 (10.7)	62.0 (9.2)
Height (cm)	163.2 (5.7)	162.3 (8.4)	161.4 (8.8)	158.7 (15.6)	162.2 (5.5)
QUI	89.7 (16.2)	84 (17.9)	64.3 (14.8)	77.9 (18.9)	81.5 (18.3)

* Data in mean (SD)

QUI of each of the 3 fracture subgroups was significantly lower ($p<0.001$) than the normal controls.

The sensitivity & specificity of QUI T-score (local normal range) were also assessed in 2 different cut-off values (-2.5 and -1). Specificity of using -2.5 as cut-off was 0.88 and sensitivity were 0.25, 0.7, 0.45 & 0.32 for "All", "Hip", "Vertebral" & "Forearm" fracture group, respectively. In contracts, the specificity of using -1 as cut-off was 0.70 and sensitivity were 0.77, 1.0, 0.86 & 0.82 for "All", "Hip", "Vertebral" & "Forearm" fracture group, respectively.

Result shows Calcaneus QUS can discriminate between healthy individuals and subjects with previous fractures. In addition, T-score cut-off at -1 will greatly increase the sensitivity of QUS assessment, compared to the conventional -2.5 cut-off, with only a slight decrease in specificity.

In Vivo Performance Evaluation Of The Achilles Insight QUS Device. C. Cepollaro, S. Gonnelli, A. Montagnani*, S. Martini*, A. Cadirni*, C. Caffarelli*, R. Nuti. Internal Medicine, Endocrine-Metabolic Sciences and Bichemistry, Internal Medicine, Siena, Italy.

Quantitative ultrasound (QUS) of the os calcis is increasingly accepted as an effective method to assess osteoporotic fracture risk. However, not all heel ultrasonometers have equivalent clinical utility; in fact they differ for technology, coupling, measurements time, precision and relationship to axial measurements. GE Achilles plus (A+) is widely used worldwide since 1990 and for its ability to predict fragility fractures, may be considered a reference standard among QUS devices. As a water-bath system, A+ has obvious practical drawbacks such as the need for draining and filling water, cumbersome size, no portability. Achilles Insight (AI) is a new generation device that uses inflatable membranes and an alcohol spray to couple the measurement transducers to the heel, and gives QUS parameters in less than a minute providing also real time imaging of the os calcis. The aim of this study was to evaluate the in vivo performance of AI in comparison with A+. The precision was evaluated in 30 healthy subjects who underwent QUS measurements (A+ and AI) twice in the same day, with repositioning. We also studied 102 postmenopausal women, 33 with and 69 without osteoporotic fractures. The difference between the QUS device were assessed using a comparison approach described by Bland and Altman. The precision, calculated by dividing the RMS SD by the mean of all subjects and express as a percentage, showed a CV of 1.9% for Stiffness obtained by A+ and 1.4% for Stiffness obtained by AI. Linear regression analysis showed a significant correlation between SOS ($r=0.83$, $p<0.001$), BUA ($r=0.81$, $p<0.001$) and Stiffness ($r=0.92$, $p<0.001$) obtained with the two devices. The evaluation of the areas under Receiver Operating Characteristic (ROC) curves showed a similar ability for A+ and AI in discriminating patients with or without vertebral fractures. The values of areas under ROC curves were 0.89, 0.80 and 0.86 for SOS, BUA and Stiffness obtained with A+, and 0.88, 0.80 and 0.86 for the same parameters obtained by AI.

We can conclude that:

the better precision of the AI with respect to A+ could be explained by the fact that the measurement with AI needs less time and gives a consequent reduction in motion artefacts. The high correlation and the similar ability to identify postmenopausal women with vertebral fracture suggest the possibility of using the database of A+ for AI.

Quantitative Ultrasound of the Calcaneus in the Evaluation of Bone Mass in Liver and Cardiac Transplantation Patients. G. Martinez*, A. Escalona*, E. Jódar*, E. García*, S. Azriel*, L. Gil-Fraguas*, J. Meneu*, E. Moreno*, F. Hawkins. University Hospital 12 de Octubre, Madrid, Spain.

Bone loss is one of the most common complications following solid-organ transplantation, and severely affects quality of life in these patients. Although DXA is the gold standard for bone mass measurement, QUS has some potential advantages over DXA. However, only a few studies have investigated the utility of this technique in transplanted patients, mainly kidney transplantation.

The purpose of this study was to determine the usefulness of QUS in comparison with DXA to identificate liver and cardiac transplanted patients with osteoporosis.

We have cross-sectionnally evaluated one hundred and forty patients (109 males/31 females; 85 liver/55 cardiac transplantation), mean age 53,6 ± 12,5 years, time since transplantation 67,9 ± 53,3 months. BMD was assessed with DXA (Hologic 4500 QDR) at lumbar spine and hip. In addition, QUS measurements at the heel were obtained at the same time with a Sahara Clinical Sonometer (Hologic Inc, MA, USA) . The quantitative ultrasound index (QUI) and the estimated heel BMD were calculated from speed of sound (SOS, m/s) and broadband ultrasonic attenuation (BUA, dB/MHz) as has been described elsewhere. QUI T-score and BMD T-score (spine & hip) were obtained from Spanish normative data.

Results: According WHO criteria, 53% of the patients had osteopenia and 17% had osteoporosis. Calcaneal QUS parameters (BUA, SOS, QUI) correlated significantly with DXA values: QUI was positively correlated with lumbar BMD (r= 0.356 , p<0.001), femoral neck BMD (r=0.351, p<0.001) and trocanteric BMD (r=0.441, p<0.001). Heel BMD was positively correlated with lumbar BMD (r= 0.356 , p<0.001), femoral neck BMD (r=0.351, p<0.001) and trocanteric BMD (r=0.441, p<0.001). ROC analysis were performed to investigate the ability of QUS to correctly identificate patients with densitometric osteoporosis (Table 1). To obtain a 5% of false-negative, QUI T-score cutoff should be -0.6 SD but specificity drops to 42%; conversely, to obtain a 5% of false-positive, QUI T-score cutoff should be -2.1 SD.

Table 1. QUS parameters. ROC analysis

QUS Parameter	Area under curve (AUC)	95% Confidence Interval (CI)	p
SOS	0.805	0.707-0.903	<0.001
BUA	0.742	0.625-0.859	<0.001
T-score QUI	0.777	0.669-0.886	<0.001

Conclusion: A positive correlation exists between lumbar and femoral BMD and QUS parameters in liver and cardiac recipients. QUS could be recommended for screening in transplanted patients.

Axial and Transverse Transmission Quantitative Ultrasound may Selectively Assess Material and Structural Properties of Bone. G. M. Kiebzak[1], C. G. Ambrose[2]. [1]St. Luke's Episcopal Hospital, Houston, TX, USA, [2]Orthopaedics, UT Health Science Center at Houston, Houston, TX, USA.

Fracture resistance is dependent on both material properties (collagen cross-linking, mineral content, etc) and structural properties (bone size, trabecular patterns, etc). Axial quantitative ultrasound (QUS) measurements, dependent on elastic modulus and mineral density, may reflect mainly material properties (assuming bone width > wavelength) whereas transverse QUS may better reflect overall bone strength. We compared ulnar QUS (Sunlight Omnisense, speed of sound, SOS, m/s, measured at the 33% region) and heel QUS measurements (GE Lunar Achilles Express, stiffness, which combines SOS and ultrasound attentuation) to ulnar size, bone mineral content (BMC, g/cm) and area density (BMD, g/cm^2, a variable partially corrected for bone size) for total ulna (entire distal third of ulna) and 33% region using dual-energy x-ray absorptiometry (DXA) and in vivo cross-sectional bending strength (EI, Nm^2, at midshaft) using MRTA (a low-frequency mechanical vibrational test; J Clin Densitometry 2(2): 143, 1999) in 138 women (18-86 yrs). EI, considered the most direct measure of whole bone strength, was significantly correlated with total ulna area (from DXA) r = +0.478, P<0.0001, and BMC, r = +0.597, P<0.0001. SOS was significantly correlated with total ulna BMC, r = +0.309, P=0.0002, but not area, r = +0.05. Correlation with 33%BMD was better for SOS, r = +0.438, P<0.0001, than for EI, r = +0.361, P<0.0001. EI and SOS were significantly correlated, r = +0.218, P= 0.01. SOS and total ulna BMD were used to estimate elastic modulus, which correlated with EI, r = +0.377, P<0.0001. Ulnar EI (r = +0.288) but not SOS (r = +0.06) was significantly correlated (P=0.0007) with heel stiffness. Heel stiffness (r = +0.303), but not SOS (r = +0.167), significantly correlated (P=0.0003) with the estimated maximum axial force to failure (derived using EI). These weak correlations may be related to the imperfect development of the MRTA technology and/or use of the ulna instead of a direct weightbearing bone. Alternatively, given the composite nature of the MRTA and QUS measurement systems (being dependent on multiple bone properties), perhaps only weak correlations should be expected. The general lack of significant correlations between SOS and variables reflective of bone size suggest that SOS was primarily measuring material properties of bone. The correlation between variables from different bones, heel and ulna, suggests that the heel measurement may provide a better assessment of global skeletal status whereas SOS may be a better site-specific measurement. Combined use of MRTA technology and QUS may expand options for in vivo bone assessment.

Effects of Leptin and IGF-1 on Bone Mineral Density in Long-Term Survivors after Allogeneic Stem Cell Transplantation for Hematological Malignancies. L. Tauchmanova*[1], B. Serio*[2], C. Carrella*[3], T. Musella*[1], G. Maziotti*[3], G. Mossetti[4], G. Lombardi*[1], B. Rotoli*[2], A. Colao*[1], C. Selleri*[2]. [1]Dept of Molecular and Clinical Endocrinology and Oncology, University of Naples Federico II, Naples, Italy, [2]Unit of Hematology, University of Naples Federico II, Naples, Italy, [3]Dept of Internal Medicine, II University of Naples, Naples, Italy, [4]Dept of Internal Medicine, University of Naples Federico II, Naples, Italy.

Previously we and others have described a persistent decrease in femoral and phalangeal bone mineral density (BMD) after allogeneic stem cell transplant. The transplant procedure, gonadal failure and immunosuppression were pointed out as principal risk factors for bone loss, however, they influence mostly trabecular bone and the cause of persistent BMD decrease at cortical bone is not clear. This study investigated the effects of two factors: leptin and IGF-1, known to influence bone mass in physiological conditions, but not considered important in transplant recipients. Thirty six patients (15 F; age, 32±10.2 yrs; BMI, 24.6±3 kg/m^2; time from transplant, 18±15 mos) were enrolled and compared to 36 controls matched for age, gender and BMI. DEXA technique was used to determine BMD at lumbar spine and femoral neck; quantitative ultrasonometry was used at proximal phalanges and amplitude-dependent speed of sound (AdSoS) was considered. Serum leptin, IGF-1, INF-γ, cortisol and gonadal status were determined. BMD was lower in patients than in controls at all skeletal sites considered (p<0.01). Serum leptin was higher (p<0.05) and IGF-1 lower (p<0.05) in patients than in controls. IGF-1 was lower also in the patients without growth hormone deficiency, likely mirroring their poor metabolic state. Leptin correlated with BMI in controls (r=0.73; p<0.005) but not in the patients (r=-0.057; p=0.8). In these latter leptin levels correlated with INF-γ (r=0.4; p<0.05), produced by activated Th1 lymphocytes. Femoral BMD correlated positively with IGF-1 in the patients (p<0.05) and with leptin values in females (p<0.05). A negative correlation was found between leptin and lumbar BMD in males (p<0.05). A negative correlation was observed between leptin and AdSoS in both females and males and between INF-γ and AdSoS in females (p<0.05). Neither leptin nor IGF-1 were correlated with age, period of time elapsed from transplant, cortisol and gonadal function. In conclusion, both increased leptin and decreased IGF-1 levels have important influence on bone density in long-term survivors after allo-SCT. Quantitative ultrasonometry is likely influenced throughout immune system derangement**.** However, further investigations are needed to better clarify this relationship.

M148

Correlation Between Quantitative Ultrasound Parameters and Physical Performance Ability in Children. H. Kudo*, I. Owan, H. Horizono*, H. Arakaki*, F. Kanaya*. Orthopedic Surgery, University of the Ryukyus, Nishihara, Okinawa, Japan.

The purpose of this study was to determine whether physical performance ability in children was reflected by quantitative ultrasound parameters. We measured calcaneal broadband ultrasound attenuation (BUA) and velocity of sound (VOS) in 697 children aged 6 to 12, 347 boys and 350 girls, using a CUBA Clinical Paediatric device. Basic anthropometric data (body weight, height, foot length and septum of heel) and total scores from physical performance ability tests were collected. The physical performance ability tests comprised 8 tasks including grip strength, trunk extension, sitting flexion, side step, 50 meter run, standing long jump, ball throw, and 20 meter shuttle run. Subject age, weight, height, and scores strongly correlated with BUA, and age and height, and scores weakly correlated with VOS. Multiple regression analysis showed that weight, VOS, and septum of heel were the best predictors of BUA (R2=0.711 for boys, R2=0.684 for girls), and BUA, septum of heel, and scores were the best predictors of VOS (R2=0.527 for boys, R2=0.440 for girls). In conclusion, physical performance ability affects VOS more than BUA indicating that increase ability of physical strength influence the quality of bone more than bone mineral density or bone structure in children.

Osteoporosis Screening: Comparison of Heel Ultrasound Measurement to Calculated Risk Assessment Tools. S. Poriau*[1], P. Geusens[2], F. Van den Bosch*[1], F. De Keyser*[1]. [1]Locomotorisch Centrum, Sijsele-Damme, Belgium, [2]Biomedical Research Institute, Diepenbeek, Belgium.

Quantitative ultrasound of the os calcis is accepted as an effective, low-cost method to assess osteoporotic fracture risk. Recently the International Society for Clinical Densitometry (ISCD) recommended the use of peripheral densitometry to identify patients who might have osteoporosis and should therefore undergo BMD testing at the hip and spine. This recommendation requires the use of a device specific T-score cutpoint on the peripheral device that detects 90% of individuals with osteoporosis at either the spine or hip. In this study, we wished to determine the 90% sensitivity cutpoint that could be used with the Achilles bone ultrasonometer. We also compared the performance of this ultrasonometer as a screening tool to a calculation-based osteoporosis risk assessment screening tool (OST). A total of 1087 women aged 50 years and older (mean age 68 ± 10 years) had DXA measurements of the spine (L1-L4) using a Lunar Prodigy (GE Healthcare) or a Lunar DPX-NT, as well as a heel ultrasound measurement using Achilles Solo. The OST ((weight in kg - age)*0.2) was calculated for each subject. From the ROC analysis the AUC values were determined for heel T-score and OST as well as the heel T-score cutpoint with 90% sensitivity for identifying subjects with osteoporosis (T-score ≤ -2.5) at the spine.

From the DXA results, 332 out of the 1087 subjects were classified as osteoporotic at the spine. A heel T-score of -1.4 demonstrated 91% sensitivity and 38% specificity in identifying osteoporotic subjects. Higher specificity of nearly 50% could be obtained with a T-score cutpoint of -1.8, which has a sensitivity of 85%.

ROC AUC for Osteoporosis at the AP Spine

Diagnostic Variable	AUC (95% Confidence Interval)
Stiffness Index T-Score	0.758 (0.727 - 0.790)
OST Risk Assessment Tool	0.747 (0.715 - 0.778)
Combined: T-score & OST	0.790 (0.761 - 0.819)

Comparison of ROC AUCs

Comparison	AUC Difference	p
T-Score - OST	0.011	0.543
Combined Risk - T-Score	0.032	0.0009
Combined Risk - OST	0.043	<0.0001

We conclude that the Achilles bone ultrasonometer can be used as a valid screening tool for osteoporosis according to ISCD recommendations. The Achilles Stiffness Index T-Score and OST provide independent assessment of risk for osteoporosis at the spine. Combining these risk factors yields better diagnostic performance than either used separately. However, a similar study using both hip and spine measurements for identifying subjects with osteoporosis showed that heel T-score performs better as a diagnostic tool than OST (M. Gambacciani *et al.*, 2004, presented at the World Congress Osteoporosis, Rio de Janeiro).

Disclosures: ***S. Poriau****, None.*

M150

Autosomal Dominant Pattern of Inheritance in an Australian Family with Low Bone Mineral Density. C. Meier[1], M. Kennerson*[2], G. Nicholson*[3], M. J. Seibel[1]. [1]Bone Research Program, ANZAC Research Institute, University of Sydney, Concord NSW, Australia, [2]Neurobiology Laboratory, ANZAC Research Institute, University of Sydney, Concord NSW, Australia, [3]Molecular Medicine Laboratory, Concord Hospital, Concord NSW, Australia.

Low bone mineral density (BMD) is a major risk factor for osteoporotic fractures. Based on family and twin data it is estimated that 60-80% of the variance in BMD is attributable to genetic factors.

We have identified a family of Anglo-German derivation (21 members, 3 generations, aged 19-86 years) in which 14 members are affected by low BMD at the spine and/or the femoral neck. The 1st generation consists of a female patient aged 86 yrs presenting with multiple low trauma fractures, a lumber spine BMD (LSBMD) T-Score of -4.1 SD (Z-Score -2.2 SD) and a femoral neck BMD (FNBMD) T-Score of -7.4 SD (Z-Score -5.5 SD). In the 2nd generation, all four members (2 females, 2 men, median age 58.2 yrs) are affected by low BMD (LSBMD: median T-score -3.1 SD, median Z-Score -2.8 SD; FNBMD: T-Score -1.8 SD, Z-Score -1.2 SD). Two members presented with prevalent fragility fractures. In the 3rd generation, 9 members (56%, 3 females, 6 males, age 30.7 yrs) had low BMD (LSBMD: T-Score -1.7 SD, Z-Score -1.4 SD; FNBMD: T-Score -1.3 SD, Z-Score -1.0 SD), whereas 7 individuals (3 females, 4 males; age 26.6 yrs) had normal BMD (LSBMD: T-Score -0.4 SD, Z-Score -0.3 SD; FNBMD: T-Score -0.1 SD, Z-Score -0.1 SD). One member of the 3rd generation was diagnosed with a fragility fracture. Secondary causes of osteoporosis were excluded in all affected individuals. Segregation of low BMD in this family is consistent with an autosomal dominant mode of inheritance.

In simulation studies using the SIMLINK program and four allele markers (n=450) a theoretical mean maximum logarithm of odds (LOD) score of 5.34 was obtained at a recombination fraction (θ) of 0.0. Simulation data also indicated the family had the power to exclude 10.2 cM on either side of an unlinked marker. Two-point linkage analyses excluded mutations in the genes for *COL1A1* (D17S1795, LOD score -2.91, θ of 0.10) and *COL1A2* (D7S3050, LOD score -3.29, θ of 0.10). In addition, the *LRP5* gene has been excluded by linkage analysis (D11S987, LOD score -2.16, θ of 0.5). Based on the autosomal dominant inheritance pattern of low BMD it seems likely that in this family, accrual and maintenance of BMD is under the predominant control of a single gene. A 10 cM genome wide screen is presently under way.

In summary, the study of this family has the statistical power to define a locus on a single chromosome demonstrating that an individual gene produces the observed phenotype.

Disclosures: ***C. Meier****, None.*

Identification of Novel Genetic Loci for Bone Size and Mechanosensitivity in an ENU Mutant Exhibiting Decreased Bone Size. A. K. Srivastava, S. Kapur*, G. Masinde*, S. Kapur*, R. Chadwick*, J. Wergedal, S. Mohan, D. J. Baylink. JLP VAMC / Loma Linda Univ Dept Med, Loma Linda, CA, USA.

Using the ENU mutagenesis approach to reveal gene function, we have identified a mutant with reduced bone size in a dominant screen in C57BL/6J mice. Data from 16-week old progeny from this mutant showed that total body bone area was 10-14% lower and mean periosteal circumference was 4-8% lower at femur and tibia mid-diaphysis, as compared to WT B6 mice. Interestingly, the phenotype was mainly expressed in males while <5% females showed decreased bone size phenotypes. Since periosteal bone expansion is involved in bone adaptive response to mechanical loading, we predicted that genes regulating bone size could also be sensitive to mechanical loading. We used an in-vitro model of mechanical loading, a fluid flow induced shear stress, to study the effect of loading on periosteal osteoblasts isolated from tibia and femur (n=3) of mutant and wild type mice by collagenase digestion. Osteoblasts from wild type animals show a 70-80% increase in cell proliferation in response to shear stress, which was reduced by 60-70% ($p<0.01$) in cells from mutant mice. These observations suggest that in addition to bone size regulation, the mutant gene may be involved in modulating response to mechanical stress. In addition, the periosteal osteoblasts from mutant mice showed significantly reduced cell proliferation ($p<0.01$) and increased apoptosis ($p<0.01$), as compared to wild type controls (n=3), indicating a potential cellular mechanism for reduced bone size. To determine the chromosomal location of the mutation, we bred mutant B6 mice with C3H in an intercross breeding to generate B6C3H F2 mice (n=69 males) for a low-resolution (46-50 markers) QTL mapping. By using interval mapping, a mutant locus was identified in Chr 4 with a LOD score of 7.6 with genome wide significance of $p<0.001$. Based on the findings that genetic alleles from B6 contributed to low bone size and that a similar locus regulating bone size could not be identified in F2 mice generated from non-mutagenized C3HB6F2 (n=75 males), we consider this to be a mutant locus. In addition, this locus (7.5-12.1 cM) is novel since no QTL regulating bone size has been identified in this region of Chr 4 in any other crosses. In conclusion, an ENU mutant with decreased bone size was identified, the phenotype of mutant includes an impaired response of osteoblasts isolated from mutant mice to proliferation and mechanosensitivity, and QTL mapping indicates involvement of a new locus on chromosome-4 in regulating the bone size phenotype. Fine mapping is potentially more rapid for ENU mutations than a QTL gene.

Disclosures: ***A.K. Srivastava****, None.*

QTL Mapping Of Blood Levels Of Alkaline Phosphatase In F2 Population Of MRL/SJL Mice Indicate Loci That Cosegregate With Bone Density And Bone Size. A. Srivastava, G. Masinde*, H. Yu*, D. J. Baylink, S. Mohan. JLP VAMC / Loma Linda Univ Dept Med, Loma Linda, CA, USA.

To examine the hypothesis that serum alkaline phosphatase (ALP) levels have a heritable component, we analyzed blood from two inbred strains of mice, MRL/MpJ and SJL, which exhibit 90% difference in total serum ALP activity (268±26 *vs.* 140±15 U/L, respectively, $P<0.001$). A genome-wide scan was carried out using 137 polymorphic markers in 518 F2 female mice. Serum ALP activity in the 7-week old F2 progeny showed a normal distribution with an estimated heritability of 56%. Genome-wide scan for co-segregation of genetic marker data with serum ALP activity revealed five significant quantitative trait loci (QTL), one on chromosomes 2 (LOD score 3.8), three on chromosome 6 (LOD scores, 6.5, 12.0, 5.8), and one on chromosome 14 (LOD score 3.7). In addition, one suggestive QTL on chromosome-2 exhibited LOD score of 3.3. Combined together, these QTLs explain 34.3% of the F2 variance in serum ALP levels. Serum ALP showed a moderate (Pearson r=0.12, p=0.0108) but significant correlation with body weight adjusted total body bone mineral (measured by DEXA) in F2 mice. The chromosome-6 locus harboring the major serum ALP QTL also contains a major BMD and bone size QTL identified earlier in the F2 population of these two strains of mice. In addition, this QTL is also close to locus that regulates IGF-I levels (LOD score 8-9) in C3HB6 F2 mice. Three additional QTLs of Chromosome 2 and 14 also harbor QTLs for BMD and bone size. Presences of these common QTLs indicate that the observed difference in ALP, BMD, and bone size may be regulated by the same loci (or genes). Osteoblast cells isolated from femur and tibia of MRL mice showed significantly higher number of ALP +ve cells/colony and higher ALP activity ($p<0.05$) as compared to the cells isolated from SJL mice, thus suggesting that differences in serum ALP between MRL and SJL mimic expression of osteoblasts from bone of these strains of mice. These data suggest that serum ALP levels are genetically determined and correlate with cellular mechanisms that differentiate BMD accrual in these two strains of mice. The findings that ALP and BMD traits share the same loci on chromosome-6 indicate a role for genetic determinants of bone formation in overall BMD accretion. To our knowledge this is the first study describing QTLs that regulate variation in serum levels of alkaline phosphatase among inbred strains of mice.

Genetic Linkage Exclusion of Six Candidate Loci for the Gene Causing Idiopathic Multicentric Osteolysis. W. Balemans*[1], E. Van Hul*[1], T. J. L. de Ravel*[2], E. Cleiren*[1], J. P. Fryns*[2], W. Van Hul[1]. [1]Dept. Medical Genetics, University of Antwerp, Antwerp, Belgium, [2]Centre for Human Genetics, UZ Gasthuisberg, Leuven, Belgium.

Idiopathic multicentric osteolysis (IMO) or Thieffry-Kohler syndrome is a rare, progressive bone disorder which mostly occurs as an autosomal dominant trait, but a number of isolated cases have been described and an autosomal recessive mode of inheritence has also been suggested. The condition presents already in early childhood with pain and swelling of peripheral joints. Radiographically, destructive bone lesions are observed starting at the carpal and tarsal bones, and spreading to the adjacent bones. Affected individuals may have distinct facial abnormalities with frontal bossing, protruberant eyes and micrognathia. Variable renal involvement has been described predominantly in isolated cases. We have studied a three-generation family with nine affected members showing the radiological and clinical features of IMO. The pedigree shows an autosomal dominant mode of inheritence. Previous linkage analysis (de Ravel et al., J. Med. Genet. 2000;37:E34) already excluded a region on chromosome 18q22.1 in which the gene encoding the receptor activator of nuclear factor kappaB (RANK) is located, the gene mutated in familial expansile osteolysis (FEO). Our objective was to carry out a linkage study on a number of other candidate loci. We investigated three regions harbouring a functional candidate gene: the osteoprotegerin (OPG) gene on chromosome 8q24, the gene encoding receptor activator of nuclear factor kappaB ligand (RANKL) on chromosome 13q14 and the matrix metalloproteinase 2 (MMP2) gene located on chromosome 16q13. These regions were studied because OPG and RANKL share a common pathway with RANK and mutations in MMP2 have been found in patients with multicentric osteolysis and arthritis syndrome. Additionally, three regions on chromosome 2q36, 5q35 and 10p13 for which suggestive linkage with familial Paget disease of bone has been reported, were investigated. Analysis of microsatellite markers for the six candidate loci, a haplotype study and two-point LOD score calculations did not reveal linkage with any of these regions. Therefore, we can conclude that the IMO phenotype segregating in our family is not linked to any of the six regions analyzed. In a further effort to localize the disease-causing gene in IMO we are currently performing a genome wide linkage study with microsatellite markers covering the entire genome.

Disclosures: ***W. Balemans****, None.*

Fine Mapping Provides Further Evidence of Linkage for Bone Mineral Density to 3p21. S. G. Wilson[1], P. W. Reed*[2], T. Andrew*[3], M. Langdown*[4], R. L. Prince[5], T. D. Spector[3]. [1]Sir Charles Gairdner Hospital, Nedlands, Australia, [2]SignaGen, Rotorua, New Zealand, [3]St Thomas' Hospital, London, United Kingdom, [4]Sequenom Inc., San Diego, CA, USA, [5]University of Western Australia, Nedlands, Australia.

Low bone mineral density (BMD) is a major risk factor for osteoporotic fracture. Studies of BMD in families and twins have shown that this trait is under strong genetic control. We previously performed genome screens in two populations of Caucasian women in an attempt to localize the position of quantitative trait loci that regulate BMD (1). In that study we found evidence for linkage of lumbar spine BMD to markers on chromosome 3p, which was replicated in both genome screens. The aim of this study was to confirm and refine our previous linkage results for chromosome 3 by genotyping an expanded number of highly polymorphic microsatellite markers in available samples.

We studied a cohort of highly selected, extreme discordant and concordant sib pairs (1098 individuals). Lumbar spine and total hip BMD were determined using dual x-ray absorptiometry (QDR 2000, Hologic Inc, MA, USA). Laboratory analysis involved the genotyping of thirty additional microsatellite markers in the 3p region using standard fluorescence-based genotyping methodologies and ABI 377 automated sequencers (Applied Biosystems, CA, USA). At the conclusion of the study the average marker spacing in the region of interest (50cM - 111cM) was 2cM. Nonparametric multipoint linkage (NPL) analysis was undertaken for age adjusted lumbar spine and total hip BMD using MAPMAKER/SIBS. The maximum evidence of linkage defined by this analysis was LOD 3.6 for age-adjusted spine BMD at 68cM (Genethon linkage map). This is approximately the same position highlighted in the initial analysis. NPL analysis of age adjusted total-hip BMD provided a LOD <2.0. Average information content in the region increased to 0.6 and the -1 LOD support interval was reduced to 17cM. PTHR1 is positioned at approximately 67cM and continues to be a strong candidate for the QTL. Other positional candidate genes include MST1, MST1R and TNA.

The data further supports the presence of a gene(s) regulating BMD at 3p21 by providing an improved linkage map of the region in this cohort and by removing reliance of the linkage on a small number of widely spaced markers. This study provides strong support for the validity of our initial findings (1) and contributes to the goal of localizing and identifying QTL that regulate BMD.

Androgen Receptor CAG Repeat Polymorphism and Bone Density: A Family and Case-control Association Study in Men with Primary Osteoporosis. P. R. Ebeling[1], Z. Hussein*[1], J. Ellis*[2], A. Lamantia*[2], K. Greenland*[3], S. Yeung*[1], Z. Y. H. Wong*[2], J. D. Zajac[4], S. Harrap*[2]. [1]Diabetes and Endocrinology, The Royal Melbourne Hospital, Parkville, Australia, [2]Physiology, The University of Melbourne, Parkville, Australia, [3]Centre for Hormone Research, Murdoch Children's Research Institute, Parkville, Australia, [4]Medicine, Austin Hospital, The University of Melbourne, Heidelberg, Australia.

Androgens are important modulators of bone mass in men. The CAG trinucleotide repeat length in exon 1 of the AR gene is inversely associated with its transcriptional activity and may affect bone metabolism. Previous studies in normal men have yielded conflicting results on the role of AR CAG repeat polymorphisms on bone density (BMD).

We therefore investigated the association between the AR CAG repeat length, by DNA sequencing of exon 1 of the AR gene, and BMD in men with primary osteoporosis, their first-degree relatives and in normal men. Lumbar spine (LS), proximal femur and total body BMD was measured by DXA.

Forty-nine pedigrees were recruited and 38 sib-pairs were available for linkage analysis. From the family studies, hereditability was 0.74 (0.11) at the lumbar spine and 0.56 (0.17) at the femoral neck. Standardised bone density (Z-score) were mean z-LS = -1.35; and mean z-FN = -0.91. The CAG repeat length effect was equivalent to 0.3 SDs per 5 base pair difference in CAG repeat length at the lumbar spine, but not at the femoral neck.

Two association studies were also performed. The first was a case-controlled study of 81 men with primary osteoporosis and spinal fractures (mean age 55.6 years, mean LS T-score -2.53 and mean FN T-score -2.93) and 25 normal men (mean age 44.7 years, mean LS T-score 0.46 and mean FN T-score -0.14). Median AR CAG repeat length for the osteoporotic group was 20 (SD 3.2) versus 21.0 (SD 2.4) for the control group. Each group was also dichotomised with regards to with regards to short (less than 22) or long (greater than 22) repeat lengths. BMD was similar at all sites in men with either short or long CAG repeat length. The second study comprised 157 unrelated men (mean age 54.3 years, mean LS T-score -1.60, mean FN T-score -2.11 and median CAG repeat length of 20) who were subdivided according to genotypes of different AR CAG repeat lengths (range 6-29). BMD was then compared using one-way ANOVA. No associations were seen between CAG repeat length and BMD in either study.

Hereditability of BMD in families of men with spinal fractures is high and greater for the spine than proximal femur or total body sites. CAG repeat length in the androgen receptor has a small effect on spinal, but not femoral neck BMD. Other genetic factors are therefore likely to be more important.

Genome Screen for Femoral Structure QTLs in Men. D. L. Koller[1], S. L. Hui[2], C. C. Johnston[2], M. J. Econs[2], T. Foroud[1], M. Peacock[2]. [1]Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Medicine, Indiana University School of Medicine, Indianapolis, IN, USA.

Femoral structure contributes to bone strength and predicts hip fracture risk independently of BMD. We previously reported an autosomal genome screen for femoral structure phenotypes in Caucasian premenopausal sister pairs (JBMR 16:985-91, 2001). Several of these loci were confirmed in an expanded sample of sister pairs (JBMR 18:1057-65, 2003). Reports in mice suggest that genes regulating BMD may be sex-specific. Thus we collected a sample of 257 healthy Caucasian brother pairs (age 18-61) to compare with our sister pairs and test the hypothesis that genes underlying normal variation in femoral structure are sex-specific. Pelvic and femur axis lengths, and widths of femur head, neck and femur midshaft were measured from radiographs. A genome screen using 392 microsatellite markers was completed on the brother pairs. Multipoint quantitative linkage analysis was performed using Mapmaker/SIBS. All chromosomal positions (cM) reported here correspond to the Marshfield map coordinates.

The most significant linkage finding in this study was for pelvic axis length, with a LOD score of 4.1 at position 70 cM on chromosome 4p. Pelvic axis length also produced a suggestive linkage finding (LOD > 2.2) on chromosome 17q (LOD=2.8 at 85 cM). The other LOD score exceeding 3.0 was for femoral head width on chromosome 15q (LOD=3.11 at 66 cM). Head width also demonstrated suggestive linkage on distal chromosome 11q (LOD=2.3 at 109 cM). We also found evidence of linkage of femur midshaft width to chromosome 14q (LOD=2.7 at 72 cM). There is no overlap between the linkage regions identified in men with the femoral structure linkages in women that we have previously reported. This suggests that different genes underlie the observed variability in femoral structure among healthy men and women.

Genome-wide Scan for QTL Underlying Normal Variation in Calcaneal Quantitative Ultrasound Measures: The Fels Longitudinal Study. S. A. Czerwinski*, M. Lee, A. C. Choh*, E. W. Demerath*, W. C. Chumlea*, S. S. Sun*, R. M. Siervogel*, B. Towne*. Community Health, Wright State University School of Medicine, Kettering, OH, USA.

Despite increasing knowledge of the genetics of osteoporosis in recent years, identifying the specific genes influencing osteoporosis risk factors has remained an elusive task. Calcaneal quantitative ultrasound (QUS) measures are correlated with bone mineral density, yet they also independently predict risk for fracture. In order to identify genes influencing susceptibility to osteoporosis, we performed quantitative trait linkage analysis on calcaneal QUS measures collected in a sample of nuclear and extended families participating in the Fels Longitudinal Study. A total of 453 participants ranging in age from 18-91 years had at least one calcaneal QUS assessment and genetic marker data. Each of these individuals were genotyped for 377 autosomal markers spaced approximately every 10 cM along the genome. Three calcaneal QUS measures were obtained from each participant including speed of sound (SOS), broadband ultrasound attenuation (BUA), and quantitative ultrasound index (QUI) using the Sahara ® bone sonometer (Hologic, Inc., Waltham, MA). Using a variance-components based maximum likelihood method (SOLAR) for pedigree data, we calculated initial heritability estimates (h^2) and identified quantitative trait loci (QTL) influencing variation in the three calcaneal QUS measures. In this sample, each of the QUS measures were highly heritable ranging from h^2=0.49 to 0.72 ($p<0.000001$) after adjusting for the effects of age, sex, age^2, age-by-sex, and age^2-by-sex. Preliminary results of the quantitative trait linkage screen revealed several chromosomes with LOD scores > 1 including regions of chromosomes 1, 11, 12, 13, and 20. The strongest evidence for linkage (maximum LOD = 2.12) was found at chromosome 4p15 near marker D4S419, a region identified in a previous study to influence variation in forearm bone mineral density.

Associations Between Genetic Variation in the IL-1 Gene Cluster and Risk of Vertebral Fractures in Elderly Women. L. Lui[1], J. Rogus*[2], J. M. Zmuda[3], K. Kornman*[2], G. W. Duff*[4], K. Martha*[2], M. C. Nevitt[1], K. L. Stone[1]. [1]UCSF, San Francisco, CA, USA, [2]Interleukin Genetics, Waltham, MA, USA, [3]University of Pittsburgh, Pittsburgh, PA, USA, [4]University of Sheffield, Sheffield, United Kingdom.

Cytokines such as interleukin-1 (IL-1) are known to play a role in bone metabolism. Several studies have found polymorphisms of the IL-1 receptor antagonist gene (IL-1RN) to be associated with bone mineral density and spine bone loss in postmenopausal women. To test the hypothesis that genetic markers in the IL-1 gene cluster influence risk of vertebral fractures, we conducted a case-control study within a prospective study of 9,704 community-dwelling non-black women aged 65 years and older.

Whole blood samples were collected on filter paper at the second examination (1988-9). Prevalent and incident vertebral fractures were determined by morphometry using X-rays collected at baseline and an average of 3.5 years later. In 2003, polymorphisms in the IL-1 gene cluster on chromosome 2 (IL-1A +4845, IL-1B -511, IL-1B -3737, IL-1B +3954, IL-1RN +2018) were determined by PCR analysis. Polymorphisms were compared among 1237 women who had either a baseline prevalent or incident vertebral fractures and 1290 controls using logistic regression. Odds ratio (OR) and 95% confidence interval (CI) are reported. All models were adjusted for age, modified body mass index (using knee-height), age at menopause, and hormone use (ever vs. never use).

Overall, there was a modest 30% increase in risk of vertebral fracture among women with IL-1B (-511) 2.2 genotype compared to those with type 1.1 (OR=1.3; 95% CI 1.0 - 1.8; p=0.07). Similarly, those with IL-1RN type 2.2 were more likely to suffer a vertebral fracture than those with type 1.1 (OR=1.3; 0.9-1.9; p=0.10). Among women who had never used hormone replacement, these results were more pronounced. Never users of hormone replacement with IL-1B (-511) 2.2 genotype were at 60% increased risk of vertebral fractures compared to those with type 1.1 (OR=1.6; 95% CI 1.1-2.3; p=0.02), while those with IL-1RN genotype 2.2 were at 80% increased risk of fracture compared to type 1.1 (OR=1.8; 1.1-2.8; p=0.01). We found no consistent pattern of association for other polymorphisms of the IL-1 gene cluster and risk of vertebral fracture. Genetic variation in the IL-1 gene cluster may influence risk of vertebral fracture in elderly women, particularly among those who have never been treated with hormone therapy. Further study is needed to explain differences in patterns of association.

Vitamin D Receptor Polymorphisms and the Risk of Prostate Cancer. E. T. Jacobs[1], M. R. Haussler[2], M. E. Reid*[3], A. R. Giuliano*[1], E. Panczyk*[2], G. K. Whitfield[2], J. R. Marshall*[3], M. E. Martinez*[1]. [1]Arizona Cancer Center & Mel and Enid Zuckerman Arizona College of Public Health, University of Arizona, Tucson, AZ, USA, [2]Biochemistry & Molecular Biophysics, University of Arizona, Tucson, AZ, USA, [3]Roswell Park Cancer Institute, Buffalo, NY, USA.

In the United States, prostate cancer has the highest incidence rate of all cancers in males, with few known modifiable risk factors. The hormonal form of vitamin D, 1,25-dihydroxyvitamin D_3 (1,25D), has been shown to exert antiproliferative and prodifferentiating effects on prostate cancer cell lines via interaction with the vitamin D receptor (VDR). Alterations in the concentration or activity of this receptor could have a significant impact on the functions of the 1,25D ligand within the cell. The human VDR exhibits polymorphic variation, with two common unlinked variants identified via *FokI (F/f)* and *TaqI (T/t)* restriction enzymes. Data indicate that the *F* VDR allele generates an intrinsically more transcriptionally potent receptor, whereas the *T* haplotype (tightly linked to an *L* singlet (A) repeat allele) is associated with enhanced total VDR activity. The role of these VDR gene variants in the incidence of cancer is not well understood; therefore, we sought to determine whether the *FokI* and *TaqI* VDR polymorphisms were associated with the risk of prostate cancer among participants from the Nutritional Prevention of Cancer trial. In a nested case-control design with 92 prostate cancer cases and 174 controls matched for age, treatment group, and clinic site, we calculated the adjusted odds ratios for each VDR genotype. Compared to the *ff* genotype, the adjusted odds ratios (95% CI) for *Ff* and *FF* were 1.07 (0.52-2.20) and 1.34 (0.67-2.65), respectively. Although not statistically significant, this trend supports a recent result that the *F* VDR allele tends to enhance the risk of prostate cancer. For the *TaqI* polymorphism, the odds ratios were 0.73 (0.32-1.69) and 0.63 (0.27-1.45) for *Tt* and *TT,* respectively, compared to *tt*. Although not statistically significant, this trend is contrary to previous reports that the *T* VDR haplotype imparts a 4-fold increase in the risk of prostate cancer. Exploratory analyses of the combined VDR genotypes did not reveal any significant trends with respect to the incidence of prostate cancer. Therefore, in contrast to bone mineral density and fracture prevention, where the biochemically more active *F* and *T(L)* VDR alleles appear to be beneficial and additive, the incidence of prostate cancer appears to be influenced independently by the *F/f* and *T/t* variants in an opposing fashion. These data may explain the contradictory nature of reported individual VDR polymorphism correlations with the risk of prostate cancer.

Lack Of Association Between Androgen Receptor Polymorphisms And Bone Mineral Density Or Physical Function In Older Men. A. M. Kenny[1], D. McGee*[2], C. Joseph*[1], C. Abreu*[3], L. G. Raisz[3]. [1]Geriatrics, UConn Health Center, Farmington, CT, USA, [2]Biostatitics, Florida State University, Tallahassee, FL, USA, [3]Clinical Research Center, UConn Health Center, Farmington, CT, USA.

Individuals whose androgen receptors have short polyglutamine tracts (CAG repeats) exhibit greater transcriptional activation of the androgen receptor. Studies of the impact of this polymorphism on bone density have been conflicting and frequently lack a control group. We, therefore, evaluated the association between bone mineral density and the number of CAG repeats in older men with normal,osteopenic or osteoporotic femoral neck bone mineral density (FN BMD) and with or without a history of femoral fracture.

The number of CAG repeats was determined in 42 men with a history of a hip fracture in the preceding 3 years (FX), 33 men with no fracture but FN BMD T score -1.0 (C). In addition we measured bioavailable testosterone (BioT) and several measures of physical performance, including walking speed, chair rise time and standing balance as well as self-reported physical activity (PASE).

Mean age of the men was 76 + 7 years and body mass index was 27 + 4 kg/m2, with no difference among the groups. FN BMD t scores were -2.16 + 1.08 (FX), -2.26 + .74 (OP), and -0.20 + 0.40 (C) ($p<.001$). CAG repeats ranged from 17-29 and mean length was 21.9 + 2.7 (FX), 22.5 + 2.4 (OP), and 22.3 + 2.9 (C) ($p=.63$). The correlation between CAG and FN BMD was $r=.06$ ($p=.55$). Further, no significant correlations were found between CAG and bioavailable testosterone levels ($r=.02$, $p=.82$) or physical performance including walking speed ($r=.07$, $p=.52$), hand grip strength ($r=-.06$, $p=.63$), chair rise time ($r=.09$, $p=.40$) or composite physical performance (CPP) score ($r=.08$, $p=.44$). BioT levels were 66 + 36 ng/dl (FX), 63 + 32 ng/dl (OP), and 115 + 36 ng/dl (OC) ($p<.001$). Eight foot walk times were 3.4 + 1.3 s (FX), 2.8 + 1.0 s (OP) and 2.6 + .2 s (C) ($p=.046$). CPP scores were 8.0 + 3.0 (FX), 9.7 + 2.0 (OP), and 11.3 + .9 (C) ($p<.001$). PASE scores were 91 + 66 (FX), 122 + 66 (OP), and 200 + 55 (C)($p<.001$).

Thus in this cross-sectional study no association was found between the number of CAG repeats and FN BMD in older men with normal or low bone mineral density or with femoral fracture. Men with osteoporosis had significantly lower bioavailable testosterone levels than the control group. Further, physical performance and physical activity were lower in men with osteoporosis. The impact of BioT and physical activity and performance on BMD was substantial. These results do not rule out effects of CAG repeats and androgen receptor activity on age-related bone loss and changes in physical function, which need to be analyzed in longitudinal studies.

Genetic and Environmental Determinants of Bone Mineral Density in Chinese Women. H. H. L. Lau[1], M. Y. M. Ng*[1], A. Y. Y. Ho[1], K. D. K. Luk*[2], A. W. C. Kung[1]. [1]Medicine, The University Of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [2]Orthopaedic Surgery, The University Of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

Genetic and Environmental Determinants of Bone Mineral Density in Chinese Women
BMD is a complex trait determined by genetic and lifestyle factors. To assess the genetic and environmental determinants of BMD in southern Chinese women, we studied a community-based cohort of 531 pre- and postmenopausal southern Chinese women and assessed the influence of 12 candidate gene loci and lifestyle risk factors on spine and hip BMD. The candidate genes studied include estrogen receptor alpha (ESR1) and beta (ESR2), calcium sensing receptor (CASR), vitamin D receptor (VDR), collagen type Iα1 (COLIA1) and LDL receptor-related protein 5 (LRP5). Social, medical, reproductive history, dietary habits and lifestyle factors were determined using a structured questionnaire. Single nucleotide polymorphisms (SNPs) of the COLIA1 and LRP5 gene in Chinese were determined by direct sequencing. Nucleotide (nt) -1363C/G and -1997 G/T of COLIA1, nt 266A/G, 2220C/T and 3989C/T of LRP5 gene were analyzed.
Using stepwise multiple linear regression analyses, body weight was the strongest predictor for BMD in premenopausal women (n=262), which accounted for 15.9% of the variance at the spine, 20% at femoral neck, 17.1% at trochanter, 24.3% at total hip and 10.9% at the Ward's triangle. Other significant predictors were ESR1 Ivs1 -397T/C genotype (2.2% at the spine); LRP5 2220C/T genotype (1.3% at the spine, 1.6% at the trochanter); LRP5 266A/G genotype (1.1% at Ward's triangle); age at menarche (1.3% at trochanter) and age (2.0% at Ward's triangle). As for postmenopausal women (n=269), body weight (~25% at various sites) and age (~16% at femoral neck, trochanter, total hip and Ward's triangle sites) were the strongest predictors of BMD. Other significant predictors were age at menarche (4.4% at spine, 0.7% at femoral neck, 1.4% at trochanter, and 1.4% at Ward's triangle); weight bearing physical activity (2.1% at trochanter and 1% at total hip); calcium intake (1.1% at femoral neck, 0.9% at trochanter, and 1.7% at total hip) ; height (0.7% at trochanter); and ESR2 1082A/G genotype (0.8% at trochanter). We conclude that BMD at various sites and at different time span of a woman is modified by different genetic and lifestyle factors, suggesting that BMD is highly dependent on gene-environmental interactions.

Association of Single Nucleotide Polymorphisms in The Promoter Region of Pro-opiomelanocortin Gene (*POMC*) with Low Mineral Density of Adult Women. Y. Sudo*[1], Y. Ezura[1], H. Yoshida*[2], T. Hosoi[2], S. Inoue[3], M. Shiraki[4], H. Orimo[2], H. Ito*[5], M. Emi*[1]. [1]Molecular Biology, Nippon Medical School, Institute of Gerontology, Kawasaki, Japan, [2]Tokyo Metropolitan Institute of Gerontology and Geriatrics Hospital, Tokyo, Japan, [3]Department of Geriatric Medicine, University of Tokyo, Faculty of Medicine, Tokyo, Japan, [4]Research Institute and Practice for Involutional Diseases, Nagano, Japan, [5]Orthopaedics, Nippon Medical School, Tokyo, Japan.

Osteoporosis, a multi-factorial common disease, results from interplay of multiple environmental and genetic factors, including the corticoid actions on bone mineral status. To investigate the genetic susceptibility of primary osteoporosis in adult women, we focused on a gene encoding the pro-opiomelanocortin (*POMC*), one of whose processing products adrenocorticotrophic hormone (ACTH) is a key regulator of the serum corticoid level. Association study was conducted on 384 adult Japanese women, whose bone mineral density (BMD) on distal radius was measured by DXA, and was adjusted for age and body mass index. Correlation between the adjusted BMD and the numerically categorized genotypes was tested by analysis of variance and the linear regression test as a post hoc test. Eight single nucleotide polymorphisms (SNPs) were investigated, including -2353G>A, -2345G>A, and -2313A>C. Linkage disequilibrium between every combination of the two SNPs was investigated by calculating indices of D' and r^2. Significant correlation between the genotypes and the BMD was detected for three promoter variations -2353G>A, -2345G>A and -2313A>C, among which the most significant correlation was detected for -2353G>A ($r = -0.16$, $p = 0.002$). The homozygous carriers of the major G-allele (G/G) had the highest BMD (mean ± SD = 0.405 ± 0.054 g/cm^2), the heterozygous carriers (G/A) had the intermediate (0.390 ± 0.053 g/cm^2) and the homozygous A-allele carriers (A/A) had the lowest (0.369 ± 0.048 g/cm^2). These three promoter variations appeared to be in strong LD at the level of almost complete LD ($D' \geq 0.978$, $r^2 \geq 0.856$). No significant correlation was detected for the other covariates (age, body weight, height, BMI, adjusted serum levels of cholesterols and triglyceride), except the significant association between -2313A>C and the adjusted total-cholesterol levels ($r = -0.12$, $p = 0.019$). Sequential consensus binding motif analysis of this promoter to the transcription factors revealed that two of the correlated SNPs were within the consensus binding-sites for known transcription factors (-2353G>A for GATA-1 or GATA-2 site, -2345G>A for the AML-1a site). These results suggested that variation of POMC might be one of the important determinants for postmenopausal osteoporosis.

Aromatase CYP19 Genetic Polymorphism Is Associated with Adult Stature, Androgen Levels, and Bone Mineral Density in 18-20-year-old Swedish Males. M. Lorentzon, C. Swanson, A. Eriksson, C. Ohlsson. Department of Internal Medicine, Center for Bone Research at the Sahlgrenska Academy (CBS), Gothenburg University, Gothenburg, Sweden.

Peak bone mass is to a large extent genetically determined and believed to be a predictor of future risk of osteoporosis. Androgens and estrogens are key regulators of skeletal growth and maturation in males. The aromatase CYP19 enzyme catalyzes the biosynthesis of estrogens from androgens.
The aim of the present cross sectional study was to determine if a tetranucleotide repeat polymorphism $(TTTA)_n$ in intron 4 of the aromatase CYP19 gene was associated with circulating androgen levels, adult stature, and bone mineral density (BMD) in 18-20-year-old Swedish males, currently included in The *G*othenburg *O*steoporosis and *O*besity *D*eterminants (*GOOD*) study.
941 men (age 18.9±0.6) were genotyped and classified according to the amplified fragment length, where fragments ≥182 and <182 bp, where coded L (long allele) and S (short allele), respectively. Subject homozygous for LL (n=141) where found to have 7.6 % higher serum levels of testosterone (p=0.008), 10.6 % higher free androgen index (FAI; p=0.015), and 1.4 cm higher stature (p=0.028) than their SL heterozygote and SS homzygote counterparts (n=800). Bone parameters were measured using both DXA and pQCT.
The aromatase CYP19 repeat polymorphism was found to be an independent predictor (in a multivariate analysis including present physical activity, age, height, weight, smoking, and calcium intake) of areal BMD of the lumbar spine as measured by DXA (p=0.03). To determine the associations between the aromatase CYP19 repeat polymorphism and the different bone compartments pQCT was utilized, demonstrating that this genetic polymorphism was an independent predictor of the radius cortical volumetric BMD (p<0.05), but not of the trabecular volumetric BMD. In conclusion, we demonstrate that the aromatase CYP19 repeat polymorphism is associated with adult stature and bone mineral density in young Swedish men, and propose that this association might be explained by the genotype specific differences in circulating levels of androgens.

Cytochrome P450c17α (*CYP17*) Gene Polymorphism Indirectly Influences on Bone Density through Their Effects on Endogenous Androgen in Postmenopausal Japanese Women-Are the Effects of Age and Body Mass Index Greater than Those of Endogenous Sex Steroids? I. Gorai[1], M. Inada*[2], H. Morinaga*[2], Y. Uchiyama*[2], H. Yamauchi*[2], O. Chaki[2], F. Hirahara*[2]. [1]Obstetrics and Gynecology, International University of Health and Welfare Atami Hospital, Atami, Japan, [2]Obstetrics and Gynecology, Yokohama City University School of Medicine, Yokohama, Japan.

We aimed to assess whether circulating sex steroid hormones influence bone measured as bone density and biochemical markers, and whether some part of this influence can be explained by genetic variation measured as polymorphisms in candidate genes influencing circulating hormone levels in 250 postmenopausal Japanese women aged 46 yr and over who had been followed for eight years. Bone mineral density (BMD) at lumbar spine, femoral neck, total hip and distal radius was measured by DXA method every year and endogenous sex steroid hormone levels are determined at the start of the study. We investigated the polymorphisms of estrogen metabolizing enzyme genes, *CYP17*; estrogen biosynthesis (high activity, A2/A2), *CYP1A1*; hydroxylation (high inducibility, vt/vt) and *COMT*; inactivation (low activity, L/L) with PCR-based restriction fragment length polymorphism assays. The *CYP17* has both 17α-hydroxylase and 17, 20-lyase activities and catalyzes two distinct steps in steroid hormone production. There were significant correlations between the levels of androstenedione (AND) or dehydroepiandrosterone (DHEA), and bone densities at all sites examined. AND levels significantly correlated with annual bone loss in lumbar spine. After the adjustments of sex steroid levels with age and body mass index (BMI), all the significant associations between endogenous androgens and BMD or bone loss have disappeared. Women with A2/A2 genotype had significantly higher level of DHEA than that with A1/A1 or A1/A2 genotypes (DHEA P=0.0021 and P=0.0013, respectively). There was no significant difference between estrogen levels and *CYP17* genotype. We could not find any significant correlations between sex steroid hormone levels and *CYP1A1* or *COMT* gene polymorphism. There were no significant differences in bone density and annual changes of BMD at each site examined among each *CYP17*, *CYP1A1* or *COMT* genotypes except in bone loss at distal radius. The results suggest *CYP17* gene polymorphisms may have some indirect influences on bone density through their effects on endogenous androgen and these effects might be overcome by both ages and BMI.

Functional Genomics of Tissue-nonspecific Alkaline Phosphatase. M. Goseki-Sone[1], N. Sogabe*[1], M. Fukushi-Irie*[1], L. Mizoi*[1], H. Orimo*[2], T. Suzuki[3], H. Nakamura*[4], H. Orimo[5], T. Hosoi[6]. [1]Food and Nutrition, Japan Women's University, Tokyo, Japan, [2]Biochemistry and Molecular Biology, Nippon Medical School, Tokyo, Japan, [3]Tokyo Metropolitan Institute for Gerontology, Tokyo, Japan, [4]Chemistry, Gakushuin University, Tokyo, Japan, [5]Health Science University, Tokyo, Japan, [6]Tokyo Metropolitan Geriatric Medical Center, Tokyo, Japan.

Alkaline phosphatase (ALP) is present mainly on the cell membrane in various tissues and hydrolyzes a variety of monophoshate esters into inorganic phosphoric acid and alco-

hol at a high optimal pH (pH8-10). Human ALPs are classified into four types: tissue nonspecific, intestinal, placental, and placental-like types. Based on studies of hypophosphatasia, which is a systemic skeletal disorder resulting from a tissue-nonspecific ALP (TNSALP) deficiency, TNSALP was suggested to be indispensable for bone mineralization. However, the polymophisms of TNSALP gene have not been studied as a possible determinant for the variation of bone mineral density or as a genetic predisposing factor for osteoporosis. We explored the possibility that the TNSALP gene may contribute to age-related bone loss in humans by examining the association between TNSALP gene polymorphisms and bone mineral density (BMD) in 501 Japanese post-menopausal women. We genotyped two single nucleotide polymorphisms (787T>C [Tyr246His] and 876A>G [Pro275Pro]), and these two polymorphisms were proved to be in complete linkage disequilibrium. There was a significant difference in BMD and Z score among haplotypes (p=0.041): lowest among 787T/876A homozygotes, highest among 787T>C/876A>G homozygotes, and intermediate among heterozygotes. In subgroups divided by age, haplotypes were significantly associated with BMD in aged postmenopausal women (>74 years; p=0.001), but not in younger postmenopausal women (≤74 years; p=0.964). Expression of the 787T>C TNSALP gene using COS-1 cells demonstrated that protein translated from 787T>C had ALP specific activity similar to that of 787T. Interestingly, the Km value for TNSALP in cells transfected with the 787T>C TNSALP gene was decreased significantly compared to that of cells bearing the 787T gene, reflecting the higher affinity. These results suggest that variation of TNSALP may be one of the important determinants of age-related bone loss in humans and that the phosphate metabolism pathway may provide novel targets for prevention and treatment of osteoporosis.

The Cannabinoid CB2 Receptor: A Potential Target for the Diagnosis and Treatment of Osteoporosis. M. Karsak*[1], O. Ofek*[2], M. Fogel*[2], K. Wright*[3], J. Tam*[2], Y. Gabet[2], R. Birenboim*[2], M. Attar-Namdar*[2], R. Müller[4], M. Cohen-Solal[5], M. de Vernejoul[5], E. Shohami*[6], R. Mechoulam*[7], A. Zimmer*[1], I. Bab[2]. [1]Psychiatry, University of Bonn, Bonn, Germany, [2]Bone Laboratory, Hebrew University of Jerusalem, Jerusalem, Israel, [3]Pharmacology, University of Bath, Bath, United Kingdom, [4]Institute for Biomedical Engineering, ETH and University Zürich, Zürich, Switzerland, [5]Unite de Recherche 349, INSERM, Paris, France, [6]Pharmacology, Hebrew University of Jerusalem, Jerusalem, Israel, [7]Medicinal Chemistry, Hebrew University of Jerusalem, Jerusalem, Israel.

Endocannabinoids signal via G-protein coupled central CB1 and peripheral CB2 cannabinoid receptors. Although both receptors were discovered more than a decade ago, the physiologic function of the CB2 receptor remains obscure. Here we report the presence of CB2 receptors in trabecular, diaphyseal and MC3T3 E1 osteoblasts as well as osteoclasts. Reminiscent of post-menopausal osteoporosis in humans, the skeletal phenotype of CB2 deficient mice, which are otherwise normal, is characterized by a low trabecular bone mass, cortical expansion and increases in bone formation rate and osteoclast number. To extrapolate these findings to the human scenario, we performed genetic association studies in a case-control approach typing single nucleotide polymorphisms covering a region of about 100 kb. We found a highly significant difference of allelic and genotypic distributions, strongly arguing for a causative involvement of this locus with human osteoporosis. In line with the low trabecular bone mass phenotype of *CB2* knockout mice we found that HU-308, a specific CB2 agonist, stimulated dose dependently the number and activity of primary and MC3T3 E1 osteoblastic cells. Using the same dose range, HU-308 also restrained osteoclast differentiation of bone marrow derived monocytes. Most importantly, HU-308 attenuated ovariectomy-induced bone loss mainly by inhibiting osteoclast number. Collectively these results assign a skeletal regulatory role for CB2 signalling and offer a new molecular target for the diagnosis and treatment of osteoporosis.

Interleukin 1ß -511 C/T Polymorphysm Is Related to the Response to Bisphosphonate Treatment in Paget Disease of Bone (PDB). J. del Pino-Montes*[1], L. Corral-Gudino[2], R. Gonzalez-Sarmiento*[3], C. A. Montilla*[1], I. Pastor*[2], J. García-Aparicio*[2]. [1]Medicine. Rheumatology, University Hospital. Universidad de Salamanca, Salamanca, Spain, [2]Medicine, University Hospital. Universidad de Salamanca, Salamanca, Spain, [3]Medicine, Universidad de Salamanca, Salamanca, Spain.

Bisphosphonates (BP) are used frequently for the treatment of PDB. BP suppress bone resorption by inhibiting both osteoclast (OCL) proliferation and activity, and inducing OCL apoptosis. The interleukines 1ß and 6 (IL-1ß, IL-6) play a role in OCL formation and activity so they could influence the response to BP treatment.

We evaluated whether genetic variability at the IL-1ß and the IL-6 loci are associated with the response to BPS in PDB.

We analysed single-nucleotide polymorphisms (SNP) in the promoter region of IL-1 ß gene (-511 C/T), exon 5 of IL-1 ß gene (3953 T/C), IL-1 receptor gene (IL-1 R1), IL-1 receptor antagonist gene (IL-1 RN) and promoter region of IL-6 gene (-174 G/C). Genotypes were tested for an association with the percentage of successful responses to BSP treatment (% SRB) in a group of 96 patients with sporadic non familial PDB: Tiludronate (n = 42), Etidronate (n = 34), Risedronate (n =22), Clodronate (n = 11), Pamidronate (n = 2) and Alendronate (n = 1). We considered a successful response to treatment when a decrease of, at least, 50% of the levels of total serum alkaline phosphatase (SAP) previous to the treatment were achieved at six months. Moreover we tested the skeletal extension (Renier anatomic index) and the clinical activity (AP) (number of times that SAP is over the upper normal limit at diagnosis). ANOVA test and Tukey Post Hoc Multiple comparison test were used for continuous variables.

The IL-1ß promoter region genotype was significantly associated with the response to BSP treatment. The multiple comparison with the genotype A1/A1 was statistically significant (A2/A2-A1/A1 p value 0,05, A1/A1-A1/A2 p value < 0,01, A2/A2-A1/A2 p value 0,82).

There were no differences in the extension and activity of the PDB between the different genotypes. ANOVA test for the comparison of Renier index according to exon 5 of IL-1 ß gene was statistically significant but Tukey test did not show any significance.

In conclusion, the A2 allele of the -511 C/T IL-1ß polymorphism could be a marker of favourable outcome to the BSP treatment in PDB patients. This observation still needs to be clarified through further study.

Faster Bone Growth During Puberty Contributed by the COL1A2 Polymorphism - A Benefit or Risk? M. Suuriniemi*[1], A. Mahonen*[2], A. Lyytikäinen*[1], V. Kovanen*[1], M. Alén*[3], S. Cheng[1]. [1]University of Jyväskylä, Jyväskylä, Finland, [2]University of Kuopio, Kuopio, Finland, [3]PEURUNKA - Medical Rehabilitation Center, Jyväskylä, Finland.

We have previously found an association between the COL1A2 polymorphism and fractures in pre- and early pubertal Finnish girls. The purpose of this study was to search for possible explanations behind the increased fracture risk of the *PP* genotype from the rate of growth in bone mass. The subjects were 10-13 yr-old girls (n=218) with Tanner stage I-III, who participated in an intervention study (the CALEX-study). Measurements were made at baseline, year 1, and year 2. Genotyping of the COL1A2 locus at the *PvuII* polymorphic site was performed. Bone properties of the total body (TB), total proximal femur (TF), femoral neck (FN), and lumbar spine (L2-L4) were measured by DXA (Prodigy, GE Lunar). Our results showed that girls with different genotype were evenly distributed into the different intervention groups. Bone properties were similar at baseline between the genotypes. There were no significant differences among the genotypes in Tanner stage during the trial or in 2-yr changes (%) of weight, height, body mass index, and bone areas of the measured bone sites. However, girls with the *PP* genotype had significantly greater increases (%) of bone mineral content (BMC, g) [*PP* (28±11) vs. *Pp* (24±10), p=0.031, and *pp* (23±9), p=0.023] and areal bone mineral density (aBMD, g/cm^2) [*PP* (17±7) vs. *Pp* (13±7), p=0.004, and *pp* (14±6), p=0.023] of FN, compared to the others. They also tended to have greater increases (%) of BMC [*PP* (38±13) vs. *Pp* (33±11), p=0.086, and *pp* (33±11), p=0.080] and aBMD [*PP* (17±8) vs. *Pp* (14±6), p=0.052, and *pp* (14±7), p=0.094] of TF. Compared to the others, the increments of BMC and aBMD of TB and L2-L4 were 2-4% and 1-2% higher in the *PP* girls, respectively, but the differences did not reach statistical significance. Interestingly, girls with the *PP* genotype tended to be taller (cm) at birth than girls with the *pp* genotype [*PP* (50.3±2.0) vs. *pp* (49.6±1.8), p=0.098]. Fathers of the *PP* girls were taller (cm) as well compared to those of the *pp* girls [*PP* (179.4±6.4) vs. *pp* (176.8±6.0), p=0.034]. Our results suggest that the COL1A2 polymorphism may contribute to acquisition of bone mass during puberty. The rapid growth in bone matrix of the *PP* girls may exceed the capacity of mineralization, leading to an increase in bone fragility and fracture risk. In addition, the COL1A2 polymorphism may affect skeletal growth during fetal period of rapid growth. Whether the increased incidence of fractures due to fast growth of the *PP* girls is just a price that has to be paid in order to maximize bone accumulation during growth, or a real risk for osteoporotic fractures in older age, needs to be clarified.

LRP5 **Gene Polymorphisms Predict Bone Mass and Incident Fractures in Elderly Australian Women.** J. Bollerslev[1], S. G. Wilson*[2], I. M. Dick*[2], A. F. M. Islam*[2], T. Ueland*[1], A. Devine*[2], R. L. Prince*[2]. [1]Rikshospitalet University Hospital, Oslo, Norway, [2]University of Western Australia, Nedlands, Australia.

Postmenopausal osteoporosis and bone mass are influenced by multiple factors including genetic variance. The importance of LDL Receptor-Related Protein 5 (*LRP5)* for the regulation of bone mass has recently been established, where loss of function mutations is followed by severe osteoporosis and gain of function related to increased bone mass. The aim of this study was to evaluate the role of polymorphisms in the *LRP5* gene for bone mass and prospective fracture frequency in a well described, large cohort of normal, ambulatory Australian women. A total of 1301 women were genotyped for 7 different single nucleotide polymorphisms (SNPs) within the *LRP5* gene and related to basal biochemistry, calcaneal Quantitative Ultrasound measurements (QUS) and osteodensitometry of the hip. Two SNPs were found to be associated with fracture rate and bone mineral density. The two SNPs were in strong LD, the LD block spanning from exon 15 to intron 19. Homozygous mutation of rs556442 was associated with significant reduction in bone mass at most femoral sites. The difference in total hip BMC was 3.4%, (P< 0.037), in femoral neck BMC 3.9% (P = 0.012), femoral neck BMD 3.9% (P = 0.005), in trochanter BMC 4.4% (P = 0.033), and in BUA 1.4% (P = 0.038). In the 5 years follow-up period, 227 subjects experienced a total of 290 fractures which were radiologically confirmed. The incident fracture rate was significantly increased in subjects homozygous for the polymorphism (RR of fracture = 1.61, 95% CI [1.05 - 2.44], P = 0.027). After adjusting for total hip BMD, the fracture rate was still increased (RR = 1.67 [1.02 - 2.78], P = 0.045), indicating factors other than bone mass are of importance for bone strength. In conclusion, genetic variance of *LRP5* seems to be of importance for regulation of bone mass and osteoporotic fractures.

Insulin-Like Growth Factor I (IGF-I) Gene Microsatellite Repeat Polymorphism and Its Relation to Hyperthyroidism and Thyroid Hormone-stimulated Bone Loss. E. Bajnok*, A. Tabak*, I. Takacs, P. L. Lakatos*, C. Horvath, Z. Nagy, G. Speer, P. Lakatos. First Department of Medicine, Semmelweis University, Budapest, Hungary.

The knowledge and understanding of the molecular and genetic mechanisms that generate toxic adenoma (TA) producing hyperthyroidism, and resulting in thyroid hormone-stimulated bone loss are far from complete. In this study we investigated the previously described IGF-I gene CA microsatellite repeat polymorphism, located 1 kb upstream from the IGF-I gene transcription start site. These gene variants are involved in the influence of different serum IGF-I concentrations, tumorgenesis and bone metabolism. We studied the possible functional contribution of this gene polymorphism to the pathogenesis of hyperthyroidism and bone loss as a consequence of TA.

Allele and genotype frequencies for the IGF-I gene and bone mineral density (BMD) values were determined among 182 postmenopausal women: 68 patients with TA (TA, mean age: 57.03 ± 9.15 [40-70] years) and 114 healthy controls (C, mean age: 54.21 ± 5.38 [40-68] years). The polymorphic regions of IGF-I gene were amplified by PCR technique using genomic DNA isolated from blood. BMD of the lumbar spine, femoral neck and distal radius was measured by DEXA and SPA, respectively. For statistical analysis SPSS for Windows 9.0.0 was applied.

We have found the allele “192” (67.03%) and “194” (18.14 %) to be the most common gene variants in our population. We have demonstrated the higher presence of the noncarrier subjects of allele “192” in the TA group compared to the controls (p =0.028). Studying subjects by BMD, “192/192” genotype was found to be exhibited more frequently in TA patients having normal BMD compared to TA subjects with osteoporosis and to healthy controls (p=0,0267). This polymorphism of IGF-I gene was also correlated with BMD in TA group. Z-score values at the radius, as being among the sites affected by hyperthyroidism, were higher in the subjects homozygous for “192” allele compared to that be heterozygous or noncarrier of it (p=0,025).

This is the first study reporting the possible functional contribution of IGF-I gene promoter polymorphism in the pathogenesis of TA. Based on our observations we suppose that the absence of “192” allele might predispose for the susceptibility of toxic adenoma and thyreogen bone loss in postmenopausal women. Extension and confirmation of these preliminary data are needed.

Association between Collagen Type I Alpha1 (COL1A1) Gene Sp1-, Calcium-sensing Receptor (CaSR) Gene A986S-, Interleukin-1 Receptor Antagonist (IL-1LN) Gene VNTR Polymorphisms and Osteoporosis; Their Impact in Prediction of Osteoporotic Bone Fracture. E. Bajnok*, G. Lakatos*, A. Tabak*, I. Takacs, C. Horvath, J. Kosa*, G. Speer, E. Madarasz*, Z. Nagy, P. Lakatos. First Department of Medicine, Semmelweis University, Budapest, Hungary.

Osteoporosis (OP) is the most common bone disease. The disabilities, which result from osteoporotic fractures (OPF), have enormous impact on the health of individuals, societies and economies. Twin and family studies have shown that genetic factors play an important role in regulating bone mineral density (BMD) as well as contributing to the development of OPF itself. The genes responsible for these effects are incompletely defined and require a multi-gene approach. Based on the results of former studies, our aim were to investigate the importance of the COL1A1 gene G1245T Sp1-, the CaSR gene A986S- and the IL-1RN gene 86 bp VNTR polymorphism in BMD, and their possible functional contribution to the susceptibility to OPF in Hungarian postmenopausal women.

Frequencies of genotypes and BMD values were determined among 180 postmenopausal women [40-70 yrs]: 90 subjects with serious OP (sOP, mean age: 60.79 ± 8.75 yrs*)* and 90 healthy controls (C, mean age: 54.2 ± 4.83 yrs). BMD of the lumbar spine, femoral neck and distal radius was measured by DEXA and SPA, respectively. Patients were enrolled in the study if the BMD value was below -4 t-score at any measured site. Prevalent fractures were estimated by obtaining a fracture history from each subject. OPF was diagnosed if it was occurred after the age of 40 years and was due to minimal trauma included at the femoral neck-, thoracolumbal vertebral region or at the wrist.

The ss genotype of COL1A1 gene- and the AS/SS genotypes of CaSR gene were found to be more frequent in patient with sOP compared to C subjects (p=0.028/p=0.04). We have found significant correlation between BMD and COL1A1/CaSR genotypes (p=0.05/0.021). No clinical significance of these polymorphisms on OPF was proved. There was no association between the IL-1RN gene polymorphism and BMD. On the other hand, in the sOP group the A2A2/A1A2 genotypes were more frequent in patients with OPF than in the subject without it.

Our results affirm that certain genotypes of COL1A1 gene Sp1 and CaSR gene A986S polymorphisms might predispose to postmenopaual osteoporosis and might also be a prognostic marker of the disease. We could not prove any clinically significance of these gene variants on bone fracture. Based on our observation we conclude that IL-1RN VNTR polymorphism may not play an essential role in the determination of BMD in postmenopausal osteoporosis; however, our data support a hypothesis that it may influence the bone fracture risk, independent of BMD.

Disclosures: ***E. Bajnok****, None.*

Polymorphisms in the Osteoclast-associated Receptor Gene Are Associated With Risk of Osteopenia and Osteoporosis. J. Koh[1], E. Park[2], G. Kim[1], H. Shin*[3], S. Kim[4]. [1]Department of Endocrinology and Metabolism, University of Ulsan School of Medicine, Seoul, Republic of Korea, [2]Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea, [3]Department of Genetic Epidemiology, SNP Genetics, Inc, Seoul, Republic of Korea, [4]Department of Orthopedic Surgery, Kyungpook National University Hospital, Daegu, Republic of Korea.

Osteoclast-associated receptor (OSCAR) is expressed specifically in preosteoclasts or mature osteoclasts. and has been suggested that it may be an important bone-specific regulator of osteoclast differentiation.

Despite the important role as bone regulator of the OSCAR, little is known concerning the genetic study of this gene. The human OSCAR (alternatively, MIM 606862), located on chromosome 19q13.4, has two Ig-like domains.

In an effort to discover polymorphisms in OSCAR gene, we scrutinized the single nucleotide polymorphisms (SNPs) in OSCAR as a potent candidate gene for osteoporosis by direct sequencing in 24 Korean individuals. Ten sequence variants were identified: 2 in 5' flanking region, 1 in intron 1, 1 in 5'UTR, 3 in exon 4, 2 in exon5, and 1 in exon 6. Five of these polymorphisms were selected for a large scale genotyping (n=683) by considering their allele frequencies, haplotype-tagging status, and linkage disequilibrium coefficiencies (LDs) among polymorphisms. Using statistical analyses for association of *OSCAR* polymorphisms with bone mineral density (BMD), no significant signals were detected. However, in case-control analysis, one polymorphism in 5' flanking region, *OSCAR-2322A>G,* and two haplotypes (*OSCAR-ht1* and *-ht4*) were associated with the risk of osteopenia and osteroporosis.

In conclusion, we identified ten genetic polymorphisms in the OSCAR gene and *OSCAR-2322A>G, -ht1*, and *-ht4* were significantly associated with the risk of osteopenia and osteoporosis, although no significant associations of OSCAR variants with the change of BMDs were detected. OSCAR variation/haplotype information identified in this study will provide valuable information for future association studies of other genetic diseases.

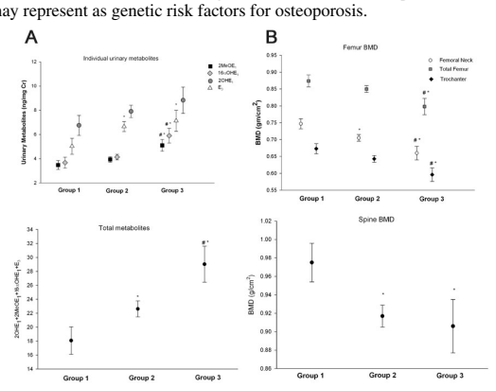
Effect of CYP450 Gene Polymorphisms on Estrogen Metabolism and Bone Density. N. Napoli, S. Mumm, S. Sheik*, G. B. Rini, R. C. Villareal. Medicine, Washington University School of Medicine, St. Louis, MO, USA.

Polymorphisms of the CYP450 enzymes that metabolize estrogen are linked to hormone-related disorders, but little is known on their effect on estrogen metabolism in-vivo, and on bone density (BMD). The objective of this study, is to evaluate the effect of polymorphisms of the CYP1A1, CYP1A2, CYP1B1 and CYP3A4 on estrogen metabolism and BMD. We previously reported that the A allele of the CYP1A1 C4887A polymorphism is associated with a profile of accelerated estrogen catabolism, and lower femoral BMD. Here, we report new findings from this ongoing study which, to date, enrolled 193 postmenopausal women and 74 men ≥ 50 years old. Genotyping was done by restriction fragment length polymorphism and pyrosequencing. BMD of the lumbar spine and femur were measured by dual energy X-ray absorptiometry, and urinary metabolites [2-hydroxyestrone ($2OHE_1$), 2-methoxyestrone ($2MeOE_1$), 16α-hydroxyestrone ($16\alpha OHE_1$), and estriol (E_3)] by enzyme immunoassay. Our latest findings indicate that women with the C allele (GC+CC) of the G1294C polymorphism of the CYP1B1 gene have higher urinary metabolites and lower BMD of the spine and femur. Women subjects were further stratified into 3 composite genotypes for CYP1A1 C4887A and CYP1B1 G1294C polymorphisms. Group1: no genes “affected” i.e. CC for CYP1A1 and GG for CYP1B1; group 1: one gene “affected”, "affected" CYP1A1 (CA or AA) and "unaffected" CYP1B1 (GG), or “unaffected” CYP1A1 (CC) and “affected” CYP1B1 (GC or CC); and group 3: where both genes are “affected” i.e. CA or AA for CYP1A1 and GC or CC for CYP1B1. Group 3 have the highest levels of individual and total metabolites (Figure, Panel A) group 1 the lowest, and group 2 levels intermediate groups 1 and 3. In contrast, spine and femoral BMD (Figure, Panel B) were lowest in group 3, highest in group1, and group 2 values intermediate groups 1 and 3. Serum estradiol were comparable among the groups. In conclusion, the C allele of the CYP1B1 G1294C polymorphism is associated with increased estrogen catabolism and lower BMD. A combination of the A allele (CYP1A1 C4887A) and the C allele (CYP1B1 G1294C) resulted in an augmented rate of estrogen catabolism, and much lower BMD relative to those with none or only one of these alleles are present. These polymorphisms may represent as genetic risk factors for osteoporosis.



Disclosures: ***N. Napoli****, None.*

Polymorphisms in the IGF-II Gene are Associated with Body Weight and Bone Mass. B. L. Langdahl, L. B. Husted*, L. Stenkjaer*, M. Carstens*. Endocrinology, Aarhus University Hospital, Aarhus C, Denmark.

Insulin-like growth factor (IGF)-I and -II stimulate proliferation of osteoblast-like cells in vitro. With this role in the control of bone development and osteoblast activity the IGFs have been suggested as candidate genes for genetic control of bone mass and fracture risk. We therefore examined the 9 exons with surrounding intron sequences and the four promoter regions of the IGF-II gene for polymorphisms by sequencing in 50 osteoporotic patients and 50 normal controls. We found 6 polymorphisms, of which some have been reported earlier. We here report the analyses of the effects of one polymorphism in the first promoter: 6815delAGGGC, one polymorphism in exon 3: 1252T-C, two polymorphisms in the third promoter (intron 4): 1543C-T and 1981C-T and one polymorphism in the 5'UTR: 266C-T on prevalence of osteoporotic fractures, bone mass and bone turnover in 409 osteoporotic patients and 340 normal controls.

The 6815delAGGGC polymorphism has previously been reported as a SNP: 6815A-T, however, sequencing revealed that the polymorphism was a deletion of 5 bases. This polymorphism has previously been found to be associated with BMI in middle-aged men.

In the present study, the C allele of the 1252T-C polymorphism in exon 3 was associated with reduced weight in normal men: 75.5±10.2 kg vs. 82.8±12.5 kg ($p<0.05$), none of the other examined polymorphisms was significantly associated with BMI, height or weight in neither osteoporotic patients or in normal controls.

None of the examined polymorphisms was significantly associated with osteoporosis either defined by the presence of osteoporotic fractures or BMD T-score of the spine or hip less than -2.5.

The 3'UTR polymorphism 266C-T was significantly associated with BMD at the hip sites. In women with the CC, CT and TT genotypes, femoral neck BMD were: 0.739±0.119 g/cm^2, 0.762±0.092 g/cm^2 and 0.891±0.104 g/cm^2, respectively, $p<0.05$. At the total hip the corresponding values were: 0.846±0.142 g/cm^2, 0.869±0.136 g/cm^2 and 1.042±0.025 g/cm^2, respectively, $p<0.05$. The 266C-T was not associated with biochemical markers of bone turnover. None of the other polymorphisms was associated with bone mass or bone turnover.

In conclusion: We have identified 6 polymorphisms in the IGF-II gene and we have found that a polymorphism in the first promoter: 6815delAGGGC is associated with body weight and that a polymorphism in the 3'UTR: 266C-T is associated with increased bone mass at the hip.

A DNA Variant Correlated to Lactose Intolerance Interacts with VDR Gene Variants to Determine Height, Bone Geometry and BMD. J. van Meurs[1], C. Zillikens*[1], Y. Fang*[1], H. Zhao*[1], J. van Leeuwen[1], A. Hofman*[1], B. Obermayer-Pietsch*[2], H. Pols[1], A. Uitterlinden[1]. [1]Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands, [2]Internal Medicine, Karl-Franzens Hospital, Graz, Austria.

Adult-type lactose intolerance affects about half of the world's population. It is caused by developmental down-regulation of the lactase-phlorizin hydrolase (LPH) gene in the small intestinal epithelial cells. Lactose intolerance may affect calcium supply and, thus, might influence bone strength and risk for osteoporosis. Recently, the C-allele of a functional T/C substitution at position -13910 bp upstream of the LPH-gene was found to be expressed >4-times lower in intestinal biopsies, and was found associated with lactose intolerance. We therefore examined whether this variant is associated with dietary habits, calcium levels, bone characteristics, and fracture risk. Since calcium absorption is regulated by vitamin D, we also studied interaction between the LPH variant and polymorphisms at the 3'end of the VDR gene, as previously defined by haplotype tagging SNPs, encompassing the 3'UTR. We determined LPH and VDR genotype in a population-based sample of 6,464 Dutch Caucasian elderly men and women who participated in a large prospective follow-up study. BMD data were available for 5321 subjects while 957 incident fractures were validated.

We found the LPH C-allele (31% allele frequency) to be associated in an allele-dose dependent way with lower calcium-intake ($p<0.001$), lower serum calcium levels ($p=0.005$), smaller stature ($p<0.001$), and smaller bone size ($p=0.003$). These associations were present in both men and women and were independent of age. The associations with stature and bone size were not dependent on calcium-intake or calcium serum levels. The LPH SNP was not associated with BMD or with fracture risk.

For analysis of interaction with VDR polymorphisms, subjects were divided by carrier status for VDR haplotype allele 1. We observed that only in carriers of VDR haplotype 1 (n= 4,581), the LPH C-allele was associated with lower height, smaller bone size, and with lower BMD. We detected significant interaction between both genetic variants with respect to height (p interaction term = 0.02), bone size ($p=0.01$), BMD at the femoral neck and lumbar spine ($p=0.04$). We could not detect an interaction for fracture risk.

In conclusion, variation at the VDR- and LPH-gene interact to determine height, bone geometry and bone mineral density, but not fracture risk. The biological mechanism underlying this interaction probably involves calcium-absorption. Further research will focus on interaction of dietary components and the vitamin D system with the LPH polymorphism.

Intragenic Interaction of VDR Haplotype Alleles Determines Fracture Risk. Y. Fang*, J. van Meurs, H. Y. Zhao*, J. van Leeuwen, H. Pols, A. Uitterlinden. Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.

Polymorphisms of the vitamin D receptor (VDR) gene have been found associated with complex diseases, including osteoporosis. Most studies have used polymorphisms at the 3'end or in exon 2, but information on other polymorphism across the VDR gene is scarce. In 15 Caucasians, we sequenced 22 kb genomic VDR sequence, including the 3'untranslated region (3'UTR), all coding exons and the 6 promoter exons 1f - 1c. We determined linkage disequilibrium (LD; pair-wise D') between single nucleotide polymorphisms (SNPs) across and flanking the VDR gene in 234 Caucasians, 107 Asians and 58 African Americans. We performed association studies with "haplotype tagging" SNPs (htSNPs) and fracture risk in 6535 elderly Caucasians from the Rotterdam Study. 5819 subjects had BMD measurement, and 950 osteoporotic fractures and 356 vertebral fractures were validated in 7.4 follow-up years. Dietary calcium intake was assessed by food frequency questionaire.

We identified 62 polymorphisms, of which 22 SNPs (40%) are new. In the promoter region, 14 polymorphisms change the putative recognition sequences of transcription factors, 4 SNPs are located in destabilizing elements in the 3'UTR. LD analysis of common SNPs (frequency ≥ 5 %) revealed 4 - 8 haplotype blocks ($D' > 0.8$) which are conserved among Caucasians and Asians, but more fragmented in Africans. Haplotype blocks in the VDR gene show no or low linkage to other genes nearby, and 15 htSNPs were used for the association study. The 1e - 1a promoter haplotype block 2 (containing the Cdx-2 SNP), was associated with 32 % increased risk for vertebral fracture ($p = 0.03$). Haplotype block 5 (including the 3'UTR) was associated with 26 % increased risk of osteoporotic fracture ($p = 0.004$). The combined risk alleles showed 46% increased risk for vertebral fracture ($p = 0.03$) and 34% increased risk for osteoporotic fracture ($p = 0.01$) with adjustment for age, gender, height and weight. Overall, no or small genotype effects on BMD were observed. Dietary calcium intake is positively correllated with BMD ($r = 0.10$; $p < 0.001$), but this correlation (r) was absent and non-significant in carriers with promoter and 3'UTR VDR risk haplotype alleles (n = 204) vs. non-carriers (n = 2818): $r = -0.001$; $p = 0.98$ vs. $r = 0.11$; $p < 0.001$.

This "whole gene" analysis demonstrates intragenic interaction of VDR polymorphisms in the promoter region and in the 3'UTR to significantly contribute to fracture risk. We found differential VDR genotype-dependent effects on the influence of dietary calcium intake on BMD. Our finding suggests these risk alleles to encode a "less-sensitive" VDR, probably by encoding lower numbers of VDRs on target cells.

Genetic Variation in *LRP5, RANKL, RANK, OPG* and *VDR* Gene Is Associated with BMD. Y. Hsu[1], T. Niu*[1], X. Xu*[1], Y. Feng[1], H. Terwedow*[1], T. Zang*[2], D. Wu*[2], G. Tang*[2], Z. Li*[2], X. Hong*[2], B. Wang*[1], M. L. Bouxsein[3], J. Brain*[1], C. Rosen[4], X. Xu[1]. [1]Program for Population Genetics, Harvard School of Public Health, Boston, MA, USA, [2]Anhui Medical University. Institute of Medicine, Anhui, China, [3]Beth Israel Deaconess Medical Center, Boston, MA, USA, [4]Maine Center for Osteoporosis Research and Education, St. Joseph Hospital, Bangor, ME, USA.

The variation of BMD is influenced by both genetic and environmental factors. The purpose of this study was to assess the contribution of *LRP5 (low density lipoprotein receptor-related protein 5), RANKL (tumor necrosis factor ligand superfamily, member 11), RANK (tumor necrosis factor receptor superfamily, member 11a, activator of NFκB), OPG (osteoprotegerin, tumor necrosis factor receptor superfamily, member 11b)* and *VDR* (*vitamin D receptor*) polymorphisms to the population-based variation in BMD among Chinese. For each candidate gene, we selected SNPs in exon (nonsynonymous SNPs), 5' flanking region, and 3' UTR region and intron haplotype tagSNPs with minor allele frequency larger than 5% in Chinese population. Forearm BMD was measured by pDEXA in 540 men and women aged 20-80 among residents of Anhui Province, China. Multivariate regression models were performed to access the association with adjusting for age, gender, body mass index and other confounders. The table below showed the result with significant level. For each SNP, the β coefficient was calculated by compared the genotype of minor allele homozygosity to the genotype of major allele homozygosity. Haplotype analysis also showed significantly associated with forearm BMD for LRP5, OPG, VDR and RANKL gene. In summary, we found polymorphisms in LRP5, OPG, RANKL, RANK and VDR gene were strongly associated with forearm BMD in Chinese population. An ongoing large scale case control study will be used to confirm these result. Supported by NIAMS grant R01 AR045651

Genetic Variation in *ALOX15, BMP2, PPARr* and *IGF1* Gene Is Associated with BMD. Y. Hsu[1], Y. Zhang[1], X. Xu*[1], Y. Feng[1], H. Terwedow*[1], T. Zang*[2], D. Wu*[2], G. Tang*[2], Z. Li*[2], X. Hong*[2], B. Wang*[1], M. L. Bouxsein[3], J. Brain*[1], C. Rosen[4], X. Xu[1]. [1]Program for Population Genetics, Harvard School of Public Health, Boston, MA, USA, [2]Anhui Medical University. Institute of Medicine, Anhui, China, [3]Beth Israel Deaconess Medical Center, Boston, MA, USA, [4]Maine Center for Osteoporosis Research and Education, St. Joseph Hospital, Bangor, ME, USA.

The variation of BMD is influenced by both genetic and environmental factors. The purpose of this study was to assess the contribution of *ALOX15 (arachidonate 15-lipoxygenase), BMP2 (bone morphogenetic protein 2), PPARr (peroxisome proliferative activated receptor, gamma) a*nd *IGF1 (insulin-like growth factor 1)* polymorphisms to the population-based variation in BMD among Chinese. For each candidate gene, we selected SNPs in exon (nonsynonymous SNPs), 5' flanking region, and 3' UTR region and intron haplotype tagSNPs with minor allele frequency larger than 5% in Chinese population. Hip BMD was measured by DXA in 6743 men and women aged 25-65 among residents of Anhui Province, China. The subjects were then grouped into men, post-menopausal women and pre- (or peri-) menopausal women. For each group, a multiple linear regression model including age, BMI, weight and lifestyle factors was used to calculate the hip BMD residual. Subjects with hip BMD residual below the 10th and above the 90th percentile of the reference distribution were defined as extreme low BMD case and extreme high BMD control, respectively. We genotyped 547 cases and 547 controls. (53% were men, 18% post-menopausal women). The table below showed a partial result. For each SNP, the OR was calculated by compared genotypes to the reference genotype (homozygosity of major allele). In summary, this study has identified several novel associations between genetic variation and the BMD in Chinese population. The genetic effect seems not contribute the same way between men, pre- (peri-) menopausal and post-menopausal women. An ongoing cross-sectional study will be used to confirm these results. Supported by NIAMS grant R01 AR045651

A VNTR in the *CLCN7* Gene Influences Bone Density in Patients with Autosomal Dominant Osteopetrosis (ADO) Type II and in Post-menopausal Women. U. Kornak*[1], S. Branger*[2], A. Ostertag*[2], M. C. de Vernejoul*[2]. [1]Research Group Development and Disease, Max Planck Institute for Molecular Genetics, Berlin, Germany, [2]Inserm u 606, Hôpital Lariboisière, Paris, France.

The ClC-7 chloride channel is crucial for bone resorption as it is part of the osteoclast acid secretion mechanism. Heterozygous mutations in ClC-7 are responsible for autosomal dominant osteopetrosis type II (ADOII), a disorder characterized by a highly variable phenotype even within the same family. We hypothesized that polymorphisms in the *CLCN7* gene could be associated with the variability of bone density in ADO II and in the general population. We therefore investigated a large family with a mild variant of ADO II caused by the heterozygous mutation 2423DelAG in *CLCN7*. The penetrance was exceptionally low with 9 affected and 8 non-affected mutation carriers. Instead of sandwich vertebrae, some affected carriers only showed a diffuse osteosclerosis at the spine that is more typical for other high bone mass traits, e.g. ADO type 1. We investigated the non-coding SNP 126C/T in exon 1, the coding SNP 1252A/G in exon 15 and a VNTR in intron 8 that ranges between 2 and 10 repeat units. No association between the phenotype of the carriers and the SNPs was observed. All the affected carriers, however, had 3 repeat units in intron 8 of the allele without mutation, whereas the corresponding number in 5 of 8 non-affected carriers was higher than 3 (p=0.002). We therefore investigated if the length of the intron 8 VNTR could be associated with a higher bone density in 394 post-menopausal women with an average age of 64+5 years. Women with 3 repeat units on both alleles (17%) had a higher BMD at the femoral neck (0.78+0.14 vs. 0.74+0.12 mg/cm2 (p<0.009) than individuals with higher repeat numbers. The difference between both groups persisted when the BMD was adjusted for age, height, weight, years since menopause and hormone replacement therapy.

In conclusion, a VNTR polymorphism in intron 8 of *CLCN7* has a small impact on BMD in ADO II and in the normal population. In both cases the allele containing 3 repeat units is associated with a higher bone density, presumably because of a reduced osteoclast activity.

LRP5 Amino Acid Substitutions: Ethnic Differences in Allele Frequencies and Association with Bone Density and Structure in Afro-Caribbean Men. J. I. Oakley[1], S. P. Moffett*[1], N. Petro*[2], J. A. Cauley[1], T. J. Beck[3], C. H. Bunker*[1], A. L. Patrick*[4], V. W. Wheeler*[4], R. E. Ferrell*[2], J. M. Zmuda[1]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Human Genetics, University of Pittsburgh, Pittsburgh, PA, USA, [3]School of Medicine, Johns Hopkins University, Baltimore, MD, USA, [4]Tobago Health Studies Office, Scarborough, Trinidad and Tobago.

Recent studies have indicated that the low-density lipoprotein (LDL) receptor related protein 5(LRP5) gene located on chromosome 11q12-13 in humans is a major contributor to bone mass and morphology. Mutations within the gene have been linked to both high bone mass syndromes and low bone mass disorders like osteoporosis-pseudoglioma. We investigated the association of two amino acid substitutions in the LRP5 gene with bone mineral density (BMD) and structural geometry in men of African ancestry age 38-90 years (mean, 57) from Tobago.

BMD was measured at the hip by dual-energy X-ray absorptiometry (DXA; Hologic QDR 4500). Bone structural geometry was assessed at the femoral neck and shaft by hip structural analysis on hip DXA scans. Men were genotyped for two SNPs that altered the amino acid sequence of the protein by missense substitution. At exon 9 a G to A substitution changes the amino acid from valine to methionine at codon 667 (V667M) and at exon 18 a C to T substitution changes the amino acid from arginine to valine at codon 1330 (A1330V).

We sequenced the first 171 men for the V667M polymorphism and only found two heterozygotes (G/A) and 169 homozygotes (G/G). The minor allele frequency (MAF) was 0.006, considerably less than that reported in Caucasians (MAF, 0.06); thus we did not genotype any additional individuals.

Of the 778 men genotyped by fluorescence polarization for the A1330V polymorphism the majority were homozygous (C/C) and only 5% heterozygous (C/T). The genotypes were in Hardy-Weinberg Equilibrium. The minor allele frequency was 0.02 which is considerably less than that reported in Caucasians and Asians (MAF, 0.15 and 0.21 respectively). Despite sufficient sample size to detect modest genotype related differences we found no significant association between the A1330V polymorphism and femoral neck and shaft BMD, cortical thickness, or biomechanical indices of bone strength (p=0.35-0.90).

Since lower BMD in Caucasians and Asians has been found in other studies to be associated with the A1330V polymorphism, our non-significant association to BMD in this Afro-Caribbean cohort parallels ethnic differences seen in bone mass across these ethnicities. We conclude that ethnicity may influence the impact of the A1330V polymorphism on bone mass and morphology.

Nuclear Receptor Coactivator-3 (*NCOA3/AIB1/SRC3*) Alleles are a Strong Correlate of Bioavailable Testosterone and Vertebral Bone Mass in Older Men. J. M. Zmuda[1], J. A. Cauley[1], R. E. Ferrell[2]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Human Genetics, University of Pittsburgh, Pittsburgh, PA, USA.

Nuclear receptor coactivator-3 (*NCOA3/AIB1/SRC3*) is a member of the steroid receptor coactivator family that interacts with nuclear hormone receptors to enhance their transcriptional activator functions. The protein encoded by this gene has histone acetyltransferase activity and recruits p300/CBP-associated factor and CREB binding protein as part of a multi-subunit coactivation complex. We describe a novel and strong association between genetic variation at this locus, androgenic hormone levels, and bone mass among older men. We analyzed the association between alleles at this locus and bone mineral density (BMD) (Hologic QDR) in 263 community-dwelling Caucasian men (age 66±7 yrs, mean±SD; range, 51-84 yr). Men were genotyped for a CAG repeat polymorphism of *NCOA3* which encodes a polyglutamine tract of variable length in the C-terminus of the encoded protein. We found a significant monotonic decrease in lumbar spine BMD with increasing copies of the 224 bp allele (Table). Men with two copies of this allele had 7% or 0.5 standard deviations (SD) greater spine BMD than men without this allele, and *NCOA3* genotype explained 3.5% of the phenotypic variation in spine BMD independent of age, weight and height. Serum levels of bioavailable testosterone and sex hormone binding globulin paralleled genotype related differences in spine BMD. In contrast, there was no significant association between *NCOA3* alleles and hip BMD. An association with spine, but not hip, BMD raises the possibility that *NCOA3* alleles act in a bone compartment (trabecular *vs* cortical) and/or skeletal site specific (spine *vs* hip) manner. We conclude that allelic variation at the *NCOA3* locus may contribute to the genetic regulation of androgenic hormones and vertebral bone mass among older men.

Table. NCOA3 224 bp Alleles

	0	1	2	*P*-Value
Number of Men	67	112	84	
Bioavailable Testosterone (ng/dl)	140 (38)	122 (48)	124 (43)	0.01
Sex Hormone Binding Globulin (ug/dl)	1.09 (0.36)	1.18 (0.51)	1.35 (0.63)	0.003
Lumbar Spine BMD (g/cm^2)	1.10 (0.16)	1.08 (0.16)	1.02 (0.16)	0.006
Total Hip BMD (g/cm^2)	0.96 (0.15)	0.95 (0.13)	0.94 (0.15)	0.54

Estrogen Receptor-a Genotype and Hip Fracture Risk in Older Women: Evidence for a Strong Interaction with Body Mass Index. J. M. Zmuda[1], J. A. Cauley[1], L. Lui[2], D. R. Greene*[3], J. Li*[3], K. Walker*[3], K. L. Stone[2], K. E. Ensrud[4], T. A. Hillier[5], G. Peltz*[6], S. R. Cummings[7]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Epidemiology, University of California, San Francisco, CA, USA, [3]Roche Molecular Systems, Alameda, CA, USA, [4]University of Minnesota, Minneapolis, MN, USA, [5]Kaiser Permanente Center for Health Research, Portland, OR, USA, [6]Roche Palo Alto, Palot Alto, CA, USA, [7]California Pacific Medical Center, San Francisco, CA, USA.

Women with low levels of endogenous estrogen have an increased risk for hip fracture. Adipose tissue is a major source of endogenous estrogen among older women and obesity is inversely related to hip fracture risk. In the current study, we analyzed the independent and joint effects of an estrogen receptor alpha (*ESR1*) polymorphism (IVS -401 T→C) which has been shown to enhance estrogen sensitivity and body mass index (BMI) on the risk of hip fracture among 6177 women aged 65 years and older in the Study of Osteoporotic Fractures. *ESR1* genotype was determined by the TaqMan 5' exonuclease assay. A total of 522 hip fractures occurred over an average of 10 years. *ESR1* genotype was not associated with the risk of hip fracture in the total cohort (Relative Risk, 0.97 per C allele; 95% CI: 0.86, 1.10). However, the relationship between *ESR1* genotype and fracture risk was modified by BMI (*P*=0.009 for interaction). For example, among women with BMI above the median (25.6 kg/m^2), the RR per C allele for hip fracture was 0.74 (95% CI: 0.61, 0.91) vs. 1.15 (95% CI: 0.98, 1.34, p=0.08) for those with BMI above the median. Among women with BMI below median, the RR of hip fracture for those with the C/C genotype compared to T/T was 0.47 (95% CI: 0.30, 0.76). Results were adjusted for age, use of hormone therapy, hip bone mineral density, and clinical center. These findings suggest a role of the *ESR1* locus in the genetic susceptibility to hip fracture among a subgroup of older women. The decreased risk of hip fracture among heavier women with the *ESR1* C allele might be explained by an increased sensitivity to endogenous estrogen in this subgroup of women.

Effects of PGE2 EP4 Receptor Agonist on Distraction Osteogenesis. F. Chang*, H. Mishima, H. Akaogi*, T. Ishii*, N. Ochiai*. Department of Orthopaedic Surgery, Institute of Clinical Medicine,University of Tsukuba, Tsukuba,Ibaraki, Japan.

As a bone remodeling factor, PGE2 exerts the effects mainly via the EP4 receptor. It is reported that the EP4 receptor agonist stimulated bone formation both in vivo and in vitro. In present study, we examined whether EP4 selective agonist enhanced the bone consolidation during distraction osteogenesis.

First, rats were operated to make the distraction osteogenesis models in left femur. The lengthening protocol included a seven-day latency period, followed by twice daily incremental lengthening of 0.25 or 0.5 mm (Tab 1). Normal saline, EP4 selective agonist (ONO-4819-CD) 3, 10, 30 μg /kg were delivered by subcutaneous injection twice daily. Lengthening and injection were performed until animals were sacrificed. This protocol was approved by the ethics committee of Tsukuba University.

Tab 1 Experimental groups

	0.5 mm/day			0.25 mm/day
	10 day	17 day	21 day	21 day
30μg /kg	3	3	5	6
10μg /kg			6	6
3μg /kg			5	6
normal saline	3	3	6	6

To evaluate the results, hardness, soft X-ray and histological examination were performed. The hardness of the middle parts of distraction area was measured. Using soft X-ray photo, bone mineral density was determined by Scion Image.

As a result, bone mineral density was higher in EP4 agonist injection group in both 0.25 mm and 0.5 mm (fig 1, 2) lengthening groups ($P<0.05$). As to hardness examination, EP4 agonist injection group was harder than control group ($P<0.05$). Both effects were dose dependent. In histological section, compare to the abundant fiber tissue in control group, there was more bone like tissue in EP4 agonist injection group.

In conclusion, subcutaneous injection of EP4 receptor agonist stimulated the regenerate ossification and increased bone mineral density during distraction osteogenesis.

Osteoinduction of Human Mesenchymal Stem Cells by Adenovirus-Mediated ALK-2 Gene Therapy. S. Moon, H. Kim*, U. Kwon*, K. Lee*, J. Jeon*, J. Jahng, K. Yang*, H. Lee*, S. Park*. Department of Orthopaedic Surgery, Yonsei Univesity College of Medicine, Seoul, Republic of Korea.

Human mesenchymal stem cells (hMSCs) from the bone marrow represent a potential source of pluripotent cells for autogenous bone tissue engineering. Various growth factors, chemicals, and signaling molecules were utilized to facilitate osteogenic differentiation of hMSC. Transforming growth factor-betas (TGF-betas) and bone morphogenetic proteins (BMPs), members of a TGF-beta superfamily, are known to play an important role in osteogenic cell differentiation and consequently bone formation. Activin-receptor-like kinase-2 (ALK-2) has osteogenic activity through phosphorylation by BMP-2 induced TGF-beta type II receptor. In this study, osteogenic activity of hMSC through overexpression of ALK-2 was tested. hMSC were harvested from bone marrow and cultured. Type 5 adenovirus-ALK-2 gene constructs (Ad/ALK-2) were engineered and amplified in 293 cells. hMSC cultures were transfected by Ad/ALK-2 with an multiplicity of infection (MOI) of 150 and 300 with or without BMP-2 (20ng/ml). Then cultures were incubated for 3, 7, 14 days in 5% serum added medium. Immunohistochemistry and ELISA for osteocalcin, stains for alkaline phosphatase, von Kossa, alizarin-red S were performed. RT-PCRs and Western blot analysis for ALK-2, Smad8, and osteocalcin were also performed. hMSC cultures with Ad/ALK-2 showed positive stain for alkaline phosphatase, von Kossa, alizarin red-S, and increased expression of osteocalcin at 7 and 14 days compared control. hMSC culture with Ad/ALK-2 also demonstrated increased expression of ALK-2, Smad8, and osteocalcin in mRNA and protein level in dose dependent manner. hMSC cultures with Ad/ALK-2 (150 MOI) and BMP-2 (20ng/ml) showed synergistic effect in osteogenic differentiation compared to those of Ad/ALK-2 alone. However, hMSC with BMP-2 alone did not show osteogenic differentiation. In summary, overexpression of ALK-2 rendered osteogenic differentiation of hMSC, which effect was synergistic with low dose of BMP-2. In conclusion, ALK-2 gene therapy to MSC provides a feasible option for osteoinduction and osteogenesis.

A Crucial Role of Membrane-bound Prostaglandin E Synthase (mPGES) in Inflammatory Bone Loss. C. Matsumoto*[1], S. Uematsu*[2], S. Akira*[2], C. Miyaura[1]. [1]Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Tokyo, Japan, [2]Research Institute for Microbial Disease, Osaka University, Osaka, Japan.

Prostaglandin E2 (PGE2) is produced by osteoblasts and acts as a potent stimulator of bone resorption. We have found that the production of PGE2 by osteoblasts is induced by lipopolysaccharide (LPS), and regulated by the release of arachidonic acid (AA) from membranous phospholipids by cytosolic phospholipase A2, the conversion of AA to PGH2 by COX-2, and the synthesis of PGE2 by membrane-bound PGE synthase (mPGES). However, the relationship between mPGES-dependent PGE synthesis and inflammatory bone loss is not known. In this study, using mPGES-null mice, we examined the role of mPGES in PGE2 synthesis by osteoblasts, and LPS-induced bone loss in femur and mandibular alveolar bone. To examine the role of mPGES in PGE2 synthesis by osteoblasts, bone marrow cells were collected from mPGES-null and wild-type (WT) mice, and cultured for 2 weeks to obtain osteoblastic stromal cells. LPS greatly stimulated PGE2 production by the osteoblastic stromal cells in WT mice, but not in mPGES-null mice. When mPGES-null and WT mice were injected with LPS intraperitoneally, we detected the reduced bone mineral density (BMD) in femur in WT mice, but not in mPGES-null mice. In histological sections of distal femoral metaphysis, LPS administration induced osteoclastic bone resorption in femoral cancellous bone in WT mice, but not in mPGES-null mice. To examine the role of mPGES in bone loss associated with an experimental periodontitis, LPS was injected into gingiva in mPGES-null and WT mice, and alveolar bone was collected from mouse mandible to measure the BMD. LPS injection into gingiva markedly reduced alveolar bone mass with increased osteoclasts in WT mice, but not in mPGES-null mice, suggesting the role of mPGES in inflammatory bone loss associated with periodontitis. In conclusion, our results indicate that mPGES-dependent PGE synthesis is essential to LPS-induced bone loss in femur and mandibular alveolar bone in mice, and suggest a possible new approach to inflammatory bone destruction including periodontal diseases by inhibiting mPGES.

Platelet-Derived Growth Factor-D (PDGF-D) Is a Novel Osteogenic Factor. S. Topouzis*, K. Lum*, D. Thompson*, M. Holdren*, J. Shin*, C. Birks*, A. Haran*, R. Kuestner*, H. Ren*, D. Gilbertson*, T. Palmer*, D. Dong*, S. Hughes*, E. Moore. ZymoGenetics Inc., Seattle, WA, USA.

We describe the in vivo and in vitro bone anabolic properties of a new member of the PDGF family, PDGF-D. PDGF-D is elaborated as an inactive precursor dimer, PDGF-DD-Full-Length (PDGF-DD-FL). Proteolytic cleavage releases the bioactive C-terminal moiety, PDGF-DD-Growth-Factor-Domain (PDGF-DD-GFD), which selectively binds to the PDGF receptor-beta.

PDGF-B has been previously reported to possess bone-anabolic properties. For this reason, we compared the effects of PDGF-B and PDGF-D on the skeleton by bolus delivery of adenoviral constructs expressing human PDGF-BB (hPDGF-BB) or hPDGF-DD-FL into two-month-old female mice (8 mice per group). ELISA analysis of sera showed that circulating PDGF-BB and PDGF-DD protein levels peaked around 10-15 days post virus treatment and had returned to basal by 4-6 weeks. Histopathological evaluation of multiple bones including the femur, humerus and vertebrae revealed extensive formation of mineralized endosteal bone within the marrow cavity as early as 2 weeks after treatment with

either hPDGF-BB or hPDGF-DD-FL adenoviral constructs but not with a parental adenoviral construct. The newly formed bone persisted with some signs of remodeling for at least 8 weeks post-treatment.
In order to elucidate the underlying mechanism of action, we tested the effect in vitro of recombinant factors on marrow-derived human Mesenchymal Stem Cells (huMSC) from 2 independent donors. Both PDGF-BB and PDGF-DD-GFD induced 8- to 10-fold increases in thymidine incorporation. When huMSC were maintained in an adipogenic medium, both growth factors abrogated adipogenic differentiation, as assessed by the appearance of lipid droplet-filled cells. In contrast, when huMSC were maintained in an osteogenic medium, treatment with PDGF-BB or PDGF-DD-GFD resulted in increased mineralization at 3 weeks, as assessed by von Kossa staining and calcium content. In addition, immunocytochemical analysis showed that treatment with either protein enhanced the nuclear accumulation of the osteoblast-specific marker Osf2/CBFA-1. Finally, both PDGF-BB and PDGF-DD-GFD induced increases of steady-state mRNA levels of the osteogenic differentiation markers osteocalcin and osteopontin at day 9 of differentiation.
These observations are consistent with a positive effect of PDGF-B and PDGF-D on osteoblast differentiation from multipotential precursors and may explain their dramatic effects on trabecular bone in vivo. In combination, the present results support the notion that PDGF-D, like PDGF-B, has significant bone anabolic potential and may be clinically useful in bone regeneration.

Adiponectin Is Expressed in Human Osteoblasts. J. E. Reseland*[1], H. Berner*[1], M. Monjo*[1], L. Thommesen*[2], C. Drevon*[3], U. Syversen*[4], S. P. Lyngstadaas*[1]. [1]Oral research laboratory, University of Oslo, Oslo, Norway, [2]Department of Physiology & Biomedical Engineering, University of Science and Technology, Trondheim, Norway, [3]Department of Nutrition, University of Oslo, Oslo, Norway, [4]Department of Intra-Abdominal Diseases, University of Science andTechnology, Trondheim, Norway.

Adiponectin is a recently discovered adipokine, which is highly expressed in adipose tissue. Body weight is associated with increased bone mineral density and decreased risk of fractures. The mechanisms explaining this relation are, however, not completely understood. Here we provide information to the link between adipokines and bone homeostasis by demonstrating transcription, translation and secretion of adiponectin, as well as expression of its receptors, AdipoR1 and AdipoR2, in bone forming cells. We also show that adiponectin and the receptors are expressed in primary human osteoblasts from femur and tibia. The phenotype of the cells was characterized by the expression levels of alkaline phosphatase, collagen type 1, osteocalcin and CD44, and formation of mineralization nodules. The expression of adiponectin and AdipoR1 was also confirmed in murine osteoblast cells (MC-3T3-E1). Immunostaining with monoclonal antibodies demonstrated the presence of adiponectin in human osteosarcoma cells and normal osteoblasts. Both expression of mRNA and secretion of adiponectin to the medium increased during differentiation of human osteoblasts.
How adiponectin is regulated is still obscure. We observed higher adiponectin mRNA level for cells cultured 24 h with dietary fatty acids (0.5 mM palmitic acid), and dexamethasone (1 μM) compared to untreated control.
Administration of recombinant adiponectin enhances the proliferation of MC-3T3-E1, indicating a functional role for adiponectin in bone homeostasis.
The present findings of adiponectin expression and secretion from bone forming cells demonstrate that adiponectin is not adipocyte-specific, but may have other important functions related to bone growth and maintenance. Furthermore, the expression of adiponectin in bone cells appears to be regulated, suggesting that also in these cells, this factor can be influenced by external stimuli known to regulate adipokines. The regulation of bone metabolism is complex, and the observed expression and secretion of adipokines by bone forming cells add to the complexity, to this intriguing tissue.

Inhibition of Stem Cell Factor Activity Modulates Proliferation and Differentiation Patterns in Human Dental Pulp Cells. E. Gagari*[1], L. Suri*[2], P. D. Damoulis[3]. [1]Oral and Maxillofacial Pathology, Tufts University, Boston, MA, USA, [2]Orthodontics, Tufts University, Boston, MA, USA, [3]Periodontology, Tufts University, Boston, MA, USA.

Stem cell factor (SCF), an important growth factor typically produced by stromal cells, affects primarily hematopoietic cells that bear its receptor, c-kit. Human dental pulp (HDP) cells are of mesenchymal origin and co-express SCF and c-kit. However, the functional role of SCF in these cells is unclear. The purpose of this project was to explore the effects of inhibiting SCF bioactivity on cell proliferation and differentiation in mineralizing HDP cultures. Cells were cultured in αMEM supplemented with ascorbic acid and β glycerol phosphate for 38 days, with media changes every 3 days starting on d2. Assays were performed every 6 days, starting on d14. Inhibition of SCF activity was achieved with the addition of an anti-SCF neutralizing antibody (A) or an anti-c-kit receptor antibody (B). Addition of the respective antibody was performed with every media change, starting either on d8 (at confluence, gr. 1), or d20 (when soluble SCF [sSCF] typically peaks, gr. 2). Cell growth was assessed by DNA and total protein content, whereas cell viability was monitored through LDH release. Alkaline phosphatase (AlP) activity and alizarin red staining for mineralization were also measured. sSCF was measured by ELISA. Control cultures showed a gradual increase in DNA and protein content until d26, with a sharp drop on d32, coinciding with peak AlP activity and initiation of mineralization. At the same time, a significant drop in sSCF and increased LDH release were observed. Inhibition of SCF bioactivity produced a variety of phenotypic changes, which greatly depended on the timing of antibody addition. The mechanism of inhibition (A vs B) also resulted in some qualitative and quantitative differences. The most striking observation was that late inhibition of SCF (gr. 2, both A and B) caused a sharp drop in cell growth on d26 accompanied by a decrease in sSCF, increased LDH release and acceleration of mineralization. In contrast, gr.1 showed higher cell growth on d14 and d20, but changes at the later time points varied depending on the mechanism of inhibition. Addition of anti-c-kit receptor antibody in gr. 1 showed the highest variability from control, resulting in a more gradual decline in cell growth after d26, with a sSCF peak and a concomitant decrease in mineral content on d32. Taken together, these findings implicate SCF as an important regulator of cell growth and mineralization potential in HDP cultures. Establishing a role for SCF as a negative regulator of mineralization is an intriguing proposition, which could provide more insight in our understanding of bone formation.

Regulation of SDF-1 (CXCL12) Production by Osteoblasts in the hEmatopoietic Microenvironment- A Mechanism for Stem Cell Homing. Y. Jung*[1], J. Wang*[1], A. Schneider[1], Y. Sun*[1], A. J. Koh-Paige*[1], N. I. Osman*[2], L. K. McCauley[1], R. S. Taichman[1]. [1]Periodontics,Prevention,Geriatrics, University of Michigan Dental School, Ann Arbor, MI, USA, [2]Anesthesiology, University of Michigan Medical School, Ann Arbor, MI, USA.

SDF-1 controls many aspects of stem cell function including stem cell trafficking and development. Previously we demonstrated that DNA-damaging agents such as irradiation, cyclophosphamide, or 5-fluorouracil caused an increase in the expression of SDF-1 in the marrow of mice or in cultured osteoblastic cells. Recently transgenic mice expressing constitutively active PTH/PTHrP receptors were found to have increased numbers of hematopoietic stem cells recovered from the animals bone marrow. Here we evaluated SDF-1 secretion by ELISA in response to cytokines known to be particularly important in bone physiology in primary human osteoblasts (HOBs), mixed marrow stromal cells (BMSCs), MG-63 and SaOS-2 human osteosarcoma cell lines, the murine MC3T3-E1 clone 4 cells and the rat osteosarcoma ROS 17/2.8 cell line. Examination of SDF-1 synthesis vs time *in vitro* revealed that SDF-1 secretion is a feature of early osteoblastic induction, which can be modulated *in vitro* and in response to a variety of cytokine and hormonal signals. In particular, TNF-α, IL-1ß, VEGF, PDGF-BB and PTH all increased SDF-1 synthesis while TGF-$ß_1$ decreased secretion. Subsequent examinations of the medium or cell/extracellular matrix lysates from either BMSCs or MG-63 cells demonstrated an equal distribution of SDF-1 between all fractions. Surgical transplantation of mixed BMSCs into 4- to 6-week-old male mice (N:NIH-bg-nu-xid) and subsequent daily administration of 40 μg/kg PTH (1-34) or vehicle for 21 days increased the expression of SDF-1 mRNA in developing ossicle implants but not in endogenous bone. Interestingly, SDF-1 protein levels were significantly decreased in the serum (24%) of the PTH-treated animals (Vehicle: 408±25 Vs. PTH 308±20 SDF-1 pg/ml). These data suggest a possible mechanism for localizing stem cells into a developing marrow. Increased expression of SDF-1 in the local marrow environment along with decreased SDF-1 in the serum may create a homing gradient for the localization of hematopoietic stem cells to developing bone marrow.

Leukemia Inhibitory Factor has Biphasic Effects on Bone Formation In Vivo. D. Falconi[1], J. E. Aubin[2]. [1]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada, [2]Department of Medical Genetics and Microbiology & Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada.

Members of the gp130 family of cytokines elicit both anabolic and catabolic effects on bone, either directly or as mediators of at least some of the actions of factors such as PTH, IL-1 α and TNF α. Previously, we showed that leukemia inhibitory factor (LIF) has differentiation stage-specific inhibitory effects in rat calvarial (RC) cell cultures, but biphasic effects in the rat bone marrow (RBM) stromal cell model, with stimulation of osteogenesis during proliferation phase in the RBM model and inhibition at late osteoprogenitor-preosteoblast stages in both models. To determine whether LIF may elicit similar effects in vivo, we treated one-day-old neonatal Wister rats with increasing doses (1, 5 and 15 μg/kg in a volume of 20 μl) of mouse recombinant LIF or its vehicle (PBS), once a day for five consecutive days, by subcutaneous injections over the calvaria along the sagittal suture. The animals (12-16 per group) were sacrificed on the sixth day and the calvariae dissected for analyses. Hematoxylin-eosin staining revealed no significant differences in cell morphology in the suture or bones. Histomorphometric analyses indicated a biphasic effect of LIF on sagittal suture width, with a trend towards narrowing of the suture at 1 and 5 μg/kg but widening of the suture at 15 μg/kg (n=8; $p<0.05$) in LIF-treated compared to PBS-treated animals, suggesting respectively stimulation or inhibition of bone formation at the osteogenic front. The biphasic effect of LIF was also seen in calvaria width, measured at three sites (250, 500 and 750 μm from the middle of the suture), with bone width greatest at 5 μg/kg and least at 15 μg/kg compared to control. By real-time PCR, expression of ALP was slightly decreased with LIF at 1 μg/kg and 5 μg/kg but increased at 15 μg/kg. Levels of Osx and BSP were not significantly affected but OCN levels were slightly reduced by LIF. However, Runx2 levels were decreased at 1 μg/kg (2X), but were increased at the higher doses (5>15 μg/kg) compared to PBS. OPG and RANK expression levels were not significantly affected by LIF at the doses tested. RANKL levels were decreased in calvariae from mice treated with 1 μg/kg LIF, but increased with 5 μg/kg of LIF (6.5X) and 15 μg/kg (2X), a pattern mimicking the expression changes in Runx2, confirming Runx2 regulation of RANKL and consistent with increased osteoclastogenesis at higher LIF doses. Taken together, our results suggest that LIF effects in vivo are biphasic, with stimulation of bone formation and remodeling at low doses but inhibition of bone formation and stimulation of resorption at higher doses.

High-throughput Quantification of Femoral Bone Strength in Murine Inbred Strains. G. H. van Lenthe[1], T. Kohler*[1], R. Voide*[1], L. R. Donahue[2], R. Müller[1]. [1]Institute for Biomedical Engineering, ETH, Zurich, Switzerland, [2]The Jackson Laboratories, Bar Harbor, ME, USA.

The gold standard to determine bone strength is experimental biomechanics. However, it has its limitations, as it is a destructive test, laborious, and prone to errors, especially when testing small bones. Therefore, we recently used microstructural finite element (μFE) analysis to determine bone strength directly from bone structure. We have applied this technique to femora of two murine growth-hormone deficient inbred strains (B6-*lit/lit* and C3.B6-*lit/lit*), and found that although having higher bone volume and higher cortical thickness, C3.B6-*lit/lit* had lower femoral strength than B6-*lit/lit* (Table 1).

Phenotypic data on two murine inbred strains [mean(SD), all data p<0.0001]

Location	Parameter		B6-*lit/lit* N=17	C3.B6-*lit/lit* N=19
Whole femur	Total Volume	[mm^3]	17.9 (1.23)	15.9 (1.27)
	Bone Volume	[mm^3]	8.41 (0.87)	9.96 (1.06)
	App.Vol.Dens	[%]	46.9 (2.63)	62.7 (3.62)
Cortex,1 mm slab	Ct.Th	[mm]	0.11 (0.01)	0.21 (0.02)
	Total Volume	[mm^3]	1.08 (0.06)	0.82 (0.06)
Neck	Strength	[N]	2.28 (0.21)	1.87 (0.19)

To further investigate the genetics causing these differences, an F2 population of 2,000 mice was produced. Genetic loci can be identified when genomic markers as well as bone strength have been assessed for all these animals. However, although huge progress has been made in fast acquisition of genomic data, fast characterization of bone strength is not well developed. Therefore, the aim of the present study was to implement high-throughput μFE analyses for bone strength assessment. 100 femora of the F2 population were μCT scanned using a 20 μm resolution. After automated alignment, μFE models were created from which strength was calculated. As expected, we found large variations in strength between femora. Interestingly, the present data suggest that there is a shift towards stronger femora (Fig. 1), indicating that the combination of high bone mass (C3.B6-*lit/lit*) and favorable geometry (B6-*lit/lit*) often works towards a stronger bone. We conclude that high-throughput characterization of murine femoral bone strength is now possible, allowing scanning, morphometric and functional analysis of 70 femora per day, depending on computational resources; it will allow the location of genetic loci directly for bone strength, rather than for surrogate markers of bone strength, such as bone volume or other architectural parameters.

Does Increased Bone Formation Associated to Decreased Adipogenesis Participates to Mechanical Loading-Induced Bone Adaptation? V. David*, M. Lafage-Proust, S. Peyroche*, A. Guignandon*, A. Rattner*, L. Vico. Lbto, Inserm, St Etienne, France.

Osteoblasts and adipocytes develop from common bone marrow mesenchymal precursors. Aging and unloading inhibit bone formation and increase adipogenesis. It is not known whether mechanical loading has the ability to reverse such situation. Pluripotent C3H10T1/2 cells and bovine primary marrow stromal cells, cultured on a permissive osteoblastic and adipocytic medium (DMEM, 10% SVF, 10μg/ml insulin, 0.5mM IBMX, and dexamethasone, ascorbic acid, retinoic acid, at 10^{-8}M) were expended 72 hours on type I collagen-coated-silicone membranes then daily submitted to cyclic strain (10 min, 0.5%, 1Hz; FLEXCELL FX-3000 unit). C3H10T1/2 growth in stretched cells (S) was not affected after 3, and 7 days, and slightly decreased thereafter. After 14 days, osteoblastic markers measured in cell lysates increased in S as compared to non stretched cells (NS): alkaline phosphatase (ALP) activity by 49%, osteocalcin (OC) and Runx2 (sandwich ELISA) by 37% and 63%, respectively. At this time, we observed a 74% decrease in the adipogenic determining factor PPARγ2 (sandwich ELISA). Levels of mRNA were assessed by real time PCR for osteoblastic and adipogenic markers. The expression of Runx2, Msx2 and OC showed dramatic increases after 3 days in S vs. NS (4-fold, 7-fold, and 60-fold, respectively) which lowered thereafter; those for GAPDH, PPARγ2, and cytoplasmic retinoic acid binding protein 1 (CRABP1) decreased after 7 and 14 days (all more than 80%). After 14 days, alkaline phosphatase positive cells (osteoblasts) are more numerous in S than in NS (+18%) whereas the contrary is seen for red oil positive cells (adipocytes) (-46%). As for primary bovine cells, stretch induced cell growth increase during the first 3 days only. After 14 days of stretching, protein evaluation showed that ALP activity and OC increased by 147% and 76%, respectively. After 3 days of stretching, Runx2 increased by 67% then reached NS level. At 14 days, osteoblasts are more numerous in S (+35%). At 14 days, PPARγ2 decreased by 80%, glyceraldehyde-3-phosphate dehydrogenase (GAPDH) decreased by 50 % and adipocytes are less numerous (-65%) in S as compared to NS. We demonstrated that cyclic strain enhances osteoblastogenesis and decreases adipogenesis in vitro suggesting that this reciprocal fate can be manipulated in order to improve bone formation.

Estrogen Modulates Osteoclast Responsiveness To Mechanical Strain By Altering Glutamate Receptor Subtype Expression. K. M. Black*[1], B. Theriault*[2], G. I. Anderson[3]. [1]Pharmacology, Dalhousie University, Halifax, NS, Canada, [2]Surgery, Dalhousie University, Halifax, NS, Canada, [3]Surgery, Flinders University, Adelaide, Australia.

Glutamate receptors (gluRs) of both the ionotropic and metabotropic subytpes are expressed in osteoblasts and osteoclasts of the long bones of rat, rabbit, and mouse. Glutamate receptors are sensitive to mechanical stimulation, a major driving force for the maintenance of bone density. Glutamate signalling in the central nervous system is involved in the processes of learning and memory: we postulate that gluRs mediate mechanical stimulation in bone cells to increase bone density in a manner analogous to their role in mediating CNS synaptic plasticity. In our mixed murine marrow-derived cultures, gluR antagonists MK801 and NBQX inhibit osteoclast differentiation and function, implying that these glutamate receptors are functional. We have also shown by RT-PCR and western analysis that mechanical stimulation appears to decrease the expression of NMDAR1 and NMDAR2B, but increase expression of NMDAR2A, AMPAR1, and AMPAR3. These changes in glutamate receptor subtype expression suggest that mechanical stimulation of osteoclasts appears to precipitate a shift in the balance of ionotropic receptor function from NMDA receptor-mediated pathways (calcium entry, calmodulin kinase II) to AMPA receptor-mediated pathways(sodium entry, MAP kinase). The endpoint effect of this shift is to decrease osteoclast activity to low levels in the presence of mechanical stimulation. Since estrogen levels are known to be important in in vivo bone balance, we wished to characterize the effects of estrogen on gluR mechanosensitivity in our cultured osteoclasts. Bone marrow cells from femora and tibiae of 7-week old female CD1 mice were seeded onto collagen-I coated silastic membranes, and grown for 8 days with mechanical stimulation on days 4, 5, and 6 (1 Hz, 900 cycles) and or 1x10E-6 M 17-beta estradiol doses added on days 1, 4, & 6. Mature osteoclasts were partially purified from harvested cells using anti-RANK coated immunomagnetic beads and total RNA or total protein was isolated. Using RT-PCR, and Northern and Western analyses, we showed that estrogen effects glutamate receptor subtype expression and therefore modulates the sensitivity of osteoclasts to mechanical strain. We did not detect by RT-PCR the expression of estrogen receptor subtype alpha or beta mRNA in osteoclast-enriched fractions that may suggest that the actions of estrogen are mediated either through paracrine signalling from osteoblast-lineage cells or via a non-genomic mechanism directly on osteoclasts. Studies are ongoing to further understand the mechanisms by which estrogen modulates glutamate receptor-mediated mechanotransduction in osteoclasts and ultimately how these mechanisms might contribute to the maintenance of bone density.

Fluid Shear Stress Induces Cyclooxygenase-2 Via Activation of Protein Kinase D in Murine Primary Osteoblasts. M. Mehrotra, C. B. Alander*, O. S. Voznesensky*, L. G. Raisz, C. C. Pilbeam. Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Protein kinase D (PKD), also known as protein kinase Cμ (PKCμ), is a novel serine threonine kinase that is distinct from PKCs in structure and substrate specificity. However, PKD can be activated by phorbol esters in parallel with PKCs or downstream of PKC phosphorylation, and inhibitors of PKCs may also inhibit PKD. PKD has a potentially important role in growth factor and stress-induced signaling pathways, the same pathways that may mediate responses of bone to mechanical loading. Mechanical loading is transmitted to bone cells via the action of fluid shear stress (FSS) on cell surfaces. Cyclooxygenase (COX-2) is induced by FSS in osteoblasts and osteocytes and is thought to mediate some of the anabolic effects of loading on bone. We examined the role of PKD in the FSS induction of COX-2 in primary murine calvarial osteoblasts obtained from CD-1 mice. Cells were obtained by sequential digestion of calvariae. Populations 2-5 were pooled, grown to confluence, and replated on type I collagen-coated glass slides and grown to near-confluence for experiments. Cells were subjected to a FSS of 10 dynes/cm^2 in medium with 1% FCS for 1 h or maintained in stationary culture in the same medium (no flow controls). Induction of COX-2 mRNA was measured by Northern analysis. Treatment with GF109203X (1.25 μg/ml), which inhibits both conventional and novel PKC isoforms and also inhibits PKD at the dose used, reduced the FSS induction of COX-2 mRNA by 60%. Another PKC/PKD inhibitor, Go6976 (1 μM), which inhibits conventional isoforms of PKC as well as PKD at the dose used, reduced the FSS induction of COX-2 mRNA by 50%. However, Go6983 (1 μM), which inhibits conventional, novel and atypical PKC isoforms but does not inhibit PKD at the dose used, had no effect on the FSS induction of COX-2 mRNA. Western analysis was performed using antibodies specific for phosphorylated serine residues Ser744 and Ser748, transphosphorylation sites located in the activa-

tion loop of PKD; antibodies specific for Ser916, the autophosphorylation site located at the C-terminal of PKD; and antibodies for total PKD. PKD was constitutively expressed. Phosphorylation of PKD at both Ser744/748 and Ser916 sites was induced by 40 min of FSS. These data suggest that FSS activates PKD in calvarial osteoblasts and that activation of PKD plays a role in the FSS induction of COX-2.

Fluid Shear Stress Induces RANKL Expression in Primary Osteoblastic Cells. M. Mehrotra, S. K. Lee, M. Saegusa, C. B. Alander*, L. G. Raisz, C. C. Pilbeam. Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Expression of receptor activator of nuclear factor kappa B ligand (RANKL) on osteoblastic cells is critical for osteoclast formation and activity. The activity of RANKL is opposed by osteoprotegerin (OPG), a decoy receptor for RANKL. There is conflict in literature regarding the effects of mechanical forces on RANKL expression. Decreased expression of RANKL has been observed in murine bone marrow stromal cells subjected to biaxial 0.2-2% strain (J Biol Chem 278: 34018, 2003; J Bone Min Res 17:1452, 2002; Am J Physiol Cell Physiol 278: C1126, 2000). On the other hand, continuous compressive forces up-regulated RANKL expression in periodontal ligament cells and this effect was dependent on PGE_2 production (J Bone Min Res 17: 210, 2002). We used a parallel plate flow apparatus to apply laminar fluid flow, equivalent to a fluid shear stress (FSS) of 10 dynes/cm^2, to primary calvarial osteoblasts plated on collagen-coated glass slides and grown to about 90% confluence. Cells were subjected to FSS for 1 h and subsequently cultured under static conditions (post FSS) for varying lengths of time up to 24 h. Because FSS induces cyclooxygenase-2 (COX-2) expression and because this induction results in PGE_2 production that can induce RANKL, experiments were performed in the presence of NS398 (0.1 μM), an inhibitor of COX-2 activity, to block production of prostaglandins. Little or no RANKL mRNA was seen by Northern analysis in control (no flow) cultures, but RANKL mRNA was detectable in these cultures by RT-PCR. RANKL mRNA was induced at 1 h post-FSS, levels peaked at 4 h post FSS and declined thereafter. By real-time quantitative PCR, RANKL mRNA was induced up to 20-fold at 4 h following 1 h of FSS. Five min of FSS was sufficient to induce the expression of RANKL mRNA at 4 h post FSS to the same level as observed 4 h post 1 h FSS. On the other hand 4 h of continuous FSS decreased RANKL mRNA to lower levels than seen in the control cultures. There was little change in OPG mRNA levels under any conditions. On Western blot analysis, RANKL protein was undetectable in no-flow cultures, slightly elevated at 2 and 4 h post 1 h of FSS, and strongly induced at 8 h post FSS. A role of a protein kinase C (PKC) pathway in the FSS regulation of RANKL expression in primary osteoblasts is suggested by the observation that GF109203X (1.25 μg/ml), an inhibitor of the PKC pathway, decreased the FSS induction of RANKL mRNA by 60-90% at 2 h post FSS. We conclude that 1 h of FSS induces RANKL mRNA and protein expression in primary calvarial osteoblasts and that this induction is independent of PGE_2 production and may occur via a PKC pathway..

Activation Of The Mechanosensitive Channel And Intracellular Ca^{2+} Response To Mechanical Stimulation In Osteoblasts Is Regulated By Actin Filament Length. J. Zhang*, J. A. Bethel*, K. D. Ryder*, R. L. Duncan. Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

Osteoblasts respond to mechanical stimulation with a rapid increase in intracellular free Ca^{2+} ($[Ca^{2+}]_i$) that is dependent on activation of the mechanosensitive, cation-selective channel (MSCC). We have recently shown that parathyroid hormone significantly enhances both the $[Ca^{2+}]_i$ response to mechanical stimulation and the activity of the MSCC. Since PTH has been shown to alter the organization of the actin cytoskeleton, we postulated that the effects of PTH on the MSCC and $[Ca^{2+}]_i$ resulted from actin cytoskeletal reorganization. Using both UMR-106.01 and MC3T3-E1 osteoblast-like cells, we examine the effects of disorganizing actin filaments to varying degrees using three actin cytoskeletal poisons; cytochalasin D (cyto D), latrunculin A (lat A) and jasplakinolide (jasplak). Previous studies have shown that cyto D severs actin filaments into short-length chains, but does not alter the insoluble fraction of actin in MC3T3-E1 cells. Lat A increases the solubilized fraction of actin to 68% of total actin while jasplak increases solubilized actin to 98%. Fura-2 Ca^{2+} imaging demonstrated that pretreatment with 1-5 μM cyto D for 30 min significantly increased the peak $[Ca^{2+}]_i$ response to fluid shear or hypotonic challenge approximately 2.5 fold over the peak $[Ca^{2+}]_i$ response to mechanical stimulus alone in either cell type. This increase in peak $[Ca^{2+}]_i$ was similar to that induced by PTH pretreatment and addition of the MSCC blocker, $GdCl_3$, significantly inhibited the $[Ca^{2+}]_i$ response to both PTH and cyto D . Pretreatment for 30 min with 1 μM lat A did not significantly alter the peak $[Ca^{2+}]_i$ response compared to mechanically-stimulated controls. Jasplak (1 μM) produced varied patterns of $[Ca^{2+}]_i$ response to mechanical stimulation. Using patch clamp analyses, we examined the effects of cyto D and lat A on MSCC activity in response to mechanical stimulation in UMR-106.01 cells. We have previously shown that when MSCC's are activated by negative pressure applied to the patch pipette, PTH increases MSCC activity (NP_O) 3.5 fold. This increase was negated when the actin cytoskeleton was stabilized with phalloidin. We found that cyto D produced a similar increase in MSCC NP_O, but that lat A decreased suction-induced MSCC NP_O. These data would suggest that actin reorganization into short-chained actin filaments increases MSCC activity resulting in an increased $[Ca^{2+}]_i$ response to mechanical stimulation, but that more complete disruption of actin filaments reduces these responses. These data also suggest that the synergistic response of PTH and mechanical loading may be mediated through the actin cytoskeleton.

$P2X_7$ Purinergic Receptor Activation Modulates Prostaglandin Synthesis And Release From Osteoblasts In Response To Fluid Shear. D. Liu[1], J. Li[2], C. H. Turner[1], R. L. Duncan[1]. [1]Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

We have shown that ATP is rapidly released from osteoblasts in response to fluid shear stress (FSS), suggesting that purinergic (P2) receptor activation may be involved in mechanotransduction in bone. Recently, $P2X_7$ receptor knockout mice have been shown to be less responsive to mechanical loading than wild type mice. To examine the mechanisms associated with FSS-induced $P2X_7$ activation, we used $P2X_7$ antagonists and antibody to examine changes in the response of MC3T3-E1 osteoblasts to FSS. MC3T3-E1 cells, grown on type I collagen-coated glass slides, were pretreated with $P2X_7$ antagonists for 10-30 min prior to, and during, application of 12 dynes/cm^2 fluid shear. Distinct from other P2 receptors, activation of $P2X_7$ receptors results in insertion of membrane pores capable of conducting large (<900 Da) molecules. We found that 30 min of FSS significantly increased the number of cells that incorporated YO-PRO-1, a 630 Dalton dye (46.9 ± 10. 7%, p<0.001), indicating that a mechanical stimulus causes membrane pore formation. The uptake of YO-PRO-1 was completely blocked by hydrolysis of ATP with apyrase (6.4 ± 4.5%) or with the P2X7 inhibitor, Brilliant Blue G (BBG) (7 ± 3.42%). Activation of P2X7 receptors in static, non-flowed MC3T3-E1 cells resulted in an increase in PGE_2 release, whereas addition of apyrase nearly abolished the FSS-induced increase in PGE_2 release. BBG also significantly reduced PGE_2 release in response to shear. To determine the specificity of the P2X7 receptor in the release of PGE_2, we added antibody against the extracellular domain of this receptor to the cells 10 min prior to flow. PGE_2 release as reduced by 75% (P<0.01) during block of the P2X7 receptor. To determine if COX-2 protein production was affected by ATP signaling, we examined COX-2 production in the presence of apyrase. FSS-induced COX-2 production was decreased by 90% (P<0.01) when extracellular ATP was hydrolyzed. Neutralization of the $P2X_7$ receptor with antibody produced a similar decrease in COX-2. These data indicate that the $P2X_7$ receptor plays an important role in prostaglandin synthesis and release in response to FSS and may be essential for the complete response of bone to mechanical loading.

NO-Dependent Decreased Expression of eNOS Following Pulsatile Fluid Flow. J. L. Picconi, M. L. Johnson. Osteoporosis Research Center, Creighton University Medical Center, Omaha, NE, USA.

Mechanical stimulation of osteogenic cells activates the production of NO that is immediate and sustained throughout stimulation. Previous *in vitro* studies have shown eNOS mRNA to be increased in bone cells in response to mechanical stimulation. Following fluid flow, we found decreased eNOS mRNA levels immediately after the cessation of flow that later increased. We hypothesize this is the result of NO-induced destabilization of eNOS mRNA followed by later increases due to eNOS gene transcription. A major target of NO is guanylate cyclase (GC). Activation of GC increases cGMP production, which is known to downregulate the mRNA stabilizing protein HuR and results in the destabilization of a number of mRNA species. Analysis of the 3' UTRs of human and bovine eNOS mRNAs revealed the presence of conserved elements known to be important in the stabilization in COX-2 and VEGF mRNAs by HuR. 2T3 clonal preosteoblast-like cells were subjected to pulsatile fluid shear stress of 4.0 ±; 0.6 dynes/cm^2 for 2 hours followed by post-flow incubation for 0 to 24 hours. Total RNA was extracted and quantified for eNOS, COX-2, VEGF, and HuR mRNAs by real time PCR. Following fluid flow, eNOS mRNA was immediately decreased to 20% of controls and was increased 4 hours later. Pretreatment with the GC inhibitor methylene blue prevented this flow-dependent decrease, while the NO donor SNP mimicked this response in control cells. Following fluid flow, VEGF and HuR mRNA levels were unchanged from controls, while COX-2 mRNA was increased. Pretreatment with methylene blue in the presence of flow dramatically increased COX-2 and VEGF mRNA levels and mildly increased HuR mRNA levels. From these results, we conclude that the decreased eNOS mRNA levels immediately following fluid flow are the result of flow-induced NO but the mechanism mediating this feedback remains unknown. It is clear, however, that the decrease in eNOS mRNA is not the result of decreased stabilization by HuR. One possibility is this is the result of activation of destabilizing proteins such as AUF1, TTP, or KSRP.

Gene Expression in 2T3 Cells in Response to Fluid Flow

	eNOS Mean (±;SEM)	COX-2 Mean (±;SEM)	VEGF Mean (±;SEM)	HuR Mean (±;SEM)

Biphasic Expression of COX-2 in Response to Pulsatile Fluid Flow. J. L. Picconi, M. L. Johnson. Osteoporosis Research Center, Creighton University Medical Center, Omaha, NE, USA.

The hypothesis of this project is the magnitude of fluid shear stress to which bone cells are exposed determines their osteogenic response. *In vivo* experiments have shown lamellar bone formation in response to moderate mechanical loads that is prevented by pretreatment with COX-2 specific inhibitors. In contrast, exogenous administration of PGE_2 is synergistic in combination with moderate loads for woven bone formation. A biphasic production of PGE_2 or cAMP in primary bone cells subjected to increasing magnitudes of mechanical strain or fluid shear stress was shown in 2 previous studies. To further explore this pattern, clonal 2T3 preosteoblast-like and MLO-Y4 osteocyte-like cells were subjected to fluid flow regimens of 2, 4, 8, 16, 24, or 32 dynes/cm^2 with pulses of 0.6 dynes/cm^2 at a frequency of 5 Hz for 2 hours and then incubated in flow medium for 0 or 24 hours (n=6/group). Total RNA was extracted and COX-2 mRNA quantitated by real time PCR. In response to pulsatile fluid flow, both 2T3 and MLO-Y4 cells demonstrated biphasic induction of COX-2 expression at both 0 and 24 hours post-flow. The magnitude of the first peak was significantly less than the second and occurred over a much narrower range (2-8 dynes/cm^2 in both cell types) than the second peak (16-32 dynes/cm^2 in 2T3 cells and 8-24 dynes/cm^2 in MLO-Y4 cells). These patterns are similar to previous studies and support the hypothesis that the response of osteogenic cells is dependent on the magnitude of stimulation. Additionally, MLO-Y4 cells responded and recovered rapidly to changes in stimulation, while 2T3 cells were still increasing COX-2 expression at 24 hours, supporting the role of osteocytes as the mechanosensors in bone. It is tempting to compare the biphasic expression of COX-2 in bone cells to the lamellar and woven bone formation responses observed *in vivo*, although further studies are needed. Regardless, it is clear that the osteogenic response of bone cells does not follow a linear dose response or logarithmic pattern and this should be considered when interpreting current or future studies.

Protein Kinase C Modulates Mechanical Load-Induced $[Ca^{2+}]_i$ Changes and Prostaglandin E_2 Production in MC3T3-E1 Osteoblasts. V. Fomin, D. Liu, J. Lincoln*, B. Chelladurai*, R. L. Duncan. Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

Osteoblasts respond to mechanical stimulation with a rapid increase in intracellular free calcium ($[Ca^{2+}]_i$) and activation of a number kinase cascades that culminates in prostaglandin-dependent bone formation at the tissue level. Several reports have indicated that protein kinase C (PKC) alters osteoblastic responses to mechanical stimulation leading us to postulate that activation of PKC would enhance the $[Ca^{2+}]_i$ response to load. Using fura-2 loaded MC3T3-E1 preosteoblastic cells grown on glass coverslips, we examined changes in the $[Ca^{2+}]_i$ response when PKC was acutely activated (≤ 10min) with 4β phorbol 12 myristate 13 acetate (PMA). Acute activation of PKC produced a 3.4 fold increase in peak $[Ca^{2+}]_i$ response to hypotonic swelling as well as a significant increase in the rise slope of the response. Inhibition of PKC with 1 μM GF109203X (GFX) for 10 min decreased the peak $[Ca^{2+}]_i$ response below the hypotonic swelling control levels (65% of the control). As in other tissues, we found that chronic PMA (1μM) stimulation for more than 6 hours completely downregulated PKC protein in MC3T3-E1 cells. Interestingly, when PKC levels were abolished with chronic PMA treatment, the peak $[Ca^{2+}]_i$ response and rise slope to hypotonic swelling was again increased (6 and 22 fold, respectively) over hypotonic control levels, suggesting two mechanisms for PKC regulation of this response. Examination of the effects of acute and chronic activation of PKC on prostaglandin production found that acute PKC activation significantly increased arachidonic acid (AA) release in static MC3T3-E1 cells and potentiated the release of AA in response to mechanical stimulation. This increase in AA release by PKC activation was mirrored by release of PGE_2 in both static and fluid sheared (12 dynes/cm^2) MC3T3-E1 cells. Inhibition of PKC with GFX significantly blocked the release of AA and PGE_2 during mechanical stimulation. However, cyclooxygenase-2 (Cox-2) production in response to fluid shear was not enhanced with acute PKC stimulation. These data would suggest that acute PKC activation may be stimulating phospholipases, such as PLA_2, to increase the substrate for prostaglandin synthesis. Chronic downregulation of PKC with PMA also stimulated AA and PGE_2 release, suggesting that the control of the $[Ca^{2+}]_i$ response by PKC is important in prostaglandin release, but that this control may be mediated through two different mechanisms.

A Novel Alginate Carrier System to Evaluate Osteoblast Apoptosis in Vector-averaged Gravity using Rotating Wall Vessels. M. A. Bucaro*[1], A. M. Zahm*[1], M. V. Risbud*[1], P. S. Ayyaswamy*[2], K. Mukundakrishnan*[2], M. J. Steinbeck[1], I. M. Shapiro[1], C. S. Adams*[1]. [1]Thomas Jefferson University, Philadelphia, PA, USA, [2]University of Pennsylvania, Philadelphia, PA, USA.

It has been hypothesized that an elevated rate of osteoblast apoptosis contributes to the osteopenia that occurs during spaceflight, possibly due to a loss of gravitational forces at the cellular level. We have evaluated apoptosis in osteoblasts subjected to vector-averaged gravity using a novel system in which MC3T3-E1 osteoblast-like cells are encapsulated in alginate carriers and cultured in a high aspect ratio vessel (HARV). The encapsulated cells retained a well defined osteoblast phenotype in static culture, maintaining expression of osteopontin and osteocalcin and exhibiting increased expression of Runx2/Osf2 relative to cells cultured on tissue culture plastic. Two types of carriers that could be co-cultured in the HARV were developed to ensure that the effects observed in simulated microgravity were not due to shear stresses or other factors characteristic of the HARV culture system: "nonpolar" carriers that spun with the HARV's rotation, were used to expose cells to vector-averaged microgravity, and "polar" carriers that remained vertically oriented throughout the HARV's rotation served as controls. Video microscopy of the carriers in the HARV confirmed that the polar carriers maintained a stable vertical orientation (unit gravity) while nonpolar carriers underwent clinorotation, exposing cells to time-averaged gravitational accelerations of 0.99g and 0.05g, respectively. To determine if simulated microgravity induced osteoblast apoptosis, MC3T3-E1 cells in polar and nonpolar carriers were cultured together in the same HARV at 3/15 rpm for 24 h, and then sorted. In contrast to other studies which used cells in static culture as unit gravity controls, no difference in viability was detected between cells cultured in the polar and nonpolar carriers. Furthermore, we investigated the hypothesis that cells exposed to vector-averaged gravity would exhibit increased sensitivity to apoptosis when treated with staurosporine, relative to control cells. While our results using static culture controls indicated that vector-averaged gravity sensitized the cells to apoptosis, we consistently found no difference in viability using the polar and nonpolar carriers. We conclude that the use of alginate carriers in the HARV is an optimal system for evaluating apoptosis of osteoblasts in simulated microgravity. Moreover, the use of polarized carriers accounts for the unique environment of the HARV, providing a tightly controlled system for evaluating the direct effects of vector-averaged gravity on cellular behavior.

High Salt Intake Promotes Urinary Loss of Vitamin D Metabolites by Dahl Salt-Sensitive Rats in a Space Flight Model. M. Thierry-Palmer[1], S. Cephas*[1], P. Sayavongsa*[1], T. Cleek*[2], S. B. Arnaud[3]. [1]Biochemistry, Morehouse School of Medicine, Atlanta, GA, USA, [2]Life Sciences Division, NASA Ames Research Center, Moffett Field, CA, USA, [3]Life Sciences Division, NASA Ames Research Center, Moffett Field, CA, USA.

Vitamin D metabolism in the Dahl salt-sensitive (S) rat, a model of salt-induced hypertension, differs from that in the Dahl salt-resistant (R) rat. We have demonstrated that female S rats are more vulnerable than female R rats to decreases in plasma 25-hydroxyvitamin D (25-OHD) and 1,25-dihydroxyvitamin D (1,25-$(OH)_2$D) concentrations during hind limb unloading (a space flight model). We report here on the response of the vitamin D endocrine system of S and R rats to hind limb unloading during high salt intake. Dahl female rats (2.4-month-old) were tail-suspended (hind limb unloaded) for 28 days, while fed a diet containing twice the salt in standard rat chow (2 % sodium chloride). Control rats were fed the same diet, but were not hind limb unloaded. Vitamin D metabolites were analyzed by HPLC and radioimmunoassay kits from Diasorin. Significantly higher amounts of 25-OHD ($P < 0.001$) and 24,25-$(OH)_2$D ($P < 0.05$) were excreted into urine by S rats, compared with R rats, and excretion by S rats was increased by hind limb unloading ($P < 0.05$). The consequence was lower plasma concentrations of these two metabolites in S rats than in R rats ($P < 0.05$). Plasma parathyroid hormone concentration was twice that of rats fed a low salt diet (0.3 %) in previous experiments and was similar in all four groups of rats. Urinary calcium was increased ($P < 0.001$) by salt sensitivity. Urinary 25-OHD binding activity and protein of S rats were greater ($P < 0.001$) than that of R rats and were increased by hind limb unloading of S rats ($P < 0.05$). These data suggest that plasma 25-OHD and 24,25-$(OH)_2$D concentrations of S rats are lower that that of R rats during hind limb unloading, because of urinary excretion of protein-bound vitamin D metabolites. Urinary 25-OHD, 25-OHD binding activity, and protein were increased by hind limb unloading of S rats during 2 % salt intake, but not during 0.3 % salt intake (earlier study). This suggests that low salt intake can prevent the increased urinary loss of vitamin D metabolites by S rats that is related to hind limb unloading.

Loss of Myostatin (GDF8) Function Attenuates the Osteogenic Response Observed with Exercise. M. Hamrick[1], C. Pennington*[1], C. Byron[1], D. Xie[2], C. M. Isales[2]. [1]Cellular Biology & Anatomy, Medical College of Georgia, Augusta, GA, USA, [2]Institute of Molecular Medicine & Genetics, Medical College of Georgia, Augusta, GA, USA.

Mice lacking myostatin (GDF8) show a significant (40-100%) increase in muscle mass compared to normal mice, and our previous research also indicates that these mice have significantly greater bone mineral density (BMD) in their femora compared to normal mice. The goal of this study was to determine if BMD in exercised normal mice is comparable to that of sedentary myostatin-deficient mice. We also sought to determine if exercise

further increased BMD in myostatin-deficient animals beyond that observed in exercised normal mice. We exercised 12 week-old female normal and myostatin-deficient mice (n=12 per group) for 30 minutes a day, 5 days per week, for four weeks. Mice were run on a motorized treadmill at a speed of 12 m/min. Whole-bone mineral content and density were measured in the femur using DEXA (PIXImus system) and cross-sectional slices from the femur midshaft and metaphysis were taken using pQCT. Results indicate that quadriceps muscle mass did not increase significantly in either group of exercised mice compared to sedentary controls. Exercised wild-type mice show significantly greater periosteal expansion, measured as periosteal circumference, at both the midshaft and metaphysis (+15%, P<.01) compared to exercised myostatin-deficient mice. The increase in bone size with exercise in the normal mice is mostly in the mediolateral direction, so that the area (*Iyy)* and polar (*J)* moments of inertia are significantly (20%, P<.01) greater in the exercised wild-type mice. Furthermore, exercised wild-type mice show significantly greater (20%, P<.01) trabecular BMC and BMD at the metaphysis than exercised myostatin-deficient mice. These data suggest that mice lacking myostatin may be less responsive to the effects of exercise than normal mice. Furthermore, these data indicate that the positive effects of regular exercise on bone mass and density are not necessarily dependent upon marked increases in muscle mass.

Estrogen and an ERα Agonist Suppress the Osteogenic Response to Exercise. L. K. Saxon*, C. H. Turner*. Orthopaedic Surgery, IUPUI, Indianapolis, IN, USA.

It is well established that exercise has the potential to increase bone density and strength. It has been proposed that estrogen enhances the osteogenic response to exercise, particularly through estrogen receptor α (ERα). The aim of this study was to determine the combined effect of exercise and estrogen or PPT (an ERα agonist) on bone formation. Forty-three young (8 wks) male Sprague-Dawley rats were randomized to one of following groups: 1) high dose 17-α ethynylestradiol (High EE_2), 2) low dose 17-α ethynylestradiol + mechanical loading (Low EE_2), 3) propyl pyrazole triol + mechanical loading (PPT), 4) vehicle treated + mechanical loading (control) or 5) baseline control. Low EE_2 was selected to undergo mechanical loading because this dose closely reflects physiological levels of serum estrogen. An axial load was applied to the right ulna for 120 cycles, at 17N, 3 days/wk for 5 weeks. Calcein labels were given on days 5 and 12 of the experiment allowing histomorphometric measurement of bone formation rates of the midshaft ulnae. At the end of the 5 week intervention, High EE_2 and PPT showed reduced gains in body weight, longitudinal growth and cortical area ($p<0.05$). In contrast, High EE_2 also increased trabecular vBMD at the lumbar spine and distal femur ($p<0.05$) but PPT did not. Five weeks of mechanical loading increased cortical area and polar moment of inertia (Ip) in the control group, and only partially increased cortical area in the Low EE_2 and PPT groups. Exercise increased BFR/BS of the loaded ulna, however the response was reduced in the Low EE_2 and PPT groups versus controls (Figure 1). In conclusion, High EE_2 inhibits gains in longitudinal growth and cortical area, but also increases trabecular bone density. When combined with exercise, Low EE_2 and PPT decrease the osteogenic response to exercise by inhibiting periosteal bone formation.

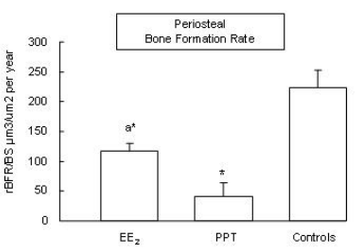

Figure 2. The effect of exercise and Low EE_2, PPT or vehicle (control) treatment on periosteal bone formation rate (loaded verus nonloaded ulna) after 1-2 weeks of mechanical loading in growing male rats. *p<0.05 vs controls, a p<0.05 vs PPT

Three-Dimensional Mandible Bone Architectures Simulated by a Reaction-Diffusion Bone Remodeling Model. K. Tezuka[1], T. Takeda*[1], Y. Wada*[2], A. Takahashi*[2], M. Kikuchi*[2]. [1]Dept. Tissue and Organ Development, Gifu University Graduate School of Medicine, Gifu, Japan, [2]Dept. Science and Technology, Tokyo University of Science, Noda, Japan.

Bone is a complex system with adaptation and repair functions. Therefore, simulation of bone remodeling under various mechanical conditions will be very useful to understand patho-physiological state of bone from structural information. To understand how bone cells can create a structure adapted to the mechanical environment, we proposed a simple bone remodeling model, iBone, based on a reaction-diffusion system (JBMR 2003, vol. 18 suppl. 2, pp. S220). To analyze three-dimensional models, we constructed a PC cluster system with 11 Pentium4 desktop computers, and adapted finite element analysis and reaction-diffusion softwares for parallel computation. A three-dimensional mandible bone model consisting of approximately 1.4 million elements was constructed from sequential CT images of a 14-year old female. Both teeth and bone were modeled with isoparametric voxel elements with Young's Modulus = 20GPa and Poisson's ratio = 0.3. Both heads of mandible were fixed allowing rotation and horizontal movement. Teeth were fixed vertically allowing horizontal movements. Incisor, right or left group, and right or left molar biting conditions were simulated by fixing corresponding teeth. The locations and directions of masseter, temporalis, and medial pterygoid muscles, and their muscle forces were predicted from the CT images. Remodeling simulation was performed by 10 sets of finite element analysis, reaction-diffusion calculation, and remodeling simulation to obtain internal structure adapted to each loading condition.

As a result, major part of the corpus of the simulated mandible bone showed similar internal structures under different biting conditions. Moreover, these simulated structures resembled that of real mandible bone. On the other hand, some regions of the simulated bone, for example mentum, showed different shape under each biting condition, and any single loading condition could not give the real bone structure. These results suggest that part of the internal structure of mandible bone can be simulated by relatively simple modeling method and remodeling simulation. However, some regions which shows different shapes under different loading conditions will require combination of multiple conditions for shape simulation.

Does Marathon Training Influence Calcaneal BUA. I. P. Drysdale, H. J. Hinkley*, D. Bird*, N. J. Walters*. British College of Osteopathic Medicine, London, United Kingdom.

Physical activity has been shown to be associated both positively and negatively with bone mineral density. Marathon running requires the athlete to participate in strenuous activity if they are to complete the 26.2 mile distance. The purpose of this study was to determine the BUA of the calcaneus of participants in the 2004 Flora London Marathon and make comparisons with age matched normative data from a population of non-marathon runners. Caucasian athletes (n=408) aged 18-75 gave informed consent for ultrasound (McCue CUBA Clinical) determination of BUA of the calcaneus. Prior to running in the marathon, duplicate readings were made of right and left BUA of both calcanei. Participants also completed a questionnaire in order that their recent training history could be evaluated. We have previously reported age categorised normative data for males and females aged 20-75 years. Statistical differences (t score,% males=6.2; females=&7.3 in a two-tailed t-test, $p<0.0001$) were observed between the marathon runners and normative data for both males and females. When the age grouped data from this study were compared with normative data using one-way ANOVA, significant differences ($p<0.01$) were observed in the 40-49 and 50-59 years of age groups for both male and female subpopulations with mean BUA being higher in all marathon runners independent of age or gender. The data for BUA was split at the 4 hrs completion time threshold (at ~9min/mile pace) and an unpaired two-tailed t-test performed which showed significant difference ($t=2.9$;$P<0.0035$). It is suggested that those who train and complete a marathon at moderate, or better, running pace intensities display a higher BUA than those who train and complete at a slower pace.

Retired Collegiate Artistic Gymnasts Retain Higher Bone Mass: A 10-Year Follow-Up. N. K. Pollock*, E. M. Laing, R. D. Lewis. Foods and Nutrition, The University of Georgia, Athens, GA, USA.

Fifteen years after cessation of the sport, we found that retired collegiate artistic gymnasts (GYM; n=18) had higher measures of areal bone mineral density (aBMD; g/cm^2) at all skeletal sites compared to nongymnast controls (CON; n=15) of similar age (years), height (cm) and body weight (BW; kg). It is unknown, however, if the aBMD differences in GYM and CON observed at that time are maintained into the years approaching menopause. A 10-year follow-up study was conducted to compare aBMD in GYM (n=16; age=44.8± years) and CON (n=13; age=44.2 years) and the changes over time. Total body fat mass (kg), percent fat (%FAT), fat-free soft tissue (FFST; kg) and aBMD of the total body, lumbar spine, non-dominant proximal femur (PF), femoral neck and Ward's triangle were assessed using dual-energy X-ray absorptiometry (DXA; Hologic QDR-1000W). Past physical activity was estimated using a self-report, study-designed questionnaire. Independent samples *t*-tests were employed to compare aBMD in GYM and CON at baseline and at the 10-year follow-up. Analysis of covariance was used to compare the changes (Δ) in aBMD between GYM and CON and to quantify the magnitude of the effects (i.e., partial eta-squared; η^2; where 0.06 and 0.13 are medium and large effects, respectively). GYM had significantly lower BW, fat mass and %FAT ($p<0.05$; $\eta^2>0.14$), and higher measures of FFST/BW and aBMD at all skeletal sites compared to CON ($p<0.05$; $\eta^2>0.14$) at both time points. Over time, changes in GYM and CON did not differ significantly with respect to BW ($p=0.12$; $\eta^2=0.09$), %FAT ($p=0.92$; $\eta^2<0.01$), or aBMD at any skeletal site ($p>0.05$; $\eta^2<0.08$), except the PF, where CON had greater gains than GYM (3.27 ± 2.45% vs. -3.22 ± 1.57%; $p=0.03$; $\eta^2=0.16$). CON also had greater gains in FFST than GYM (8.68 ± 1.80% vs. 3.22 ± 0.92%; $p=0.01$; $\eta^2=0.23$). When controlling for changes in FFST, statistically significant differences in PF aBMD between groups no longer existed. There were no significant differences in the total minutes of physical activity per week reported over the past 10 years between groups. In conclusion, the higher aBMD observed in GYM compared to CON fifteen years after the cessation of the sport, was maintained over the following 10 years. While loading activity in GYM is clearly less than when competing, it is possible that a minimal defined level of physical activity is needed in the years following retirement to sustain the high aBMD.

Marrow and Bone Responses in the SAMP6 Osteoporotic Mouse Following *in vivo* Mechanical Loading. M. D. Brodt*, M. Ko*, W. J. Hucker*, M. J. Silva. Orthopaedic Surgery, Washington University, St. Louis, MO, USA.

Senile osteoporosis is characterized by low rates of bone formation. A contributing factor may be an age-related reduction in skeletal responsiveness to mechanical loading, perhaps due to a reduced ability of the marrow to support osteogenesis. The senescence accelerated mouse SAMP6 is a model of senile osteoporosis with reduced marrow osteogenic potential and endocortical bone formation (vs. control SAMR1 mice). Our aim was to characterize the mechano-responsiveness of SAMP6 mice by assessing marrow and endocortical osteogenesis after increased mechanical loading *in vivo*. Male SAMP6 and SAMR1 (control strain) mice (4-5 mo) were subjected to three-point tibial bending. Prior to *in vivo* experiments, finite element models of tibias were generated from μCT scans and used to simulate bending. The predicted ratio of peak endocortical:periosteal strain was 0.6 for both SAMP6 and SAMR1. Strain gages were used to record periosteal strains for 4-24 N bending force (n = 6). From the combined data we estimated the forces to produce 1000 and 2000 microstrain (με) on the endocortical surface at the mid-shaft. Due to their larger size, SAMP6 tibiae require 20% higher force vs. SAMR1. Right tibiae of anesthetized mice were then loaded daily for two weeks using a rest-inserted protocol (60 cycles/day, 10 s rest interval); left tibiae (contralateral control) were not loaded. Calcein was injected on days 5 and 12; mice were killed on day 15. Bone marrow cells were cultured under osteogenic conditions and stained for alkaline phosphatase (ALP) and alizarin red on days 14 and 28. There were no significant changes in ALP or alizarin staining in cultures from loaded limbs vs. controls ($p > 0.05$), indicating that bending did not increase the osteogenic potential of the marrow. Based on histomorphometry, SAMR1 mice exhibited a dose-response, with increases in the relative values of bone formation indices in proportion to endocortical strain (Table). In contrast, SAMP6 osteoporotic mice did not exhibit a dose-response and were less responsive than SAMR1 in terms of double-labeled bone surface and mineral apposition rate ($p < 0.05$). In conclusion: 1) SAMP6 osteoporotic mice have impaired responsiveness to loading, 2) tibial bending *in vivo* does not upregulate the *in vitro* osteogenic potential of the bone marrow, which suggests that it acts primarily on mature osteoblasts.

Transient Muscle Paralysis Rapidly Induces Bone Loss in Mice. S. E. Warner[1], D. A. Sanford*[1], B. A. Becker*[1], S. D. Bain[2], C. Lin*[2], H. C. Zheng*[2], S. Srinivasan[1], T. S. Gross[1]. [1]Orthopaedics & Sports Medicine, University of Washington, Seattle, WA, USA, [2]SkeleTech, Inc, Bothell, WA, USA.

A murine model in which bone loss was primarily achieved by bone resorption would hold substantial potential for elucidating the role of mechanical stimuli in the maintenance of bone mass. Given the integral role of muscle action in mechanical loading of the skeleton, we therefore hypothesized that transient hindlimb muscle paralysis would rapidly induce bone loss in the mouse. To test this hypothesis, we developed a murine model of disuse in which hindlimb extensor muscle action was transiently paralyzed via intramuscular (IM) injections of Botulinum neurotoxin type A (Botox). Twenty female C57B6 mice (16 wk) were randomized into four groups (n=5 each): 1) 3 wk Botox, 2) 3 wk saline, 3) 6 wk Botox, and 4) 6 wk saline. At day zero all animals received IM injections of either saline or Botox in both the calf and quadriceps of the right leg. The 6 wk mice received a second injection on d 21. Calcein was injected 8 and 2 d prior to sacrifice. Alterations in tibia metaphyseal trabecular bone (0.8 mm volume distal to the growth plate) and cortical bone (1 mm volume centered 1.7 mm proximal to the tib-fib junction) were assessed by micro-CT. Static and dynamic histomorphometry was then performed at the metaphyseal site. Differences are presented as a percent of saline control values. Botox treatment significantly diminished both calf (3 wk: -54%, 6 wk: -64%) and quadriceps (3 wk: -34%, 6 wk: -62%; all $p < 0.001$) wet weights. Trabecular BV/TV loss observed by 3 wk (-33%) progressed to a near total removal of trabeculae by 6 wk (-80%, $p < 0.001$), which was achieved mostly by trabecular thinning (3 wk: -20%, $p < 0.01$; 6 wk: -27%, $p < 0.001$). Cortical bone volume was significantly reduced at both 3 wk (-9%, $p < 0.01$) and 6 wk (-22%, $p< .001$), primarily via endocortical expansion (3 wk: +12%, 6 wk: +23%, $p < 0.01$) as periosteal volume was unchanged (3 wk: 0.4%, 6 wk: -5.0%). Trabecular osteoclast surface was elevated (+55%), but bone formation rate (BFR) was not (+1%). By 6 wk, both osteoclast surface (-25%) and BFR (-16%) were reduced in Botox mice. We conclude that our model demonstrated rapid muscle atrophy and bone degradation, with the bone loss achieved primarily via osteoclastic resorption. It is likely that the transient muscle paralysis induced by Botox altered both low magnitude, high frequency strains typically induced by muscle and higher magnitude, lower frequency strains induced by joint contact during gait. As such, this model holds substantial promise to enable mechanistic exploration of fundamental, yet poorly understood, interactions between muscle and bone.

Bone Size and Strength Is Related to Long-Term Impact Sports Participation in Older Men. R. M. Daly, S. L. Bass*, S. Kukuljan*. School of Exercise and Nutrition Sciences, Deakin University, Melbourne, Australia.

Lifetime loading history is thought to be a significant determinant of bone strength in old age. However, little is known about the effects of long-term participation in impact sporting activities during different stages of the lifespan on bone strength in older adults. Thus, we asked in men aged 50+ yrs (61.3 ± 7.4 yrs), does participation in moderate-high impact sports during adolescence and/or adulthood enhance bone strength? We assessed FN, L2-4, and UD radial BMD by DXA (n=159), and femoral mid-shaft total (ToAr), cortical (CoAr) and medullary area (mm^2), and the polar moment of inertia (Ip, mg/cm) by QCT (n=105). Current (50+ yrs) and past hours of sports participation during adolescence (13-18 yrs) and adulthood (19-50 yrs) were assessed by questionnaire. Because load magnitude and frequency are more important than duration for stimulating an osteogenic response, an osteogenic index (OI) for mod-high impact sports was then calculated for each participant at each time period by adapting the formula developed by Turner and Robling (Ex Sports Sci Rev 31:45-50, 2003). Regression analysis was used to examine the relationship between each bone trait and the OI after adjusting for age, height, weight, smoking, calcium and alcohol intake, and lifetime non-low impact sports activity (hours). A greater lifetime OI (13-50+ yrs) was associated with a greater femoral ToAr (adj. ß ± SE; 0.50 ± 0.21, $p<0.05$), CoAr (0.32 ± 0.17, $p=0.06$), and Ip (1.19 ± 0.46, $p<0.05$). Similarly, a greater OI in adulthood (19-50 yrs) was related to greater femoral ToAr, CoAr and Ip ($p<0.05$), but no association was found between adolescent (13-18 yrs) OI scores and bone size or strength. Furthermore, no relationship was detected between OI scores at any time with DXA BMD at any site. Subjects were then categorised into either a high (H) or low/non-impact (L) group according to their OI scores in adolescence and adulthood. Four groups were then formed to reflect impact categories during adolescence and adulthood: LL (n=28), LH (n=7), HL (n=40) and HH (n=32). Regression analysis revealed that compared to the LL group, femoral ToAr and Ip were 7-14% ($p=0.05$) higher in the HH and 11-21% ($p<0.01$) higher in the LH group of older men. No significant differences were detected between the LL and HL groups; nor were there any differences between groups for DXA BMD. In summary, lifetime participation in impact sports was a determinant of bone size and strength (not BMD) in older men. We conclude that: 1) regular impact loading in men led to an increase in bone strength due to an increase in bone size and not BMD, and 2) continued participation in weight-bearing impact exercise throughout life is important for reducing the risk of low bone strength in old age.

Differences in DXA Body Composition Observed in Active and Inactive Populations. C. Maes*[1], B. Jacobs*[1], A. Ferdinande*[2], S. Poriau*[2]. [1]Medical Centre for Sports, Business and Related Research MENSANA, Sijsele-Damme, Belgium, [2]Locomotorisch Centrum, Sijsele-Damme, Belgium.

While the value of total body BMD as measured by DXA is well recognized, less is known of the assessment of fat and lean soft tissue from these measurements. Differences in total fat as well as regional fat distribution between men and women, and between athletes and non-athletes, may provide insight to physiological changes with age, disease, or fitness programs. In this study we examined if there are differences in fat mass distribution as a function of the level and type of sports activity.

Total body DXA measurements of 348 men and 80 women were performed on the Lunar Prodigy (GE Healthcare). Body composition results for total body, android (A), and gynoid (G) regions (figure), as well as the A/G fat ratio were calculated automatically by the software. In some obese subjects manual adjustment of android and gynoid regions was necessary. Subjects who didn't participate in sports were defined as inactive while active subjects participated in sports.

The average percentage of total body fat (% TB Fat) for the 80 women was 28.5 ± 8.6% while the average A/G fat ratio was 0.73 ± 0.20. For the 348 men the average % TB Fat was 17.4 ± 8.2% while their average A/G fat ratio was 1.06 ± 0.27. Inactive men had significantly higher %TB Fat (23.4%) compared to men who were active in sports (18.9%, $p<0.005$) while the A/G fat ratio was not significantly different. Significant differences in %TB fat ($p<0.001$) were also observed when comparing the different types of sports (running, biking, mountain biking, duathlon, triathlon , fitness and survival) while there was again no significant difference ($p = 0.17$) for the A/G fat ratio. Percent TB fat of male professional athletes (14.7%), amateur competitors (17.4%) and recreational sports enthusiasts (20.6%) were significantly different ($p < 0.001$). Although there was no difference in A/G fat ratio between professionals and amateur competitors, the recreational sports men had a significantly higher A/G fat ratio ($p = 0.001$).

In conclusion, we observed a significant difference in %TB fat between active and inactive male subjects, but the A/G fat ratio showed no differences. In active men, % TB fat was significantly different depending on type and level of sports; and the A/G fat ratio was significantly higher in men participating in recreational vs. competitive sports.

Level of Physical Activity and Vitamin D Modify the Effectiveness of Calcium Supplementation in Bone Mass Accrual during Rapid Growth: A 2-year Randomized Trial. S. Cheng[1], A. Lyytikäinen[1], Q. Wang*[1], M. Alen*[2], H. Suominen[1], A. Koistinen*[3], R. Korpela*[4], C. Lamberg-Allardt[5], H. Kröger[6]. [1]Jyväskylä Univ, Jyväskylä, Finland, [2]PEURUNKA, Jyväskylä, Finland, [3]Central Hospital, Jyväskylä, Finland, [4]Valio, Helsinki, Finland, [5]Helsinki Univ, Helsinki, Finland, [6]Kuopio Univ, Kuopio, Finland.

This two-year double-blind (dairy was blind for researchers), placebo-controlled and randomized trial (the CALEX-study) was to evaluate whether vitamin D (VD) supply and level of physical activity (PA) modify the effectiveness of calcium (Ca) supplementation on bone mass accrual during rapid growth. Normal healthy girls aged 10-12 years (n=195) at Tanner stage I-II with dietary Ca intake <900 mg/day were first stratified into two groups by their PA level and then randomly assigned into four groups: 1) Placebo (Ca and VD pla, Pla, n=48); 2) 1000 mg Ca carbonate + 5µg VD daily (Ca+VD, n= 49); 3) 1000 mg Ca carbonate daily + VD pla (Ca, n=49); 4) 1000 mg Ca from dairy products (mainly low fat cheese, Che, n=49). Altogether 159 girls completed the trial. Bone mineral content (BMC), bone area (BA) and area bone mineral density (BMD) of the total body (TB), femoral neck and lumbar spine were assessed using DXA (Prodigy, GE Lunar). There were no significant differences among the groups at baseline in any of the variable studied. The compliance in taking the supplements was 70%, 74%, 64% and 72 % for Ca and 76 % for active VD, respectively. Girls in the Che group gained on average 3% more BMC of the TB than other groups. However, after adjusting for growth speed using multilevel analysis, no significant difference in bone gain was found at any measured bone site between the intervention groups. While girls with high initial level of PA had consistently higher BMC and BMD in all measured bone sites after adjusting for growth speed. At the menarche, the high PA group were on average 176 g higher in BMC of the TB than the low PA group ($p<0.01$). No significant difference was found in BA between the low and high PA groups. When comparing the percentage change over the two-year period between low and high PA within the intervention groups (controlled for baseline), we found that in the Ca+VD group, those with high PA gained 1.1% more BMC of the TB than those with low PA, but the difference did not reach statistic significance. On the contrary, girls with high PA in the Ca, Che and Pla groups gained less compared to the low PA girls (-3.4%, -5.7% and 1.4%, respectively). Our results indicate that during the rapid growth period, Ca intakes exceeding 800 mg/day (diary or tablets) has no significant effect on bone mass accrual. Vitamin D plus high physical activity may, however, modify the effectiveness of calcium supplementation on bone mass accrual during rapid growth.

Relationship Between Daily Impacts and BMD. T. J. Jämsä*[1], A. Vainionpää*[1], R. Korpelainen*[2], E. Vihriälä*[1], A. Rinta-Paavola*[3], J. Leppäluoto*[4]. [1]Department of Medical Technology, University of Oulu, Oulu, Finland, [2]Oulu Deaconess Institute, Oulu, Finland, [3]Newtest Ltd, Oulu, Finland, [4]Department of Physiology, University of Oulu, Oulu, Finland.

Osteoporosis has become one of the major health problems in developed countries. It has been suggested that regular exercise, especially high-impact activities, contributes to development of high peak bone mass and deceleration of bone loss. However, there have been no quantitative data on the exercise needed for strengthening bone. Here we studied the effect of daily impacts at different acceleration levels on BMD. We performed a population-based randomized intervention study with 80 women (35-40 years). The subjects carried an activity monitor (Pat.WO03/055389A1, Newtest Ltd, Oulu, Finland) daily for 12 months for individual quantification of their daily physical activity. Half of the subjects were assigned to an exercise group with high-impact exercise training, while the others continued their normal life. The average number of daily impacts was defined at 33 acceleration levels from 0.3g to 9.9g. The numbers were normalized by the mean values of the controls and analysed in four acceleration regions, 0.3-1.7g, 1.9-3.3g, 3.6-5.7g and 6.1-9.3g. The relationship between the physical activity data and percentage changes of different bone parameters were evaluated using linear regression analysis, adjusted for percentage weight change, smoking and calcium intake. The BMD change was related to the physical activity data. The relative number of daily impacts at the acceleration levels of 3.6-5.7g and 6.1-9.3g had a significant relationship with femoral BMD, accounting for up to 20% of the annual change in BMD. The calcaneal ultrasound measurements showed a significant exercise-induced increase in speed of sound (SOS) and quantitative ultrasound index (QUI) even at the low acceleration levels, while broadband ultrasound attenuation (BUA) was correlated only with the number of high-acceleration impacts. We conclude that the acceleration level of daily impacts is a significant determinant of the changes in BMD.

Correlation coefficients between BMD change and number of daily impacts at different g levels.

Characteristics of Mechanical Strain Engendered in the Rodent Femur by Planar Orbital Shaking and Hindlimb Suspension. D. J. Adams, D. K. Sung*. Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA.

A new noninvasive rodent model of skeletal loading, planar orbital shaking, has been reported to stimulate immature osteoblasts in the mouse skeleton. To characterize the magnitudes and temporal features of skeletal loading engendered in rodents by orbital shaking relative to physiologic activities, uniaxial mechanical strain gages with a sensing grid of 0.15 mm^2 were bonded to the anterolateral surface of the femur mid-diaphysis in adult Sprague-Dawley rats. Strain signals were recorded during volitional wheel running and cage activities to provide comparisons to physiologic loads, and with the animals' hindlimbs unloaded via tail suspension as a comparison to disuse. The animals were also subjected to in-plane orbital shaking at incremental speeds up to 220 rpm, using a laboratory shaker with a ¾-inch diameter circular path. Videographic archival of all activities provided for matching strain signals to specific activities involving the instrumented femur. Strain magnitudes, strain rates, and dynamic frequencies were compared between volitional activities, hindlimb suspension, and orbital shaking. Longitudinal strain magnitudes recorded on the anterolateral surface of the femur ranged up to 200-300 microstrain (με), corresponding closely to strain magnitudes measured at this femoral site in other rat studies. Volitional wheel running produced the largest femoral strain magnitudes among physiologic activities (127 ± 29 με), demonstrating characteristic footstrike frequencies of approximately 2 Hz. Strain magnitudes engendered by orbital shaking increased with orbital velocity in an exponential manner ($p<0.05$, $R^2=0.96$), and reflected the characteristic frequency of orbital velocity from 0 to 220 rpm (i.e., only one pulse of mechanical strain per revolution). However, maximum strain amplitudes associated with orbital shaking at 220 rpm (85 ± 34 με) did not exceed those for volitional wheel running. Strain magnitudes were negligible during hindlimb suspension when the animals remained stationary, but were substantial when the animals forcefully moved their freely suspended hindlimbs (50-100 με). These results suggest that planar orbital shaking engenders mechanical signals on the anterolateral femur that are not larger in magnitude than those associated with physiologic activities. Surprisingly, exertions of suspended hindlimbs were sufficient to cause substantial strain magnitudes, suggesting that the tail suspension model may not provide a temporally uniform model of disuse as is often assumed.

Inbred Mouse Strains Exhibit Variations In The Skeletal Adaptive Response to 4-Point Bending: Evidence For Involvement Of Different Genetic Mechanisms. C. Kesavan*, D. J. Baylink, J. E. Wergedal, S. Mohan. JLP VAMC / Loma Linda Univ Dept Med, Loma Linda, CA, USA.

A fundamental feature of skeletal tissue is its adaptive response in the amount of bone tissue present and the configuration of this tissue in response to mechanical loads. The present study was undertaken to test the hypotheses that: 1) different inbred strains of mice would show variable responses to a given mechanical load; and 2) within these mouse strains, the mechanisms involved in these adaptive interactions to mechanical loads would be variable. We compared bone anabolic response to 4 point bending in four different, commonly used inbred strains of mice (C57BL/6J [B6], DBA, C3H/HeJ [C3] and Balb/c). A 9N load (except for Balb/c in which 8N was used since 9N caused fractures) at 2Hz for 36 cycles was applied for 12 days on right tibia and left tibia was used as internal control. Two days after last loading, skeletal changes were evaluated by pQCT. A dramatic 15.7% and 10.8% increase in total vBMD ($P<0.0001$) was seen in C57BL and DBA mice after 12 days of loading. While vBMD increased by 3% ($P<0.05$) in Balb/c, no increase in vBMD was seen in C3H mice (-0.5%) after the same duration of training. We subsequently performed dose response studies (6, 7, 8 and 9 N load) using B6 as good responder and C3H as poor responder strain. While 4 point bending caused a dose-dependent increase in BMD in B6, it did not cause a BMD increase in C3 mice at any of the four loads tested. The lack of BMD response in C3H mice cannot be explained on the basis of differential mechanical strain since strain gage measurements revealed a slightly higher mechanical strain in C3 mice compared to B6 mice at all four loads tested. 4 point bending increased endosteal circumference in a dose-dependent manner in both B6 and C3 mice in a similar manner with no difference in slopes (B6=y:5.891x -34.44,C3H- y:5.859x -32.44,$p>0.05$). On the contrary, the increase in periosteal circumference in response to 4 point bending was greater in B6 mice compared to C3 mice (B6=y:5.3x-29.58, C3H=y:2.98x-14.23, $p<0.05$). Conclusions: 1) the increase in BMD by 4-point bending is variable in four strains tested, from no response to 15.7% increase in BMD after 2 weeks; 2) in B6 mice, 4 point bending increased both periosteal and endosteal circumference in a dose-dependent manner; 3) in C3 mice, there was an impaired periosteal response, but the magnitude of increase at the endosteum was similar to that of the B6 mice; 4) because the C3 mice responded as well as the B6 mice to the endosteum, it follows that the impairment in responsiveness to C3 mice is not due to an overall decrease in detection of the mechanical signal and accordingly, different genetic mechanisms may regulate periosteal and endosteal responses to mechanical loading.

Comparison of Skeletal Disuse Models in Mice: Spaceflight Versus Hindlimb Suspension. J. R. Milstead*[1], S. J. Simske*[2], T. A. Bateman[1]. [1]Bioengineering, Clemson University, Clemson, SC, USA, [2]Bioserve Space Technologies, University of Colorado, Boulder, CO, USA.

The effects of microgravity have been examined in rats on several occasions, and a ground based model, hindlimb suspension (HS), has been developed to mimic the skeletal unloading aspects of spaceflight (SF) on the hindlimbs. However, because STS-108 was the first Space Shuttle flight to examine the skeletal system of mice, a direct comparison of HS and SF has never been examined in mice. The objective of this research was to closely repeat the STS-108 profile, with HS replacing SF, to determine the degree to which HS predicts the effects SF on the murine skeleton.

10-week-old female C57/BL6J mice (n=12/group) were flown on STS-108 for a 12-day spaceflight (HS was repeated for the same duration). Mass and age-matched vivarium housed (VC) mice were used as controls. The effects of SF and HS on the skeletal system of mice were investigated using four different assays: micro-computed tomography, dynamic histomorphometry, mechanical testing, and compositional analysis. *Denotes significant difference between SF and HS groups ($p<0.05$).

MicroCT analysis of the proximal tibia determined that trabecular bone volume was decreased in both SF (18%) and HS (42%*) when compared with vivarium ground controls. Trabecular thickness was decreased in SF groups (8%) as well as HS (15%*). Histomorphometry determined that SF resulted in a 50%* decrease in periosteal bone formation rate (BFR), whereas there was no significant effect from suspension. SF also resulted in a 60% decrease in endocortical BFR, and HS resulted in a 40%* decrease in endocortical BFR. Average mineral apposition rate was decreased by 52% in SF groups, and 21%* in HS groups. Mechanical strength was reduced by 8% by SF and 15%* by HS. Compositional analysis determined that whole bone percent mineral composition was reduced by 4%* in HS groups, whereas SF reduced mineral composition by 3%.

In general, results showed that both SF and HS result in osteopenia. However, each method reduces bone quantity and quality to differing degrees. HS appears to have a greater effect on trabecular bone than SF. HS reduces bone strength to a greater degree than SF, with mineral composition and BFR differentially contributing to strength changes in each model.

This study was approved by Clemson University's Animal Care and Use Committee (ARC protocol# 40002).

Ulna Loading Response Altered by the HBM Mutation. D. M. Cullen, M. P. Akhter, M. L. Johnson, S. Morgan*, R. R. Recker. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

The G171V substitution in the human LRP5 gene is a naturally occurring mutation that results in extremely high bone mass (HBM) in humans. An HBM heterozygote mouse HBM model has been constructed by inserting the human LRP5 G171V gene into C57Bl6 (WT)mice. HBM mice tibiae are overadapted to daily loads since body mass is the same as WT but tibial bone size and strength are much greater. This study confirms structural differences in the ulna and tests the ulna response to in vivo compression loading. Adult female HBM and WT mice (23.9 +/- 1.6) were randomized into 3 load groups (n=15/grp). Loads were adjusted for each genotype to achieve three strain levels: Low (1000με), Medium (1350με), and High (1950 με). The right ulna was loaded in compression for 99 cycles, at 2Hz, 3 d/wk for 3 weeks. Right and left ulna were fixed in 70% EtOH, embedded in MMA, and cortical sections taken from the midshaft for histomorphometry. The loading response is reported as difference between loaded and non loaded ulna for midshaft periosteal mineralizing surface (MS/BS)and bone formation rate (BFR). The nonloaded, proximal ulna bone mass and structure were measured by micro computed tomography at 9micron resolution and 50 msec integration time (μCT20, Scanco Medical AG, Bassersdorf, Switzerland). The scan region extended from 0.8 to 1.3 mm from the proximal end and the results are the average of 60 continuous 2D sections (proximal total area, cortical area, and trabecular BV/TV). Similar to the tibia, the HBM bones were larger and contained more bone tissue. In fact the proximal tibial cancellous bone was densely packed. Loading increased midshaft periosteal formation but differences in WT were not seen until 1950 με while formation began at lower strains in HBM ulna. While the pattern resembles that of the tibia, the ulna is much less sensitive to new loads. Tibial responses in WT mice are routinely seen with 1300 με and only 36 cycles. The higher forces required for the ulna may be a result of a more physiological loading pattern that medial to lateral bending in the tibia. The histology data represents the average of three sections (70μm) per bone, but there was considerable variability within bone. More precise localization of section or more sections should be considered for future studies to decrease variability between bones.

Low-Level Mechanical Vibrations Reduce Bone Resorption in the Growing Skeleton. L. Xie*[1], E. Choi*[1], L. Donahue*[2], C. Rubin[1], S. Judex[1]. [1]Biomedical Engineering, State University of New York at Stony Brook, Stony Brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, MN, USA.

Extremely small magnitude but high-frequency (>25Hz) mechanical stimuli can increase trabecular bone formation rates in the adult skeleton of a variety of species including mice. We have further demonstrated that these extremely low-level whole body vibrations can enhance bone morphology in the growing skeleton. Exposing the skeleton of 8wk old mice to 15 min/d of vibrations led to significantly enhanced trabecular bone volume fraction and thicker trabeculae over a 6wk period. The mechanism by which these morphologic changes were achieved was not immediately clear. Here, we investigated the influence of low-magnitude vibrations on the *resoptive* activity in trabecular bone of the growing skeleton. Eight-week old male BALB/cByJ (BALB) mice were randomly divided into three groups; baseline control (n=8), age-matched control (n=10), and mice that were vibrated at 45Hz (0.3 g) for 15 min/d (n=10). After the 3-wk experimental protocol, trabecular bone volume fraction, bone surface, and trabecular thickness of the tibial metaphysis were quantified via standard histomorphometry. Tartrate resistant acid phosphatase (TRAP) staining was used to determine bone resorptive activity by measuring osteoclast surface (Oc.S/BS) of the metaphyseal trabecular bone surface. Normal growth within the 3-wk period did not significantly alter activity levels of osteoclasts or produce architectural changes in the metaphysis of the tibia. Superimposing subtle vibrations onto the skeleton for 15 min/d, however, significantly decreased trabecular Oc.S/BS by 31% ($p<0.01$). No significant changes in bone morphology were observed over the 3-wk mechanical loading period. These results demonstrate, for the first time, that extremely small levels of vibrations are not only capable of stimulating bone's anabolic activity but can also decrease levels of bone resorption. Thus, this biomechanical countermeasure, in contrast to current pharmacologic interventions, may be able to increase peak bone mass and decrease the incidence of osteoporosis later in life by exertting positive effects on both bone formation and resorption. This work was supported by the Army.

Nutrient Artery Hypertrophy Induced by Cyclic Intramedullary Fluid Flow Loading. H. Lam*[1], P. Brink*[2], C. Rubin[1], Y. Qin[1]. [1]Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA, [2]Biophysiology, Stony Brook University, Stony Brook, NY, USA.

Bone fluid flow induced by intramedullary pressure (ImP) has been demonstrated to mediate bone modeling in the absence of mechanical strain. To further evaluate the potential mechanism of this fluid flow effect on altering the nutrient supply, we hypothesize that fluid flow generated by ImP oscillation will generate nutrient vasculature adaptation which may trigger bone modeling. Thus, our objective is to investigate the relationship between cyclic hydraulic stimulation in the marrow cavity and nutrient blood vessel adaptation. We have previously demonstrated that the cross-sectional vessel wall area increased up to 50% at 3Hz loading and up to 60% at 30Hz with various intramedullary pressures applied. We are now interested in determining the contributions toward this increase in vessel wall area. Using an avian model, cyclic hydraulic stimuli was applied to the left ulnae, 10 minutes per day, with magnitude of 50-90mmHg at 3Hz and 30Hz for 2, 3, & 4 weeks (n=32), while the right ulnae were left unloaded as sham control. Four additional birds were used as age-matched control, in which both left and right ulnae were unloaded. After euthanasia, the nutrient arteries were dissected, embedded in paraffin wax, sectioned to ~8μm and stained with H&E. The average vessel wall thickness, lumen perimeter and smooth muscle cell (SMC) layer number were assessed. The lumen area was calculated from the measurement of lumen perimeter. Our data showed that the loaded side, increased in average vessel wall thickness and SMC layer number, yet decreased in lumen area. For instance, loading at 3Hz, 90mmHg for 3 weeks produced 29% increase in wall thickness and 45% in SMC layer number. Loading at 3Hz, 70mmHg for 3 weeks and 90mmHg for 4 weeks showed a lesser increase in wall thickness, 13%, and SMC layer number, 2% and 10% repetitively, but a stronger decrease in lumen area, 26% and 31% respectively. Likewise, similar trends were seen for loading at 30Hz, up to 19% increase in wall thickness, 29% in SMC layer number, and 50% decrease in lumen area. In conclusion, the results strongly suggested cyclic hydraulic stimulation does affect the adaptive response of the nutrient artery. More specifically, these repetitive ImP loading leads to nutrient artery hypertrophy, by thickening of the vessel wall with increased SMC layer and/or reducing of the lumen area. This study strongly implies that ImP fluid loading could further influence the blood supply to bone and trigger remodeling in bone tissue, which may contribute to certain skeletal diseases. Future targets will be focused on cellular level changes within the nutrient artery and along with modeling the nutrient supply to bone.

Identification and Characterization of the Ubiquitin-Proteasome Pathway-Targeting Molecular Chaperone, Valosin-Containing Protein (VCP/p97) in Untransformed Osteoblast-Like Cells. K. Behnam*[1], S. S. Murray*[2], E. J. B. Murray[2]. [1]Physiological Sciences, University of California, Los Angeles, CA, USA, [2]GRECC/Medicine, VAGLAHS/University of California, Sepulveda/Los Angeles, CA, USA.

Valosin-containing protein (VCP or p97) is a member of the AAA ATPase family (ATPases associated with a variety of cellular activities) that acts as a molecular chaperone that targets polyubiquitinylated proteins to the 26 S proteasome for degradation. VCP also mediates Golgi, ER (endoplasmic reticulum), and nuclear membrane fusion; ER-mediated protein degradation; protein transport from the ER to the cytoplasm; and cellular proliferation. High constitutive levels of VCP gene and protein expression are associated with enhanced degradation of phosphorylated inhibitor of NF-kappa B-α, persistent activation of the NF-kappa B transcription factor, suppression of apoptosis, and high pulmonary metastatic potential in osteosarcoma cells. The purpose of this study was to determine the occurrence and distribution of VCP protein expression in untransformed MC3T3-E1 osteoblast-like cells. Cellular protein was separated by 2D IEF/SDS-PAGE. An abundant spot with a M_r of 94 kDa and acidic pI of 5.4 was definitively identified as VCP by MALDI/ToF MS and peptide mass fingerprint analysis. Constitutive expression of VCP in subconfluent and confluent resting and mildly physiologically stressed MC3T3-E1 cells was confirmed by Western blotting. Under resting conditions, indirect immunofluorescent staining indicated that VCP is abundant in the cytoplasm, perinuclear Golgi, and nuclei of MC3T3-E1 cells, while mild physiological stress sufficient to stimulate the ubiquitin-proteasome pathway was associated with reduced diffuse cytoplasmic and enhanced nuclear immunofluoresence. In conclusion, VCP is an abundant protein in untransformed osteoblast-like cells under all conditions tested. It is not simply a marker for high metastatic potential in osteosarcomas. VCP may play previously unrecognized roles in normal osteoblast-like cell functions, such as protein turnover, membrane fusion, and mitosis.

Wnt Signaling Prevents Apoptosis of Both Uncommitted Osteoblast Progenitors and Osteoblasts through Src, ERK, PI3K and β-catenin Pathways. M. Almeida, L. Han, A. D. Warren*, V. G. Lowe*, S. Kousteni, S. C. Manolagas. Div. Endocrinol., Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. Arkansas Med. Sci., Little Rock, AR, USA.

Genetic studies in humans and mice with mutations in LRP-5 and secreted Frizzled-related protein-1 (SFRP-1) have revealed an important role of the Wnt signaling pathway in the regulation of bone formation and mass, resulting from potent effects on the control of osteoblast progenitor proliferation, commitment, differentiation and perhaps osteoblast apoptosis. To establish the linkage between Wnts and osteoblast survival and elucidate the molecular pathways that link the two we have utilized three cell models: the uncommitted bipotential C2C12 cells, the pre-osteoblastic cell line MC3T3-E1 and bone marrow-derived OB-6 osteoblasts. We report that in cultures of all three cell types withdrawal of serum from the medium induced apoptosis within six hours, as assayed by an average of 3-fold increase in caspase 3 activity. The induction of apoptosis in all three models was reversed by the addition of 50 ng/ml of purified Wnt3A (R&D) protein. The protective effect of Wnt signaling against apoptosis was not restricted to Wnt3A, as MC3T3-E1 cells transfected with expression plasmids carrying wnt1 or wnt5A were also protected from serum withdrawal-induced apoptosis. As expected, transfection of MC3T3-E1 cells with Dkk1, a secreted inhibitor of Wnt signaling, abrogated the anti-apoptotic effect of Wnt3A. Furthermore, the anti-apoptotic effect of Wnt3A was abolished in MC3T3-E1 cells transfected with a dominant negative mutant of β-catenin. Treatment of MC3T3-E1 cells with Wnt3A protein induced phosphorylation and nuclear accumulation of ERKs within 2 min; and this effect was transient. The anti-apoptotic effect of Wnt3A was abrogated by expressing dominant negative MEK as well as Src or PI3 kinases or by the addition of cycloheximide into the culture medium. Further, Wnt3A induced phosphorylation of the glycogen synthase kinase 3β (GSK-3β), and the effect of Wnt3A was inhibited by the MEK kinase-specific inhibitor PD98059. Likewise, PD98059 inhibited Wnt3A-induced transcription of Wnt/β-catenin as measured in C2C12 cells carrying a TCF-luciferase reporter. Finally, Wnt3A induced an increase (2-fold) in the expression of the anti-apoptotic protein Bcl-2 in MC3T3-E1 cells. These results demonstrate for the first time that Wnt signaling prolongs the survival of osteoblast progenitors and their progeny via activation of both the canonical pathway and ERKs, with GSK-3β representing at least one convergence point between the two signaling cascades. Src and PI3 kinases are evidently also involved.

ERK and p38 MAPKs Activation Contribute Synergistically to Osteoblast Survival in Etoposide-Induced Apoptosis. N. Ibargoyen*, A. Patiño*, M. San Julián*, L. Sierrasesúmaga*, F. Lecanda. Center of Applied Biomedical Research, University of Navarra, Pamplona, Spain.

Mitogen-activated protein kinase (MAPK) signaling pathways are key transduction cascades mediating cell proliferation, differentiation in response to various growth factors and cell survival. The three classical MAPK cascades include ERK (extracellular signal-regulated kinase) induced by mitogens, and the stress-stimulated kinases p38 and JNK (c-Jun N-terminal kinase). The aim of this study was to examine the contribution of each of the MAPK pathways to cell survival and apoptosis. For this purpose, we have established a low passage chemonaive tumoral cell line (OS-491) from a pediatric osteogenic sarcoma and a normal osteoblastic cell line (N-491) from the same patient. OS-491 displayed constitutive activation of the three MAPK pathways compared to N-491 and other osteoblastic primary cell lines. Treatment of OS-491 cells with specific p38 inhibitor SB 203580, ERK inhibitor U0126, and JNK II inhibitors led to a decreased phosphorylation of the three MAPK pathways. Phenotypic characterization by RT-PCR revealed decreased expression of osteocalcin, osteopontin and bone sialoprotein in OS-491 compared to N-491 cells. No differences were found in collagen type I. Inmmunocytochemical alkaline phosphatase staining was slightly reduced in OS-491 compared to N-491. Serum-induced proliferation was similar in both OS and N cells in a 5-day MTT assay. Resistance to apoptosis was measured by treatment with etoposide Interestingly, OS-491 cells were more resistant to etoposide-induced apoptosis than N-491 cells during the 5-day treatment period. Another osteosarcoma cell line, OS-500, with non-activated MAPK, showed no differences in cell survival compared to normal osteoblastic cell line N-500, by either serum depletion or etoposide-induced apoptosis in MTT assay. Specific inhibition of ERK, p38 or JNK in constitutive active MAPK OS-491 cells or non-activated MAPK OS-500 cells did not affect apoptotic rate after etoposide treatment compared to vehicle treated cells. Similarly, dual inhibition of JNK with either p38 or ERK inhibitors did not have any effect on apoptosis in any of the cell lines compared to vehicle-treated cells. However, concomitant inhibition of p38 and ERK pathways in OS-491 cells led to a dramatic increase in the apoptotic rate compared to vehicle treated cells, suggesting that p38 and ERK activation contribute synergistically to osteoblastic cell survival. Taken together, these data suggest that MAPK cascades could play important roles in osteoblast survival and drug resistance. Simultaneous inhibition of p38 and ERK may be required to reach a therapeutic effect.

PTHrP Control of the Cell Cycle Machinery in Differentiating Osteoblasts. N. S. Datta, C. Chen*, J. E. Berry*, L. K. McCauley. Perio/Prev/Geriatrics, University of Michigan, Ann Aror, MI, USA.

PTHrP has been implicated in the control of bone cell turnover but the mechanisms underlying its effect on osteoblast proliferation and differentiation have not been clearly defined. To establish the role of PTHrP, cell cycle analysis was performed in proliferating and differentiating MC3T3-E1 cultures with and without PTHrP (0.1μM) treatment. Flow cytometric analysis found 82% of differentiating MC3T3 cells in G0/G1 phase compared to 58% of proliferating osteoblasts. PTHrP significantly decreased S-phase cells (12 to 2%) and increased cells in G0/G1 (80 to 95%) suggesting PTHrP causes growth arrest. Cell cycle progression is dependent on periodic and phase specific abundance and activity of cyclin-cell division kinase (CDK) complexes. Western blot analyses of total cellular extracts from PTHrP or vehicle treated differentiated MC3T3 cells indicated that cyclin D1 (a G1 progression cyclin) was dramatically reduced (5-10 fold) in PTHrP treated cells. In contrast, cyclins E, A (responsible for G1/S transit and S-phase progression) or B (G2/M progression) were unchanged. Among the CDKs, the catalytic subunit of the protein kinase complexes, only the relative protein abundance of CDK1 was down regulated. Cell cycle progression is also controlled by CDK inhibitors (CDKIs) which negatively regulate the cell cycle machinery by forming complexes with CDKs. PTHrP induced p16 (INK4) CDK inhibitory protein abundance. No significant differences were noted in p19 (the alternative spliced form of p16), p21 (CIP1), or p27 (KIP1) protein abundance between vehicle and PTHrP treated MC3T3 cells. Cyclin D1- CDK complex formation was assessed by measuring the presence of CDK4/CDK6 and CDKIs in immunoprecipitations performed using antibodies to cyclin D1. Analysis of immunoprecipitates from whole cell lysates revealed a decrease in CDK4/CDK6 and an increase in p16, p21, and p27 association with cyclin D1 following PTHrP induction. In addition, the functional role of the kinase complexes were determined by *in vitro* kinase assays using either GST-Rb (for CDK4/6) or H1-histone (for CDK1, CDK2) as substrates. PTHrP down-regulated cyclin D1-CDK4/CDK6 as well as CDK1 kinase activities in differentiating MC3T3 osteoblasts. Finally, expression of JunB, an AP-1 transcription factor known to regulate cyclin D1 and p16 transcription, was found to be significantly up regulated via western, ELISA, and northern blot analysis implying involvement of JunB in PTHrP mediated growth arrest of MC3T3 cells. These data suggest cell cycle control may be a mechanism through which PTHrP impacts the life span and bone forming activity of osteoblasts.

Regulation of Human Osteoblast Survival and Differentiation by Death Receptor-3. C. W. Borysenko, V. García Palacios, A. P. Brunskill*, Y. Li*, W. F. Furey*, H. C. Blair. Pathology and Physiology & Cell Biology, University of Pittsburgh and Veteran's Affairs Medical Center, Pittsburgh, PA, USA.

Background: Several growth factors are known to be necessary for osteoblast differentiation, but no mechanism that specifically regulates the decision to secrete bone matrix has been reported. We demonstrate in this study that Death Receptor-3 (DR3) can regulate this transition in MG63 human osteoblast-like cells. DR3, a TNF-receptor family member, was discovered as a regulator of immune cell survival, but its occurrence in bone was unknown.
Methods and Results: Western analysis, cDNA cloning, and flow cytometry demonstrate expression of alternatively spliced soluble (blocking) and full length transmembrane (signaling) isoforms of DR3 in human osteoblasts and in MG63 cells. Transmembrane DR3 was activated in MG63 by antibody crosslinking and effects on cell survival and osteoblast differentiation were determined. In low density (10^3/cm^2) MG63 cultures, anti-DR3 crosslinking reduced cell survival, studied by tetrazolium dye reduction and nuclear labeling, via an apoptotic mechanism as shown by annexin V labeling. Conditioned media from high-density cultures, containing soluble DR3, was protective against apoptosis. In high-density cultures ($3x10^4$/cm^2) under conditions allowing bone nodule formation, DR3 crosslinking prevented bone formation, shown by absence of mineral deposition, reduced alkaline phosphatase activity, and increased MMP-2 secretion. Three-dimensional comparative modeling of the ligand-binding domain predicts reduced structural integrity for a variant of DR3 linked to rheumatoid arthritis, further supporting the role of DR3 in normal bone physiology.
Conclusions: DR3 is expressed in osteoblasts in soluble forms that may prevent apoptosis and in a transmembrane form, which in isolated cells can mediate apoptosis, but in high density cells is a direct regulator of osteoblast matrix production. Thus, these results establish a direct role for DR3 in controlling survival and regulating whether human osteoblast-like MG63 cells grow in a mesenchymal cell-like form or differentiate to synthesize bone matrix. That bone-forming cells express functional DR3 suggests that the RA-linked mutations in DR3 may contribute to pathology, beyond its role in T cell regulation, by affecting the response of bone cells directly.

Bioactive Peptides IPP and VPP have Multifunctional Properties on UMR-106 Osteoblastic Cells. M. M. Huttunen*, M. E. Ahlström*, M. Pekkinen*, J. Loponen*, C. J. E. Lamberg-Allardt. Department of applied chemistry and microbiology, University of Helsinki, Helsinki, Finland.

Protein accounts for 30% of bone mass, making bone one of the most protein-dense tissues of the body. Continuous dietary intake of protein is essential for bone turnover and matrix formation since large amount of bone collagen amino acids cannot be reutilized. In the digestive tract dietary protein is hydrolyzed by proteolytic enzymes into shorter amino acid chains. Some of these peptides possess biological functions in addition to bone matrix formation. Such bioactive peptides must be resistant to further proteolysis and absorb efficiently into blood in order to reach their target. These peptides are typically 2-5 amino acids in length and often they have a proline residue in the C-terminus. This structure is common among food-derived angiotensin converting enzyme (ACE) -inhibitory peptides such as Ile-Pro-Pro (IPP) and Val-Pro-Pro (VPP). Both of these peptides are shown to lower blood pressure in spontaneously hypertensive rats. High blood pressure is associated with abnormalities in calcium metabolism and increased bone loss. Agents interfering the renin-angiotensin-system (RAS), such as ACE-inhibitors, might also affect bone metabolism. ACE-inhibitors are good candidates since they hinder the formation of angiotensin II, the major effector peptide of the RAS. However, the effect of food-derived ACE-inhibitory peptides on bone cells *in vitro* has not been studied.
The aim of this study was to investigate if IPP and VPP have an effect on UMR-106 osteoblastic cell proliferation, differentiation, mineralisation and apoptosis. Cell proliferation was assessed by thymidine incorporation after 24 h treatment with 5, 50 and, 500 μM IPP or VPP. The effect of IPP and VPP on proliferation was biphasic, peaking at 50 μM with IPP and at 5 μM with VPP. Alizarin red S was used to assess mineralised nodule formation. As the proliferation increased, the formation of mineralised nodules decreased. Cell differentiation was assessed by measuring alkaline phosphatase (ALP) activity but neither IPP nor VPP had any effect on ALP. Preliminary results indicate that 50 μM IPP prevents etoposide-induced apoptosis in UMR-106 cells, whereas VPP has no such effect.
As a conclusion ACE-inhibitory peptides IPP and VPP possess *in vitro* osteoblast effects. Especially IPP increases UMR-106 cell proliferation and has anti-apoptotic properties and therefore it can be referred to as multifunctional peptide.

Enhanced Apoptosis Associated with Anabolic Actions of Androgens in AR-Transgenic Mice: Requirement of Reduced Bcl-2/Bax Ratio. K. Wiren, A. Toombs*, X. Zhang. VA Medical Center, Oregon Health & Science Univ, Portland, OR, USA.

Like estrogen, non-aromatizable androgens have significant beneficial effects on skeletal homeostasis. Estrogen has been shown to protect osteocytes from apoptosis but the effects of androgen are still poorly understood. We demonstrated that prolonged androgen signaling leads to reduced osteoblast viability, mediated via inhibition of the extracellular signal regulated kinase (ERK) cascade in both primary cultures and in an osteoblastic model with enhanced androgen responsiveness: MC3T3-E1 cells stably transfected with androgen receptor (AR) under the control of the 3.6-kb α1(I)-collagen promoter (colAR-MC3T3). Based on this evidence, we sought to elucidate the effects of 5α-dihydrotestosterone (DHT) on osteoblast apoptosis in colAR-MC3T3 cultures. In addition, recently characterized AR-transgenic mice with AR overexpression in the osteoblast lineage provide an enhanced model to examine in vivo relevance of androgen signaling. ColAR-MC3T3 cultures were treated with DHT and the effects on osteoblast apoptosis were assessed by three independent assays: accumulation of cytoplasmic mono- and oligonucleosomes, caspase-3 activity using DEVD cleavage, or changes in mitochondrial membrane potential. In proliferating cultures, apoptosis was induced by treatment with the topoisomerase II inhibitor etoposide (50μM; 18h). Continuous treatment with DHT (10^{-8}M DHT; 5 days) enhanced apoptosis over two-fold ($P<0.001$), but as expected similar treatment with 17ß-estradiol (E2) inhibited apoptosis. In highly confluent osteocytic cultures (day 29) apoptosis was induced by serum withdrawal. In osteocytic cultures continuous DHT treatment also enhanced ($P<0.001$) while E2 inhibited apoptosis. The involvement of apoptotic regulators bcl-2 (antiapoptotic) and bax (proapoptotic) was characterized by qRT-PCR and Western analysis. Bcl-2 mRNA levels were unchanged and Bax was modestly elevated with DHT treatment by qRT-PCR. The ratio of Bax to Bcl-2 was increased by Western analysis. Overexpression of bcl-2 or knockdown of bax expression with siRNA abrogated the effect of DHT to enhance osteoblast apoptosis. The physiologic relevance of androgen regulation of osteoblast apoptosis was evaluated in vivo in calvaria from male AR-transgenic mice. TUNEL staining demonstrated increased apoptosis in areas of new bone growth and in osteocytes. These results are consistent with the hypothesis that apoptosis is important during bone growth to make room for new bone. Collectively, these findings demonstrate that androgen signaling through the AR in bone directly influences osteoblast survival and offers valuable insight into the role of androgen in bone homeostasis.

Menin Inhibits Osteoblast Maturation by Antagonizing Osteoblast Differetiation Induced by JunD in Mouse Osteoblastic Cells. J. Naito*[1], H. Kaji[1], H. Sowa[1], G. N. Hendy[2], T. Sugimoto[1], K. Chihara*[1]. [1]Endocrinology/Metabolism, Neurology and Hematology/Oncology, Kobe university graduate school of medicine, Kobe, Japan, [2]Medicine,Physiology and Human Genetics, McGill University, Montreal, PQ, Canada.

Menin, the product of the multiple endocrine neoplasia type 1 gene, is ubiquitously expressed.Homozygous menin knockout mice exhibit cranial and facial hypoplasia, suggesting a role for menin in bone formation. Menin interacts with the bone morphogenetic protein (BMP)-2 signalling molecules Smad1/5, and the key osteoblast transcriptional regulator, Runx2, and is required for the commitment of multipotential mesenchymal stem cells
into the osteoblast lineage. However, menin inhibits the later differentiation of committed osteoblasts by unknown mechanisms. The AP-1 transcription factor, JunD, is expressed in osteoblasts and has been shown to interact with menin in other cell types. In the present study, we examined the consequences of menin-JunD interaction on osteoblast differentiation in mouse osteoblastic MC3T3-E1 cells. JunD,
assessed by immunoblot, gradually increased during osteoblast differentiation. Stable expression of JunD enhanced expression of differentiation markers, Runx2, type 1 collagen and osteocalcin, and
alkaline phosphatase (ALP) activity and mineralization. Hence JunD promotes osteoblast differentiation. In MC3T3-E1 cells in which menin expression was reduced by stable menin antisense cDNA transfection,
JunD levels were increased. When JunD and menin were co-transfected in MC3T3-E1 cells, they co-immunoprecipitated. JunD overexpression increased the transcriptional activity of an AP-1 reporter construct
and this activity was reduced by co-transfection of menin. Therefore, JunD and menin interact both physically and functionally in osteoblasts. Furthermore, menin overexpression inhibited the ALP activity induced by JunD. In conclusion, these findings suggest that menin suppresses osteoblast maturation by inhibiting the bone anabolic actions of JunD.

The Effect of Parathyroid Hormone (1-34) on Angiopoietin-1 Expression in Human Osteoblast-like Cells. J. Park*, J. Kim*. Division of Endocrinology and Metabolism, Department of Internal Medicine, Chonbuk National University Medical School, Chonju Chonbuk, Republic of Korea.

The effect of parathyroid hormone on osteoporosis has been established. However, the mechanism is not fully known. To elucidate the molecular mechanism in related to anabolic action of parathyroid hormone, we investigated the effect of PTH (1-34) on angiopoietin-1 expression in primary-cultured human oseoblast-like cells. Quiescent cultures of osteoblasts were exposed to PTH (1-34) or vehicle for 24 or 48 hours. Reverse transcription-polymerase chain reaction (RT-PCR) analysis showed that mRNA expressions of angiopoietin-1 (Ang-1) were increased in PTH-treated osteoblasts compared to vehicle-treated one. Western blotting showed the similar pattern with mRNA expression at 24 or 48 hours. The adenylate cyclase activator forskolin induced the increase of Ang-1 mRNA expression, the protein kinase A inhibitor H-89 inhibited the increase of Ang-1 mRNA by PTH (1-34). These data indicate that PTH (1-34) increase Ang-1 expression in osteoblasts by protein kinase A dependent pathway, and may be a mechanism of anabolic action of PTH (1-34) on bone through the improvement of vascularity.

Runx2 as a Transcriptional Repressor of Steroid Hormone Receptors. H. Kawate*[1], Y. Wu*[1], K. Ohnaka*[1], H. Nawata*[2], R. Takayanagi*[1]. [1]Department of Geriatric Medicine, Kyushu University, Fukuoka, Japan, [2]Department of Medicine and Bioregulatory Science, Kyushu University, Fukuoka, Japan.

Purpose: Both steroid hormone receptors and Runx2 are transcription factors and play a crucial role in the skeletal development and maintenance. We have examined the functional relationship between Runx2 and steroid hormone receptors.
Methods: Runx2 and one of the steroid hormone receptors (androgen receptor (AR), estrogen receptor (ER) or glucocorticoid receptor (GR)) were expressed in osteoblastic cells, MC3T3-C1. Luciferase assay was performed to evaluate the effect of Runx2 on the transactivation mediated by steroid hormone receptors. Green fluorescent protein (GFP)-tagged polypeptides were used for observation of the intracellular localization of the proteins under the confocal laser scanning microscopy.
Results: Luciferase assay using promoters carrying the hormone-responsive elements revealed that Runx2 suppressed the ligand-dependent transcriptional activation mediated by all three steroid hormone receptors. Coexpression of Cbfb, which is a transcriptional cofactor for Runx2, enhanced the Runx2-mediated repression. We previously observed that after the treatment of ligands steroid hormone receptors were translocated from the cytoplasm into the nucleus and produced the intranuclear foci. In this study, we have identified that Runx2 was located in the nucleus and showed foci formation and were colocalized with the steroid hormone receptors. Moreover, one of the nuclear receptor coactivators, TIF2, was colocalized with Runx2 and steroid hormone receptors after adding the ligands.
Conclusions: These data indicate that Runx2 plays an important role in the regulation of steroid hormone receptor-mediated transcriptional activation in the osteoblasts.

Large Scale Transcriptional Profiling Across the Time Course of Fracture Healing. K. H. Wang*[1], V. Prashanth*[2], G. Eichler*[2], C. M. Edgar[1], T. Smith*[2], L. C. Gerstenfeld[1]. [1]Orthopaedic Surgery Research Laboratory, Boston University Medical Center, Boston, MA, USA, [2]Department of Biomedical Engineering, Boston University School of Engineering, Boston, MA, USA.

Skeletal tissue regeneration occurs through the recapitulation of many aspects of the original endochondral developmental process that formed the osseous skeleton during embryogenesis. The repair process that is initiated in response to fracture entails the complex interaction of multiple cell types and cellular processes and is reflected in the complexity of the transcriptional expression that occurs during fracture healing. The transcriptional expression of ~13,000 genes was assessed over the first 21 days of fracture healing. Standard mid-diaphyseal tibia fractures were generated in C57B6 murine tibiae. The profile of transcriptional expression of ~13,000 genes was carried out across the time course of fracture healing using 75mers covalently linked onto oligo-nucleotide microarray chips. Ribonuclease protection analysis was used for a small number of candidate genes, to verify the time course of chondrogenic and osteogenic gene expression and validate the accuracy of the predictive values of the micro array analysis. The data that were obtained from these experiments were analyzed using a novel algorithm called a Gene Expression Dynamics Inspector (GEDI) that produces self organizing maps of the expressed genes, which are graphically presented as colored coded mosaics that enables individual clusters of genes to be identified, easily visualized and associated with various temporal stages of fracture healing. Using unfractured bone tissue as the reference and ln 2 fold greater or lesser from the reference, ~1000 mRNAs within ~13,000, were identified that varied across the time course of healing. These data identified the heat shock (HSP) gene family to be tightly expressed immediately after injury at day 3 and is the first demonstration that this family of stress related genes, which is activated in response to burn or chemical toxicity is also activated as a consequence of mechanical trauma. On the other hand a sub family of genes within the metalloproteinase (MMP) family was identified as having a complex pattern of expression during the chondrogenic and osteogenic phases of fracture healing. Showing both excluded expression during chondrogenesis MMP8 and elevated expression during endochodnral resorption (MMP2,9,13 and 14). In conclusion these data demonstrate the potential uses of a global transcriptional profiling approach to identify complex networks of gene interactions that are regulated over the time course of fracture healing.

NFAT Negatively Regulates Osteoblast Differentiation. H. Yeo*, M. Zayzafoon, J. M. McDonald. Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Nuclear Factor of Activated T cells (NFAT) is a family of transcription factors which play a key role in regulating expression of several genes. Protein phosphatase 2B (PP2B), also known as calcineurin, dephosphorylates and activates NFAT by allowing it to translocate to the nucleus and bind to a specific DNA consensus sequence. In addition, it has been reported that NFAT binds synergistically with transcription factors of activator protein-1 (AP-1 : fos/jun) on a composite DNA element which contains an NFAT and an AP-1 binding site. This highly stable ternary complex regulates the expression of many genes. The purpose of this study is to examine the expression of NFAT in osteoblast-like cells (MC3T3-E1) and to elucidate its role in osteoblast differentiation. Here we show by RT-PCR and Western blot analysis that NFAT c1, c2 and c3 are expressed in osteoblasts. Immunofluorescence staining and Western blotting of osteoblast nuclear proteins demonstrate that NFAT c1 and c3 are found in the nucleus and in the cytoplasm, while NFAT c2 is only present in the cytoplasm. To determine the role of NFAT in osteoblast differentiation, we used Cyclosporin A (CsA), a pharmacological inhibitor of PP2B, that is known to prevent NFAT dephosphorylation and nuclear translocation. CsA inhibits PP2B activity between 10nM - 100nM in a dose dependent manner. Interestingly, at these concentrations, CsA induces osteoblast differentiation, in a dose-dependent manner, demonstrated by increases in alkaline phosphatase (ALP) and Von Kossa (VK) staining. This increase in osteoblast differentiation was confirmed by demonstrating an increase in the expression of osteoblastic gene markers, ALP, collagen I and osteocalcin, in response to treatment with PP2B inhibitor by semi-quantitative RT-PCR. In addition, using a mouse calvaria *in vivo* model, we demonstrate that treatment with CsA increases bone thickness, osteoblast numbers and mineralization. To elucidate the mechanism by which NFAT inhibition induces osteoblast differentiation, we examined the effect of CsA on the DNA binding activity of AP-1 by EMSA. Inhibition of NFAT by CsA is associated with increased Fra2 and JunD binding to the AP-1 consensus sequence and decreased binding of c-Jun and c-Fos. These novel findings suggest that NFAT negatively regulates osteoblast differentiation by increasing c-Jun and c-Fos binding to AP-1.

1,25(OH)$_2$D$_3$ Suppresses cbfa1 Gene Expression Transcriptionaly: Identification of Regulatory Elements. K. Hasegawa*[1], Y. Seino*[2], H. Tanaka*[1]. [1]Okayama University Graduate school of medicine and dentistry, Okayama, Japan, [2]Osaka Kosei Nennkinn Hospital, Osaka, Japan.

Cbfa1 is an essential regulator of bone specific cell differentiation.

We have shown increased expression of cbfa1 mRNA in vitamin D receptor knock out mice compared with wild type mice by the bone transplantation experiment and the organ culture experiment. To clarify the mechanism of suppressive effect of 1,25(OH)$_2$D$_3$(D3) on cbfa1 gene expression, we performed reporter gene assay using distal promoter of cbfa1 gene, which contains 17 E-box like sequences and 1 typical DR3 sequence (DR3:-98 /-84) near the transcription start site.

Materials and Methods We cloned the distal promoter region of mouse cbfa1 gene (-4579 /-8) into pGL3-Luciferase vector (Promega). Based on this sequence, several truncation mutant constructs (-168/-8, -1825/-8, -2165/-8, -2269-8) were generated. Vector was transfected to MC3T3E1 cell by FuGENE6 (Roche). Cells were treated with D3(1x10-8M) for 12 hours and measured luciferase activities at 48 hours after transfection.

Results While shorter constructs (-168/-8, -1825/-8) showed no repression activities by D3 treatment, D3 induced repression (30%) was observed only in longer constructs (-1927/-8, -2165/-8, -2269/-8). Thus D3 seemed to suppress cbfa1 gene expression thorough 100bp sequence between -1825 and -1927. For this construct, PKA activation by Forskolin did not exert any effects on basal luciferase activity in contrast to the negative VDRE in vitamin D 1 a-hydroxylase gene.

To delineate the function of DR3 motif located at -98 /-84, we next introduced a mutation into the DR3 motif to abrogate its binding activity to liganded VDR/RXR. This mutation enhanced the repression activity of D3 from 30% to 50%.

Conclusions From these results, we conclude that D3 suppresses cbfa1 gene expression transcriptionally thorough the sequence between -1825 to -1927. The DR3 sequence located at -98 /-84 is positive VDRE and this may interfere repressive activity of D3.

Expression Pattern of Core Binding Factor-β in Skeletal Tissues. H. Kim[1], M. Hwang*[1], M. Han*[1], A. Javed[2], B. Lee*[1], R. Park*[1], S. Kim[3], H. Ryoo[3], J. L. Stein*[2], A. V. Wijnen[2], J. B. Lian[2], G. S. Stein[2], J. Choi[1]. [1]Dept.of Biochemistry, Kyungpook Natl. Univ. School of Medicine, Daegu, Republic of Korea, [2]Dept.of Cell Biology, UMASS Medical School, Worcester, MA, USA, [3]Skeletal Diseases Genome Research Center, Daegu, Republic of Korea.

Core binding factor-β (Cbf-β) is a partner protein of RUNX family transcription factor. Recently, knock-in and rescue mice of Cbf-β result in skeletal abnormalities. However, exact expression of Cbf-β has not been studied in skeletal tissues. To determine the expression pattern of Cbf-β in bone, we performed cDNA cloning, Cbf-β purification, antibody production, and immunohistochemical staining in mice skeletal tissues. Open reading frame of Cbf-β cDNA isolated from rat osteoblasts showed 188 amino acids. Anti-Cbf-β antibody was produced using recombinant Cbf-β protein. The expression of Cbf-β during osteoblast and chondrocyte differentiation was determined by Northern and Western blot analysis in MC3T3-E1 and ATDC5 cell culture system, respectively. Cbf-β and its mRNA were gradually increased during osteoblasts or chondrocytes differentiation. This pattern was similar in primary cultured osteoblast differentiation system. The expression of Cbf-β on growth plates was observed in osteoblasts, articular chondrocytes, and hypertrophic chondrocytes from both embryonic day 15 and postnatal 2 weeks mice long bones. Collectively, the expression patterns of Cbf-β from both *in vivo* growth plates and *in vitro* bone cell culture systems suggest that Cbf-β may play an important role in skeletal growth and differentiation.

Ectopic Overexpression of Adipogenic Transcription Factors Induced Transdifferentiation of MC3T3-E1 Osteoblasts. S. W. Kim*[1], S. J. Her*[2], T. J. Cho[3], D. H. Kim*[4], S. Y. Kim*[4], C. S. Shin[4]. [1]Department of Internal Medicine, Seoul National University Boramae Hospital, Seoul, Republic of Korea, [2]Clinical Research Institute, Seoul National University Hospital, Seoul, Republic of Korea, [3]Department of Orthopedic Surgery, Seoul National University College of Medicine, Seoul, Republic of Korea, [4]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.

Osteoblasts and adipocytes originate from a common mesenchymal progenitor cells and it has been shown that the differentiation to a particular lineage has been associated with reciprocal inhibition of differentiation to the other pathways. We have investigated whether MC3T3-E1 cells - the committed osteoblast originated from mouse calvarial cells - can be induced to transdifferentiate into mature adipocytes by the ectopic expression of two adipogenic transcription factors, PPARγ, C/EBPα, or both. In osteoblastogenic culture condition, the alkaline phosphatase activity was decreased by retrovirus-mediated overexpression of PPARγ whereas its activity was slightly increased by retroviral overexpression of C/EBPα. Overexpression of both PPARγ and C/EBPα had a neutral effect. Under conditions for promoting adipogenesis by treatment with insulin, dexamethasone and IBMX, cells overexpressing PPARγ alone or PPARγ and C/EBPα showed transdifferentiation to mature adipocytes expressing molecular markers of this lineage. Cells expressing both PPARγ and C/EBPα showed more robust phenotype of adipocytes than the cells expressing PPARγ. Overexpression of C/EBPα alone did not result in adipogenesis. Taken together, these results suggest that PPARγ is a key molecular switch for the transdifferentiation to adipocytes whereas C/EBPα differentiate MC3T3-E1 cells into osteoblasts as well as adipocytes.

Expression Profiles of Osteogenesis Related Genes in Calvarial Bone Development. J. Cho*[1], W. Lee*[1], H. Kim*[1], H. Shin[2], H. Ryoo[1]. [1]Biochemistry, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea, [2]Pathology, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea.

Understanding of osteogenesis-related gene profile is very important in the development of a new regimen for the osteopenic conditions. Developing calvaria undergoes typical intramembranous bone forming process. In embryonic day 15.5 of mouse, the parietal bones are clearly separable from the overlying skin, the underlying dura mater. Moreover, the intervening sutural mesenchyme that includes osteoprogenitor cells could be clearly demarcated from the bone tissue. To identify genes related to osteoblast differentiation, we isolated total RNAs from parietal bones and sutural mesenchyme, and analyzed a comprehensive gene expression profile of each tissue by oligo-based Affymetrix microarrays containing 22,690 probes. About 2100 genes with “Present” calls showed more than 2-fold higher signals in bones compared to sutures and 73 out of them showed more than 8-fold higher. Some of them are already known as bone-related biomarkers; VitD receptor, bone sialoprotein, osteocalcin, osteopontin, MMP13, etc, or already reported their differential gene expression patterns in the same tissue by *in situ* hybridization. Ten genes were selected and subjected to confirmation by quantitative real-time RT-PCR analyses. All the genes tested showed higher expression in bones, ranging 5 to 140-folds. Several of these genes are ESTs and the others are already known but their functions in osteogenesis are still unknown. These results suggest that all the processes, including tissue isolation, RNA preparation, microarray hybridization and Genechip scanning were properly executed. Our data imply the result is so convincing that it can be used as a good standard for the mining of osteogenesis-related genes.

FK506 Modulates Osteoblast-specific Transcription Factors Cbfa1 and Osterix Gene Expression in ROS 17/2.8 Cells. S. S. Varanasi, H. K. Datta. School of Clinical &Laboratory Sciences, University of Newcastle, The Medical School, Newcastle upon Tyne, United Kingdom.

FK506 like other immunosuppressants binds to an abundant cytosolic immunophilin called FK506 binding protein 12 (FKBP12). Although acute osteoporosis is one of the prominent and debilitating side effects on osteoblast differentiation and function, the direct effect of FK506 on osteoblast specific transcription factors, Cbfa1 and Osterix, has never been investigated. In the present study we have characterised FKBP12 by using RT-PCR, immuno-localisation and Western blotting and investigated the effect of FK506 on expression of osteoblast-specific transcription factors in ROS 17/2.8 cells. Western blotting extracts of ROS17/2.8 cells revealed the 12 KDa isoform, which was immuno-localized

predominantly in the cytosol. The transient exposure of serum-starved ROS17/2.8 cells to H_2O_2 (100 µmol/L) was found to elevate FKBP12 mRNA after 10 min and increase protein expression after 24h. Interestingly, both PTH (0.1 µmol/L) and 1,25 $(OH)_2D_3$ (1 nmol/L) suppressed FKBP12 protein expression. The fact that different osteoblast proliferating agents had dissimilar effect on an ubiquitous but important cytosolic protein FKBP12 led us to examine possible functional significance of this observation. Therefore, we studied the regulation of osteoblast-specific transcription factors Cbfa1 and osterix by FK506 in ROS 17/2.8 cells. Our study showed a marked inhibition of Cbfa1 isoforms II/III and osterix gene expression in serum-starved ROS 17/2.8 cells by therapeutic level of FK506. The exposure of these cells to FK506 (50 µmol/L) for 0, 30 ad 240 min was found to lead to inhibition of both Cbfa1 isoforms II/III and osterix mRNA expression. The inhibition of Cbfa1 expression was evident both at 30 min and 240 min, whereas osterix mRNA expression was found to be more inhibited after 240 min. The dose-dependant inhibition of osterix in these cells, carried out using 2.5, 25 and 250 µmol/L of FK506, showed maximal inhibition at 2.5 µmol/L; the extent of inhibition remaining similar at higher concentrations. Interestingly, Cbfa1 isoforms II/III were also maximally inhibited at 2.5 µmol/L, however the inhibition became less marked at 25 and 250 µmol/L. alkaline phosphatase, FKBP12 and GAPDH mRNAs levels were unaffected both in the time-course and dose-response studies. In conclusion, this study characterises FK506-binding proteins in osteoblasts and suggests a possible involvement of immunophilins in directly mediating osteoblast-specific transcription factor gene regulation. The results of this study thus suggest that FK506-induced osteoporosis may also be accentuated by the inhibition of osteoblast differentiation and function.

Dlx5 Knock Out Calvaria Cell Cultures Have Decreased Osteoblast Differentiation. H. Li*[1], M. S. Kronenberg[1], M. Stover*[1], M. J. Depew*[2], J. R. Rubenstein*[2], A. C. Lichtler[1]. [1]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Nina Ireland Laboratory of Developmental Neurobiology, University of California at San Francisco, San Francisco, CA, USA.

Previous studies have shown that Dlx5 induces osteoblast differentiation of calvarial osteoblasts and bone marrow stromal cells. Dlx5 knockout mice have defective calvarial development. Lentivirus delivered RNAi targeting both Dlx5 and Dlx3 blocked osteoblast differentiation in calvarial cell cultures. To better understand the role of Dlx5 in regulating osteoblast differentiation, we did in vitro studies on Dlx5 knock out mice. The mice were in 129J, CD1 and C57BL/6J mixed background. Dlx5 heterozygous mutant mice were crossed and embryos were collected at stage E18.5 because the Dlx5 homozygous knock out mice were neonatal lethal. Calvaria were isolated and maintained in culture media temporarily while genotyping was being done. Calvaria with the same genotype were pooled and cultures were made from serial digestions with trypsin and collagenase. Cells were kept in DMEM until they became confluent (day 6-8) and were then switched into aMEM supplemented with ß-glycerophosphate and ascorbic acid. Cell cultures were taken down at different time point from day 11 to day 20 and Northern blot and quantitative RT-PCR were carried out to study the expression levels of key markers of osteoblast differentiation. The expression levels of alkaline phosphatase in Dlx5 homozygous knock out calvaria cell culture decreased about 40%-50%, bone sialoprotein decreased about 15% to 40%, and osteocalcin decreased about 40% to 50% compared to wild type and heterozygous Dlx5 mutant cell cultures. The decreases in osteoblast marker expression were most pronounced at the earlier time points of the cell cultures. Dlx3 expression was not changed significantly, and its expression may partially compensate for the absence of Dlx5. Our studies support the concept that Dlx5 has a positive regulatory role in osteoblast differentiation.

Abnormal Transdifferentiation Associated with Delayed Fracture Healing in Older Rats. M. H. Meyer, R. A. Meyer. Department of Orthopaedic Surgery, Carolinas Medical Center, Charlotte, NC, USA.

Formation of bone to bridge the fracture gap of healing skeletal fractures slows with age in rats and humans. While six-week-old rats reach radiographic union in four weeks following mid-shaft femoral fracture, adult 26-week-old rats need 10 weeks, and older 1-year-old rats need in excess of 6 months. To explore factors related to this delayed healing, microarray analysis was employed. Simple, transverse, mid-shaft femoral fractures with intramedullary rod fixation were induced in intact female Sprague-Dawley rats at 6, 26 and 52 weeks of age. At 0, 0.4, 1, 2, 4, and 6 weeks after fracture, the fracture site, including the external callus, cortical bone, and marrow elements, was harvested. Total RNA was extracted and pooled between pairs of rats of the same age and time after fracture, and cRNA was prepared and hybridized to 54 Affymetrix U34A microarrays (3/age/time point) with 8,700 genes on each array. GenBank entries are shown for each gene in parentheses. The average for each gene for each of the 18 treatment groups was calculated from the 3 arrays per group and analyzed by the SOM (self-organizing map) algorithm in the Data Mining Tool (3.0, Affymetrix). Several clusters contained genes with greater up-regulation in the older rats than in the young rats following fracture. Biomechanical data, bone morphogenetic protein expression, and expression of types II and X collagen suggested similar rates of formation of soft callus in young and older rats. However, two genes suggested delayed progression to calcification. ACLP (AEBP1, AA799755) and mesenchyme homeobox 2 (Meox2, Z17223) were increased more and longer in the older rats than in the younger rats. These two genes are up-regulated in cells differentiating towards mature osteoblasts. The failure of these two genes to down-regulate in the older rats suggests a failure of the osteoblasts to finish the maturation process. Also found to be up-regulated more and longer in the older rats were additional genes that are known to be up-regulated as stem cells undergo maturation towards the osteoblast and chondrocyte lineage. These genes include alpha smooth muscle actin (AA866452, AI104567, and X80130) and sarcomeric myosin heavy chain (K03467 and K03468). In conclusion, these changes suggest a stronger stimulus in the older rats for differentiation of precursor cells towards chondrocyte and osteoblast formation. However, the continued expression of ACLP and Meox2 suggest that the osteoblasts failed to fully mature and were thus slower to make bone in their fracture callus.

PTHrP Mediation of AP-1 Signaling in Mesenchymal (Cementoblast) Cells. J. E. Berry*[1], E. L. Ealba*[1], L. R. McCabe*[2], L. K. McCauley[1]. [1]Periodontics/Prevention/Geriatrics, University of Michigan, Ann Arbor, MI, USA, [2]Michigan State University, East Lansing, MI, USA.

The major components of the AP-1 family of transcription factors include the Fos members (c-Fos, Fra-1, Fra-2, FosB) and Jun members (c-Jun, JunB, JunD). These transcriptional regulators form heterodimers (Fos/Jun) or homodimers (Jun/Jun) to interact with sites (CRE or TRE) in a large number of genes important in bone. Skeletal hormones and growth factors such as PTH and PTHrP have been found to regulate AP-1 proteins and suggest these regulators may be instrumental in determining effects of anabolic agents in bone. The purpose of this study was to examine the impact of PTHrP on gene expression and nuclear protein levels of AP-1 family members in a mesenchymal cell line derived from mouse cementum (OCCM). Cells lining the tooth root from day 41 (birth at day 19) transgenic OC-TAg mice were isolated, and a clonal population that expresses markers of mineralization, including osteocalcin and bone sialoprotein, were utilized. Timed studies with PTHrP (0.1 µM) for 0, 60, 120 min. and 6 h. were performed. Northern blot analysis revealed that PTHrP rapidly increased mRNA for c-*fos* (peak at 60 minutes of 5-fold), *fra*-1 (peak at 120 minutes of 2.5-fold), *fra*-2 (peak at 60-minutes of 2-fold) and *fos*B (peak at 60-minutes of 1.5-fold). PTHrP also increased mRNA for *jun*B (peak at 60 minutes of 4-fold) but did not alter c-*jun* or *jun*D expression. Levels of Fos and Jun proteins were determined from nuclear extracts using an ELISA-based protein assay at the same time points. Levels of c-Fos peaked at 120-minutes and were the most highly elevated (12-fold) in response to PTHrP. Levels of Fra-1 peaked at 6-hours and were 2-fold elevated. Fra-2 levels peaked at 120 min and were 3-fold elevated. Levels of FosB peaked at 120-minutes and were elevated 2-fold. JunB was the only Jun family member significantly elevated at the protein level (peak at 120-minutes and 2.5-fold increase). Protein levels for phosphorylated c-Jun were reduced with PTHrP treatment at 120-minutes, and JunD levels were unchanged. Similar results for AP-1 member RNA and protein levels were obtained for MC3T3-E1 osteoblastic cells treated with PTHrP. Since JunB has been reported to be a key regulator of bone formation in osteoblasts, these data suggest that PTH and PTHrP may exert anabolic actions in bone via AP-1 heterodimerization containing one of the Fos family members and JunB. Furthermore, these data with a cementoblastic cell line suggest that PTHrP may have effects on cementum development through its action on AP-1 containing genes.

Oncofetal Fibronectin Correlates with Decreased Markers of Bone Formation in vivo and Modulates Osteoblast Proliferation and Differentiation in vitro. I. Nakchbandi, P. Feick*, A. Geursen*, M. Singer*. Department of Medicine II, University of Heidelberg at Mannheim, Mannheim, Germany.

Hepatic osteodystrophy, a disease associated with significant morbidity, results mainly from decreased bone formation. Three observations suggest that abnormal production of fibronectin (FN) may be involved in the development of hepatic osteodystrophy. First, patients with liver disease exhibit altered FN production. Second, treatment of liver stellate cells with carbontetrachloride results in the production of fibronectin isoforms not normally produced by these cells. Third, FN is important for the survival and differentiation of osteoblasts in vitro.

Circulating oncofetal fibronectin (oFN), an isoform of FN, was found to be elevated in patients with cholestatic liver disease (4.0±0.5 µg/ml, n=20) compared to age-, sex-, and BMI-matched controls (2.9±0.2 µg/ml, n=20), p=0.056. Circulating oFN correlated negatively with osteocalcin in the whole group (r= -0.39, $p<0.05$, n=40) and in the patients (r= -0.49, $p<0.05$, n=20). Next, the effect of oFN on proliferation and mineralisation of cultured human osteoblasts was examined. Treatment of osteoblasts with increasing doses of oFN resulted in a small increase in proliferation (peak response 1.32-fold induction with 10 µg/ml, $p<0.05$, n=5). Simultaneous addition of GRGDSPK and oFN showed no significant decrease in proliferation compared to oFN alone, suggesting that the oFN effect is not mediated by RGD-binding integrins. Treatment of osteoblasts in mineralising conditions with increasing doses of oFN showed that the area of mineralised nodules (determined by von Kossa staining) was decreased in oFN-treated cultures. At 100 µg/ml mineralisation was maximally reduced by 69% as compared to control (n=5, $p<0.01$).

The data show that oFN correlates with decreased bone formation markers in patients with liver disease, and that oFN modulates osteoblast proliferation and differentiation in vitro. This effect seems unrelated to RGD-signalling. Since oFN promotes proliferation, it may indirectly inhibit differentiation. In conclusion, the increase in oFN production by the liver and its release into the circulation influences osteoblasts and hence may contribute to the decreased bone formation seen in chronic cholestatic liver disease.

Computer Simulations Support the Regulatory Role of the Matrix in Bone Formation. M. J. Martin, J. C. Buckland-Wright*. Applied Clinical Anatomy Research, King's College, London, London, United Kingdom.

The development of pharmaceutical treatments for bone disease can be enhanced by mathematical models that predict their effects on formation during cancellous bone remodeling.

The amount of bone formed and the duration of the formation phase at one micro-site on the surface of cancellous bone was simulated by, the number of mature osteoblasts and changes in rates of osteoblast activity. The number of mature osteoblasts at the start of osteoid formation was simulated by a relationship that describes the proliferation of muscle stem cells in the presence of growth factors (Deasy et al., 2002). Osteoblast activity was described by Michaelis-Menten enzyme kinetic equations adapted to describe cellular activity.

The model incorporated four negative feedback effects on the rate of bone formation:

- the reduction in size of mature osteoblasts with differentiation, which limited the maximum capacity of cellular osteoid-forming activity;
- the reduction in osteoblast cell numbers due to osteocyte formation;
- the apoptosis of surplus osteoblasts that are not required for lining cell or osteocyte formation;
- and, as mineralization progresses, the limited availability of osteoid substrate.

The model was parameterised by fitting simulations to data of changes in absolute osteoid seam thickness and it's depth of formation and mineralization, together with relative changes in rates of osteoid formation and calcification (Eriksen et al., 1984).

Simulated depth of new bone formed was increased by 12.2% and 6.4% by a 2% increase in mitotic fraction, and a 2% decrease in division time, respectively. The duration of formation was increased by 2.6% with a 2% increase in maximum capacity of osteoid-forming activity. A 2% change in other input variables produced less than 2% changes in depth and duration.

The high sensitivity of bone formation to mitotic fraction supports the potential role played by the matrix in mediating cell number, not only by embedded mitogenic growth factors, but also by the amount of surface area of matrix that is available for cell attachment. The bone matrix factors that control the mitotic fraction and division time of pre-osteoblasts during proliferation are therefore suggested to be potentially useful areas for future pharmaceutical research.

Tartrate-Resistant Acid Phosphatase Deficient Mice Have Defective Osteoblast Function And Increased Mineralization. H. C. Roberts*[1], L. Dufaur*[1], T. M. Cox*[2], M. J. Evans*[3], A. R. Hayman[1]. [1]School of Clinical Veterinary Science, University of Bristol, Langford, Bristol, United Kingdom, [2]Medicine, University of Cambridge, Cambridge, United Kingdom, [3]School of Biosciences, University of Cardiff, Cardiff, United Kingdom.

Tartrate-resistant acid phosphatase (TRAP) is an iron-containing protein expressed by osteoclasts, macrophages and dendritic cells. The enzyme is secreted by the osteoclast during bone resorption and serum TRAP activity correlates with the level of resorptive activity in diseases of bone metabolism. Although its precise role is unknown, we have shown using 'knockout' mice that TRAP is essential for the normal mineralization of cartilage in developing bones and the maintenance of the adult skeleton. Mice lacking TRAP were shown to have a skeletal phenotype characterised by developmental deformities of the limbs and axial skeleton. These bones were wider and shorter than normal with thickened cortices and disorganised, enlarged growth plates. An increase in mineralization density was also observed. Osteoclasts isolated from TRAP knockout animals demonstrated a defect of bone resorption in vitro which over time may have resulted in the increased bone density observed. However, osteoblast function could also be affected in the animals lacking TRAP and contribute to the altered bone density. We now demonstrate studies on osteoblast function in vitro.

The development of the osteoblast phenotype normally involves three distinct phases: a proliferative phase, a matrix development and remodelling phase followed by a mineralization phase. Osteoblasts were isolated from the bone marrow of 6 week old TRAP deficient and normal (wild-type) mice and cultured in α-MEM medium containing 10%FCS and antibiotics. The cell growth rate was determined spectrophotometrically by measuring the activity of living cells via mitochondrial dehydrogenase activity. In the proliferative phase cell growth for osteoblasts isolated from wild-type mice was approximately 55% higher than osteoblasts lacking TRAP. To evaluate the ability of osteoblasts to form and mineralize bone nodules in vitro, wild-type and knockout osteoblasts were cultured in media supplemented with ascorbic acid (50μg/ml), using β-glycerophosphate (10mM) as the phosphate source. At selected time points, the cultures were fixed and stained with von Kossa. The number of mineralized nodules was significantly greater in the osteoblast cultures from the TRAP knockout mice.

We conclude from these studies that the growth of cells is reduced in osteoblasts deficient in TRAP and that mineralization is increased. This suggests that TRAP plays a role in the regulation of bone formation and its mineralization.

Parathyroid Hormone Related Peptide (1-36) Decreases Bone Nodule Formation and Reduces Bone Sialoprotein mRNA during Intramembranous Ossification by Neonatal Rat Calvarial Cells. S. A. Kamel*, J. A. Yee. Biomedical Sciences, Creighton, Omaha, NE, USA.

The appearance of neonatal mice that develop in the absence of parathyroid hormone-related peptide (PTHrP) established that the peptide is necessary for normal development and growth of the skeleton. The shortening of appendicular bones in knockout mice is explained by an effect of PTHrP on endochondral bone growth where it functions to inhibit the hypertrophy of chondrocytes in the epiphyseal growth plate. Whether or not PTHrP influences intramembranous ossification is less clear. The purpose of this study was to examine the expression of PTHrP and its receptor (PTH1R) by osteogenic cells involved in intramembranous ossification *in vitro* and to determine the effect of exogenous PTHrP on this process. Cells isolated from calvariae of neonatal rats were plated at 75 cells /cm^2 so that individual cell colonies could be studied over a period of 3 weeks. Continuous and intermittent treatment with PTHrP (1-36) was compared to address whether the pattern of exposure to PTHrP influenced the response by rat calvarial cells. PTHrP and PTH1R were localized by immunohistochemistry and alkaline phosphatase (AP) was detected by enzyme histochemistry. Staining was visualized by confocal microscopy. Calvarial cells were exposed to 100 nM PTHrP (1-36) continuously or for the first 1 or 6 hrs of each 48 hr incubation interval (intermittent treatment). The effects of PTHrP on proliferation, apoptosis and gene expression were measured using BrdU incorporation, TUNEL staining and real time RT-PCR respectively. It was found that PTHrP and PTH1R were co-localized in cell colonies as early as day 3 while AP was not detected until day 6. During the course of bone nodule development PTHrP and its receptor were co-localized in pre-osteoblasts, osteoblasts, and osteocytes. By comparison, the AP activity exhibited by pre-osteoblasts and osteoblasts disappeared in osteocytes. Both continuous and intermittent exposure to PTHrP (1-36) caused a reversible inhibition in bone nodule formation. Treatment with PTHrP (1-36) had no effect on AP activity, cell proliferation, apoptosis, or the level of osteopontin mRNA. However, bone sialoprotein (BSP) mRNA was reduced by > 90% compared to control. These results suggest that PTHrP may be function as an autocrine/paracrine factor for cells in the osteoblast lineage involved in intramembranous ossification. Since PTHrP inhibited bone nodule formation and reduced BSP gene expression, we conclude that PTHrP may influence bone mineralization by controlling the production of BSP.

Therapeutic Touch Affects Proliferation and Bone Formation in Vitro. A. P. Jhaveri*[1], M. B. McCarthy*[1], Y. Wang*[2], G. Gronowicz[1]. [1]Orthopaedic Surgery, UCONN Health Center, Farmington, CT, USA, [2]Statistics, UCONN, Storrs, CT, USA.

Pioneered and developed by Dr. Dolores Krieger and Dora Kunz, modern-day Therapeutic Touch (TT) is a highly disciplined and orchestrated 5-step process by which a practitioner can promote healing. TT is performed by holding hands 5-10 cm away from the patient or the culture dish. Our goal was to determine if TT had an effect on the growth and differentiation of bone cells *in vitro*. Human osteoblasts (HOBs) obtained from orthopaedic procedures, and an established osteoblast-like cell line originally dervived from a human osteosarcoma (SaOs-2) were used. Cells were plated into 6-well culture dishes at 10,000 cells/cm^2/$2ml^{-1}$ and incubated at 37°C, saturated humidity for 2 days prior to treatment. To test the effects of TT on cells, the culture plates were removed from the incubator for 10 minutes twice per week and divided into the following treatment groups; 1. qualified TT practitioners, 2. non-TT practitioner (an individual unfamiliar w/TT) and 3. untreated. Results were statistically analyzed with the Wilcoxon Rank Sum test.

At 1 and 2 weeks, cell proliferation was determined by [^{3}H]-thymidine incorporation and by immunocytochemistry for Proliferating Cell Nuclear Antigen (PCNA) (Zymed Laboratories Inc., San Fransisco, CA). No significant differences were found in proliferation assayed by [^{3}H]-thymidine incorporation at 1 or 2 weeks for SaOs-2 cells and 1 week of TT for HOBs. However, TT significantly ($p=0.01$) increased HOB proliferation after 2 weeks. PCNA staining confirmed these data. At 2 and 4 weeks, calcium content was measured biochemically (Eagle Diagnositics, De Soto, TX) and was visualized by fluorescent microscopy with calcein and phalloidin. No calcium content increase was observed in HOB or SaOs-2 cells at one week, but mineralization increased significantly in HOBs ($p=0.002$) and significantly decreased in SaOs-2 ($p=0.004$) after 2 weeks of TT, which was confirmed by calcein/phalloidin staining. Northern blots were performed to determine the expression of mRNA levels (Qiagen Inc., Valencia, CA) of Type I collagen, bone sialoprotein and alkaline phosphatase. Northern blots indicated an increase in mRNA expression for bone matrix proteins in HOBs and a decrease for SaOs-2 cells at 2 and 4 weeks of culture.

In conclusion, Therapeutic Touch increases human osteoblast proliferation, differentiation and bone mineralization, and decreases differentiation and mineralization in human osteosarcoma-derived cells. This is the first demonstration of TT being able to affect osteoblast proliferation and differentiation, and is the first to demonstrate statistically significant effects of TT *in vitro*.

In Vitro Assessment of Demineralized Bone Matrix on Murine Mesenchymal Stem Cell Differentiation. J. L. Fitch*[1], D. Knaack*[2], T. A. Einhorn[1], L. C. Gerstenfeld[1]. [1]Orthopaedic Surgery Research Laboratory, Boston University Medical Center, Boston, MA, USA, [2]Osteotech, Inc, Eatontown, NJ, USA.

In 1965, Marshall R. Urist demonstrated that implantation of demineralized bone matrix (DBM) at extraskeletal sites induced *de novo* formation of cartilage and bone. While it is assumed that BMPs are the primary inductive factors in DBM, the bone matrix contains many other morphogens, cytokines and mitogens. However, few comparative studies of DBM and BMPs have been performed. The purpose of our investigation was to develop an in vitro system to assess the effects of DBM treatment on skeletal cell differentiation. Specifically, we wanted to determine the duration of bioactivity within DBM, its dose dependency and the underlying molecular mechanisms by which it effects differentiation. Initial experiments examined the inductive activities of DBM on C3H10T1/2 murine mesenchymal stem cells. Previous studies using C3H10T1/2 cells have shown that they would undergo an endochondral sequence of cellular differentiation when exposed to BMPs. Comparison of the gene expression of cells treated with BMP-2 and DBM indicated that, while both induce expression of collagen-α1 type X, collagen-α1 type II and osteopontin, the inductive effects of BMP-2 were four times greater than that of the highest dose of DBM. However, the known concentrations of BMP in this quantity of DBM would be ~50 fold less than the added BMP. Interestingly, treatment with high doses of DBM induced expression of bone sialoprotein while BMP-2 treated C3H10T1/2 cultures never showed the induction of this gene. Noggin is a demonstrated antagonist of BMPs. We applied Noggin to the media of C3H10T1/2 cell cultures treated with DBM in a dose previously demonstrated by our laboratory to inhibit the effects of BMPs on C3H10T1/2 cells. These results indicated that Noggin did not have an antagonistic effect on DBM's bioactivity. Qualitatively, the ability of DBM to induce bone sialoprotein and its resistance to antagonism by Noggin suggest that there are other bioactivities in DBM than simply BMPs. These data suggest that DBM appears to promote a fuller range of osteogenic gene activity in the C3H10T1/2 cells than BMP alone.

Polyphenols in the Extract of Greens+™ Herbal Preparation Have Effects on Cell Proliferation and Differentiation of Human Osteoblast Cell Line SaOS-2. B. Balachandran*[1], V. Rao*[2], T. Murray[1], L. Rao[1]. [1]Medicine/Division of Endocrinology & Metabolism, St.Michael's Hospital, Toronto, ON, Canada, [2]Nutritional Sciences, University of Toronto, Toronto, ON, Canada.

Postmenopausal osteoporosis is a condition resulting from an abnormality in bone remodeling. There is evidence to implicate oxidative stress in the pathophysiology of osteoporosis. Epidemiological studies associate polyphenol intake with increased bone mineral density. Polyphenols are a natural component of plants that have potent antioxidant properties. greens+™ is a commercially available herbal preparation that is an important source of antioxidant polyphenols. The purpose of this study was to determine the effects of antioxidant polyphenols in the extract of greens+™ on the cell proliferation and differentiation of human osteoblast cell line SaOS-2 and to compare these effects with those of a standard pure phenolic compound**,** epicatechin. The total content of polyphenolics in Greens+ ™ was found to be 1.396 ± 0.29 mg of expressed as gallic acid equivalents/100g. The SaOS-2 cells were cultured in supplemented Ham's F-12 medium in the absence or presence of greens+™ extracts containing various concentrations (0.4, 0.8, 1.2, 1.6, 2.0mg/ml) of greens+ extract corresponding to 5.6, 11.7, 16.8, and 22.3, 27.9ng/ml of total polyphenol expressed as gallic acid equivalents/ml respectively. Control cultures received the vehicle extract. greens+™ extracts were added at day 8 and at every medium change thereafter. The cultures were stopped and the cell numbers determined after 2, 4, 7 and 9 days of treatment using the Methylene Blue Assay. Our results showed that the cell numbers increased significantly ($p<0.05$) compared to vehicle control after 2 and 4 days of treatment. The effects on cell proliferation of greens+™ extracts containing free polyphenol of 5.6 to 27.9 ng gallic acid equivalent/ml were found to be greater and more potent than those of the standard pure polyphenolic compound, epicatechin, at concentrations of 11.6 and 116.4 ng/ml. However, the cell numbers were reduced significantly after 7 days of treatment with greens+™ extract. Treatment with greens+™ extract from day 13 to the end of culture period resulted in **a** significant ($p<0.05$) inhibition of alkaline phosphatase activity in a time ($p< 0.0001$) and dose dependent ($p<0.0001$) manner. In conclusion, our results showed that greens+™ extract influenced human osteoblasts in a manner consistent with its effects on the proliferation and subsequent differentiation of osteoprogenitors towards progression to a bone-forming stage. Our data suggest that greens+™ may have beneficial effects on bone formation.

MMP-13 Negatively Regulates Osteoblast Activity. J. M. Owens[1], P. S. Chockalingam*[1], J. J. Wu*[2], J. M. Wozney[1], S. Fukayama[1]. [1]Womens Health & Bone, Wyeth Research, Cambridge, MA, USA, [2]Chemical & Screening Sciences, Wyeth Research, Cambridge, MA, USA.

Matrix metalloproteinase-13 (MMP-13/Collagenase-3) plays an important role in extracellular matrix remodeling. MMP-13 is expressed in osteoblasts and hypertrophic chondrocytes and specific cell-surface receptors for MMP-13 have been cloned from rat osteoblastic UMR-106 cells. Although it has recently been reported that MMP-13 knockout mice have increased bone volume, (Inada et al ASBMR 2002), the functional role of MMP-13 in bone remodeling remains unclear. We used the neonatal mouse calvaria organ culture to examine the action of an MMP-13 inhibitor on bone remodeling. This inhibitor was active at 3nM against MMP-13, with more than 10,000 fold selectivity over MMP-1 and MMP-14. Incubation of calvaria with MMP-13 inhibitor for 7 days was without effect on either total bone area or number of osteoblasts. MMP-13 inhibitor was also without effect on basal or fibroblast growth factor-2 (FGF-2)-induced bone resorption, as assessed by measuring calcium release from calvaria into the medium. However, the osteoblasts surrounding the calvaria became cuboidal after treatment with MMP-13 inhibitor, suggesting that they were activated. These findings suggest that MMP-13 plays a role in regulating osteoblastic function. To investigate this we examined the effect of MMP-13 inhibitor on two well-established osteoblastic cell lines. First, we confirmed that human osteoblastic SaOS-2 cells produce MMP-13 by fluorometric analysis of cell lysates and conditioned media. Incubation with MMP-13 inhibitor for 72 hours significantly increased alkaline phosphatase (ALP) activity in these cells. Osteocalcin expression was also up-regulated following treatment with MMP-13 inhibitor, as assessed by RT-PCR. On the other hand, treatment with 1nM MMP-13 enzyme, significantly inhibited ALP activity in UMR-106 cells. Incubation with other MMPs, such as MMP-2, MMP-9 or aggrecanase, did not significantly alter ALP activity in these cells. In addition, neutralization of MMP-13 enzyme activity with MMP-13 inhibitor did not reverse the inhibitory effect of MMP-13 enzyme on ALP activity in these cells. These findings argue against the possibility that the action of MMP-13 is mediated via its enzymatic interaction with extracellular matrix proteins. We also examined the effect of MMP-13 inhibitor on osteoclast differentiation and activity. Multinucleated TRAP-positive cell number and pit number were not significantly altered by the inhibitor, in mouse bone marrow cultures treated with M-CSF and RANKL. Together, our data are consistent with the hypothesis that MMP-13 negatively regulates osteoblastic function possibly via its specific receptor on osteoblasts.

Differentiating Human Adipocytes Reduce Osteoblast Function and Survival through the release of Fatty Acids: Senile Osteoporosis as a Lipotoxic Disease. G. Duque. Medicine/Geriatrics, McGill University, Bloomfield Centre for Aging Studies, Montreal, PQ, Canada.

BACKGROUND: The increasing bone marrow adipogenesis in aging bone is a consequence of the dysdifferentiation of mesenchymal adipocyte-like default cells which release large amounts of fatty acids that could affect osteoblast proliferation, action and survival. Although previous studies using mature adipocytes in co-cultures with osteoblasts have shown that secreted fatty acids affect osteoblast proliferation without affecting survival, no studies have looked at pre-differentiated adipocytes which are the predominant cells in the aging bone marrow.

AIM: To determine the influence of differentiating adipocytes on the proliferation and activity of human osteoblasts *in vitro*.

METHODOLOGY: Human primary osteoblasts (Cambrex, Pittsburgh, PA) were co-cultured with adipogenic differentiating mesenchymal stem cells (MSC) for three weeks being separated by a porous membrane (0.4 μm). Osteoblasts were seeded either in the upper or the lower side of the membrane. Osteoblasts cultured under the same conditions but without the presence of MSC were used as a control. After three time intervals (first, second and third week) cell proliferation and viability were assessed using MTS-Formazan and trypan blue staining respectively. In addition, alkaline phosphatase and mineralization staining were used as markers of osteoblastic activity. Finally, cerulenin, a known inhibitor of fatty acid oxidation, was used to potentially reverse the toxic effect of fatty acids and to assess the potential mechanism.

RESULTS: Although at all time intervals all parameters were significantly lower, a more significant effect was found on proliferation (-32±4%, $p<0.005$) and viability (-70%± 4%,$p<0.01$) of human osteoblasts at one week as compared with the control. In addition, the proportion of alkaline phosphatase and mineralization expressing cells was significantly lower in co-cultured osteoblasts than in the control (42%±4 vs. 86%± 3,$p<0.01$). Finally, the addition of cerulenin (10 μg/ml) induced a recovery in osteoblast function and viability at all three time points.

CONCLUSION: We found that both pre-adipocytes and differentiated adipocytes not only inhibited osteoblast proliferation but also affected their survival and activity. The potential mechanism involves the release of fatty acids by adipocytes more significantly in their early stages of differentiation. The regulation of the presence of pre-adipocytes in bone marrow might constitute a new approach for the treatment and prevention of age-related bone loss.

Knockdown of Chordin Using siRNA Induces Osteoblastic Differentiation in MC3T3-E1 Preosteoblastic Cells. W. Huang, G. Rudkin*, K. Ishida*, D. T. Yamaguchi, T. A. Miller*. Plastic Surgery, VA Greater Los Angeles Healthcare System, Los Angeles, CA, USA.

Signaling of bone morphorgenetic proteins (BMPs) is regulated at multiple levels: intracellularly, at the membrane site and extracellularly. Chordin is one of major extracellular antagonists of BMPs. In order to better understand the role of chordin in BMP-2 induced osteoblastic differentiation, we silenced expression of chordin in MC3T3-E1 cells using small interfering RNA and studied the effect of silencing of chordin on osteogenic differentiation in targeted cells. Among the four double-stranded siRNAs designed for targeting chordin, one of them was effective in silencing chordin when transiently transfected into MC3T3-E1 cells. Transfected cells demonstrated a decrease of approximately 70% in steady state chordin mRNA accompanied by an about 80% decrease in chordin protein secreted into culture medium. Those cells also exhibited drastic increases (>100-fold) in the mRNA expression of osteocalcin and alkaline phosphotase. Protein expression of alkaline phosphatase was significantly increased as measured by its enzymatic activity. The effect of chordin siRNA on osteoblastic differentiation can last up to 7 days. Comparison of mineralization showed little effect after 10 days of siRNA transfection. These data indicate that a decrease in chordin expression results in an increase in osteoblastic differentiation. The chordin siRNA is a potent enhancer of osteoblastic differentiation. It has an implication in the development of therapeutic agents that increase bone formation.

Co-culture of Human Umbilical Vein Endothelial Cells (HUVEC) with Human OsteoProgenitors (HOP): Effects on Osteoblastic Differentiation and/or Neoangiogenesis. B. Guillotin*, R. Bareille*, C. Bourget*, L. Bordenave*, J. Amedee. Gironde, INSERM U 577, Bordeaux, France.

Osteogenesis relies on a balance between bone formation and bone resorption, and occurs in striking interaction with neoangiogenesis. In this tightly regulated process, cell-to-cell communication supported by Connexin-43 in bone plays a pivotal role. Assuming that endothelial cells are located in very close vicinity to bone formation sites, we have been interested for several years in the potential role of endothelial cells and Connexin-43 in osteoprogenitor differentiation.

Our previous work has detailed an immunomagnetic-based method to separate primary HUVEC from primary HOP after a time of co-culture. Thus, molecular effects of HUVEC could be specifically studied on the HOP and reciprocally. The aim of our study was to identify bone specific markers as well as extracellular matrix (ECM) proteins which are regulated by the co-culture.

We first focused on the analysis of the temporal expression of osteogenic markers such as Alkaline phosphatase (ALP), CBFA1 and Osteocalcin (OC) in HOP co-cultured with HUVEC up to 48 hours. The results, as assessed by RT- real time quantitative PCR (RT-QPCR) have confirmed previous work showing an up regulation of ALP in the co-cultured HOP compared to HOP alone. Surprisingly, we also showed that the co-culture induced a 2 fold down regulation of CBFA1 in the HOP, and a 4 to 5 fold down regulation of OC.

Second, we took advantage of macroarrays to study the effects of the co-culture on the expression pattern of osteogenesis markers in the HOP. This global study revealed that genes implicated in ECM remodelling were regulated in co-cultured HOP as compared to steady-state expression in controls. HSP47, which participates in fibrillar Collagen (type I and type V) assembly, was 2 fold up-regulated in co-cultured HOP. A 4 fold up-regulation of type V Collagen was also observed. Timp-1, an inhibitor of metalloproteinase was also up-regulated whereas MMP-2 (type 2 metalloproteinase) was 2 fold down-regulated. Finally, preliminary microscopic observations indicate that the co-culture induces tube formation by the HUVEC in our model, to which ECM synthesis and remodelling could partly contribute.

Put together, our results suggest that osteoblast/endothelial cells communication modulate osteoblast differentiation and ECM synthesis. This should have some significance for bone remodelling or/and neoangiogenesis.

Exploring the In Vitro Proteome of Differentiating Osteoblasts. S. C. Verberckmoes, A. Hufkens*, L. Oste*, G. J. Behets*, M. E. De Broe*, P. C. D'Haese*. Nephrology-Hypertension, University of Antwerp, Wilrijk, Belgium.

Primary osteoblast cultures isolated from rat bone marrow have widely been used as a model of in vitro osteogenesis. The effects of various culture conditions on the protein expression of this model has been investigated in the past by others using classical protein analysis techniques such as ELISA and Western blotting. One of the major drawbacks of these techniques is the very limited number of proteins that can be analyzed in each experiment. Recently, methods such as differential proteome analysis based on two-dimensional polyacrylamide gel electrophoresis (2D-PAGE) have become available allowing the comparison of the expression of many proteins simultaneously. To the best of our knowledge, no reports on the osteoblast proteome have been reported so far. Therefore we have used the 2D-PAGE technique to construct a reference proteome map of the rat osteoblast under standard mineralizing in vitro conditions.

Bone marrow was flushed from the femoral cavity of five 22 week-old rats. The released cells were collected in five 75 cm^2 flasks and grown until confluence in alpha-MEM medium supplemented with 10 % fetal calf serum, 50 µg/ml ascorbic acid and 10^{-9} M dexamethasone. At confluence the cells were passed into 6-well plates after which the experiment was started. From confluence in the 6-well plates the medium was further supplemented with 2 mM beta-glycerolphosphate after which the cultures were further cultivated for 2 weeks. Medium samples for the analysis of alkaline phosphatase (ALP) activity and Ca-incorporation were taken from 3 different parallel experiments during medium refreshments 3 times per week. Cell samples for proteome analysis were taken from 3 independent cultures at the time of confluence, 1 and 2 weeks post-confluence to build up a time evolution map of the differentiating osteoblast proteome.

ALP activity, Ca-incorporation and nodule development showed a normal time-evolution characteristic for the in vitro osteoblast differentiation as reported in literature. The 2D-PAGE profiles showed 326 ± 42, 450 ± 133 and 1082 ± 183 individual spots at confluence, 1 and 2 weeks post confluence respectively. Differential analysis of the protein profiles was performed based on a spot intensity ratio threshold of 2 and revealed an up-regulation of 755 spots and a down-regulation of 9 spots over time.

Identification of these spots using MALDI tandem mass spectrometry is ongoing and will allow us to further complete the construction of an osteoblast proteome database. In the near future this proteome database will be used as a reference for the detection of changes in osteoblast protein expression in response to a large range of physiological and pathophysiological stimuli.

The Transcription Factor Osterix Controls Both Osteoblast Proliferation and Osteoblast Differentiation. C. Zhang, K. Sinha*, X. Zhou*, K. Nakashima*, B. de Crombrugghe*. Department of Molecular Genetics, University of Texas M. D. Anderson Cancer Center, Houston, TX, USA.

Osterix (Osx) is an osteoblast-specific transcription factor required for bone formation and osteoblast differentiation. Indeed, in Osx-null embryos, which completely lack both endochondral and intramembranous bone formation, preosteoblasts are arrested in their differentiation and fail to express many osteoblast marker genes, despite normal expression of the transcription factor Runx2 in these cells. To determine whether Osx plays a role in control of osteoblast proliferation, we now compared proliferation rates of primary calvarial cells isolated from wild type and Osx-null E18.5 embryos. BrdU incorporation in Osx-null cells was increased compared to wild type cells. We also generated C2C12 cells in which expression of a stably integrated Osx DNA could be induced using the Tet-off system. Induction of Osx expression inhibited cell proliferation. To begin to examine possible mechanisms by which Osx could control osteoblast proliferation, we used microarrays to compare the RNA expression profiles of wild type and Osx-null calvarial cells from E18.5 embryos. These experiments have revealed the broad repertoire of genes that constitute the genetic program of osteoblasts controlled by Osx, and strongly support the view that Osx is a major effector of the osteoblast program. Among the differentially expressed genes, expression of a Wnt inhibitor, Dkk1, which is high in wild type osteoblast, was abolished in calvarial cells of Osx-null embryos. In addition, expression of several Wnt target genes such as c-Myc and cyclin D1 increased in Osx-null calvarial cells. These results are consistent with the notion that Osx could control osteoblast proliferation through the Wnt pathway, a pathway that has been implicated in several human bone genetic diseases. We hypothesize that Osx coordinates both osteoblast differentiation and proliferation.

Downstream Mitogenic Signaling of Osteogenic Growth Peptide C-Terminal Pentapeptide Involves Transcriptional Activation of MAP Kinase-Activated Protein Kinase 2. S. San-Miguel*, M. Attar-Namdar*, I. Bab*. Bone Laboratory, Hebrew University of Jerusalem, Jerusalem, Israel.

The osteogenic growth peptide (OGP) is a 14-mer bone cell mitogen that reverses ovariectomy-induced bone loss and enhances fracture healing. Its active derivative comprises the C-terminal pentapeptide, OGP(10-14). Mitogenic signaling by OGP(10-14) involves G_i-protein and MAP kinase activation. To further explore the downstream signaling activated by OGP(10-14) we examined its effect on phosphorylation of the MAP kinases ERK1, ERK2 and p38 in murine osteoblastic MC3T3 E1 cells. Immunoblot analysis using antibodies against the phosphorylated forms of these MAP kinases showed dose-dependent activation of ERK1 and ERK2, but not p38, 5-15 min after a challenge with OGP(10-14). The optimal OGP(10-14) concentration, 10^{-13} M, is also the dose with the highest OGP(10-14) mitogenic activity in these cells. In line with these results, the ERK1/2 inhibitor PD98059, but not the p38 inhibitor SB203580, inhibited the OGP(10-14) stimulation of BrdU uptake. We then subjected RNA from OGP(10-14)-treated MC3T3 E1 cells to microarray analysis using a cDNA array designed to interrogate the MAP kinase pathway. Of the genes encoding nuclear proteins, only the expression of MAP kinase -activated protein kinase 2 (Mapkapk2) was changed, showing >2-fold increased mRNA levels in cells treated with OGP(10-14) for 4-8 hours. Real-time RT-PCR analysis showed 3- to 96-fold OGP(10-14)-induced increase in mRNA levels in three independent experiments. The increase in Mapkapk2 mRNA was associated with a vast increase in Mapkapk2 total protein after 8-24 h exposure to OGP(10-14), as demonstrated by immunoblot analysis. This was accompanied by a moderate inhibition of Mapkapk2 phosphorylation. Collectively, these data suggest that the OGP(10-14) mitogenic activity is mediated by ERK1/2 activation, resulting in increased Mapkapk2 levels and thus overall activity. Mapkapk2, in turn, was previously shown to phosphorylate CREB that has an important role in osteoblastic cell proliferation and differentiation.

The Effect Of Oxygen Tension On The Colony Formation Of Human Connective Tissue Progenitor Cells. S. M. Villarruel*, C. A. Boehm*, K. A. Powell*, M. Pennington*, G. M. Muschler. Biomedical Engineering, Cleveland Clinic Foundation, Cleveland, OH, USA.

Bone marrow (BM) contains connective tissue progenitor cells (CTPs) that can be activated to form new tissues. Proliferation of CTP progeny can be characterized using a colony-forming unit (CFU) assay. The number of CFUs found in a population reflects both the number of CTPs in the population and the activation efficiency of these cells under the culture conditions. Proliferation can be assayed in each colony, based on the number of cells in each colony at a fixed time. Optimization of the use of CTPs in therapeutic cellular grafts requires an improved understand of the bone healing environmental condition of hypoxia on CTPs.

BM derived cells were cultured to promote an osteoblastic phenotype for 6 days under oxygen levels: 20%, 10%, 5%, and 1% and then fixed and DAPI stained. CTP cultures were imaged using a Quantix K6303E 12 bit digital camera attached to a Leica DMXRA motorized microscope controlled by Metamorph . Individual images were collected at 512 x 768, 8-bit gray level, using a 10x objective and then montaged together to create one image of the cell culture well (2cm x 2cm). The image analysis software used for quantitative characterization of CTPs was developed using algorithms written in the C/C++ and Motif X-Windows TM environment.

In fifteen patient donors, a total of 9,174 colonies containing a total of 367,418 cells were assayed. The colony forming efficiency, based on the median number of colonies at each oxygen tension was increased at all lower oxygen tensions when compared to CTPs cultured at 20%. Oxygen tension 5% is sixty percent more efficient than the baseline value of 20% O_2 with a p-value<0.0001. In addition both 1% O_2 and 10% O_2 are also higher than the baseline. This is also reflected in that the median colony formation increased at lower oxygen tensions. All oxygen tensions possess a similar cells per colony distribution trend, but both 5% and 10% O_2 are markedly greater than oxygen tensions 1% and 20%, which themselves are comparable. Cycles of proliferation was significantly greater at all lower oxygen tensions than at 20% O_2 (p-value < 0.0002) despite large variation between individual CFUs at all oxygen tensions.

Using the CFU assay we have demonstrated that low oxygen tension conditions, even down to 1% O_2 may actually increase CTP activation and also increase the proliferation of progenitor cells in colonies. These features may enhance the CTPs capacity to survive and compete with other local cells in the wound healing environment or other transplantations. These findings have important implications in the biological response and survival of CTPs and also influence the design of delivery systems for CTPs in tissue engineering applications.

Bisphosphonates Differentially Affect Osteoblast Survival In Vitro. R. W. Katz[1], Q. Sun[2], J. P. Bilezikian[2]. [1]Oral Medicine, College of Dentistry, New York University, New York, NY, USA, [2]Medicine, College of Physicians and Surgeons, Columbia University, New York, NY, USA.

Bisphosphonates (BPs) have had a major impact on the management of osteoporosis and other metabolic bone diseases. Their actions have generally been ascribed to a direct inhibitory action on mature osteoclasts. Recent studies have suggested that BPs may also act directly on cells in the osteoblast lineage. Previously, we have shown that BPs affect signaling pathways utilized by the bone forming agents, parathyroid hormone and teriparatide. We intend to test the hypothesis that BPs affect osteoblast proliferation and survival. Several osteoblast cell lines were examined for their ability to grow in-vitro for 48-72 hours in the presence of BPs with a fluorometric assay of total DNA from harvested cell cultures. SaOS-2 cells displayed a 30% decrease in total DNA at 48 hours in the presence of 10-4 M risedronate (RIS) or alendronate (ALE) and at 72 hours, an even greater reduction in DNA was noted with ALE (65% of control values). The normal increases in cellular DNA of UMR-106 cultures was also inhibited significantly at 48 hours, with RIS being more potent than ALE (50% reduction with RIS compared to 30% with ALE). By 72 hours of culture, both BPs strongly inhibited cell accumulation. In experiments utilizing normal diploid rat calvarial osteoblast cultures, the effects of BPs was striking, with only minor (20-50%) increases in total DNA at 48 and 72 hours compared to initial starting values. In contrast, control calvarial cultures showed 3-4 fold increases in DNA content at 48-72 hours. To determine whether the inhibition of culture growth was due to increased cell death, the proportion of propidium iodide positive cells was examined by FACs. In UMR-106 cultures, treatment overnight with 10-6 M RIS led to a 2-3 fold increase in cell death over that seen with ALE-treated cultures. In SaOS-2 cultures, both BPs increased the percentage of dying cells three-fold over control cultures. In summary, our results indicate that BPs differentially affect osteoblast survival and cell accumulation in-vitro. Further studies are needed to understand how, under what circumstances, and by what mechanisms, BPs affect osteoblasts. These observations have key relevance to concepts of BP action, with particular reference to their potential use with bone forming agents, like teriparatide.

The PKA Inhibitor PKIγ, Is a Potent Regulator of Osteoblast Differentiation. L. Zhao*[1], S. Yang*[1], M. Petrey*[2], P. Stevens*[2], N. Jaiswal*[2], T. Zhu*[1], X. Ji[2], G. Sabatakos[2]. [1]Nankai University Medical College, Tianjin, China, [2]Skeletal Research, Procter and Gamble Pharmaceuticals, Mason, OH, USA.

In an effort to identify novel bone anabolic therapeutic targets we performed extensive genomic studies that evaluated the expression profile of regulated genes during osteoblastic differentiation of human mesenchymal stromal cells. Protein kinase inhibitor γ (PKIγ) was identified as a putative target as its expression was significantly downregulated in the presence of BMP-2. In order to elucidate the mechanism by which PKIγ regulates osteoblast differentiation we generated stable transfectants of PKIγ in C2C12 cells. Analysis of the effect of PKIγ overexpression in response to BMP-2 demonstrated a decrease in the expression of the early osteoblast markers osterix and Collagen type I. Furthermore the decrease in the mRNA levels of osteoblast marker genes in cells expressing PKIγ correlated with a decrease in alkaline phosphatase activity that was comparable to the response of control cells. In order to determine whether the inhibitory effect of PKIγ is mediated via effectors of the BMP/Smad pathway, we compared the activation of phosphorylated Smad1 between control and PKIγ overexpressing cells. Although pSmad1 levels were induced in control cells in response to BMP-2, no changes were observed in the PKIγ stable transfectants, suggesting that the effect of PKIγ could be mediated through alternative pathways. In order to investigate possible synergism between the PKA and BMP-2 pathways, C2C12 cells were treated with the PKA activator 8-Br-cAMP or inhibitor KT5720 and the alkaline phosphatase activity of the cells was determined in the presence of BMP-2. Although the alkaline phosphatase levels of the cells were not affected by treatment with either the PKA activator or inhibitor alone, co-administration of BMP-2 resulted in a synergistic increase or decrease in alkaline phosphatase activity, respectively. Having demonstrated that PKA and BMP-2 can synergistically regulate osteoblastic responses, we investigated whether the inhibitory effect of PKIγ on BMP-2 induced osteoblast differentiation was mediated via the PKA pathway. For this purpose, we studied the ability of PKIγ to modulate the activity of the cAMP-response element (CRE) using the Mercury Profiling Pathway System. As expected, BMP-2 induced AP-1 responses were inhibited by PKIγ overexpression. More importantly, PKIγ overexpression inhibited BMP-2 induced CRE responses. In conclusion our data suggest that the osteoblastic potential of C2C12 cells could be regulated by a mechanism that involves synergistic co-operation between the BMP-2 and PKA pathways and identify PKIγ is a potent inhibitor of osteoblast differentiation.

Intermittent Exposure to Vitamin D Analog (Analog V) Stimulates Mineralized Bone Nodule (MBN) Formation and Alkaline Phosphatase Activity in Cultures of Human Osteoblasts SaOS-2 Cells. L. G. Rao[1], L. J. Liu*[1], S. Reddy[2], M. S. Uskokovic*[3]. [1]Medicine/Div Endocrinology & Metab, University of Toronto & St. Michael's Hospital, Toronto, ON, Canada, [2]Chemistry, Brown University, Providence, RI, USA, [3]Hoffman-LaRoche, Nutley, NJ, USA.

Although 1α,25$(OH)_2D_3$ is used in some countries for the treatment of osteoporosis, its worldwide approval has not yet been achieved because of its narrow therapeutic window of safety in terms of dose and time duration of administration due to the toxic side effects of hypercalcemia and hypercalciuria. We previously demonstrated that 1α,25$(OH)_2D_3$ and a number of vitamin D analogs, including the noncalcemic analog, 1α,25$(OH)_2$-16-ene,23-yne-D_3 (analog V), had differential effects on normal human osteoblasts and clonal SaOS-2 cells. In this study, we tested the effect of analog V on MBN formation and alkaline phosphatase activity in long-term cultures of human osteosarcoma SaOS-2 cells. SaOS-2 cells were initially cultured in HAM's F-12 supplemented with 10 nM dexamethasone (Dex). 50 ug/ml ascorbic acid phosphate important for matrix formation and 10 mM β[[Unsupported Character - ]]-glycerophosphate needed for mineralization were added at day 8 of culture. Varying concentrations of analog V were added intermittently on day 8 for the first 30 min, 1hr 6 hr or 24 hrs, the medium replaced fresh without the hormone and the cultures continued for 48-hr. The 48-hr cycle was repeated until day 17. The cells were then fixed, stained with von Kossa and the MBN areas and MBN numbers quantitated by an image analyzer, or the cells sonicated for determination of alkaline phosphatase activity. Results were as follows: One way ANOVA analysis showed that 0.1 pM analog V significantly stimulated MBN number ((p<0.05), MBN area (p< 0.05) and alkaline phosphatase activity (p<0.05) in a time-course dependent manner after 30 min and 1 hr, but not after 6 hrs and 24 hrs of incubation. In conclusion, our data provide evidence for a stimulatory effect of analog V on mineralized bone nodule formation and differentiation via its effect on early progenitor cells. The results of our studies may prove that analog V, with its bone forming activity and low calcemic index, is a good candidate for the prevention and treatment of osteoporosis without the hypercalcemic and hypercalciuric toxicity.

Tumor Necrosis Factor Inhibition of the Osterix Promoter. X. Lu, X. He*, J. Rubin, M. S. Nanes. Medicine, Emory University, VA Medical Center, Decatur, GA, USA.

Tumor necrosis factor-alpha (TNF) is a potent suppressor of osteoblast (OB) differentiation and a mediator of bone loss after menopause. Factors shown to support the commitment of pluripotent precursor cells toward the OB phenotype are potential targets of TNF inhibition. The nuclear protein osterix (OSX) is needed for OB differentiation since mice deficient in OSX have cartilaginous skeletons and lack sufficient functional osteoblasts to form mineralized bone. We considered that OSX might be a target of TNF suppression. To test this hypothesis, we measured the TNF regulation of OSX steady state mRNA and promoter activity. OSX mRNA was measured by real time PCR (preliminary data, ASBMR 2003). The OSX promoter was cloned from murine genomic DNA using PCR primers that amplified a 1.3 kB fragment, including a portion of the 5'-untranslated region. This was subsequently cloned into pGL basic to create a luciferase reporter. MC3T3-E1 cells were grown in media supporting differentiation (ascorbate, beta-glycerophosphate) and treated with TNF at doses previously shown to completely inhibit differentiation (0.1-10 ng/ml). Real time PCR at 0, 4, 8, and 18 hours after TNF treatment (10 ng/ml) showed that TNF suppressed OSX mRNA 95% by 24 hours. The effect of TNF was dose dependent and not prevented by co-treatment with cycloheximide, suggesting that new protein synthesis was not required for TNF suppression of mRNA. TNF had no effect on OSX half-life. Transient transfection studies using the pOSX-pGL-luciferase reporter revealed that TNF treatment for 18 hours inhibited basal transcription by 71%. BMP-2, which can be shown to increase OSX mRNA and protein, increased promoter activity only slightly (28%). Suppression of promoter activity by TNF occurred independent of BMP-2 stimulation. The OSX promoter had regions of high homology for binding of numerous transcription factors including NfkB, MSX, RUNX2, DLX, TCF/LEF-1, SOX, SMAD3 and 14 repeats of a Myf5 bHLH site. To identify genes activated or suppressed by TNF in association with the inhibition of OB differentiation, MC3T3-E1 cells were treated with TNF for 4, 8, or 18 hours and mRNA was isolated for Affymatrix analysis using a chip set that included >7000 genes. Subtraction analysis of mRNA expression between differentiated (untreated) or undifferentiated (TNF-treated) cultures revealed 188 genes that were differentially regulated by TNF (>2-fold change, sustained for more than one time point). These included increased expression of NfkB precursors, RelB, JunB and down regulation of RUNX2, DLX-1, DLX-5, SOX6, and Tbx2 among others. Further analysis of the OSX promoter will be required to determine the critical factors that regulate OSX transcription.

Osteoblast-targeted ICER Expression Leads to Impaired Osteoblast Differentiation. T. K. Chandhoke*[1], Y. Huang[2], D. J. Adams[3], B. E. Kream[1]. [1]Medicine, UConn Health Center, Farmington, CT, USA, [2]Molecular Medicine, UConn Health Center, Farmington, CT, USA, [3]Orthopaedic Surgery, UConn Health Center, Farmington, CT, USA.

Inducible cAMP early repressor (ICER), a member of the CREM transcription factor family, is encoded by the P2 promoter of the CREM gene. ICER protein contains a basic leucine zipper region that serves as a site for DNA binding and dimerization, rendering ICER a dominant negative regulator of cAMP-dependent gene transcription. Prior studies have shown ICER mRNA and peptide to be induced by PTH through the cAMP-PKA signaling cascade in cultured osteoblasts and in calvariae *in vivo*. To dissect the role of ICER in osteogenesis, a transgene was developed to overexpress ICER in osteoblasts *in vivo* by cloning ICER cDNA with an N-terminal FLAG epitope downstream of a bone selective 3.6 kb fragment of the rat Col1a1 promoter (pOBCol3.6-ICER). The Col3.6 promoter targets ICER expression to nearly all cells of the osteoblast lineage. Our previous data showed that transgenic mice expressing pOBCol3.6-ICER showed lower body weight than wild type animals, decreased bone formation rate and markedly decreased trabecular bone volume. The aim of the present study was to further evaluate the role of ICER in bone remodeling by evaluating femoral bone morphometry and the effect of the transgene on osteoblast differentiation. X-ray microcomputed tomography (microCT) analysis of femurs from 8-week-old mice showed significant changes in bone microarchitecture, including an almost complete absence of trabecular bone volume in the most affected line. To determine the effect of the ICER transgene on osteoblast differentiation, hemizygous pOBCol3.6-ICER mice were bred with homozygous pOBCol2.3-GFP mice in which GFP cDNA is driven by the Col2.3 promoter. This GFP transgene is activated in mature osteoblasts and serves as a real time marker of osteoblast differentiation. Bone marrow stromal cells from 6-8-week-old ICER/GFP progeny were cultured for up to 21 days in the presence of ascorbate and ß-glycerophosphate. At days 14 and 21, ICER/GFP cells showed reduced GFP expression by fluorescence microscopy and fluorimager analysis compared to WT/GFP cells, suggesting that the ICER transgene inhibited osteoblast differentiation. Sex-matched cultures of bone marrow stromal cells from ICER/GFP mice showed the reduction in GFP expression to be conserved between males and females. Bone marrow cultures observed at day 14 and day 21 showed reduced mRNA expression of several markers of osteoblast differentiation, including bone sialoprotein and osteocalcin. In summary, these data show that overexpression of ICER led to impaired bone microarchitecture, osteoblast differentiation and osteoblast function.

Mechanism of Glucocorticoid-TGF-β antagonism: Inhibition of Smad3 Transcriptional Activity by Glucocorticoid Receptor. X. Shi, L. Yang*, X. Shen*, X. Cao. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Glucocorticoid (GC)-induced osteoporosis affects more than 30 million Americans. However, the molecular and cellular mechanism responsible for GC-induced bone disorder is largely unknown. TGF-β and GC have important, but directly opposing effects on bone metabolism. TGF-β is one of the most abundant of the known growth factors stored within the bone. During the remodeling cycle, osteoclasts resorb bone, TGF-β is released and it stimulates osteoblast proliferation and new bone formation. GCs, on the other hand, inhibit proliferation, induce the death of osteoblast and osteocytes, and result in osteoporosis and bone fractures. To determine the molecular mechanisms of GC- TGF-β antagonism in osteoblast differentiation, we examined the cross-talk between glucocorticoid receptor (GR) and TGF-β. We found that GR interacts with Smad3, a TGF-β signaling transducer, and the interaction inhibits Smad3 transcriptional activity by blocking Smad3 DNA-binding ability. Consistent with the binding studies, transient transfection and promoter activity assays showed that dexamethasone (Dex) suppressed TGF-β induced promoter reporter activity of 3TP-Lux, a TGF-β sensitive luciferase reporter, in Mv1Lu cells. We then examined the effects of GC on TGF-β regulated osteoblast differentiation marker gene expression, we treated 2T3 preosteoblast cells with TGF-β, Dex, and both TGF-β and Dex, the expression levels of alkaline phosphatase (ALP) and Rux2/Cbfa1 mRNA were determined by real-time RT-PCR. The results showed that TGF-β inhibited the expression of ALP; Dex increased the mRNA expression of ALP. Finally, we examined the effects of GC and TGF-β in osteoblast differentiation. In consistent with the real time RT-PCR experiment, ALP staining of the Dex treated 2T3 cells showed an increased number of ALP positive cells, and this increase is blocked when the cells were treated with Dex and TGF-β together. From these studies, we conclude that GC antagonizes TGF-β action in osteoblast proliferation, the GC-TGF-β antagonism is mediated by GR-Smad3 interaction and the subsequent inhibition of Smad3 DNA-binding by GR. As we know, TGF-β couples bone resorption and formation by stimulating bone marrow mesenchymal cell proliferation. Pharmacological dosage of GC could cause bone disease by uncoupling bone resorption and formation through inhibition of TGF-β function. This finding may provide an opportunity to develop a tissue specific drug target for controlling GC-induced bone loss.

Marked Improvement of Bone Allograft Incorporation and Vascularization by Tissue Engineer of Live Periosteum on Devitalized Cortical Bone Graft. X. Zhang[1], C. Xie*[1], H. Ito[1], A. Lin*[2], R. E. Guldberg*[2], R. J. O'Keefe[1], E. M. Schwarz[1]. [1]Center for Musculoskeletal Research, University of Rochester, Rochester, NY, USA, [2]Georgia Institute of Technology, Atlanta, GA, USA.

There is an increasing demand for large cadaveric structural bone allograft for reconstruction of critical defects. However, the lack of osteogenic and angiogenic potential of devitalized bone graft results in poor long term outcomes. We have developed a 4mm segmental femur cortical bone grafting model in mice. Using this model we have showed that the preservation of periosteum on bone graft leads to superior graft incorporation and repair. Periosteal donor cell fate and its cellular contribution to cortical bone graft healing were further examined using live donor bone isografts from Rosa26 mice that constitutively express b-gal. Histological analysis using X-gal stained tissue sections demonstrated the expansion of b-gal positive periosteal mesenchymal cells from day 3 to day 7 post-op, which was largely confined to donor bone graft. By day 10, at the peak of endochondral and intramembranous bone formation, 73% of chondrocytes, 50% of osteocytes and 30% of osteoblasts on donor graft were positive for b-gal staining (n=5). The graft-derived cartilage and bone tissue were rapidly replaced through host dependent remodeling. By day 28, only a few cells at the graft site remained positive for b-gal. These results further underscore the vital role of live osteogenic stem cells for bone graft incorporation and suggest a novel approach to improve healing via engraftment of osteogenic stem cells on devitalized bone grafts. To this end, we infected bone marrow stromal cells derived from Rosa 26 mice with adenovirus BMP-2, loaded the cells onto collagen gel foam and wrapped it around devitalized bone allograft. Radiographic and MicroCT analysis of the cellular bone graft healing showed the formation of completely bridged new bone callus around devitalized bone grafts 9 weeks following surgery. Quantitative measurement of the new bone around the grafts showed a 3.7-fold increase compared to the control group without cell engraftment (n=4). MicroCT vascular imaging of the grafted femur was acquired following vascular perfusion of Microfil and bone decalcification. The results indicated that total vessel volume was significantly increased at the cortical bone junction and areas surrounding the graft upon bone marrow cell engraftment. Histologic examination further confirmed the osteointegration of donor cell derived bone on devitalized bone graft. Collectively, our studies demonstrated an effective alternative to improve devitalized allograft incorporation and neovascularization via tissue engineering and stem cell engraftment.

Concentration Of Bone Marrow Derived Connective Tissue Progenitor Cells Onto Implantable Matrix Scaffolds. C. A. Boehm*[1], K. Kumagai*[1], J. Wright*[2], L. G. Griffith*[3], G. F. Muschler[4]. [1]Biomedical Engineering, Cleveland Clinic Foundation, Cleveland, OH, USA, [2]Biological Engineering Division, Massachusetts Institute of Technology, Cambridge, MA, USA, [3]Chemical and Biological Engineering Division, Massachusetts Institute of Technology, Cambridge, MA, USA, [4]Biomedical Engineering and Orthopaedic Surgery, Cleveland Clinic Foundation, Cleveland, OH, USA.

Methods for concentration and/or selection of osteoblastic connective tissue progenitors (CTPs) from bone marrow can be used to improve the outcome of bone grafting procedures. One effective method is Selective Retention, which requires a chemical surface that provides a binding site for a desired cell type, similar in concept to an affinity column. This study evaluated the highly porous polycaprolactone matrix fabricated using three dimensional printing (3DP) as a substrate for selective retention and evaluated the performance of the resulting cell-matrix composite grafts in an established canine femoral defect model. Heparinized bone marrow was aspirated from the proximal humerus. Implants were prepared as 9.5 mm diameter x 10mm cylinders with a pore size of 1000 microns and a wall thickness of 500 microns. Marrow was passed through the matrix at a constant linear flow rate of 25mm/min.. Aliquots of initial and effluent marrow were collected. Cell counts and CTP assays were performed on all samples. Four loading concentrations were compared; no marrow, 1X, 4X and 16X, based on marrow:matrix volume ratio. Loaded matrices were implanted into the 1.0 cm diameter cylindrical defects in the femur. After four weeks, the tissue in the defect was assayed for bone formation using microCT and then undecalcified histomorphometry. Mineral density and the area fraction of bone formation were primary outcome parameters.

Cell retention in the implants was 68 % +/- 1.1, 40 % +/0.6, and 28 % +/- 9, for [1X], [4X] and [16X], respectively. CTP efficiency for cells loaded onto matrix was 81%, +/- 11, 74 % +/- 14, and 71 % +/-1 8, for [1X], [4X] and [16X], respectively. The selection ratio for these concentrations was 1.16, 2.42 and 3.32, for [1X], [4X] and [16X], respectively. This represented nearly a 12 fold increase in overall CTP concentration in the 16X group compared to the 1X group. Analysis of bone formation and histologic data from 48 implants (12 per group) is pending.

These data confirm that a synthetic PCL-based 3DP matrix material can be used as an affinity column to concentrate and select bone marrow-derived CTPs. We believe that this method for harvest and transplantation of CTPs has important implications for tissue engineering strategies to repair or regenerate bone and other tissues.

Wnt10b Expression in Bone Marrow Stromal Cells are Regulated by Sex Steroids. T. Hayashi*[1], S. kido*[2], D. Inoue[2], T. Ishikawa*[1], T. Matsumoto[2], R. Okazaki[1]. [1]Third Department Medicine, Teikyo University, Chiba, Japan, [2]Medicine and Bioregulatory Science, University of Tokushima, Tokushima, Japan.

Bone marrow stromal cells (BMSCs) are the common progenitors for bone forming osteoblasts and adipocytes. We previously reported that their differentiation into osteoblasts and adipocytes is promoted and inhibited, respectively, by estrogen. Because it has recently shown that the Wnt10b-mediated signaling pathway facilitates osteoblastic differentiation and hampers adipocytic differentiation, we have examined the effects of estrogen and other sex steroids on this pathway. We used the following mouse stromal cell lines: MC3T3/PA6 cells, wild-type ST2 cells, and ST2 cells stably overexpressing human estrogen receptor (ER)α or ERβ. Cells were treated with 17β-estradiol (E2), dehydroepiandrosterone(DHEA), and 5α-dihydrotestosterone(DHT) in the presence or absence of bone morphogenetic protein (BMP)-2 and/or troglitazone, and Wnt10b mRNA levels were assessed by RT-PCR. In PA6 cells, Wnt10b expression was increased and decreased by BMP-2 and troglitazone, respectively. Similarly, in ST2 cells, Wnt10b mRNA was induced by BMP-2. In both ST2ERα and ST2ERβ cells, Wnt10b expression was up-regulated by BMP-2, E2, DHEA and DHT, and was reduced by troglitazone. These results suggest that regulation of BMSC differentiation by sex steroids may be mediated at least in part by the Wnt10b signaling pathway.

Runx2 Gene Transfer in Marrow Stromal Cells Stimulates Osteoblast Differentiation and Bone Formation. Z. Zhao*, M. Phimphilai*, M. Zhao*, G. Xiao, R. Franceschi. Periodontics, Prevention, Geriatrics, University of Michigan School of Dentistry, Ann Arbor, MI, USA.

Bone marrow stromal cells (MSCs) have the potential to differentiate into multiple cell types including osteoblasts, chondrocytes, myoblasts and adipocytes. If MSCs are to be successfully used to regenerate bone, methods must be developed to optimally stimulate the differentiation of these cells to osteoblasts. The objective of this study was to examine the feasibility of using ex vivo Runx2 gene transfer to stimulate osteoblast differentiation in MSCs. Primary MSCs harvested from 6-week old male C57BL6 mice were transduced with adenoviral vectors encoding b-galactosidase (lacZ) or Runx2 and assayed for osteoblast differentiation and mineralization. Cells transduced with Ad-Runx2 expressed Runx2 protein in a dose-dependent manner and underwent osteoblast differentiation as measured by increases in alkaline phosphatase, osteoblast marker mRNA expression and mineralization. Detailed time course studies revealed that Runx2 protein was highest 1 d after transduction and declined below the limits of detection by 15 d. Osteocalcin and bone sialoprotein mRNA levels paralleled Runx2 levels. In contrast, Runx2-dependent mineralization persisted for the duration of the experiment. In addition to stimulating osteoblast differentiation, Ad-Runx2 transduction increased BMP responsiveness of both MSCs and C3H10T1/2 mesenchymal cells. Runx2 transduction also increased autocrine BMP synthesis in C3H10T1/2 cells. This BMP activity was necessary for osteoblast differentiation in that effects of Runx2 transduction could be blocked by Noggin, a BMP antagonist. To assess in vivo osteogenic activity, Ad-Runx2 transduced and control MSCs were suspended in type I collagen hydrogels and subcutaneously implanted into C57BL6 mice. Cells expressing Runx2 formed approximately twice the amount of bone formed by control cells. Taken together, these studies indicate that Runx2 gene transfer may be an effective route to enhance the osteogenic potential of MSCs.

GNAS Is an Osteoblast Fate Suppressor Gene in Soft Connective Tissue. R. A. Kanaan*[1], W. S. Kuo*[1], F. S. Kaplan[1], R. J. Pignolo[2], E. M. Shore[3]. [1]Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA, [2]Medicine, University of Pennsylvania, Philadelphia, PA, USA, [3]Orthopaedic Surgery and Genetics, University of Pennsylvania, Philadelphia, PA, USA.

Progressive osseous heteroplasia (POH) is an autosomal dominant disorder characterized by heterotopic ossification of skin and subcutaneous adipose tissue during infancy, followed by disabling and wide spread ossification within skeletal muscle and deep connective tissue as the disease progresses. Previously, we demonstrated that POH is caused by heterozygous inactivating mutations in the GNAS gene, which encodes a G protein alpha subunit (Gsα). G proteins mediate transmembrane signaling from a diverse group of cell surface receptors to effectors that include phospholipase C, adenylyl cyclase and ion channels. We investigated the expression of Gsα in bone and fat by immunohistochemistry of mouse tissues. Normal bone (femur) was weakly positive for Gsα in osteoblasts lining bony trabeculae as well as in osteocytes. By contrast, intense staining of Gsα occurred in adipocytes within subcutaneous fat. Stromal stem cells from processed lipoaspirates (PLA) that are isolated from mouse subcutaneous fat tissue can be induced to differentiate to several cell fates, including osteoblasts and adipocytes. To examine the effect of reduced murine Gnas expression on stem cell differentiation to osteoblasts, PLA cells were transfected with Gnas siRNA. GFP siRNA was used as a negative control. Real time RT-PCR analysis to detect osteoblast markers (alkaline phosphatase, collagen type I, and osteopontin) revealed that Gnas siRNA enhanced osteoblast differentiation markedly, where as GFP siRNA had no effect. These data suggest a reciprocal relationship in the expression of Gsα in adipocytes (high) and osteoblasts (low) *in vivo*, and further support that Gnas acts as an osteoblast fate suppressor gene in soft connective tissue. [All animal studies followed IACUC approved protocols.]

Parathyroid Hormone Treatment Improves Survival after Bone Marrow Transplantation and Increases Osteoblastic Expression of the Notch Ligand Jagged1. J. M. Weber*[1], G. B. Adams*[2], M. L. Guzman*[3], C. T. Jordan*[3], D. T. Scadden*[2], L. A. Milner*[4], L. M. Calvi[1]. [1]Endocrine Unit, University of Rochester School of Medicine, Rochester, NY, USA, [2]Center for Regenerative Medicine and Technology, Massachusetts General Hospital, Boston, MA, USA, [3]Wilmot Cancer Center, University of Rochester School of Medicine, Rochester, NY, USA, [4]Pediatrics, University of Rochester School of Medicine, Rochester, NY, USA.

In the bone marrow, immature hematopoietic stem cells (HSC) are found in close proximity to osteoblasts. We recently showed that Parathyroid Hormone (PTH), through activation of the PTH/PTHrP receptor (PPR) in osteoblastic cells results in expansion of HSC. When PTH was administered intermittently after myeloablative bone marrow transplantation using limiting numbers of donor cells, mice had dramatically improved survival at 28 days (100%) compared to vehicle-treated mice (27%). Histological analysis of hind limbs from the two groups showed a striking increase in bone marrow cellularity with decreased adipocytes in the PTH-treated mice.

We had shown that activation of the Notch signaling pathway is necessary to mediate the PTH-induced expansion of HSC. This pathway plays a fundamental role in HSC self-renewal through cell-cell interactions. Since primary murine stromal cells treated with PTH (1-34) had improved ability to support HSC, we analyzed by immunocytochemistry the protein level of the Notch ligand Jagged1 in these cells. A small subpopulation of PTH-treated primary murine cells had a dramatic increase of Jagged1 protein, while this subpopulation was not identified in vehicle-treated stromal cells. Since real time PCR analysis of total RNA from primary stromal cells showed no changes in Jagged1 message in PTH compared to vehicle-treated cells, UMR106 cells were chosen to study osteoblastic cells. A 10-fold time and dose-dependent increase in Jagged1 expression was measured by real time PCR in RNA from UMR106 cells treated with PTH compared with vehicle. Western blot analysis confirmed the PTH-dependent increase in Jagged1 protein. Treatment with forskolin also increased Jagged1 message, suggesting that activation of adenylate cyclase downstream of the PPR was sufficient to reproduce this PTH-dependent effect.

In summary, PTH treatment alters dramatically the bone marrow microenvironment and improves survival from bone marrow transplantation in mice. Osteoblastic cell treatment with PTH increases expression of the Notch ligand Jagged1. UMR106 cells provide a useful model to study the molecular mechanisms underlying osteoblastic PTH-dependent increases in Jagged1 levels, which are likely to play an important role in the PTH-induced enhanced osteoblastic support of HSC.

Sp1 and Sp3 Regulate Basal Transcription of RANKL Gene in Osteoblasts and Stromal Cells. J. Liu*, Z. Shi, X. Cao*, X. Feng. Pathology, Univ. of alabama at birmingham, Birmingham, AL, USA.

RANKL and its receptor RANK have been shown to play to pivotal role in bone homeostasis. In bone, RANKL is expressed by osteoblasts/stromal cells and mediates osteoclast differentiation and function by binding RANK expressed on osteoclast precursors and mature osteoclasts. Since the unraveling of the RANKL/RANK system, it has been established that many osteotropic hormones and cytokines regulate osteoclast formation and function through modulating RANKL expression by osteoblasts/stromal cells. However, the molecular mechanism by which RANKL gene expression is regulated in osteoblast/stromal cells largely remains unclear. To investigate the molecular mechanisms by which gene expression is regulated in osteoblasts/stromal cells, in the current study we characterized the molecular mechanism underlying the basal transcription of RANKL gene in osteoblast/stromal cells. To this end, we cloned 1.1-kb murine RANKL promoter (from -953 to +150, relative to the transcription start site) and showed that this promoter fragment is highly active in both transfected osteoblasts and stromal cells. To locate the promoter region required for the basal transcription of RANKL gene, we constructed 7 deletion mutants of the 1.1-kb RANKL promoter: RL(-753)Luc, RL(-553)Luc, RL(-403)Luc, RL(-253)Luc, RL(-153)Luc, RL(-103)Luc and RL(-53)Luc. These mutants contain RANKL promoter regions starting from different 5' positions (indicated by the numbers in parentheses) and ending at the same 3' site (+150). Using these mutants, we identified a 100-bp RANKL promoter region (-154 to -54) critical for the basal transcription of RANKL gene. We then synthesized 4 overlapping oligos (Oligo I, II, II, and IV) spanning the 100-bp promoter region. Gel shift assays using these oligos showed that Oligo I and Oligo II specifically bound the nuclear proteins with high affinity from both osteoblasts and stromal cells. Computer analysis of these two oligos indicated that both oligos contain a putative Sp1-binding sequence, suggesting that these oligos may utilize members of the Sp1 family in regulating the basal transcription of RANKL gene. Supershift assays with antibodies Sp1 and Sp3 confirmed that the nuclear proteins binding to Oligo I and II are Sp1 and Sp3. Importantly, the mutation of Sp1-binding site in Oligo I profoundly reduced the basal promoter activity while the mutation of Sp1 site in Oligo II gave rise to a slight reduction in the basal promoter activity. Moreover, the mutation of both sites totally abrogated the basal promoter activity of RANKL gene. Token together, our current study revealed that Sp1/Sp3 play a key role in the basal transcription of RANKL gene in osteoblasts and stromal cells.

A Modulatory Role for Adenosine in an Osteoprogenitor Cell Line and in Primary Human Bone Marrow Cells. B. A. J. Evans[1], C. Elford*[1], K. Francis*[2], J. Ham*[2]. [1]Child Health, University of Wales College of Medicine, Cardiff, United Kingdom, [2]Medicine, University of Wales College of Medicine, Cardiff, United Kingdom.

Adenosine has a wide range of actions in many tissues, but there is little information on its role in bone physiology. We have demonstrated the presence of the four adenosine P1 receptor subtypes in HCC1 (human osteoprogenitor) cells, and shown that adenosine and adenosine receptor agonists (NECA, CCPA, and IB-MECA) stimulate the release of IL-6 from these cells. CGS2180 had no effect. Furthermore, adenosine, NECA, CGS2180 and CCPA, but not IB-MECA, inhibited the production of osteoprotegerin. RT-PCR and immunocytochemical methods showed that primary adult human bone marrow stromal (BMS) cells also expressed the four receptor subtypes. α-MEM with ribonucleosides and deoxyribonucleosides is used for routine culture of such BMS cells in many laboratories. We showed that basally secreted IL-6 concentrations by BMS in this medium were very high. Furthermore, adenosine and adenosine receptor agonists increased IL-6 secretion by these cells, but only when they were maintained in α-MEM not containing ribonucleosides and deoxyribonucleosides. RT-PCR and immunocytochemical methods showed that both cell types expressed enzymes (adenosine deaminase, adenosine kinase, ecto 5′ -nucleotidase) responsible for the synthesis and metabolism of adenosine. In addition, mineralisation studies with BMS cells either i) in medium with or without ribonucleosides and deoxyribonucleosides, or ii) in medium without ribonucleosides and deoxyribonucleosides, but with or without adenosine or adenosine receptor agonists, further demonstrated the ability of these compounds to modulate osteoprogenitor cell function. Other work showed that both HCC1 and BMS cells express IL-6 receptor and the gp130 subunit needed for IL-6 signalling. Collectively, our results indicate that adenosine modulates (possibly via IL-6) osteoprogenitor cell function and differentiation. These effects might be especially important in conditions such as rheumatoid arthritis, where high levels of adenosine due to inflammation may influence the progression of bone disease.

Human Marrow-Isolated Adult Multilineage Inducible (MIAMI) Cells Require NT-3 to Differentiate to Functional Neurons. G. D'Ippolito*[1], S. Diabira*[1], G. A. Howard[1], A. Valeyev*[2], J. Hackman*[2], P. Menei*[3], C. Montero-Menei*[3], B. A. Roos*[1], P. C. Schiller*[1]. [1]Medicine, GRECC & Research Service VAMC and University of Miami, Miami, FL, USA, [2]Neurology, Research Service VAMC and University of Miami, Miami, FL, USA, [3]INSERM ERIT-M 646, Angers, France.

We have isolated a novel population of non-transformed pluripotent human cells from bone marrow after a unique expansion/selection procedure. Based on their unique molecular characteristics and unparalleled differentiation properties, we refer to them as Marrow-Isolated Adult Multilineage Inducible cells, or MIAMI cells. Colonies of cells were expanded as single-cell derived colonies or multicolony pools on fibronectin treated substrates at low density, low oxygen tension, and 2% FBS. MIAMI cells express high levels of CD29, CD63, CD81, CD122, CD164, cMet, BMPR1B, and NTRK3, and are $CD34^-$, $CD36^-$, $CD45^-$, $CD117^-$, and $HLA\text{-}DR^-$. The embryonic stem cell markers SSEA4, Oct-4, Rex-1, and hTeRT were expressed in all cultures examined. Cells have been expanded more than 50 population doublings. This primitive population of cells was isolated from men and women of ages ranging from 3 to 72 years old. They have been differentiated to mesodermal-derived lineages including osteoblasts, cartilage-forming chondrocytes, and adipocytes. The cells were also grown as attachment-independent spherical clusters expressing genes associated with pancreatic islets, including insulin and glucagon, indicating their capacity for differentiation to endodermal-derived lineages.

Unlike other human stromal cell populations, the MIAMI cells have been differentiated to neuroectoderm-derived phenotypically mature neuronal cells expressing numerous neuronal markers including tyrosine hydroxylase and exhibiting a resting membrane potential of -70 mV as well as inward and outward ion currents. Since bone tissue is extensively innervated, these novel results open the possibility that marrow stromal cells may contribute to the motor and/or sensory neural cellular network critically important for adequate bone and skeletal function.

Early passage MIAMI cells independently differentiated into mature neurons under defined and specific treatment conditions requiring neurotrophic factors, without the need for coculture with any other type of cells in order to develop a functionally mature phenotype. MIAMI cells were found to engraft in several tissues and were not tumorigenic. In conclusion, MIAMI cells represent a novel and unique population of non-transformed human post-natal cells with a plasticity and expansion capacity resembling that of embryonic stem cells and represent the ideal candidate for cellular therapies of inherited or degenerative diseases.

The Thiazide Diuretic Metolazone Directly Stimulates Osteoblast Function. M. M. Dvorak*[1], G. Gamba*[2], D. Riccardi*[1]. [1]School of Biological Sciences, University of Manchester, Manchester, United Kingdom, [2]Instituto de Investigaciones Biomedicas, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico.

Thiazide diuretics are commonly used in the management of hypertension. There is also plethora of studies correlating such therapy with an increase in bone mineral density. It has been proposed, but not unequivocally proven, that this may be a result of increased availability of circulating calcium, due to the action of thiazides on the thiazide-sensitive sodium-chloride cotransporter (NCC) in the kidney.

We have previously reported the expression of the NCC mRNA and protein in the cells of osteoblastic origin in freshly frozen undecalcified preparations of human and rat bone, as well as in tissue culture models of osteoblasts [1]. Here we studied the effects of metolazone, a potent thiazide diuretic, on proliferation, differentiation and production of mineralised nodules in human and rat freshly isolated osteoblasts. We observed that metolazone dose-dependently attenuates BrdUrd incorporation (n=6; $p<0.05$) indicating an inhibition of osteoblast proliferation. On the other hand, metolazone increased osteoblast differentiation, evident from an increase in expression of markers such as *Runx2,* observed by western blotting (n=3; $p<0.05$) and an increase in the production of mineralised nodules quantified by von Kossa staining (n=6; $p<0.05$). These findings were specific to thiazide diuretics and were not reproduced using the loop diuretic bumetanide.

These results provide evidence for direct action of thiazide diuretics on bone, acting on the thiazide-sensitive sodium-chloride cotransporter expressed by osteoblasts. We therefore support the view that thiazides should be considered as diuretics of choice in elderly osteoporotic patients.

Eosinophil Chemotactic Factor-L (ECF-L) Enhances Osteoclast Formation by Blocking the Suppressive Effects of IL-12 on Osteoclast (OCL) Formation. H. Y. Chung[1], S. J. Choi[1], G. D. Roodman[2]. [1]Medicine-Hematology/Oncology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Medicine-Hematology/Oncology, University of Pittsburgh and Dept. of Veterans Affairs Medical Center, Pittsburgh, PA, USA.

OCL formation and bone destruction is increased in inflammatory conditions such as rheumatoid arthritis (RA). This bone destruction occurs even though known inhibitors of OCL such as IL-12, IFN-γ and IL-4 are produced by activated T-cells in the affected joints. It is our hypothesis that other factors produced in RA joints block the activity of these inhibitors of OCL formation. Recently, we identified ECF-L as a novel autocrine stimulator of OCL produced by. monocytes/macrophages and OCL, and showed that ECF-L production is increased by IL-4. Therefore, we determined if ECF-L could block the inhibitory effect of IL-12 on OCL formation. Purified ECF-L Fc fusion protein was added to murine bone marrow cultures in the presence or absence of IL-12. ECF-L increased OCL-like cell formation in a dose-dependent manner in mouse marrow cultures compared to control cultures and blocked the inhibitory effects of IL-12 on OCL formation. To further investigate the mechanism responsible for these observations, the effects of ECF-L on IL-12, and IL-12 receptor production and IL-12 receptor signaling were examined using PHA-stimulated non-adherent spleen cells as a source of lymphocytes. ECF-L decreased IL-12p40 levels by 50% in spleen cell conditioned media compared to control cultures, as determined by Western blot analysis. Furthermore, ECF-L markedly decreased IL-12 R beta1 mRNA

expression by 80% and decreased IL-12 R beta1 protein expression by 40% in PHA-activated spleen cells compared to control treatments. This decrease in IL-12 receptor expression resulted in a 70% decrease in IL-12-induced IFN-γ mRNA expression in spleen cells, as assessed by RT-PCR. Although STAT4 signaling was not decreased by simultaneous treatment of PHA activated spleen cell cultures with ECF-L and IL-12, STAT4 signaling was decreased by 30% when the cultures were pretreated with ECF-L for 24 hrs. To further investigate the mechanism responsible for ECF-L effect on IL-12 receptor expression, we determined if ECF-L increased cox-2 mRNA levels. Wu et al. (J Immunol 161, 1998) previously reported that PGE2, a major cox-2 metabolite, inhibited IL-12 receptor expression and IL-12 responsiveness. Treatment of mouse marrow cultures with ECF-L increased cox-2 mRNA and protein expression by 50% and 30% respectively. These results suggest that ECF-L may enhance OCL formation through decreases both in IL-12 and IL-12 receptor expression and that this effect may in part be mediated by increasing cox-2 metabolites such as PGE2.

Bone Loss in Inflammatory Arthritis Is Associated with a Local and Systemic Decrease in Parameters of Bone Formation. M. Stolina*[1], G. Schett*[2], B. Bolon*[1], S. Middleton*[1], H. Brown*[1], L. Zhu*[1], S. Adamu[3], F. Asuncion*[3], P. Kostenuik[3], U. Feige*[1], D. Zack*[1]. [1]Inflammation, Amgen, Thousand Oaks, CA, USA, [2]Medical University of Vienna, Division of Rheumatology, Vienna, Austria, [3]Metabolic Disorders, Amgen, Thousand Oaks, CA, USA.

Purpose: Chronic inflammatory arthritis leads to accelerated bone loss. Vanishing of bone is only possible if bone resorption outweighs bone formation. Since osteoclasts are present in inflamed joints, bone resorption is regarded as a predominant factor for bone loss in inflammatory arthritis. It is unclear, however, whether bone formation attempts to balance bone resorption or is even downregulated and aggravates bone loss. To address this question we performed a time-dependent analysis of systemic and local bone metabolism in two rodent models of inflammatory arthritis.

Methods: Lewis rats were challenged with 0.5 mg heat-killed mycobacteria suspended in mineral oil to induce adjuvant arthritis (AdA) or 1 mg porcine collagen type II emulsified in Freund's incomplete adjuvant to produce collagen-induced arthritis (CIA). Animals were sacrificed at the day of disease onset (d0), or at 10 different time points up to d27 after disease onset. Paw sections were assessed for osteoclasts and osteoblasts using immunohistochemistry for cathepsin K and in situ hybridization for osteocalcin, respectively. In addition, serum was analyzed for tartrate-resistant acid phosphatase (TRAP) and TRAP-5b as well as alkaline phosphatase and osteocalcin.

Results: In both AdA and CIA structural skeletal damage rapidly increased from d4 and peaked on d10. Osteoclast activity, as shown by the expression of cathepsin K, was dramatically increased at d4 and d1 in the paws of AdA and CIA, respectively. In contrast, osteoblast activity, as shown by expression of osteocalcin decreased after disease onset and reached its nadir on d4 in both models. Osteoblast activity partially returned after d10 when formation of osteophytes was observed. Systemic bone metabolism showed very similar kinetics with peaking of osteoclast markers, TRAP and TRAP-5b, on d4 and d2 in AdA and CIA, respectively. Concomitantly, both osteoblast markers, alkaline phosphatase (d4 for AdA, d3 for CIA) and osteocalcin (d3 for AdA, d1 for CIA) reached their nadirs. Thus, the phase of rapid bone loss in inflammatory arthritis coincides with lowered bone formation.

Conclusion: These data suggest that blunted bone formation even accelerates inflammatory bone loss. Fostering of bone formation may therefore be an additional attractive therapeutic option to counteract skeletal damage in arthritis.

Effect of Exogenous and Endogenous Prostaglandin E_2 on Osteoclastogenesis in the RAW 264.7 Macrophage Cell Line. H. Kaneko[1], S. Lee[1], J. A. Lorenzo[1], Y. Toyama*[2], C. C. Pilbeam[1], L. G. Raisz[1]. [1]Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan.

Prostaglandins can enhance osteoclast formation by effects on both the hematopoietic and osteoblastic lineages. PGE_2 increases osteoclast like cell (OCL) formation in spleen cells that are cultured with M-CSF and RANKL and in the RAW 264.7 macrophage cell line (RAW cells) cultured with RANKL. We examined the ability of exogenous PGE_2 to stimulate OCL formation in RAW cells as well as the role that endogenous PGE_2 has in the response of RAW cells to LPS and TNF-α. Exogenous RANKL increased the number of OCL, defined as TRAP (+) multinucleated cells, in a dose-dependent fashion from 1 to 30 ng/ml with no difference between 30 and 100 ng/ml. Therefore, all further experiments were performed at 30 ng/ml. In the presence of RANKL, exogenous PGE_2 increased OCL number by 60 ± 6% at 1 μM and 37 ± 6% at 0.1 μM ($P<0.01$) in the RAW cells. LPS (100 ng/ml) increased OCL number by 31 ± 12% ($P<0.05$) and TNF-α (10 ng/ml) increased OCL number by 54 ± 4% ($P<0.01$). To determine the role of endogenous prostaglandin synthesis in these responses, we used NS-398 (0.1 μM), a specific COX-2 inhibitor. NS-398 did not affect the response to RANKL but significantly ($P<0.05$) decreased responses to PGE_2, LPS and TNF-α by 60%, 64% and 74%, respectively. Treatment of RAW cells for 1 h with PGE_2 or LPS, followed by washing, increased endogenous PGE_2 production 4 h later from 1 nM to 72 and 48 nM respectively. These results demonstrate that both exogenous and endogenous PGE_2 can directly augment the ability of myeloid precursor cells to form OCL. Furthermore, it appears that endogenous production of PGE_2 enhances osteoclastogenic responses of RAW cells to LPS and TNF-α as well as to PGE_2 itself.

Interleukin-1 Is an Essential Component of TNF-α-induced Osteoclastogenesis. S. Wei, H. Kitaura, P. Zhou, F. P. Ross, S. L. Teitelbaum. Pathology and Immunology, Washington University in St. Louis, St. Louis, MO, USA.

TNF and IL-1 are pro-osteoclastogenic inflammatory cytokines but their relationship in the osteoclastogenic process is not understood. Reflecting sequential signaling of the two cytokines, we find that TNF-α induced RANKL synthesis by bone marrow stromal cells is abolished by IL-1 receptor antagonist (IL-1Ra) or deletion of the type I IL-1 receptor (IL-1RI) gene. Furthermore, TNF-α induces expression of IL-1 and its functional receptor. These data suggest TNF-α regulates the RANKL gene, in stromal cells, via IL-1 and therefore IL-1 plays a role in TNF-α-induced periarticular osteolysis. Consistent with this posture, TNF-α-stimulated osteoclastogenesis is blunted approximately 50% by IL-1Ra in a model in which osteoclasts are generated by co-culture of marrow stromal cells and TNF receptor deficient macrophages. The same results obtain when TNF is added to osteoclastogenic cultures containing stromal cells derived from IL-1RI deficient mice. Importantly, TNF-induced osteoclastogenesis, in vivo, is also dampened 50% in IL-1RI-/- mice. IL-4, an anti-osteoclastogenic cytokine, arrests IL-1-induced RANKL expression, an event associated with blunted p38 activity. Confirming TNF-α and subsequently, IL-1 regulates osteoclastogenesis via this MAP kinase, stromal cell expression of RANKL stimulated by these cytokines is blocked by the specific p38 inhibitor, SB 203580. Like TNF-α, short exposure to IL-1 can also directly stimulates marrow macrophages to commit to the osteoclast phenotype in the presence of sub-osteoclastogenic concentrations of RANKL, an event accompanied by upregulation of IL-1RI and inhibition of the decoy receptor, IL-1RII. Thus, IL-1 mediates the osteoclastogenic effect on TNF-α by enhancing stromal cell expression of RANKL in a p38 MAP kinase dependent manner and by directly stimulating differentiation of osteoclast precursors. The interdependency of the two inflammatory cytokines in the generation of osteoclasts lends credence to the observation that their combined blockade is most effective in preventing the periarticular bone loss of inflammatory arthritis.

Role of IGF-IR in Osteoclast Biology and Differentiation. S. Avnet, G. Quacquaruccio*, A. Lamolinara*, D. Granchi*, A. Giunti*, N. Baldini*. Laboratory for Pathophysiology, Istituti Ortopedici Rizzoli, Bologna, Italy.

Although IGF-1 and 2 and their receptor IGF-IR play a key role in osteoblast biology and in normal skeletal growth, only fragmentary data are available on their contribution to bone resorption. IGFs are synthetized by osteoblasts and stored in the skeletal matrix, therefore interacting with pre-osteoclasts and mature osteoclasts after being released as a consequence of bone resorption. By using monocyte-monoblast-like models (human FLG29.1 and murine RAW264.7 cell lines), by Western blot and RT-PCR we demonstrated that IGF-IR is expressed in osteoclast precursors. After exposure to an anti-IGF-IR blocking MAb (alpha-IR3, 1 mg/ml), or to suramin (500 mg/ml), a drug that is known to interfere with IGF binding to their receptor, a growth inhibition (doubling time: 34.5 h vs 23.4 h of controls) was recorded in FLG29.1 cells. A similar effect was observed in human monocytes from peripheral blood that were induced to differentiate to osteoclasts by RANK-L (30 ng/ml) and MCS-F (25 ng/ml) exposure. In fact, treatment with alpha-IR3 or suramin inhibited cell viability and TRAP activity (day 4) of osteoclast precursors, resulting in a net reduction of in vitro bone resorption (day 10). Furthermore, IGF-IR phosphorilation was found to be very low at cell seeding, greatly increased on day 2, almost null on day 4, and again increased in multinucleated osteoclasts (day 7), as shown by Western blot . In mature osteoclasts IGF-IR immunolocalization was also demonstrated by fluorescence microscopy. By Real-Time PCR we verified that the blockage of IGF-IR activity by alpha-IR3 treatment is followed by an increased synthesis of IGF-IR mRNA (Figure), further supporting the functional role of IGF-IR in osteoclast differentiation. These data show that IGF-IR acts at different times during the committment and differentiation of osteoclasts. IGF-IR-mediated signaling may therefore be considered as a fundamental pathway for osteoclast biology in addition to its well-established role in osteoblasts.

Osteoblast Specific Overexpression of Human Interleukin-7 Increases Femoral Trabecular Bone Mass in Female Mice and Inhibits *in Vitro* Osteoclastogenesis. S. Lee[1], J. F. Kalinowski*[1], D. J. Adams[2], H. L. Aguila*[3], J. A. Lorenzo[1]. [1]Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA, [3]Center for Immunotheraphy, University of Connecticut Health Center, Farmington, CT, USA.

Interleukin-7 is a potent stimulator of B and T lymphocytes and a direct inhibitor of *in vitro* osteoclastogenesis in murine bone marrow cultures. To explore the role of IL-7 in bone, we generated 3 transgenic mouse lines (A, B and C) in a C57BL/6 background (Tg) that used the 2.3 Kb rat collagen 1A1 promoter to selectively express human IL-7 in osteoblasts.

Measurable human IL-7 levels were detected by ELISA in the medium of neonatal calvarial cultures from all three lines. Line C (high Tg) produced the highest level of IL-7 while line B (low Tg) had levels that were 470 fold lower. Line A was intermediate. There was an increase in early B cells ($B220^+/IgM^-$) in the bone marrow of high Tg mice (WT = 29.1%, high Tg = 47.5%), which is a known effect of IL-7. In contrast, low Tg mice had normal bone marrow B-lymphopoiesis. hIL-7 was minimally detectable in the serum of all Tg lines. μCT analysis of high Tg mice demonstrated increased (15%, p<.05) trabecular bone mass in females but not in males at 7.5 weeks. Low Tg mice had no changes in trabecular bone mass. CFU-GM, an assay of osteoclast precursors, showed decreased colonies in high Tg females (by 44%, p<.01) but no effect of Tg on males. To investigate if locally produced IL-7 had effects on OCL formation *in vitro*, we cultured bone marrow from high Tg and WT littermates with M-CSF and RANKL (both at 30 ng/ml) for up to 7 days. OCL formation peaked at day 5 and declined thereafter. OCL formed in female bone marrow cells was greater than in male bone marrow cells (by 92% at day 4 and 26% at day 5, P<.01). Bone marrow cultures from high Tg mice showed decreased osteoclast formation on day 4 and day 5 in cells from both males and females (30% to 50% inhibition, p<.01) compared to WT littermate cells. However, at day 6 only male high Tg bone marrow cells showed decreased OCL formation (38% inhibition, p<.01). 1,25 $(OH)_2$ vitamin D_3 (10^{-8} M) treatment of bone marrow cells from high Tg and WT littermates produced a significant inhibition of OCL formation at day 6 in both male and female high TG cells (36% and 23%, respectively, p<.01) compared to WT and no significant differences at day 7.These findings demonstrate that female IL-7 high Tg mice have increased trabecular bone mass *in vivo* and decreased osteoclast formation *in vitro* compared to WT littermates. Increased bone mass in high Tg female mice likely reflects both a direct inhibitory effects of IL-7 on osteoclastogenesis and differences in responses to IL-7 between females and males.

Mechanism of Repression of Human Cu/Zn Superoxide Dismutase-1 Expression by the Pro-Inflammatory Cytokine TNF-α. V. Afonso*, G. Santos*, P. Collin*, A. Lomri. Lariboisiere Hosp., INSERM U-606, Paris 10, France.

Activation of macrophages leads to the secretion of cytokines that control the inflammatory response and increase the production of reactive oxygen species. Copper/zinc superoxide dismutase (SOD-1) is one of the major cellular defense enzymes that perform a vital role in protecting cells against the toxic effect of superoxide radicals. Over-expression of SOD-1 in monocytes renders them resistant to the toxic effect of TNF-α, indicating that TNF-α mediated growth inhibition of hemopoïetic cells occurs via the production of superoxide radicals. In this study, we evaluated the effect of TNF-α on SOD-1 transcription, and investigated the molecular & cellular mechanisms by which TNF-α regulates SOD-1 gene in the U937 and U2OS cells. Promoter deletions and mutations, over-expression experiments and specific chemical inhibitors indicate that TNF-α acts via the Sp-1 transcription factor binding sites located between -60 and -38 in the SOD-1 promoter to suppress gene expression. Electrophoretic mobility shift assays show that Sp-1 proteins constitutively bind to this consensus sequence and TNF treatment decreases Sp-1 binding to SOD-1 promoter. Promoter inhibition by TNF was associated with AP-1 activation. In contrast the anti-inflammatory curcumin, a selective c-jun/activator protein (AP)-1 inhibitor enhanced SOD-1 basal activity and suppressed AP-1 activation and SOD-1 down-regulation induced by TNF. Over-expression of Sp-1 enhances SOD-1 expression in contrast TNF inhibitory effect was repressed. Inhibition of protein synthesis with cycloheximide failed to prevent TNF inhibition of SOD-1 transcription, suggesting that a newly translated protein did not mediate the TNF effect and this effect involves post-translation modifications. In agreement with the transfection results, endogenous SOD-1 mRNA was suppressed by TNF-α (-41%) after 7 h of treatment. We also investigated the signaling pathway that mediates the effect of TNF. MEK inhibitor PD98059 inhibits SOD-1 promoter activity and mimics TNF effect, suggesting that ERK activity protects SOD-1 gene from the inhibitory effect of TNF. Furthermore, inhibition of JNK/AP-1 pathway by SP600125 prevented SOD-1 inhibition by TNF. Taken together, our results suggest that Sp-1 dephosphorylation and JNK/Ap1 activation by TNF-α are the key pathways involved in the down-regulation of SOD-1 transcription. Knowledge of the mechanisms of gene transcription in inflammation could lead to the development of novel therapies based on the pharmacological manipulation of the production of this important antioxidant gene in inflammation.

Regulation of Human Osteoclast Activity by Rearrangement of Attachment Proteins via Phosphorylation of VASP by cGMP-dependent Protein Kinase I. B. B. Yaroslavskiy, S. E. Kalla*, V. García Palacios, Y. Li*, H. C. Blair. Pathology and Physiology & Cell Biology, University of Pittsburgh and Pittsburgh Veteran's Affairs Medical Center, Pittsburgh, PA, USA.

Osteoclasts resorb bone by acid secretion into an extracellular compartment defined by an αvβ3 integrin ring, which organizes cytoplasmic F-actin. Bone attachment is reversible and detachment can be initiated with nitric oxide (NO) via guanosyl cyclase and cGMP-dependent Protein Kinase I (PKG-I); how PKG-I modifies attachment was unknown. We studied this using human osteoclasts differentiated, on bone and glass, from CD14-isolated circulating monocytes. An integrin-binding actin-organizing protein, VASP, was identified in osteoclasts by gene screening. Western analysis showed VASP in NO-activated and control osteoclasts in similar quantity, although VASP is phosphorylated, mainly on ser239 (pVASP), by PKG-I. NO donors increased pVASP with maximum 1-2 h after a pulse, 50-100 μM, of the non-hydrolysable cGMP analog 8-pCPT-cGMP, after which pVASP returned to baseline. In a blocking cGMP analog, Rp-cGMPS, immune labeling localized VASP strongly to the bone attachment and pVASP was essentially undetectible. NO donors reduced membrane and increased cytoplasmic VASP, although pVASP at the leading edge of the cytoplasm was detectible, and co-localized with PKG-I. Actin expression changed from a polymerized ring to short branched actins after activation by 8-pCPT-cGMP, with a distinct cellular polarity. Polarity corresponed to onset of migration by micro-cinematography. Transfection with siRNAs that reduced VASP or PKG-I expression modified the attachment structure, and impaired but did not abolish acid secretion. In low-VASP osteoclasts, bone attachment was unimpaired but the actin ring was broken, the cytoskeleton disordered, and these cells did not move in response to 8 pCPT-cGMP, although cGMP still caused transient membrane ruffling. In osteoclasts with low PKG-I, actin bundles were seen instead of actin rings; cells did not move in response to cGMP or NO. We conclude that VASP and PKG-I are required for NO-dependent reorganization of the osteoclastic attachment and motility, and probably are necessary for efficient bone degradation.

Estrogen and Phytoestrogens Inhibit Osteoclast Formation by Distinct Mechanisms. V. García Palacios, L. J. Robinson*, C. W. Borysenko, S. E. Kalla*, H. C. Blair. Pathology and Physiology & Cell Biology, University of Pittsburgh and Veteran's Affairs Medical Center, Pittsburgh, PA, USA.

We compared estradiol and phytoestrogen effects on growth and differentiation of Raw 264.7 cells, which express ERα and β and form TRAP positive osteoclast-like cells in RANKL, Genistein 3 μM, daidzein 3 μM, and β-estradiol 10 nM were compared in growth medium (DMEM with basal CSF-1) and in RANKL, 30 ng/ml, and CSF-1, 10 ng/ml over 5 d. Estradiol activates ERα and β; genistein is an ERβ inhibitor that also inhibits Y-kinases including Src; daidzein is a nonspecific estrogen analog. In media without RANKL, estrogen and both phytoestrogens reduced proliferation, although the genistein effect was 15-20% smaller. Estrogen, genistein, and daidzein all decreased Src phosphorylation, in contrast to expectations genistein did not have a larger effect. Fluorescent localization showed RANKL translocation of NF-κB. P65 showed greater phosphorylation in genistein, but nuclear/cytoplasmic NF-κB was unaltered relative to RANKL and CSF-1 alone. Estrogen and daidzein reduced nuclear NF-κB, but genistein did not. ERα or β siRNA suppression did not alter this, suggesting a non-ER mechanism. Erk kinase was inhibited ~50% at 1 h and stimulated 2-3 fold at 2 d by estrogen, daidzein, or genistein in the absence of RANKL and CSF-1. However, in RANKL and CSF-1, estrogen or phytoestrogens had no effect on Erk, suggesting that some estrogen and phytoestrogen effects are limited to pre-osteoclasts. However, estrogen, genistein, and daidzein all decreased multinucleated cells in RANKL at 2 d, with daidzein and estrogen more efficient (60-70% inhibition) than genistein (35%). Flow cytometry showed 80% reduction in S-phase RAW cells in estrogen, a smaller effect of genistein (40%), and no effect in daidzein. On the other hand, daidzein reduced apoptosis in G_0-G_1 cells ~20%; genistein and estrogen had no effect relative to RANKL and CSF-1. We conclude that estrogen, genistein, and daidzein regulate osteoclastogenesis under a balance between Erk and p65 pathways with a probable dominance of ER α mechanisms. Tyrosine kinase-antagonist properties of genistein appeared to be unimportant. Estrogen and phytoestrogens all increased Erk phosphorylation, but without added effect in the presence of CSF-1 and RANKL. Daidzein and estrogen shared important similarities, including reducing nuclear localization of NF-κB. Nuclear localization was unaffected with the ERβ agonist genistein, and thus it is probably an ERα-dependent estrogen effect.

Plasticity of a Myeloid Progenitor with Increased Osteoclasts from Pax5 Deficient Mice. M. Horowitz[1], D. Pflugh*[1], Y. Xi[1], J. Lorenzo[2], A. Bothwell*[1]. [1]Yale School of Medicine, New Haven, CT, USA, [2]University of Connecticut, Farmington, CT, USA.

Pax5 is a member of the paired box transcription factors and its expression is required for normal B cell development. We have demonstrated that Pax5 is also required for normal osteoclastogenesis. Loss of Pax5 results in a 5-fold increase in the number of osteoclasts (OC) in the bone of Pax5-/- mice, which are severely osteopenic. With the exception of red cells and megakaryocytes, bone marrow (BM) derived $B220^+$ pro-B cells from Pax5-/- mice can differentiate into all of the hematopoietic cell lineages including OC. Culture of Pax5-/- spleen cells results in the emergence of an adherent, $Fc\gamma R^+$, Mac-1^+, c-fms^+ macrophage-like cell line (SCL). Interestingly, these cells grow continuously in vitro, without

added growth factors, for more than 5 weeks. Addition of M-CSF and RANKL induces the rapid formation of numerous OC. Thus, it was the purpose of this work to determine if the SCL had similar plasticity of differentiation as the Pax5-/- pro-B cells.
To test this, SCL were treated with cytokines selected to induce specific lineage differentiation. Differentiation was determined by morphological changes, the expression of cell surface markers measured by flow cytometry and functionally by phagocytosis and T cell co-stimulation. Cellular proliferation was also measured.
The SCL proliferated to the cytokines in a hierarchical manner with GM-CSF>M-CSF>IL-3>IL-4. LPS also induced proliferation. The cells did not respond to IL-7 or G-CSF. Treatment of the cells with M-CSF caused no morphologic changes but induced a modest increase in FcR and Mac-1 expression. In contrast, cells treated with GM-CSF took on a marked dendritic appearance, associated with a dramatic increase in FcR, Mac-1 and CD45 expression. MHC class II expression also increased. The cells became $CD11c^+$ (dendritic cell marker), and $CD80^+$ (co-stimulatory molecule). Activation with LPS caused expression of CD40 and CD80. Cells treated with IL-4 also had increased expression of FcR, Mac-1, CD11c and CD80 but did not increase class II. In addition, the cells did not have a dendritic appearance but rather were elongated and larger than untreated cells. G-CSF caused no changes in morphology or determinant expression. Phagocytosis increased with M-CSF or GM-CSF treatment. Untreated SCL were potent co-stimulators of T cell activation.
These data indicate that the loss of Pax5 causes the appearance of a myeloid progenitor in the spleens of Pax5-/- mice. These cells can be induced to form functional macrophages, dendritic cells and OC but not granulocytes. The SCL is similar to the Pax5 BM pro-B cell in that both cells are progenitors however, the SCL is more differentiated and restricted to the myeloid lineage.

Stimulation of Resorption in Cultured Mouse Calvarial Bones by the Thiazolidinedione, Ciglitazone. A. M. Schwab*[1], B. N. Wilkes*[1], U. H. Lerner[2], H. H. Conaway[1]. [1]Physiology and Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR, USA, [2]Department of Oral Cell Biology, University of Umeå, Umeå, Sweden.

Thiazolidinedione drugs are PPARγ ligands used to treat Type 2 diabetes. Recent studies have suggested that PPARγ ligands may have effects on bone cells. In the current investigation, a natural PPARγ ligand, 15-deoxy-Δ12, 14-prostaglandin J2 (15d-PG-J2), and a thiazolidinedione, ciglitazone, were evaluated for their ability to stimulate resorption in neonatal mouse calvarial bones.
No stimulation was noted with 15d-PG-J2, but dosage-dependent release of ^{45}Ca from prelabeled mouse calvariae was observed following treatment with ciglitazone. Release of ^{45}Ca by ciglitazone was unaffected by the PPARγ antagonist GW 9662, by the mitotic inhibitor hydroxyurea, and by the cyclooxygenase enzyme inhibitor indomethacin. In contrast, significant inhibitions of ^{45}Ca release elicited by ciglitazone were noted in the presence of the carbonic anhydrase enzyme inhibitor acetazolamide, the hormone inhibitor calcitonin (CT), a bisphosphonate, 3-amino-1-hydroxypropylidene-1, 1-bisphosphonate (AHPrBP), the anti-inflammatory cytokine interleukin-4 (IL-4) and the decoy receptor osteoprotegerin (OPG). Real-time, quantitative polymerase chain reaction (PCR) analysis demonstrated enhanced expression of receptor activator of NFκB ligand (RANKL) mRNA and decreased OPG mRNA in ciglitazone treated calvarial bones. ELISA measurements of RANKL and OPG were in good agreement with the mRNA measurements, revealing an increase in RANKL protein and a decrease in OPG protein in bone explants exposed to ciglitazone. Real-time PCR analysis showed that expression of the transcription factor NFAT2 and osteoclast markers, tartrate resistant acid phosphatase (TRAP) and cathepsin K, were also increased by ciglitazone treatment of calvariae.
The data indicate that stimulation of osteoclast differentiation and activity by ciglitazone occurs by a non-PPARγ dependent pathway that does not require cell proliferation, is sensitive to inhibition by the decoy receptor, OPG, is sensitive to the osteoclast inhibitors, acetazolamide, CT, AHPrBP and IL-4 and is associated with an increased RANKL/OPG ratio.

α-Lipoic Acid Suppresses Osteoclastogenesis Despite of Increased RANKL/OPG Ratio in Bone Marrow Stromal Cells. J. Koh[1], E. S. Kim*[2], E. Chang*[3], H. Kim*[3], H. Kim*[3], G. S. Kim[1]. [1]Division of Endocrinology and Metabolism, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Department of Internal Medicine, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea, [3]Department of Cell and Developmental Biology, Dental Research Institute, and Brain Korea 21 Program, College of Dentistry, Seoul National University, Seoul, Republic of Korea.

Growing evidence has shown a biochemical link between increased oxidative stress and reduced bone density. α-Lipoic acid (ALA) has gained considerable attention due to its roles as an outstanding biological thiol antioxidant, however, its effect on bone cells has not been addressed. In this study, ALA did not have significant effects on proliferation and differentiation of human bone marrow stromal cells (BMSC, HS-5 cell), based on cell counting, cell death ELISA and alkaline phosphatase activity. However, we found six differentially expressed proteins in the conditioned media from HS-5 cells by ALA treatment using proteomic analysis. Of them, receptor activator of NF-κB ligand (RANKL) was significantly up regulated, which was confirmed by immoblotting with anti-RANKL antibody. ELISA assay revealed that ALA stimulated RANKL production in conditioned media and cellular extracts up to 4.8-fold and 22.9-fold, respectively, and did not affect osteoprotegerin secretion. However, ALA markedly suppressed osteoclastogenesis in a dose-dependent manner both in co-culture system of mouse bone marrow cells and osteoblast, and in mouse bone marrow cell culture system. These results suggest that ALA suppresses osteoclastogenesis directly, not mediated by RANKL acting.

Epigenetic Regulation of Mouse Receptor Activator NF-kappaB Ligand (RANKL) Gene. R. Kitazawa, K. Mori*, T. Kondo, S. Kitazawa. Molecular Pathology, Kobe University Graduate School of Medicine, Kobe, Japan.

To clarify the epigenetic regulation mechanism of RANKL gene expression, we analyzed the mouse RANKL gene promoter that contains three Runx2-binding sites, one CRE shared by vitamin D responsive element (VDRE), and two CpG clustering regions: one around the transcription and translation start sites (-65/+350) and the other downstream of the VDRE (-920/-800). Comparison of the two subpopulations of mouse stromal ST2 cells, P9 which expresses RANKL in response to vitamin D and P16 which does not, has revealed higher CpG methylation of the -65/+350 RANKL promoter region in P16 than in P9. Western blotting, showed the same VDR expression level in P9 and P16 cells, and EMSA, with nuclear extracts from P9 and P16 cells, showed specific binding to the oligonucleotide containing VDRE, suggesting that RANKL gene suppression in P16 cells is not due to VDR deterioration. By ChIP assay using anti-H3, -H4 antibodies and pairs of primers designed to amplify -950/-680 (containing VDRE) and -250/+10 (containing the transcription start site), in response to vitamin D, H3, H4 histone acetylation in both regions was observed in P9 cells but not in P16 cells. To determine how CpG methylation suppresses RANKL gene transcription, we examined the effect of in vitro methylation on RANKL gene promoter activity. The RANKL promoter-luciferase reporter construct pGL3-1005 was methylated with SssI methylase (as pGL3-m1005) and transfected into ST2 cells. The basal activity of pGL3-m1005 was only 20% of that of pGL3-1005, and pGL3-m1005 did not increase the promoter activity in response to vitamin D whereas pGL3-1005 did. We then examined the effect of demethylating agent 5-Aza-dC on RANKL expression in P9 and P16. Assessed by RT-PCR and Western blotting, expression of RANKL mRNA and protein in response to vitamin D in P16 cells was significantly restored by 5-Aza-dC pretreatment. Immunohistochemically, RANKL protein in cultured cells was heterogeneously distributed, reflecting the heterogeneity of CpG methylation and of RANKL gene activation. Our data suggest that CpG methylation of the RANKL promoter suppresses gene activation by vitamin D. The epigenetic mechanism may cause the heterogeneity and diversity of stromal/osteoblastic cells in response to bone-resorbing stimuli.

Protease-Activated Receptor-1-Mediated Osteoclast Differentiation. S. Sivagurunathan*[1], P. D. Campbell*[2], R. Smith*[2], C. N. Pagel*[1], R. N. Pike*[2], E. J. Mackie[1]. [1]School of Veterinary Science, University of Melbourne, Victoria, Australia, [2]Department of Biochemistry and Molecular Biology, Monash University, Victoria, Australia.

The serine protease thrombin is well known to have a central function in the blood coagulation process but it also exerts specific hormone-like effects on cells, including bone cells. Thrombin has been shown to stimulate osteoclastic bone resorption in organ culture, however little is known about the mechanism of thrombin's effect and whether it is exerted on osteoclast differentiation or activity of mature osteoclasts. It has previously been shown that two known thrombin receptors are expressed by mouse osteoblasts, protease-activated receptor (PAR)-1 and PAR-4. The aim of the current study was to investigate whether thrombin can regulate osteoclastic differentiation, and if so, whether it is mediated by PAR-1. Mouse bone marrow cultures were used to investigate thrombin's effect on osteoclast differentiation. Thrombin markedly stimulated the formation of multinucleated tartrate-resistant acid phosphatase-positive cells (TRAP+ MNC). A specific PAR-1 activating peptide (AP) was also shown to enhance the formation of TRAP+ MNC. A concentration of 100 nM thrombin stimulated a maximal increase in the number of TRAP+ MNC, and the number of TRAP+ MNC formed in response to thrombin was at least 70% of the number formed in response to 10 nM parathyroid hormone (PTH). The numbers of nuclei per osteoclast in thrombin-treated cultures (7 ± 0.60) and PAR-1 AP-treated cultures (5 ± 0.24) were lower than in PTH-treated cultures (18 ± 0.37). In bone marrow cultures prepared from PAR-1-null mice, neither thrombin nor the PAR-1AP was able to stimulate osteoclast differentiation. These results suggest that thrombin stimulates osteoclastic differentiation and that the effect is mediated by PAR-1.

Muramyl Dipeptide Synergistically Enhances Osteoclast Formation Induced by lipopolysaccharide, interleukin 1 and Tumor Necrosis Factor-α through Nod2-mediated Signals in Osteoblasts. S. Yang*[1], N. Takahashi[2], M. Takahashi*[1], M. Mogi*[3], T. Uematsu*[1], Y. Kobayashi[2], Y. Nakamiti[2], H. Takada*[4], K. Takeda*[5], S. Akira*[5], K. Furusawa*[1], N. Udagawa[6]. [1]Department of Oral and Maxillofacial Surgery, Matsumoto Dental University, Shiojiri, Japan, [2]Institute for Oral Science, Matsumoto Dental University, Shiojiri, Japan, [3]Department of Pharmacology, Aichi Gakuin University, School of Dentistry, Nagoya, Japan, [4]Department of Microbiology and Immunology, Tohoku University School of Dentistry, Sendai, Japan, [5]Research institute for Microbial Disease, Osaka University, Suita, Japan, [6]Department of Biochemistry, Matsumoto Dental University, Shiojiri, Japan.

Muramyl dipeptide (MDP), the essential structure responsible for the immunoadjuvant activity of peptidoglycan, exists in gram-positive and -negative bacterial walls. As well as bone-resorbing factors such as 1 α,25$(OH)_2D_3$ and PGE_2, IL-1 α and LPS stimulated osteoclast formation in mouse co-cultures of primary osteoblasts and hemopoietic cells. MDP alone could not induce osteoclast formation in the co-culture, but synergistically stimulated it induced by LPS and IL-1 α but not by 1 α,25$(OH)_2D_3$ or PGE_2. MDP failed to enhance osteoclast formation from osteoclast progenitors induced by RANKL and M-CSF. MDP up-regulated RANKL expression in osteoblasts treated with LPS but not with 1 α,25$(OH)_2D_3$. Recently, it was proposed that nucleotide-binding oligomerization domain (Nod) 2, a member of the Apaf1/Nod protein family, is an intracellular sensor of MDP. A frameshift mutation of Nod2, which results in deficiency in MDP-mediated NF-κB activation, is involved in the susceptibility to Crohn's disease, a chronic inflammatory disorder of the intestinal tract. Nod2 mRNA was undetectable in untreated osteoblasts, but it was strongly expressed in osteoblasts treated with LPS and IL-1 α but not with 1 α,25$(OH)_2D_3$. TNF- α also stimulated expression of Nod2 mRNA in osteoblasts. Indeed, MDP synergistically enhanced TNF- α induced both osteoclast formation in the co-culture and RANKL mRNA expression in osteoblasts. Induction of Nod2 mRNA expression by LPS but not by TNF- α in osteoblasts was TLR4 (a signal-transducing receptor for LPS) and MyD88 (an adaptor molecular of TLR4) dependent. Osteoclasts rapidly died due to apoptosis. LPS and RANKL stimulated the survival of osteoclasts, which was not enhanced by MDP. These results suggest that MDP synergistically enhances osteoclast formation induced by LPS, IL-1 α and TNF- α through RANKL expression in osteoblasts, but not the survival of osteoclasts supported by LPS and RANKL. Nod2-mediated signals appear to be involved in the MDP-induced RANKL expression in osteoblasts.

MyD88 but not TRIF Is Essential for Osteoclastogenesis Induced by Lipopolysaccharide, Diacyl Lipopeptide and IL-1. N. Sato*[1], N. Takahashi[2], K. Suda*[3], Y. Kobayashi[2], S. Akira*[4], K. Shibata*[5], T. Noguchi*[1], N. Udagawa[6]. [1]Periodontology, School of Dentistry, Aichi-Gakuin Univ., Nagoya, Japan, [2]Institute for Oral Science, Matsumoto Dental Univ., Shiojiri, Japan, [3]Biochemistry, Showa Univ., Tokyo, Japan, [4]Osaka Univ., Suita, Japan, [5]Hokkaido Univ., Sapporo, Japan, [6]Biochemistry, Matsumoto Dental Univ., Shiojiri, Japan.

LPS is a potent stimulator of bone resorption in inflammatory diseases caused by bacteria. Bacterial lipoprotein/lipopeptides are also pathogen-specific molecular patterns. Toll-like receptor 4 (TLR4) is identified as the signaling receptor for LPS. The complex of TLR6 and TLR2 recognizes diacyl lipopeptide. The signaling cascade of TLR is similar to that of IL-1 receptors, because both TLR and IL-1 receptors use MyD88 as a common signaling molecule. Toll-IL-1 receptor domain-containing adapter inducing interferon-β (TRIF)-mediated signals are also shown to be involved in LPS-induced MyD88-independent pathway. Using MyD88-deficient ($MyD88^{-/-}$) mice and TRIF-deficient ($TRIF^{-/-}$) mice, we examined roles of MyD88 and TRIF in osteoclast differentiation and function. LPS, diacyl lipopeptide (DL) and IL-1 stimulated osteoclastogenesis in co-cultures of osteoblasts and hemopoietic cells obtained from $TRIF^{-/-}$ mice but not $MyD88^{-/-}$ mice. LPS, DL and IL-1 stimulated RANKL mRNA expression in $TRIF^{-/-}$ osteoblasts but not $MyD88^{-/-}$ osteoblasts, suggesting that only MyD88-mediated signal in osteoblasts was important for RANKL expression in response to those factors. This finding was particularly interesting, because both MyD88-dependent and TRIF-dependent pathways are essential for LPS-induced cytokine production in macrophages. Indeed, LPS failed to stimulate IL-6 production in $TRIF^{-/-}$ bone marrow macrophages. But, LPS could stimulate IL-6 production in $TRIF^{-/-}$ osteoblasts. LPS and IL-1 enhanced the survival of $TRIF^{-/-}$ osteoclasts but not $MyD88^{-/-}$ osteoclasts. TRIF-related adaptor molecule (TRAM) was shown to be essentially involved in the TRIF-mediated signaling pathway. Interestingly, macrophages expressed both TRIF and TRAM mRNAs, while osteoblasts and osteoclasts expressed only TRIF mRNA. The fact that TRIF-mediated signals are not required for LPS-induced RANKL and IL-6 expression in osteoblasts and for osteoclast survival may be related to the lack of TRAM expression in osteoblasts and osteoclasts. Bone histomorphometry showed that $MyD88^{-/-}$ mice exhibited low turnover osteoporosis with reduced bone resorption and formation. These results suggest that the MyD88-mediated signal is essential for the osteoclastogenesis and function induced by IL-1 and TLR ligands, and that MyD88 is physiologically involved in bone turnover.

Novel Fluorescent Activated Cell Sorting Method for in vitro Analysis of Matured Osteoclast Differentiation Rate. C. Herath, S. Wimalawansa. Dept. Medicine, Div. Endocrinology, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

The molecular basis of age-related imbalance in bone cell coupling is complex. These include enhanced osteoclast differentiation, life span, and increased bone resorption. The procedures currently used are based on counting multi-nuclear cell formation in osteoclast cultures; but this is laborious, and adds random counting field errors. We developed a dual-color Florescent Activated Cell Sorting (FACS) method to assay the differentiation rate of mature multi-nucleated osteoclast from mono-nucleated osteoclast progenitors based on osteoclast marker RANK receptors (RANK-R) expression, and osteoclast nuclear density.
Bone marrow cells were cultured on glass cover slips to obtain >98% pure osteoclast progenitors cells. Cells were harvested at 48, 72, 96 and 192 hrs, and their differentiation rates were analyzed on reference to their expression of RANK-R protein (immuno-labeling of RANK-R using goat-anti-mouse RANK-R Ab, and secondary labeling with Green fluorochrome Labeled-rabbit anti-goat IgG). RANK-R labeled cells were stained with Propidium Iodide for simultaneous analysis of nuclear density.
Samples were analyzed using Cytomic FC 500 flowcytometer and scatter plot obtained with intensities of green fluorescents and red fluorescent exhibited phenotypically distinct sub populations of osteoclasts. Percentage of cells gated into sub population (gate 0) having high RANK-R expression and nuclear density was analyzed. Osteoclast formation rates were examined at same time points by counting multi-nucleated vs. mono nucleated cells on randomly selected 16 fields after staining with Hoechet nuclear stain in a fluorescents microscopy. Each experiment was repeated three times to obtain the average values.
The new method was accurately separate distinct sub-population of high nuclear density and RANK-R expressing mature osteoclast cells. Linearity of the method and its' simplicity allowed us to accurately measure the osteoclast cell differentiation rates per unit time (i.e., slope of the graph). The new FACS method is currently used in our laboratory to analyze osteoclast differentiation rates from bone marrow cells, osteoblast mediated regulation on osteoclasts, and to analyze the effect of novel therapeutic agents on rates of osteoclast differentiations.

Multiple Mechanisms Contribute to Stimulation of Osteoclastogenesis by Ascorbate. R. M. Kadlcek*, A. A. Ragab*, E. M. Greenfield. Orthopaedics, Case Western Reserve University, Cleveland, OH, USA.

We have previously shown that ascorbate is required for osteoclastogenesis (JBMR 13:970-77, 1998). In other cell types, the primary mechanism of action of ascorbate is to promote collagen crosslinking and extracellular matrix (ECM) assembly. To determine whether this mechanism contributes to osteoclastogenesis, we provided exogenous ECM by performing *in vitro* osteoclastogenesis assays on dentin or ivory slices. For this purpose, splenocytes were co-cultured with ST2 cells in the presence and absence of 0.284 mM ascorbate plus 10 nM 1,25-D3 and 100 nM dexamethasone. We found that exogenous ECM completely ablated the ascorbate requirement for formation of both TRAP-positive MNCs and resorption lacunae. Moreover, ECM digestion by either pronase or collagenase completely blocked the ability of dentin to overcome ascorbate deficiency. These experiments document the importance of ECM during osteoclastogenesis. Otsuka et al. (Endocrinology 141:3006-11, 2000) found that ascorbate upregulates RANKL mRNA levels and suggested that ascorbate-dependent ECM assembly increases RANKL production, thereby allowing for osteoclastogenesis. To test this possibility, we added exogenous RANKL [0.3-30.0 ng/ml] and found that RANKL partially overcomes ascorbate deficiency. Thus, RANKL dose-dependently stimulated osteoclastogenesis with maximal effects ~40% of that induced by ascorbate. Similar conclusions were obtained in experiments with highly purified osteoclast precursors cultured in the absence of mesenchymal cells. In this case, RANKL (with 10 ng/ml M-CSF) dose-dependently stimulated osteoclastogenesis in both the presence and absence of ascorbate. However, maximal osteoclastogenesis in the absence of ascorbate was ~25% of that induced in the presence of ascorbate and required 10-fold more RANKL. The primary mechanism of action of ascorbate other than ECM assembly is to regulate the intracellular redox state. To determine whether this mechanism also contributes to osteoclastogenesis, we examined the effect of N-acetyl cysteine, a reducing agent that does not promote collagen crosslinking. 2.5mM N-acetyl cysteine maximally stimulated osteoclastogenesis with effects ~40% of that induced by ascorbate.

Taken together, these results demonstrate that multiple mechanisms contribute to stimulation of osteoclastogenesis by ascorbate. These include redox regulation, direct effects on osteoclast precursors, and indirect effects through ST2 support cells (ECM assembly and RANKL upregulation).

Spontaneous Osteoclastogenesis in Solid Tumours with Bone Involvement. I. Roato*[1], M. Grano*[2], G. Brunetti*[2], S. Colucci*[2], R. Ferracini*[3]. [1]CeRMS, A.S.O. S.Giovanni, Turin, Italy, [2]Human anatomy histology, University of Bari, Bari, Italy, [3]Orthopaedic surgery, A.S.O. S.Giovanni, Turin, Italy.

We studied the mechanisms of bone osteolytic metastases in solid tumours (breast, lung, kidney, prostate). Osteoclasts (OCs), cells deriving from granulocitic-macrophagic lineage, are responsible for osteolysis, which is usually associated with severe bone pain and fragility. By inhibiting OCs formation and activity osteolysis may be reduced.

Human peripheral blood mononuclear cells (PBMCs) isolated from cancer patients with or without osteolytic metastases, healthy donors and purified $CD14^+$ cells were cultured in presence or absence of M-CSF and RANKL. TRAP staining and Vitronectin Receptor (VR) immunofluorescence were performed to characterize OCs. Flow Cytometry was utilized to identify OC precursors (OCPs) circulating by staining with anti-human CD11b, CD14, CD51/CD61. OC resorbing-activity was evaluated by analyzing the percentage area of resorption pits on dentine slices. RNA was extracted from OCs and cDNA was prepared. The expression of mRNA for OCs markers was analysed by reverse transcriptase-polymerase chain reaction (RT-PCR).

We report here that cancer patients with bone involvement have an increase in OCPs compared to those from healthy controls and cancer patients without bone metastases. PBMC from patients carrying osteolytic lesions showed osteoclastogenesis without adding RANKL and M-CSF (OCs were $TRAP^+$ and VR^+). On the other side, these factors are necessary for generating OCs from healthy donors, not osteolytic patients PBMC and purified $CD14^+$ cells. OCs derived from cancer patients showed more resorption pits than OCs derived from healthy donors, and expressed genes involved in osteoclastogenesis.

Our data show that spontaneous osteoclastogenesis occurs in patients affected by osteolytic lesions, and may be sustained by factors released by T lymphocytes, which could give a priming to OCPs and promote osteoclastogenesis. In fact, $CD14^+$ cells cultured alone do not differentiate to OCs without adding M-CSF and RANKL. However, we did not obtain a higher number of OCs by increasing RANKL doses in cultures, and OCs and lymphocytes mRNA were positive for TNF-α but not for RANKL. Furthermore we observed an inhibition of osteoclastogenesis adding anti-TNF-α in culture. These data infer the existence of specific mechanisms promoting osteoclastogenesis in solid tumours with bone involvement. Our results suggest that TNFα may be responsible for osteoclastogenesis in these tumours.

Chemokines Acting Through CCR1 or CCR5 Differentially Promote Osteoclast Recruitment, RANKL Development, and Function. X. Yu, Y. Huang*, P. A. Collin-Osdoby, P. A. Osdoby. Department of Biology, Washington University, St. Louis, MO, USA.

Chemokines are the primary signals controlling cell trafficking and are important in the differentiation, function or survival of many cells. However, our knowledge of osteoblasts (OBs) or osteoclasts (OCs) as sources or targets of specific chemokines in normal or pathological conditions is limited at present. Recently, we investigated chemokine and chemokine receptor mRNA expression and responses in murine RAW 264.7 and primary marrow (MA) mononuclear cells during their RANKL development into bone-resorptive OCs. CCR1 was the major receptor of the beta-chemokine subfamily expressed by differentiated OCs, and both RAW and MA precursor cells expressed CCR1 and responded to ligands (MIP-1 alpha, RANTES, MCP-3) that engage CCR1 by dose-dependently increasing chemotaxis and transmatrix migration. This led to greater OC formation upon RANKL development of migrated cells. MIP-1 alpha, RANTES, and MCP-3 also directly and strikingly enhanced RANKL mediated OC formation in MA cultures, but not in RAW cells. This unexpected finding was notable because RAW cells expressed only CCR1 mRNA, whereas MA cells also expressed other CCRs including CCR5, which can bind these same chemokines. Thus, we hypothesized that CCR1 might mediate the chemotactic, and CCR5 the OC developmental, actions of these chemokines. To test this, we compared transwell chemotaxis and RANKL-mediated OC development of MA cells from wild-type (wt) vs. CCR5-/- mice in response to these chemokines. We also analyzed the ability of MIP-1beta, which binds CCR5 but not CCR1, to augment RANKL induced OC formation. Consistent with our hypothesis, MIP-1α was equally able to dose-dependently stimulate chemotaxis of MA cells from either wt or CCR5-/- mice, indicating that CCR5 is not essential for this chemotactic response. However, RANKL-mediated OC formation and bone pit resorption were dramatically decreased in MA cells cultured from CCR5-/- mice compared to wt mice, both in the presence or absence of exogenous MIP-1alpha, RANTES, or MCP-3 addition. These data suggest that CCR5 has an important role in mediating the dramatic stimulatory effects of these chemokines on RANKL induced OC formation and, further, that endogenous levels of one or more of these chemokines may help regulate normal RANKL mediated OC development. Together with the ability of these chemokines to chemoattract OC precursors and stimulate their matrix migration, our findings indicate that inflammatory raised levels of these chemokines may significantly contribute to localized bone loss through stimulating multiple mechanisms that include enhanced recruitment, differentiation and migration of bone-resorptive OCs.

Tannin Compound Suppresses Receptor Activator of Nuclear Factor-*k*B Ligand-induced Osteoclast Differentiation and Function by Inhibiting p38 Mitogen Activated Protein Kinase, c-Jun N-terminal Kinase and Aactivating Protein-1 Pathways. E. Park[1], M. Kim*[1], S. Lee*[2], T. Kim*[1], I. Lee*[3], J. Jung*[4], J. Woo[5], S. Kim[6]. [1]Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea, [2]Department of Pharmacy, Yeungnam University, Daegu, Republic of Korea, [3]Department of Food Science and Technology, Keimyung University, Daegu, Republic of Korea, [4]Department of Biology, Kyungpook National University, Daegu, Republic of Korea, [5]Department of Biological Chemistry, Chubu University, Aichi, Japan, [6]Department of Orthopedic Surgery, Kyungpook National University Hospital, Daegu, Republic of Korea.

Recently polyphenolic compounds have been implicated in suppression of osteoclast differentiation/function and prevention of bone diseases. However, the effects of hydrolizable tannins of polyphenolic compounds on bone metabolism have not been elucidated. In this study, we screened hydrolizable tannins and found that K16, an ellagitannin, markedly decreases the differentiation into osteoclasts in both murine bone marrow mononuclear (BMM) cells and RAW264.7 cells as revealed by the reduced number of tartrate resistant acid phosphatase (TRAP)-positive multinucleated cells and TRAP activity. K16 appears to target the early stage of osteoclastic differentiation while having no cytotoxic effect on those cells. Furthermore, K16 also reduced resorption pit formation in osteoclasts. Analysis of inhibitory mechanisms of K16 revealed that it inhibits the receptor activator of nuclear factor-*k*B ligand (RANKL)-induced activation of p38 mitogen-activated protein kinase (p38MAPK), c-Jun N-terminal kinase (JNK), and activating protein-1 (AP-1). Taken together, these results demonstrate that naturally occurring K16 has an inhibitory activity on both osteoclast differentiation and function through a mechanism involving inhibition of the RANKL-induced p38MAPK, JNK, and AP-1 activation.

Novel Genes Regulated by Microphthalmia Transcription Factor in Macrophages and Osteoclasts. N. A. Meadows*[1], G. Faulkner*[1], C. Wells*[1], T. Ravasi*[1], D. Hume*[1], U. Sankar*[2], R. Hu*[2], M. Ostrowski*[2], A. Cassady[1]. [1]Institute for Molecular Bioscience, University of Queensland, Brisbane, Australia, [2]Department of Molecular Genetics, Ohio State University, Columbus, OH, USA.

Microphthalmia transcription factor (Mitf) is a member of the helix-loop-helix leucine zipper family of transcription factors. Mitf is a key regulator of osteoclast differentiation and regulates its target genes by binding as a homo- or heterodimer to an E-box consensus sequence (CANNTG). The macrophage cell line, RAW264.7, which has the potential to differentiate into osteoclast-like cells, has been used to generate stable transfectant cell lines expressing the Mitf-A (RAW/Mitf-A) and *mi* (RAW/*mi*) isoforms. The RAW/Mitf-A and RAW/*mi* cell lines were used to identify the effect of modulating Mitf activity on selected macrophage- and osteoclast-specific promoters and to identify novel Mitf target genes.

Western blotting established that the recombinant Mitf-A and *mi* protein are present and immunofluorescence identified that proteins are localized in the nucleus. Real time PCR validated the effect of modulating Mitf activity by identifying changes in the expression of known Mitf targets including TRAP and cathepsin K. Microarray expression profiling on the 22,000 element murine Compugen array of RAW/Mitf-A and RAW/*mi* cell lines was performed before and after induction of osteoclast differentiation with RANKL. This identified Mitf-responsive genes on macrophage and osteoclast phenotypic backgrounds. Complementary experiments using primary bone marrow-derived osteoclasts from C57BL6 mice and *mi/mi* mice using an Affymetrix array identified a similar set of genes.

A bioinformatic analysis was undertaken in parallel to identify candidate E-box-containing genes that may be Mitf targets. A large-scale Blast technique has been developed to download 5kb of DNA sequence 5' of the translation start site for all the genes on the Compugen cDNA array. These promoter regions have been searched for the presence of the E-box and a subset of potential Mitf target genes has been compiled and compared with targets generated from the microarray analysis. Of the generated targets an Ikaros family member, Eos, was shown to possess an E-box and microarray and real time PCR data has shown that it is down-regulated in osteoclasts derived from *mi/mi* spleen cells. Eos is a Zn-finger transcription factor, which has previously been shown to have a role in lymphocyte differentiation. Real time PCR also showed Eos to be up-regulated in the RAW264.7 cell line over-expressing Mitf. The data indicates that a combined bioinformatic and microarray approach can be successful in defining a specific list of possible Mitf targets.

Oxidative Stress Accelerates Human Osteoclast Differentiation: Possible Role of Thioredoxin. M. A. Chacksfield*, N. Zimmerman*, J. M. Hodge*, C. J. Aitken*, M. Constable*, C. M. Lopez*, G. C. Nicholson. Clinical and Biomedical Sciences: Barwon Health, The University of Melbourne, Geelong, Australia.

Redox-sensitive cell signaling regulates many cell functions including proliferation, activation, growth inhibition and apoptosis. Signaling pathways important for osteoclast differentiation, including NF-kappaB and AP-1 can be modulated the endogenous redox-sensitive thiol, thioredoxin.

We have used a human osteoclastogenesis model employing CFU-GM precursors treated with M-CSF and soluble RANKL for 7-14 days to investigate the effects of the ROS-donor H_2O_2 on differentiation and function of osteoclasts. In this model, proliferation, differentiation and fusion of precursors occurs in the first week of culture, and resorption in the second week.

In the presence of a high concentration of RANKL (125 ng/mL), H_2O_2 treatment increased osteoclast number and osteoclast size by 70-80% at 7 days, with 1 nM producing a maximum effect. Resorption of dentine was increased by 140% with maximum effect at 10 nM. In the presence of a lower concentration of RANKL (31 ng/mL), 100 nM H_2O_2 was required to produce maximum effects on formation (+170%) and resorption (+200%) and there was no enhancement of osteoclast size. Time-course studies showed that it was only necessary for H_2O_2 to be present for the first 24 hours of culture to achieve a maximum stimulatory effect on M-CSF/RANKL-induced osteoclastogenesis. In contrast, it was necessary for RANKL to be present for the first 6-7 days of culture for significant osteoclast generation to occur. In cultures extended for 14 days, continuous treatment with 100nM H_2O_2 had a variable effect on ultimate formation and resorption, depending on control osteoclastogenic activity. Delayed treatment after the first day of culture had no significant effect on osteoclast formation or resorption. Treatment of CFU-GM precursors with 10 mM H_2O_2 produced a 4-fold increase in thioredoxin mRNA at 12 hours (real-time PCR).

Our results show that oxidative stress induced by H_2O_2 accelerates very early RANKL-induced differentiation events in human osteoclast precursors, but does not enhance resorption by mature osteoclasts. The model used does not possess unlimited potential for osteoclast generation because of the finite number of precursors present. However, in the presence of a regenerating progenitor pool (eg in vivo), oxidative stress is likely to produce a steady-state of increased osteoclasts. The stimulatory effect of H_2O_2 is much more sensitive in the presence of a low concentration of RANKL, suggesting a common molecular mechanism. Up-regulation of thioredoxin is likely to facilitate RANKL/RANK signalling and may mediate the pro-osteoclastogenic effect of H_2O_2.

Functional Validation of Osteoclast-Specific Genes in RAW264.7 Cells by RNA Interference. G. B. Tremblay, R. Sooknanan*, A. Kalbakji*, D. Bergeron*, M. Sasseville*, M. Filion*. Target Validation, Alethia Biotherapeutics, Montreal, PQ, Canada.

The ability to maintain bone strength is controlled through bone remodeling which involves concomitant bone formation by osteoblasts and bone degradation by osteoclasts (OC). In diseases such as osteoporosis, the balance between these two processes is shifted in favor of increased bone resorption resulting in a reduction in bone mineral density. In many cases, this is due to an increase in the number or activity of OCs. Although current treatments are somewhat effective in treating osteoporosis, these are associated with many side effects. Thus, new molecular targets for treating this disease would be beneficial for developing new drugs and preventing bone loss in post-menopausal women. Using the mouse RAW264.7 (RAW) cell line as a model for osteoclastogenesis, we utilized RNA interference (RNAi) to knock-down the expression of several OC-specific genes to test whether they were required for OC differentiation or activation.

We have identified 556 genes that were upregulated in response to RANK ligand in RAW OCs and 70 of these were found to be highly specific to OCs in terms of their expression pattern. Although some of the genes were previously described, most were uncharacterized functionally. Plasmids expressing short inhibitory (si) RNAs specific for 29 of these were transfected into RAW cells and selected with G418. These cell lines were tested for osteoclastogenesis where TRAP staining and OC number was assessed and compared to cell lines transfected with the empty plasmid. OC activity was tested by growing the RAW-derived OCs on calcium phosphate and determining their ability to resorb the substrate. In addition, the RNAi effect was monitored by Northern blot and, where possible, by Western blot. To date, 10 of the 29 knocked-down genes appear to be required for OC function. We have detected three phenotypic categories: reduced OC differentiation, increased OC differentiation, and perturbed OC function. For example, one of the genes, designated AB0440, encodes an uncharacterized OC-specific protease and is required for formation of mature OCs. Cell lines containing siRNAs targeting AB0440 also display reduced expression of the OC markers TRAP and Cathepsin K. RNAi of another gene, AB0351, that encodes a protein containing a predicted membrane-anchoring domain, exhibited a similar phenotype and showed significant reduction in OC markers. These new targets, and others we have identified, have the potential to serve as the basis for the development of novel therapeutic drugs to treat osteoporosis and other bone-related diseases.

A New Hormonal Upstream Factor in the RANKL/OPG System? Effects of the Thyroid Stimulating Hormone TSH in Humans. H. P. Dimai, A. Fahrleitner*, C. Piswanger-Soelkner*, S. Ramschak-Schwarzer*, B. Obermayer-Pietsch*, G. Leb. Internal Medicine, University Hospital, Graz, Austria.

In vitro evidence indicates a possible involvement of the human thyroid stimulating hormone (TSH, thyrotropin) in the regulation of bone metabolism. Recently, a highly purified recombinant human TSH alpha (THYROGEN) has been registered for diagnostic purposes. Patients with carcinoma of the thyroid gland usually are thyroidectomized, and in addition, they are on TSH suppressive thyroid hormone therapy, in order to avoid endogenous TSH production. Administration of THYROGEN without interrupting suppressive thyroid hormone therapy provides an excellent opportunity to study the effects of TSH without changes in the serum levels of free thyroid hormones. We therefore saught to investigate the effects of THYROGEN on markers of bone metabolism and the osteoprotegerin (OPG)/receptor activator of NF-kB ligand (RANK-L) system.

We investigated 25 patients who underwent total thyroidectomy because of well-differentiated thyroid cancer. All patients received suppressive thyroid hormone therapy. THYROGEN was administered at a dosage of 0.9mg IM daily on two consecutive days. Blood samples were drawn right before the first injection, 120 minutes thereafter, and 24hrs (i.e right before the second injection), 48 hrs, and 72 hrs after the first injection. All patients continued receiving their usual dosage of thyroid hormone.

TSH (microU/mL): 0.14 ± 0.07; 100.8 ± 10.8 ($p < 0.0001$); 141.9 ± 6.7 ($p < 0.0001$); 141.8 ± 7.4 ($p < 0.0001$); 58.6 ± 7.9 ($p < 0.0001$); Interleukin-6 (pg/mL): 1.95 ± 0.36; 2.54 ± 0.47 ($p < 0.01$); 2.28 ± 0.42; 2.05 ± 0.39; 1.98 ± 0.43; Osteocalcin (ng/mL): 21.8 ± 2.6; 21.1 ± 2.6; 22.9 ± 2.6 ($p < 0.05$); 23.1 ± 2.4 ($p < 0.01$); 21.3 ± 1.7; CrossLaps (pmol/L): 3593 ± 676; 3609 ± 710; 4514 ± 673 ($p < 0.05$); 4465 ± 716 ($p < 0.001$); 3709 ± 541; RANKL: 1.65 ± 0.61; 1.78 ± 0.70; 1.64 ± 0.61; 1.76 ± 0.66; 1.54 ± 0.71. OPG: (fig.)

These data indicate that the (recombinant human) thyroid stimulating hormone is affecting bone metabolism in terms of increasing bone turnover. This effect may involve the OPG/RANK-L system which has been shown to determine the pool size of active osteoclasts. Our findings also may explain accelerated bone loss in hyperthyroidism associated with elevated serum TSH-receptor antibodies (e.g. Graves' disease).

GSK-3 Inhibitors Block Bone Marrow Cell Proliferation and Osteoclast Differentiation. R. J. S. Galvin[1], T. Fuson*[1], D. L. Halladay*[1], J. E. Onyia*[2], W. C. Roell*[2], A. Kriaucionas*[2]. [1]Bone and Inflammation, Eli Lilly and Company, Indianapolis, IN, USA, [2]Integrative Biology, Eli Lilly and Company, Indianapolis, IN, USA.

Recent studies have demonstrated the important role of the Wnt/Frizzled (Fzd) pathway in bone. Wnt activation of Fzd receptor results in inhibition of GSK-3β activity that stabilizes β-catenin. Accumulated β-catenin translocates to the nucleus and activates gene expression. Since previous studies have focused on the role of this pathway in osteoblasts, the present study evaluated the effects of GSK inhibitors on osteoclast differentiation and function. Osteoclast differentiation was studied in 2 different models: A) co-cultures of Balc cells (calvarial-derived cell line) and bone marrow cells stimulated with $1,25(OH)_2D_3$, and B) murine bone marrow or murine spleen cells stimulated with soluble rhRANKL and mM-CSF. Osteoclast differentiation was evaluated by counting the number of tartrate-resistant acid phosphatase (TRAP)-positive multinucleated cells or evaluating TRAP activity on day 6. Bone resorption was evaluated in murine calvariae stimulated with PTH (1-38) and the Cytostar T assay was used to evaluate bone marrow cell proliferation. Northern analysis of mRNA from differentiated murine osteoclasts demonstrated abundant expression of GSK-3β mRNA. LiCl, an inhibitor of GSK-3, completely blocked osteoclast differentiation from RANKL and M-CSF stimulated murine bone marrow cells (IC_{50} = 9.6 mM). Likewise, genistein (general tyrosine kinase inhibitor that inhibits GSK-3 activity) blocked osteoclast differentiation with an IC_{50} of 1.2 μM. A bisaryl maleimide (BAM) GSK-3α/β dual inhibitor also suppressed osteoclast differentiation with an IC_{50} of 17.4 nM. CTR-positive mononuclear cells, as well as, multinuclear cells were decreased in the spleen cell model by BAM. Bone marrow cell proliferation studies demonstrated that BAM decreased mM-CSF induced proliferation. Calvarial bone resorption was also suppressed by BAM in a concentration dependent manner. In summary, inhibition of GSK-3 results in decreased osteoclast differentiation and calvarial bone resorption. The inhibitory effects may be mediated in part by decreased proliferation of the progenitor cells.

Identification of Osteoclast-Specific Genes using Subtractive Transcription Amplification of mRNA (STAR). R. Sooknanan*, J. Hitchen*, A. Fortin*, V. Gagné*, L. Lapointe*, C. Straccini*, G. B. Tremblay, M. Filion*. Expression Genomics and Target Identification, Alethia Biotherapeutics Inc., Montreal, PQ, Canada.

Imbalance in bone remodeling from increased osteoclast activity (bone resorption) *versus* osteoblast activity (bone formation) leads to osteoporosis. Although the role of osteoclasts is better understood, many of the factors involved remain uncharacterized. Thus, current therapeutics for osteoporosis is only somewhat effective. Improved understanding of the biology of both osteoclast and osteoblast will likely unveil better therapeutic targets and new treatments for osteoporosis.

Gene expression analysis in order to identify genes unique to osteoclastogenesis was performed using the mouse cell line model (RAW 264.7) and human CD34+ progenitors differentiated into osteoclasts in the presence of RANK ligand. The approach that we have taken for gene expression analysis uses our core patented (US 5,712,127) STAR (Subtractive Transcription Amplification of mRNA) technology, which also enriches for rare mRNA sequences that are often missed by DNA microarrays. Additionally, STAR has the potential to discover novel sequences since it is not limited by hybridization to predetermined arrayed sequences. The differential expression patterns of sequences contained in the "STAR library" were confirmed using customized micro- and macroarrays. A "STAR library" representing 5d-osteoclast mRNA subtracted with precursor mRNA was prepared for the RAW 264.7 cell model and 1536 clones were sequenced. Amongst these clones were 744 unique sequences representing a redundancy of ~50% with 18.5% novel sequences. Following microarray analysis using subtracted cDNA probes, 556 (~75%) sequences appeared to be upregulated in osteoclasts compared to only 21% using standard cDNA probes. The use of subtracted cDNA probes markedly increased the detection of low abundance differentially expressed sequences. However, when these clones were used as probes on macroarrays comprising RNA from multiple osteoclast differentiation experiments and normal tissues from mouse, only 70 were found to be highly osteoclast-specific, most of which are as yet uncharacterized functionally. To date, validation studies using RNAi has been completed on 29 of these 70 clones. Concomitantly, the human orthologues for some of these 70 clones were used as probes, which confirms upregulation in human osteoclasts as well. Overall, STAR appears to be a robust tool for gene expression analysis yielding specific and often novel sequences as observed for the osteoclastogenesis model.

A Putative Role for the Adipocyte Peptide Hormone Resistin in Bone Metabolism. L. Thommesen*[1], A. Stunes*[1], K. Grøsvik*[1], E. Kjøbli*[2], U. Syversen[1]. [1]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway, [2]Norwegian University of Science and Technology, Department of Medical Laboratory Technology, Sør-Trøndelag University College, Trondheim, Norway.

Resistin was recently identified as a hormone secreted by adipocytes and is postulated to be an important link between obesity and insulin resistance in rodents. However, some studies failed to find a corresponding link in humans, indicating that this area is still in its beginning, and that other biological effects should be explored. Resistin belongs to a novel class of cystein-rich secreted proteins termed the RELM/FIZZ (found in inflammatory zone) family.

We have previously shown the expression of the adipocyte hormone leptin in osteoblasts. The aim of the present study was to examine if resistin is expressed in osteoblasts and osteoclasts, and whether resistin influences differentiation and proliferation of osteoblasts and osteoclasts, using cell cultures (the preosteoblast MC3T3-E1, and preosteoclast RAW 264.7 cell lines) and human peripheral blood mononuclear cells.

We found the expression of resistin mRNA in both MC3T3-E1 and RAW 264.7 cells. Western blot analysis showed the presence of resistin in differentiated MC3T3-E1 cells and in differentiated RAW264.7 and 3T3-L1 cells. Resistin increased MC3T3-E1 proliferation in a dose-dependent manner, but had no proliferative effect on RAW 264.7 cells. Moreover, resistin increased IL-6 release from MC3T3-E1 cells in a dose-dependent manner with 1800 pg/ml after 72 hrs. Resistin showed no effect on osteoprotegerin release in these cells.

Human peripheral blood mononuclear cells were treated with resistin in addition to RANKL, MCSF and dexamethasone. The number of TRAP (tartrate resistant acid phosphatase) positive cells increased with 50% compared to control.

In conclusion, these data indicate that resistin may play a role in bone metabolism by stimulating osteoclast differentiation both directly and indirectly.

NK Cells Support Osteoclast Formation in Vitro. S. Owen*, L. Danks*, U. Sarma*, M. Feldmann*, F. Brennan*, N. Horwood. Kennedy Institute of Rheumatology, London, United Kingdom.

Bystander-activated lymphocytes have been shown to contribute to inflammation by inducing pro-inflammatory cytokine production by cells of the monocyte/macrophage lineage. Cytokine-stimulated T cells (Tck's) were prepared from elutriated human peripheral blood mononuclear cells by stimulation with TNF, IL-2 and IL-6, or by stimulation with IL-15 alone, for up to 8 days. When co-cultured with primary monocytes in varying ratios, these cells are potent inducers of TNF production. We and others (1) have shown that Tck's are able to support osteoclast formation in-vitro. Cells were stimulated for up to 8 days before fixing in gluteraldehyde and co-culturing with adherent primary human monocytes for a further 10-14 days. Osteoclasts were identified by TRAP+ staining and the ability to resorb calcified matrix. Fixed cells were able to induce osteoclast formation however non-fixed cells were inhibitory. This is most likely due to the production of IFN-γ by these cells although they no longer make IL-10 and TGF-β, unlike antigen-stimulated T cells.

Tck's proliferated over the 8 day period however the T cell numbers remained constant whilst the NK population increased up to 3-fold. To further characterise the cell population(s) responsible for the osteoclast supporting activity, we FACS sorted the Tck's using CD3 as a marker of T cells and CD56 for NK cells. These cells were then used in cocultures as previously described and both subpopulations were able to support osteoclastogenesis. We also examined the ability of the NK cell line, NK92, to support osteoclast formation. Cells were stimulated and fixed as described prior to co-culturing with monocytes for 10 days. Likewise these cells were able to support osteoclast formation in-vitro. Taqman analysis and Western blotting showed that RANKL expression was elevated during the culture period and by day 8 the CD56+ NK population was expressing 10-20 fold higher mRNA levels for RANKL than the CD3+ T cell population. These findings indicate that NK cells are able to support osteoclast formation and further work is being carried out to identify the role of different subsets within the NK population.

Coupling of Bone Resorption and Bone Formation: A Comparison of a RANKL Antagonist (OPG) and Bisphosphonates in Mice. P. J. Kostenuik, F. Asuncion*, K. Warmington*, S. Morony, H. Tan, M. Grisanti*, S. Adamu. Metabolic Disorders, Amgen, Inc., Thousand Oaks, CA, USA.

Bone resorption and formation are physiologically and pharmacologically coupled. Antiresorptive therapy typically results in some suppression of bone formation, but the mechanisms and extent of this coupling are poorly understood. If physiological and pharmacologic coupling are similar, suppression of bone resorption should result in a proportional decrease in formation markers that is similar across therapeutic classes. To test this hypothesis, we studied the kinetic response of bone resorption and formation markers after treating mice with antiresorptive agents with bisphosphonates or with the RANKL antagonist OPG-Fc.

Normal young mice (4-5 weeks old) were treated once (SC) with either PBS, or human OPG-Fc, or zoledronic acid (ZOL, 5 mg/kg) or pamidronate (APD, 5 mg/kg). Groups of mice (5-10/group/drug) were sacrificed at regular intervals and serum was analyzed for calcium, PTH, TRAP-5b (a novel osteoclast-specific resorption marker), total TRAP, and osteocalcin (OC, an osteoblast-specific formation marker).

OPG-Fc caused the most rapid (6 h) suppression of bone resorption (based on serum TRAP-5b), followed by ZOL (24 h) and APD (24 h). The rapid antiresorptive effect of OPG-Fc was also associated with a greater serum PTH response compared to ZOL or APD. Serum calcium remained within the normal range in all groups throughout the study. OPG-Fc maintained >90% suppression of TRAP-5b through 21 days after a single treatment, while ZOL and APD maintained significant TRAP-5b suppression for 14 days and 3 days, respectively. While OPG-Fc caused the greatest suppression of bone resorption, ZOL caused significantly greater suppression of bone formation (i.e. serum OC) compared to OPG-Fc or APD. We attempted to quantify the coupling between resorption and formation by determining the ratio of serum OC:TRAP-5b in individual animals at each timpoint. Despite significant differences in potency, ZOL and APD treatment resulted in similar ratios of OC:TRAP-5b. In contrast, OPG-Fc treatment resulted in significantly greater OC:TRAP-5b ratios at all timepoints compared to other treatments. All antiresorptives caused significant reductions in serum markers of bone resorption and formation. OPG-Fc caused the greatest suppression of bone resorption (TRAP-5b), while ZOL caused the greatest suppression of bone formation (osteocalcin). These data suggest a difference between RANKL antagonism and bisphosphonate therapy in terms of the coupling between bone resorption and formation.

Effect of Bisphosphonate on Odontoclasts in Dental Root Resorption. R. Putranto*, Y. Oba*, K. Kaneko*, A. Shioyasono*, K. Moriyama. Orthodontics and Dentofacial Orthopedics, The University of Tokushima Graduate School, Tokushima, Japan.

Dental root resorption is a common complication during orthodontic treatment, but the regulation of root resorption remains clinically unsolved. Odontoclasts, which have been recognized as the principal cells in dental root resorption, show characteristic features of osteoclasts responsible for bone resorption. To examine the effects of bisphosphonates on the root resorption by increasing odontoclast formation due to mechanical forces, we topically administrated etidronate, alendronate, and pamidronate in rat with experimental tooth movement. A rubber elastic was inserted to the interproximal space between the maxillary first and second molars of male SD rats (7-8 weeks old) to create a mechanical force. Each bisphosphonate was subperiosteally injected (2.5 mg/kg BW) one day before the elastic rubber insertion, and the injection was continued every three days until the end of the experiment. Control groups injected with vehicle were similarly processed. At day 3, 7 and 14, the molar-bearing segments were dissected and processed for scanning electron microscope and histological examination. At day 3, the treatment with etidronate and alendronate significantly increased the number of odontoclasts and subsequent pit formation on the dental root compared with control group, and then the enhancement of root resorption in alendronate-treated group was observed until day 7. At day 14, the treatment with all three bisphosphonates reduced the number of odontoclasts and completely blocked the root resorption. Furthermore, the number of osteoclasts on the bone surface was significantly decreased at day 14 in treatment with these bisphosphonates. These results demonstrate that the short-term treatment with etidronate and alendronate cause the induction of odontoclastogenesis, suggesting that odontoclasts appear to show a different response from osteoclasts to the effect of bisphosphonate under mechanical forces.

GLP-2 Reduces Bone Resorption In Vitro Via the Osteoclast GLP-2 Receptor. M. A. Karsdal[1], J. J. Holst*[2], D. Henriksen[3]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Department of Medical Physiology, University of Copenhagen, Copenhagen, Denmark, [3]Sanos Bioscience A/S, Herlev, Denmark.

The receptor for the gastrointestinal hormone, glucagon like peptide-2 (GLP-2), has recently been found to be expressed by osteoclasts both in human and rodents. GLP-2 is thought to serve in the regulation of absorption of ingested nutrients and has been suggested to be involved in the acute postprandial reduction of bone resorption.

We assessed the direct effect of GLP-2 on human osteoclastic resorption by using monocytes isolated from peripheral blood differentiated into mature human osteoclast on bovine cortical bone slices in the presence of 25ng/mL M-CSF and 25ng/mL RANKL. After culture for 14 days, the mature human osteoclasts were exposed to GLP-2 for 24 hours at different concentrations increasing from 0 to 160 µg/mL. The treatment was followed for a further 24-hour period without GLP-2 to monitor reversibility. The release of c-terminal type I collagen fragments (CTX) from the bone slices was assessed by the CrossLaps for culture ELISA kit (Nordic Bioscience Diagnostics). The level of CTX release during the incubation period with GLP-2 from each individual well was correlated to the basal level measured at day 14.

In a different ex vivo setup, bone resorption was evaluated in cultures of mouse tibia by measuring the release of 45Ca and collagen fragments in the culture media. Culture media were replaced every day, and collected for measurements of release of 45Ca, and CTX (RatLaps, Nordic Bioscience Diagnostics). The demineralization of the bone explants during the cultures was expressed as percentage of total amount of radioactivity.

We found that GLP-2 reduces bone resorption (CTX) in a dose related manner in the human osteoclast study and that the osteoclastic bone resorption reverts to same level as the untreated cultures if GLP-2 is removed. GLP-2 treatment of the mouse tibia cultures resulted in a similar dose related decrease in CTX as was seen for the human osteoclasts. The reduction in bone resorption correlated to the 45Ca release, which was decreased as a dose related function of increasing concentration of GLP-2. The cell number was assessed by TRAP positive cell counting and was unchanged.

We provide for the first time functional data for the GLP-2 receptor on osteoclasts. Recently, subcutaneous injections of GLP-2 in human subjects have been shown to result in a significant and acute reduction of the bone resorption in a dose dependent manner. Taken together, our in vitro and ex vivo results strongly suggest that the reduction of bone resorption seen in these human studies most likely is mediated via the activation of the osteoclast GLP-2 receptor.

Nitric Oxide Directly Inhibits Mature Osteoclast Bone Resorption Through Decreasing TRAP and V-ATPase Expression and Actin Ring Formation by cGMP Dependent and Independent Mechanisms. H. Zheng, X. Yu, P. Collin-Osdoby, P. A. Osdoby. Department of Biology, Washington University, St. Louis, MO, USA.

High nitric oxide (NO) levels are well known to inhibit osteoclast (OC) development, function, and survival in vivo or in vitro. In OC development, NO prevents RANKL induction of multiple OC characteristics that must be acquired for the essential resorptive function of OCs. However, the exact mechanisms by which NO directly inhibits bone resorption by mature OCs are not well defined. To resorb bone, OCs form a tightly sealed compartment into which they secrete acid (via V-ATPase in the ruffled border membrane) and proteases (especially cathepsin K) to degrade the mineral and organic components of bone, respectively. Both V-ATPase and cathepsin K, in addition to actin ring formation, are necessary for OC bone resorption. Here, we have used highly purified preparations of differentiated OCs generated by RANKL from RAW 264.7 cells (RAW-OCs) or primary murine marrow cells (MA-OCs) from normal or mutant mice to examine the effects of a nontoxic NO donor, NOC-12, on mature OC function. NOC-12 (150uM) inhibited TRAP mRNA expression and enzymatic activity, expression of the essential a3 (ATP6i) subunit of V-ATPase, and actin ring formation in both purified RAW-OCs and MA-OCs. In contrast, neither cathepsin K nor MMP-9 mRNA expression or enzymatic activity were affected by NOC-12. Addition of the cGMP inhibitor 1H-[1,2,4]oxadiazolo-[4,3-alpha]quinoxalin-1-one (ODQ) prevented the inhibition of ATP6i expression and actin ring formation due to NOC-12, while reduced TRAP expression and activity were not recovered. Furthermore, NOC-12 caused fewer and shallower pit excavations by purified RAW-OCs cultured on ivory, whereas the inclusion of ODQ abrogated such inhibition. In other studies we have shown that RANKL induced iNOS mRNA and NO production in RAW-OCs and MA-OCs, and that an iNOS selective inhibitor, L-NIL, blocked such autocrine NO production in parallel with increasing OC bone resorption. Consistent with this, a reduction in NO levels, either by L-NIL treatment of normal MA-OCs or by generating MA-OCs from iNOS-/- mice, caused higher APT6i expression and increased bone pit resorption relative to normal MA-OCs. Therefore, we conclude that NO inhibits mature OC bone resorption through cGMP-mediated inhibition of V-ATPase and actin ring formation, while NO suppresses TRAP mRNA and activity via cGMP-independent mechanisms and does not alter cathepsin K or MMP-9 in mature OCs (although NO inhibits their developmental expression). NO therefore sensitively regulates both the development of bone-resorptive OCs and their mature function through differential paracrine and autocrine mechanisms.

TNFRI Mediated RANK/RANKL Signaling Plays Dominant Roles in Osteoclastogenesis in Lipopolysaccharide Induced Bone Loss. Y. Asou[1], N. Okuda[2], K. Shinomiya*[3], T. Muneta*[2], S. Itoh*[1]. [1]Human Genes and Science Center, Tokyo Medical and Dental University, Division of Molecular Tissue Engineering, Tokyo, Japan, [2]Devision of Bio-Matrix, Graduate School Tokyo Medical and Dental University, Section of Orthopeadic Surgery, Tokyo, Japan, [3]Tokyo Medical and Dental University, Department of Orthopaedic Surgery, Tokyo, Japan.

Lipopolysaccharide (LPS), a major constituent of Gram-negative bacteria, has been suggested to stimulate bone loss in ostemyelitis. LPS was reported to play roles in proliferation and differentiation of osteoclasts directly or indirectly via TNFα/TNFR1 and/or RANK/RANKL. However, the hierarchy of LPS function in bone metabolism in vivo remains to be elucidated. The purpose of this study was to investigate the role of RANK-RANKL pathway and TNFα -TNFR1 pathway in LPS induced bone loss in vivo. C57BL6 background wild type mice or TNFR1-/- mice were injected LPS (20mg/kg, s.c.) with or without OPG (0.05-5mg/kg, i.p.) and sacrificed 48 hours after the injection. Histological observation in wild type mice (tibial trabecular bone 200um apart from growth plate) indicated that BV/TV was suppressed by LPS injection about 40% in wild type mice. OPG administration dose dependently reversed the LPS induced bone loss. Oc.S/BS and Oc.N/BS were increased in LPS treated wild type mice. In addition, there were many TRAP positive cells apart from bone surface in bone marrow of LPS treated mice. The increase in Oc.N/BS, Oc.S/BS and the number of TRAP positive cells in bone marrow induced by LPS injection were suppressed by OPG administration in dose dependent manner. As for bone formation, Ob.S/BS and ALP positive area were increased by LPS injection, suggesting that LPS induced high turn over osteopenia 2days after the injection. OPG treatment also reduced these parameters to basal levels. To investigate the roles of TNFα and RANKL in LPS signaling, TNFR1-/- mice were injected LPS with or without OPG. BV/TV was reduced significantly in LPS injected TNFR1-/- mice two days after injection. The reduction in bone volume was reversed partially by OPG treatment. As for osteoclastogenesis, administration of LPS and OPG had less effect on Oc.N/BS or Oc.S/BS in TNFR1-/- mice compared with wild type mice. Interestingly, Ob.S/BS was remarkably reduced in LPS injected TNFR1-/- mice, this parameter was increased in LPS injected wild type mice, suggesting that TNFR1 mediated signaling might support survival of osteoblasts in acute phase of inflammation. From these observations, we concluded that TNFR1 mediated RANK/RANKL signaling played dominant roles in LPS induced osteoclastogenesis. Our data suggested that OPG could rescue bone loss in the region of infection such as osteomyelitis and periodontitis.

Secretion of Tartrate-Resistant Acid Phosphatase 5b from Human Osteoclasts Treated with Antiresorptive Agents. H. Ylipahkala*[1], J. Rissanen[2], S. Suutari*[2], H. K. Väänänen*[1], J. M. Halleen[2]. [1]Institute of Biomedicine, Department of Anatomy, University of Turku, Turku, Finland, [2]Pharmatest Services Ltd, Turku, Finland.

We have studied secretion of tartrate-resistant acid phosphatase isoform 5b (TRACP 5b) from human osteoclasts *in vitro* in the presence and absence of antiresorptive agents. In the culture system, osteoclast precursors cells (Poietics™, Cambrex, East Rutherford, NJ, USA) were cultured on bovine bone slices for 9 days in the presence of M-CSF, RANKL and TGF-β_1. After the culture period, TRACP-positive multinucleated osteoclasts were counted under microscope. Medium TRACP 5b was determined with an in-house immunoassay and medium C-terminal cross-linked telopeptides of type I collagen (CTX) with a commercial assay (CrossLaps® for culture, Nordic Bioscience, Herlev, Denmark). Cytotoxicity was determined using the ToxiLight® assay (Cambrex). The cells were cultured without added compounds and with osteoprotegerin (OPG), the cysteine protease inhibitor E64, and sodium azide. OPG was added at day 0, and the cultures were stopped at day 7. E64 and azide were added after changing the culture medium at day 7, and the cultures were stopped at day 9. OPG decreased dose-dependently osteoclast number, TRACP 5b and CTX without toxic effects. E64 did not affect osteoclast number but decreased dose-dependently both TRACP 5b and CTX without toxic effects. Azide caused toxic effects and decreased dose-dependently osteoclast number, TRACP 5b and CTX. In the presence of OPG and azide, TRACP 5b correlated significantly with both osteoclast number and CTX, but the correlation was slightly better with osteoclast number. However, in the presence of E64, TRACP 5b correlated significantly with CTX, but not with osteoclast number. As a summary: 1) Medium TRACP 5b correlated with osteoclast number during osteoclast differentiation (based on OPG results); 2) In cultures of actively resorbing osteoclasts, TRACP 5b correlated with osteoclast activity but not with osteoclast number (based on E64 results); 3) TRACP 5b was not released as an active enzyme from dying cells (based on azide results). These results suggest that TRACP 5b is released from osteoclasts by two different mechanisms, one operating during osteoclast differentiation and the other during resorption. We conclude that TRACP 5b is a useful marker of osteoclast number in *in vitro* osteoclast cultures during osteoclast differentiation, and a useful marker of osteoclast activity in cultures of resorbing osteoclasts.

Molecular Identification and Electrophysiological Properties of Cl-Channels Expressed in Mouse Osteoclasts. F. Okamoto*, H. Kajiya, E. Jimi, H. Fukushima, K. Okabe. Physiological Science and Molecular Biology, Fukuoka Dental College, Fukuoka, Japan.

CLC-7 Cl- channels are important for osteoclastic bone resorption since disruption of these channels can lead to severe osteopetrosis. However, the functional roles and expression of Cl- channels other than CLC-7 in osteoclasts are still obscure. In this study, we identified the molecular types of chloride channels expressed in osteoclasts generated from co-cultures of mouse bone marrow and osteoblastic cells and examined the properties of Cl- currents through the osteoclast cell membrane. Furthermore, we examined the effects of antisense oligonucleotides for CLCs on bone resorbing activity. RT-PCR analysis showed that mouse osteoclasts express mRNAs for CLC-3, -4, -5, -6, and -7. Although these CLC mRNA were also detected in mouse osteoblastic cells, expression level of CLC-3 mRNA was higher in osteoclasts than in osteoblasts. An outwardly rectifying Cl- current was identified using the whole-cell patch-clamp technique in osteoclasts plated on glass coverslips. This current was reversibly blocked by Cl- channel blockers DIDS and NPPB and its anion permeability sequence was I- > Cl-. When osteoclasts were seeded on calcium phosphate-coated coverslips, most of these cells formed resorption pits. Regardless whether pit-forming or not, outwardly rectifying Cl- current was observed in all osteoclasts examined. However, the current density of Cl- current (current magnitude/cell capacitance) recorded from pit-forming cells was significantly greater than that recorded from cells not forming pits. Pretreatment of osteoclasts with antisense oligonucleotides targeted for CLC-3 and CLC-7 suppressed bone resorbing activity as estimated from the total pit area on bone slices. As a control, no change in bone resorbing activity was observed when osteoclasts had been treated with sense oligonucleotides for CLC-3 and CLC-7. Bone resorbing activity was also inhibited by DIDS and NPPB. These results suggest that osteoclasts express not only CLC-7 but also other CLCs and that Cl- channels with outwardly rectifying properties are involved in osteoclastic bone resorption.

Reveromycin A, which Induces Apoptosis Specifically in Functional Osteoclasts, Inhibits Bone Resorption *in vitro* and *in vivo*. J. Woo[1], M. Kawatani*[2], M. Kato*[1], H. Yonezawa*[1], N. Kanoh*[2], T. Shinki[3], M. Takami[3], H. Osada*[2], P. Stern[4], K. Nagai*[1]. [1]Chubu University, Kasugai, Japan, [2]RIKEN, Wako, Japan, [3]Showa Universiry, Tokyo, Japan, [4]Northwestern University, Chicago, IL, USA.

Osteoclasts, which are multinucleated cells that play a crucial role in bone resorption, are formed by the fusion of mononuclear osteoclasts derived from osteoclast precursors of the monocyte/macrophage lineages. Compounds are targeted specifically to functional osteoclasts would be ideal candidates as anti-resorptive agents for clinical application. We have found that reveromycin A (RMA), a natural low molecular weight acidic compound with three carboxyl groups, inhibits bone resorption through inducing apoptosis specifically in functional osteoclasts. RMA induces apoptosis in functional multinucleated osteoclasts, but not in their progenitor cells, mononuclear osteoclasts, non-functional multinucleated osteoclasts or osteoblastic cells. The cell death induced by RMA is accompanied by nuclear condensation, DNA fragmentation, induction of caspase 3-like activity and the release of cytochrome c from mitochondria into the cell cytoplasm. The inducible effect of RMA is prevented by disruption of acidic microenvironment by addition of concanamycin B, a specific V-ATPase inhibitor, and is increased in acidic culture condition. The apoptotic effect of RMA was decreased by the methylation of the carboxyl groups. RMA inhibited both pit formation on dentine slices and pre-labeled ^{45}Ca release stimulated by PTH in long bone cultures. RMA decreased the increased calcium level in blood elicited by PTH injection in TPTX rats, and prevented the decrease of bone density induced in rats by OVX. The observations indicate that the specificity of the effect of RMA on functional osteoclasts is due to their acidic environment, which may increase the permeability of RMA by suppressing dissociation of protons from carboxyl groups, and that the inhibitory effect of RMA bone resorption in vitro and in vivo is caused by apoptosis of functional osteoclasts. The findings suggest that RMA could be a valuable tool for distinguishing activated osteoclasts in a population of mixed osteoclasts, and thus would be a unique anti-resorptive agent for the treatment of bone diseases such as osteoporosis.

Minodronic Acid (YM529/ONO-5920) Distributed on Bone Surfaces Inhibits Osteoclastic Bone Resorption in Nude Rats with Bone Metastases. S. Tanaka*[1], K. Nakano*[2], A. Nii[2], S. Kawamura*[2], S. Fukushima*[1], M. Sasamata*[1]. [1]Pharmacology Lab., Yamanouchi Pharmaceutical Co., Ltd., Tsukuba-shi, Japan, [2]Safety Research Lab., Yamanouchi Pharmaceutical Co., Ltd., Itabashi-ku, Japan.

To evaluate the interaction between osteoclasts and bisphosphonate minodronic acid in bone, the localization of ^{14}C-minodronic acid and the effects on osteoclasts were studied in nude rats with osteolytic metastases induced by A375 human melanoma cells. Metastases were induced by intracardiac injection of A375 cells into nude rats. Minodronic acid was intravenously given to nude rats after osteolytic metastases were radiologically defined. Histological examination confirmed that numerous TRAPase-positive cells (osteoclasts) appeared on the bone surfaces near the tumors. Intravenous administration of minodronic acid reduced the number of osteoclasts and the ratio of osteoclast surface to bone surface at each tumor site in a dose dependent manner. The effects of minodronic acid were statistically significant at dose of 0.1 mg/kg i.v. Under light microscopy autoradiography, silver grains were seen on bone surfaces near the tumors at 2 hr after the administration. Then, they were selectively seen above the osteoclasts. In addition, structural examination of osteoclasts showed abnormalities of morphology, such as round-shaped osteoclasts and degeneration. These findings suggest that osteoclasts interact with minodronic acid distributed on bone surfaces and that the bone-resorbing activity of osteoclasts are inhibited by these interactions, resulting in inhibition of the tumor-induced osteolysis.

Immature Dendritic Cells Transdifferentiation into Osteoclasts: A Novel Pathway Sustained by the Rheumatoid Arthritis Microenvironment. M. M. P. Mazzorana*[1], A. Rivollier*[2], J. Tebib*[3], M. Piperno*[4], T. Aitsiselmi*[5], C. Rabourdin-Combe*[2], P. Jurdic[1], C. Servet-Delprat*[2]. [1]LBMC, UMR CNRS 5161, Lyon, France, [2]INSERM U503, Lyon, France, [3]Service de Rhumatologie, Centre Hospitalier Lyon-Sud, Lyon, France, [4]Centre Hospitalier Lyon-Sud, Lyon, France, [5]Centre Livet, Lyon, France.

Dendritic cells - the mononuclear cells which initiate immune response - and osteoclasts - the multinucleated bone-resorbing cells - are hematopoietic cells derived from monocyte/macrophage precursor cells. GM-CSF and M-CSF reciprocally regulate the differentiation of both lineages in mouse. Using *in vitro* generated human monocyte-derived dendritic cells, we show that immature dendritic cells transdifferentiate into functional osteoclasts in the presence of M-CSF and RANKL. These dendritic cell-derived osteoclasts resorb dentine and display characteristic markers of monocyte- or bone-derived osteoclasts and classical organization of podosomes in belts localized at the periphery of the cells. Transdifferentiation operates through fusions of intermediate adherent bipolar fusiform mononuclear cells expressing CD14 and CD1a, RANKL and able to to induce RANKL-positive T cells proliferation. Surprisingly, *in vitro* dendritic cell-derived osteoclast formation is faster and more efficient than monocyte-derived osteoclast formation. The transdifferenciation process we report here comforts the existence of a high cellular plasticity within differentiated myeloid phagocytes. Importantly, this process is greatly enhanced by rheumatoid arthritis synovial fluid and involves pro-inflammatory cytokines such as IL-1 or TNF-α as well as fragments of some components of the extracellular matrix such as hyaluronic acid. These data suggest that dendritic cell-derived osteoclasts may be directly involved in the osteolytic lesions observed in human inflammatory bone diseases such as rheumatoid arthritis or in particular forms of Langerhans Cell Histiocytosis, characterized by accumulation of immature skin dendritic cells and chronic lytic bone lesions.

Establishment and Characterization of Pre-osteoclastic Cells Lines Derived of Osteosclerotic Mice oc / oc. C. Blin-Wakkach*[1], V. Breuil[2], J. Esdaile*[3], C. Bagnis*[4], L. Euller-Ziegler[5], G. F. Carle[6]. [1]Fre 2720 - ifr 50, CNRS UNSA, Nice, France, [2]Fre 2720 , ifr 50, CNRS - UNSA, Nice, France, [3]Fre 2720 - ifr 50, CNRS - UNSA, Nice, France, [4]EFS Alpes Maritimes Méditerranée, Department of Cellular Therapy and Genetics, Marseille, France, [5]Rheumatology, University Archet Hospital, Nice, France, [6]Fre 2720 ; ifr 50, CNRS - UNSA, Nice, France.

Infantile malignant osteopetrosis. (IMO) is a rare autosomal recessive disease, leading to death during childhood. IMO is characterized by a lack of bone resorption due to a defect in osteoclast function. Among the models of osteopetrosis, the oc/oc mouse displays a phenotype very similar to the human disease. The mutation involved is a deletion of 1.6 kb in the Tcirg1 (T cell immune regulator 1) gene encoding for the 116 kDa a3 isoform subunit of the V-ATPase pump. This protein is essential, during acidification of the resorption lacuna, for the dissolution of mineral matrix and also for enzymes activities involved in the degradation of the organic bone matrix. For the majority of IMO patients, mutations in the TCIRG1 gene have been described. The oc/oc mouse model is particularly suited to study this pathology and to develop new therapeutic approaches. We are particularly interested in cellular therapy to rescue the oc mutation in osteoclasts precursors of these animals.

To verify in vitro if this complementation of the oc mutation in pre-osteoclasts is feasible, we established several oc/oc and wildtype mouse preosteoclastic cell lines. We crossed Tcirg1 +/oc mices with p53+/- mices. Indeed, p53 is involved in the control of cell proliferation and p53-/- animals develop tumors, mostly lymphoma and osteosarcoma, around the age of 5 months. These animals have been used to obtain cell lines from various organs.

We cultured bone marrow of Tcirg1oc/ocp53-/- and Tcirg1+/oc p53-/- animals. Several oc/oc or wildtype cell lines have been obtained and characterized by RT-PCR and flow cytometry for osteoclastic and myelomonocytic markers. The cell lines display monocytic features and express among others the RANK and c-FMS receptors. In the presence of M-CSF and RANKL, these precursors are able to differenciate in cells presenting osteoclast's characteristics, including multinucleation, TRAP activity and calcitonin receptor expression.

A lentivirus encoding for the GFP gene (Green Fluorescent Protein)was used to determine the transduction conditions in these osteoclast precursors cell lines.The transduction efficiency was close to 65 % and the cells transducted kept their capacity to differenciate into osteoclasts. These pre-osteoclastic cell lines represent a new approch to investigate the role and the regulation of the Tcirg1 gene, in normal and pathological conditions.

Identification of Multiple Osteoclast Precursor Populations by Flow Cytometry in Murine Bone Marrow. C. Jacquin*[1], S. Lee[2], J. A. Lorenzo[2], H. L. Aguila*[1]. [1]Cicid, UConn Health Center, Farmington, CT, USA, [2]Medicine, UConn Health Center, Farmington, CT, USA.

The lineage of osteoclast precursors is not clearly defined. To characterize osteoclast progenitors in murine bone marrow, we fractionated cells by fluorescence activated cell sorting (FACS) and cultured them with M-CSF and RANKL (30 ng/ml) for 2 to 6 days in 96 well plates. Osteoclast-like cells (OCLs) were identified as TRAP+ multinucleated cells. Initially, cells were separated by surface expression of B220 (CD45R), a B lymphoid lineage marker and Mac-1 (CD11b), a myeloid lineage marker.

Single sorted populations of B220+Mac- (B+) cells (99.0% pure) were able to form abundant OCLs in vitro whereas, double FACS separated B+ (99.8% pure) failed to do so. Double FACS separated Mac-1+B220- (M+) cells (99.9% purity) differentiated into OCLs with low efficiency (5,000 M+ cells produced 4 ± 1 OCL on day 4 and 33 ± 6 OCLs on day 6). Unexpectedly, double negative Mac-1- B220- (DN) cells differentiated into OCLs efficiently and rapidly (5,000 DN cells produced 184 ± 36 OCLs on day 3 and 474 ± 29 OCLs on day 4). The number of OCLs in M+ and DN fractions was proportional to the number of plated cells. Additional fractionation of the DN population found the OCL progenitor activity entirely within the mono-myeloid population since it did not separate with markers for T lymphocytes (CD3) or erythrocytes (Ter119). Enrichment of DN cells (CD3-, Ter119-) for those highly (hi) expressing the M-CSF receptor (c-fms) increased the rate of OCL formation by about 2 fold on day 3. Analysis of the DN c-fms negative to low fraction (CD3-, Ter119-), showed little osteoclast formation on day 3 (5,000 cells plated), but abundant OCL formation on day 4 (298 ± 51). Interestingly, by day 4 a large number of OCLs generated from the DN c-fms(hi) cells appeared to have died. Finally, OCLs derived from the DN (CD3-, Ter119-) fraction formed resorption pits on bovine cortical bone in vitro and were positive for the calcitonin receptor.

These results demonstrate that there are multiple populations of bone marrow cells that can differentiate into osteoclasts. DN c-fms(hi) cells are the most highly enriched for late OCL precursors since they differentiated most rapidly but survived in vitro for only 1-2 days. DN, c-fms negative to low cells appeared less mature since they took longer to form OCL in vitro. M+ cells were the least enriched and took the longest time to form OCL in vitro. Previous demonstration of OCL formation in B+ murine bone marrow cells appears to result from contamination of these populations by small numbers of mono-myeloid precursors.

Src Induces Translocation of SHIP1 to Focal Adhesion. K. Yogo*[1], M. Mizutamari*[1], N. Ishida*[1], T. Sasaki*[2], T. Takeya*[1]. [1]Graduate school of Bilogical Sciences, Nara Institue of Science and Technology, Ikoma, Japan, [2]The 21st Century Center of Excellence (COE) Program, Akita University School of Medicine, Akita, Japan.

c-Src, a family of non-receptor tyrosine kinase, plays an essential role for osteoclastogenesis by regulating cytoskeletal organization and survival pathway through PI3K. To understand this mechanism, we screened and identified 10 proteins as c-Src binding partners using RANKL-induced differentiation system of RAW264 cells. Among them, SH2-containing inostol phosphatase 1 (SHIP1) was included. Although SHIP1 has been shown as a binding protein to Src family kinases and *SHIP1* knock out mice are known to cause osteoporosis, the functional relationship between c-Src and SHIP1 has been largely unknown.

First, we confirmed the direct association of c-Src and SHIP1 using pull down assay *in vitro*. We then examined the effect of Src kinase activity on their association and phosphorylation state of SHIP *in vivo*. SHIP1 could be immunoprecipitated with c-Src and its phosphorylation level was found to be increased in SrcY527F-overexpressing 293 cells. We identified two tyrosine residues, Y917 and Y1020, as major phosphorylation sites in SHIP1 by Src. Next, we examined the effect of Src kinase activity on intracellular localization of SHIP1 in HeLa cells. Immunohistochemical study showed that the localization of SHIP1 was shifted from cytoplasm to focal adhesion (FA) in the presence of SrcY527F. When PP1, a specific Src family kinase inhibitor, was administered, peripheral (presumably podosome) localization of SHIP was reduced in osteoclasts as well as HeLa cells.

To understand the mechanism of the translocation more precisely, we prepared three kinds of truncated mutants of SHIP1: SHIP1-457, SHIP401-866 and SHIP739-1190. When these mutants were introduced into HeLa cells together with SrcY527F, SHIP1-457 and SHIP739-1190 were localized in FA while SHIP 401-866 which contains the phosphatase domain remained in the cytoplasm, suggesting that the inositol phosphatase activity may not be required for this translocation. We further introduced point mutations into the SH2 domain of SHIP1-457 and Tyr917/1020 of SHIP739-1190, respectively. The resulting SHIP 1-457 R34L which lost the binding activity to phosphor-tyrosine could not be translocated to FA, whereas SHIP1 Y917F/Y1020F still could be translocated. Taken together, these results suggest that Src kinase activity induces the translocation of SHIP1 to FA and that the NH2- and C-terminal region of SHIP1, respectively, are regulated in independent manners for the translocation.

Evidence for Involvement of PYK2-Mediated Signaling in Calcitonin-Induced Sealing Zone Detachment in Osteoclasts Microinjected with Fluorescent G-Actin. J. Shyu[1], C. Lin*[2], H. Chen*[1], H. Tsung*[1], C. Shih[1]. [1]Biology and Anatomy, National Defense Medical Center, Taipei, Taiwan Republic of China, [2]Microbiology and Immunology, National Yang-Ming University, Taipei, Taiwan Republic of China.

Bone resorption is primarily carried out by osteoclasts. The osteoclastic bone resorption starts with adhesion to the bone matrix, leading to cytoskeletal reorganization that is important for the migration of these cells to and between the resorption sites and their polarization during the resorption process. It has been well studied that, the calcitonin induced quiescent and retraction effects in osteoclasts which involved PKA and PKC pathways, respectively. However, the detailed mechanism is still unknown. Recently, effects of calcitonin on the turnover of podosome and function of PYK2 had been reported. Therefore, this signaling molecule in podosome could be the potential targets for the calcitonin-induced signaling. Using immunoprecipitation and immunofluorescent microscopy methods, our previous results showed that decreased tyrosine phosphorylation and redistribution of PYK2 in osteoclasts upon calcitonin stimulation. Though the effects of calcitonin on PYK2 in osteoclasts are clear, evidence for involvement of PYK2-mediated signaling in calcitonin-induced podosome reorganization was still lacking. To address this issue, microinjection of fluorescent G-actin into authentic living osteoclasts cultured on collagen-I coated Petri dish was performed. In real time, we observed the formation of actin ring and its association of PYK2 in resorbing osteoclasts. The addition of calcitonin induced reorganization of the podosomes, disruption of the actin ring, and redistribution of PYK2 in these cells. In the same cell, calcitonin also induced dephosphorylation of Tyr402, which is the autophosphorylation site of PYK2. In conclusion, we developed a model of microinjection system in isolated living rabbit osteoclasts in which the involvement of PYK2-mediated signaling in calcitonin-induced acting ring disruption was demonstrated.

P2X7 Nucleotide Receptors Act through Two Distinct Mechanisms to Regulate Osteoclast Survival. J. Korcok*, S. M. Sims*, S. J. Dixon. CIHR Group in Skeletal Development and Remodeling, Dept. Physiology & Pharmacology, University of Western Ontario, London, ON, Canada.

Extracellular nucleotides signal through P2X (ATP-gated ion channels) and P2Y (G protein-coupled) receptors. Osteoclasts express multiple P2 receptors including P2X7, which can induce formation of membrane pores in the presence of low concentrations of divalent cations. P2X7 receptor knockout (KO) mice show enhanced trabecular bone resorption associated with increased osteoclast numbers. Osteoclastogenesis was similar in cultures of bone marrow from wild-type (WT) and KO mice, suggesting that osteoclast survival is prolonged in KO mice. The aim of this study was to examine whether P2X7 receptors regulate osteoclast survival. Osteoclasts were isolated from long bones of new-

born WT and KO mice. Acute cell death was assessed by ethidium bromide uptake in medium containing a low concentration of divalent cations. Benzoylbenzoyl-ATP (BzATP 300 μM, P2X7 receptor agonist) increased ethidium bromide uptake in WT but not in KO osteoclasts. To assess survival under more physiological conditions, osteoclasts were counted following isolation (time 0) and at 12 h, in medium containing divalent cations. Apoptosis was quantified by counting Hoechst-stained osteoclasts showing condensed and fragmented nuclei. In the absence of exogenous nucleotides, higher numbers of WT than KO osteoclasts were apoptotic at 6 h. Consistent with this observation, fewer WT osteoclasts survived at 12 h. Interestingly, BzATP had no additional effect on either apoptosis or survival. Control experiments revealed that WT and KO osteoclasts were equally susceptible to apoptosis induced by the proapoptotic agent staurosporine. Brilliant blue G (P2X7 antagonist) decreased apoptosis and increased survival of WT osteoclasts, providing additional evidence for involvement of the P2X7 receptor. To determine if P2X7 receptors induce cell death in a ligand-independent manner or are activated by constitutively released nucleotides, WT osteoclasts were treated with alkaline phosphatase (AP) to hydrolyze endogenous nucleotides. AP increased survival of WT osteoclasts to levels comparable to KO osteoclasts. These data indicate that P2X7 receptors act through two mechanisms to regulate osteoclast survival. First, activation of the receptor by high concentrations of nucleotides induces membrane pore formation leading to acute cell death. Second, under physiological conditions, activation of P2X7 receptors by low concentrations of constitutively released nucleotides induces apoptosis. Thus, the P2X7 receptor reduces bone resorption by decreasing osteoclast survival and represents a potential target for the development of antiresorptive drugs.

Evidence of Reciprocal Regulation between the High Extracellular Calcium and RANKL Signal Transduction Pathways in RAW Cell Derived Osteoclasts. J. Xu*[1], C. Wang*[1], R. Han*[1], N. Pavlos*[1], T. Phan*[1], J. H. Steer*[2], A. J. Bakker*[3], D. A. Joyce*[2], M. H. Zheng[1]. [1]Orthopaedic Surgery, The University of Western Australia, Nedlands WA, Australia, [2]Pharmacology, The University of Western Australia, Nedlands WA, Australia, [3]Physiology, The University of Western Australia, Nedlands WA, Australia.

During osteoclastic bone resorption, osteoclasts are exposed to high Ca^{2+} concentrations (up to 40 mM). High concentrations of Ca^{2+} haveextracellular Ca^{2+} has been shown to trigger a cytosolic Ca^{2+} increase, inhibit resulting in inhibition of osteoclastic bone resorption and induce induction of osteoclast apoptosis. In this study, we show that receptor activator of NF-κB ligand (RANKL) enhances osteoclast tolerance to high extracellular Ca^{2+} by protecting the cell from high extracellular Ca^{2+}-induced cell lossdeath in a dose dependent manner. We have providedshown evidence that RANKL does this by attenuating high extracellular Ca^{2+}-induced Ca^{2+} elevations. Moreover, we have found that high extracellular Ca^{2+}-induced cell death was partially inhibited by a caspase-3 inhibitor, suggesting that a caspase-3-mediated apoptosis is involvedis involved.. Conversely, using reporter gene assays and western blot analysis, we have demonstrated that high extracellular Ca^{2+} desensitizes the RANKL-induced activation of NF-κB and c-Jun N-terminal kinase (JNK), and inhibitedinhibits constitutive and RANKL-stimulated ERK phosphorylation, indicating a negatively feed-back mechanism via specific RANKL signaling pathways. Taken together, our studies providethis study provides evidence for a reciprocal regulation between high extracellular Ca^{2+} and RANKL signaling in RAW cell derived osteoclasts. Our data suggest a mechanism of extracellular Ca^{2+} on osteoclast survival through the regulation of RANKL.

Activation of the Rho-GTPase by *Pasteurella Multocida* Toxin (PMT) in Osteoclasts Reveals Contrasting Roles in Differentiation and Activation. N. W. A. McGowan*[1], D. Harmey[2], J. E. Dunford*[3], M. J. Rogers[3], A. E. Grigoriadis[1]. [1]Craniofacial Development, Kings College London, London, United Kingdom, [2]The Burnham Institute, La Jolla, CA, USA, [3]Bone Research Group, Institute of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom.

Rho family GTPases are well-known regulators of the cell cytoskeleton, cell migration and differentiation. We have recently demonstrated that the unique bacterial toxin, *Pasteurella Multocida* toxin (PMT), which activates the heterotrimeric G-protein, G_q, leading to stimulation of Rho and actin rearrangements, as well as activation of phospholipase C, protein kinase C and the Ras/MAP kinase pathway, inhibits osteoblast differentiation and bone nodule formation via activation of Rho and Rho kinase (ROK). However, PMT also targets osteoclastic cells, since the main *in vivo* effect of PMT is the porcine bone resorbing disease, atrophic rhinitis, resulting in pathological bone resorption. Since Rho proteins play an important role in the rapid cytoskeletal rearrangements during bone resorption, the effects of PMT on osteoclast differentiation and activity were investigated.

In RANKL- and MCSF-based cultures of human PBMCs or murine bone marrow cells PMT inhibited osteoclast differentiation and resorption in a dose-dependent manner. Molecular analysis revealed that PMT had no effect on RANK or *c-fms* gene expression, but inhibited the expression of the specific osteoclast markers calcitonin receptor and cathepsin K. Biochemical studies demonstrated that 6h incubation with PMT induced a 4-fold increase in the levels of active GTP-bound Rho, with no significant increase in the levels of GTP-bound Rac or Cdc42. Furthermore, PMT also induced a sustained activation of the MAP kinase pathway as shown by an increase in the levels of pERK 1 and 2. Using specific pathway inhibitors to investigate the relevance of these signalling mechanisms, treatment of murine or human osteoclast precursors with the ROK inhibitor, Y-27632, partially rescued the inhibition of osteoclast differentiation, whereas the MEK inhibitor PD98059 failed to rescue the PMT effect. In contrast to the inhibitory effects on differentiation, PMT appeared to promote resorption and survival of the mature osteoclast as addition of PMT to human osteoclast cultures at day 10 increased the proportion of F-actin ring-containing, vitronectin receptor-positive osteoclasts, with a concomitant increase in resorption. Overall, these data suggest an important inhibitory role for the Rho-ROK pathway in osteoclast differentiation and we are currently investigating how the divergent effects of PMT on osteoclast differentiation and activity may converge to produce the bone loss observed *in vivo*.

Inhibition of Src Kinase Activity Decreases M-CSF-Induced Cell Survival in Human Osteoclasts. R. J. S. Galvin[1], T. Fuson*[1], A. Regmi*[1], A. Bansal*[2]. [1]Bone and Inflammation, Eli Lilly and Company, Indianapolis, IN, USA, [2]Integrative Biology, Eli Lilly and Company, Indianapolis, IN, USA.

M-CSF prolongs cell survival in fully differentiated osteoclasts. However, the mechanisms by which M-CSF blocks apoptosis have not been extensively evaluated. This study evaluated the pathways involved in the regulation of caspase activity by M-CSF in differentiated human osteoclasts. Osteoclasts were generated from human cord blood cells, which had been maintained in Delta Culture for 7-9 days. The Delta culture cells were treated with rhM-CSF and shRANKL for 7 days. The differentiated cultures contained predominately large tartrate-resistant acid phosphatase (TRAP)-positive multinucleated osteoclasts. The cells were treated with various factors and caspase 3 activity was determined by measuring z-VAD-FMK cleavage. rhM-CSF inhibited caspase activity in a time dependent manner with 24-30 h significantly reducing caspase activity. RANKL also blocked caspase activity, but the effects were small compared to the effects of M-CSF. M-CSF blocked caspase activity in a concentration dependent manner. The src kinase inhibitor PP2, but not the control PP3, reversed the suppression of caspase activity seen with M-CSF in a concentration-dependent manner with a maximal effect at 20 uM. To further define the mechanism of apoptosis we evaluated the effects of M-CSF on AKT-phosphorylation in human osteoclasts and found that it was enhanced by 3 ng/ml and greater concentrations of M-CSF at 5 min. The effects of M-CSF on caspase activity were blocked by the phosphoinositol 3-Kinase (PI3K) inhibitor, LY294002, but not by the MEK inhibitor PD980592 or the p38 MAP kinase inhibitor SB203580. In summary these studies demonstrate that M-CSF blocks the increase in caspase activity that is seen with its removal and that these effects are reversed by treatment with src kinase inhibitors and PI3K inhibitors.

Fas Binding to Calmodulin (CaM) Regulates Apoptosis in Osteoclasts. X. Wu[1], E. Ahn*[2], M. A. McKenna[1], H. Yeo*[1], J. M. McDonald[1]. [1]Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]University of California, San Diego, San Diego, CA, USA.

CaM, the major intracelluar Ca^{2+} receptor, is an important signaling modulator in osteoclasts, modulating not only osteoclastogenesis but also bone resorption. TFP, a CaM antagonist, rescues bone loss in ovariectomized mice (Endocrinology, Vol.144, p4536). Whether CaM plays a role in regulating osteoclast survival has not been investigated. CaM interacts with Fas, the death receptor, in Jurkat cells. This interaction has been implicated in regulating Fas-mediated apoptosis (J Biol Chem Vol.279, p5661). Whether CaM binds Fas and the significance of this binding in osteoclasts is unknown. Apoptosis in osteoclasts, derived from mouse primary monocyte/macrophage progenitors, is measured by nuclear staining and fluorescent caspase-3 activity assay. The interaction between Fas and CaM in osteoclasts is analyzed by CaM-Sepharose pull-down, coimmunoprecipitation, and ^{125}I-CaM overlay. After three-hour treatment with the CaM antagonists, tamoxifen (TMX) and trifluoperazine (TFP), osteoclasts undergo apoptosis dose-dependently. TMX, 10 μM, and TFP, 10 μM, induce a 7.3 ± 1.5-fold and a 5.3 ± 1.3-fold increase in osteoclast apoptosis, respectively. Both TFP and TMX activate caspase-3 dose-dependently, as detected by Western blotting. Importantly, in osteoclasts, CaM binds Fas. A point mutation in the death domain of the human Fas molecule (V254N) reduces binding to CaM *in vitro*. A similar mutation (I225N) in the Lpr^{cg} mouse renders Fas inactive, and osteoclasts, derived from Lpr^{cg} mouse bone marrow, have markedly diminished Fas/CaM binding. Interestingly, osteoclasts derived from Lpr^{cg} mice are more sensitive to CaM-antagonist-induced apoptosis than osteoclasts from wild type (wt) mice. TMX, 10μM, induces 42 ± 6 % of Lpr^{cg} osteoclasts to undergo apoptosis compared with 27 ± 2.2 % in wt osteoclasts. Similarly, 10μM TFP induces 37 ± 0.8 % of Lpr^{cg} osteoclasts to undergo apoptosis in comparison with 24 ± 2.8 % in wt osteoclasts. Results are confirmed using a fluorescent caspase-3 activity assay. Furthermore, when osteoclasts, derived from RAW264.7, a macrophage cell line, are treated with 10 μM TFP for 0-60 min, the binding between Fas and CaM is dramatically decreased at 15 min and gradually recovers over 60 min. In summary, in osteoclasts, CaM antagonists induce apoptosis and activate caspase-3 dose-dependently by a mechanism that involves interfering with CaM binding to Fas. The involvement of CaM in regulating osteoclast survival and specifically the effects of Fas/CaM binding on CaM-antagonist-induced apoptosis may open a new avenue for therapeutics.

PI3 Kinase Has Divergent Impacts on Osteoclast Survival Depending on TGF-β Levels During Differentiation. A. Gingery[1], M. J. Oursler[2]. [1]Biochemistry and Molecular Biology, University of Minnesota, Duluth, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Modulating osteoclast survival can alter bone resorption levels by changing osteoclast numbers. We have therefore studied the mechanisms by which osteoclast survival is regulated. PI3 kinase (PI3K) is a component of osteoclast survival signaling since inhibition leads to apoptosis of 100% of the cells within 3 hours of treatment. PTEN, a known tumor suppressor inactivates PI3K when phosphorylated, there by regulating PI3K activity. To elucidate a possible role of PTEN regulation of PI3K in osteoclasts, levels of PTEN and phospho-PTEN (pPTEN) in osteoclasts generated by co-culture of marrow precursors and ST2 cells were examined.

Mature osteoclasts from which ST2 cells were removed contained high levels of pPTEN, with the resultant decrease in PI3K activation of survival pathways. This is in concordance with PI3K inhibition increasing osteoclast apoptosis. TGF-β addition increased pPTEN, PI3K activity was decreased and increased osteoclast apoptosis. Thus, PTEN regulation of PI3K is important in osteoclast survival and targeting PTEN is one mechanism by which TGF-β increases osteoclast apoptosis.

Since TGF-β is present in high levels during periods of elevated bone resorption, it is important to discover the impact of osteoclast differentiation in the presence of TGF-β on osteoclast survival. In contrast to TGF-β-mediated osteoclast apoptosis induction in cells differentiated without TGF-β addition (naïve cells), TGF-β-induced osteoclasts had elevated apoptosis following TGF-β removal from mature cells while continued TGF-β treatment reduced apoptosis. These data support that TGF-β-induced osteoclast survival is dependent on TGF-β.

We also examined whether PTEN is likely to be involved in regulating apoptosis of TGF-β-induced osteoclasts. Levels of PTEN are high in both un-induced and TGF-β induced osteoclasts, indicating regulation of PI3K activity. When TGF-β-induced osteoclasts were cultured without TGF-β, pPTEN levels increased, resulting in increased osteoclasts apoptosis. TGF-β maintenance during culture resulted in a dramatic decrease in pPTEN and increased survival. We therefore propose that PI3K is mediating survival in naive osteoclasts and TGF-β induced osteoclasts. Therefore osteoclasts may have divergent signaling pathways downstream of PTEN/PI3K that are dependent on the presence or absence of TGF-β during osteoclast differentiation.

Tyrosine 559 and 807 in c-Fms Regulate M-CSF Dependent Signaling and Proliferation of Osteoclast Precursors. S. Takeshita[1], R. Faccio[1], J. Chappel*[1], J. D. Weber*[2], S. L. Teitelbaum[1], F. P. Ross[1]. [1]Pathology, Washington University, St. Louis, MO, USA, [2]Cell Biology, Washington University, St. Louis, MO, USA.

We studied how M-CSF stimulates proliferation of osteoclast (OC) precursors. Bone marrow macrophages (BMMs) were tranduced with a chimeric erythropoietin receptor (EpoR)/c-Fms receptor that transmits intracellular signals following exposure to Epo, enabling us to define the role of individual Y residues in c-Fms signaling in authentic M-CSF responsive cells. Following transduction and cytokine treatment, all Epo-generated data were normalized to results from cells exposed to M-CSF. We first confirmed that cell proliferation is identical in M-CSF treated cells expressing endogenous c-Fms or in Epo-treated cells expressing a chimera containing the wild type (WT) c-Fms cytoplasmic tail. Next, we examined the impact on cell division of mutating individual Y residues to phynylalanine (F) in the chimeric c-Fms tail and established that Y559 and Y807 and, to a lesser extent, Y697 each play regulate proliferation. Turning to signal transduction, we analyzed the first step of M-CSF signaling, namely auto-phosphorylation of the receptor and determined that the mutants Y559F and Y 697F both strongly inhibit phosphorylation of Y807. The finding that Src family members bind Y559 suggests that they phosphorylate Y807. Confirmation of this hypothesis is provided by the observation that the src family kinase inhibitor PP2 inhibits phosphorylation of Y807. Furthermore, the src family member Lyn, but not c-Abl, phosphorylates Y807 in an vitro kinase assay. Attesting to specificity, both Lyn and c-Abl phosphorylate Y721. We next turned to the role of c-Fms Y559, Y697 and Y807 on activation of ERKs and Akt and expression of cyclin D, the central regulator of the cell cycle. By expressing both single and combined point mutations we find that Y559F, but not Y697F, strongly suppresses phosphorylation of the two kinases, down-regulates cyclin D1 levels and decreases cell proliferation. Surprisingly, cells expressing Y807F exhibit enhance both autophosphorylation of c-Fms Y721 and cyclin D 1 expression, but are hypo-proliferative. Next, we expressed in BMMs a series of add-back EpoR/c-Fms chimeras, each containing one or more specific Y residues, with all others mutated to F. The triple add-back Y559/Y697/Y807 is sufficient to promote ERK and Akt activation and cell proliferation, confirming data obtained with mutational analysis. In summary, tyrosines 559 and 807, and to a lesser extent Y697, in c-Fms regulate M-CSF-dependent signaling and proliferation of OC precursors.

The Associations between Body Composition, Muscle Strength and Bone Mineral Density in Postmenopausal Women: A Cross-sectional Study. T. P. Rikkonen*[1], J. Sirola[1], H. Kröger*[2], M. Tuppurainen[3], J. Jurvelin*[4], R. Honkanen[1]. [1]University of Kuopio, Bone and Cartilage Research Unit, Kuopio, Finland, [2]Kuopio University Hospital, Department of Surgery, Kuopio, Finland, [3]Kuopio University Hospital, Department of Ostetrics and Gynecology, Kuopio, Finland, [4]University of Kuopio, Department of Applied Physics, Kuopio, Finland.

Objective: The aim of this study was to examine relationships between muscular strength, body composition and bone mineral density in postmenopausal women. Subjects and methods: A population based cohort of 414 Finnish postmenopausal females (Mean age 68, 4 years; SD ± 1, 8 years). BMD at the proximal femur, lumbar spine (L2-L4) and total body was assessed by dual energy X-ray absorptiometry (DXA) (GE Lunar Prodigy). Total body composition, fat mass index (FI) (Fat/Height²) and lean mass index (LI) (Lean/Height²) variables were obtained from the total body scan. Strength measurements included handgrip dynamometer (Jamar) and isometric knee extension by sitting in bench (Metitur). Study population was divided into 3 groups by WHO osteoporosis criteria, according to femoral neck value with normal (N=189), osteopenia (N=204) and osteoporosis (N=21) status. Results: There were significant differences between osteoporotic and normal subjects in lean mass index (P<0.001), grip strength (P<0,001) and knee extension strength (P=0.007) but not in fat mass index (P>0.05). Grip Strength was 18% (p<0.001) and quadriceps strength was 19 % lower (p<0.001) in osteoporotic women compared to women with normal BMD status. In our results fat mass alone explained 85% and lean mass 32% of BMI variation. Both variables together predicted 87%. After adjusting for age, BMI, use of medications, diseases, alcohol consumption and smoking with logistic regression model, grip strength remained as an independent determinant for osteoporosis at the proximal femur (Adjusted OR=1.36; CI95% 1.13 - 1.54; P<0,001) and lumbar spine BMD (Adjusted OR= 1.20; CI95% 1.09 - 1.32; P<0,001) (AUROC 75% for FN and 67 % for LS respectively). Quadriceps strength measurements showed similar trend with these results. Conclusions: BMI and strength measurements are independently associated with postmenopausal BMD. Grip strength measurement is simple, useful and moderately sensitive tool for osteoporosis risk assessment patterns. Keywords: Muscle strength, body composition, postmenopausal, bone mineral density.

Correlates of Osteoporosis Screening, Diagnosis and Treatment in Women with Arthritis at High Risk for Osteoporosis. S. M. Cadarette, D. E. Beaton*, M. A. M. Gignac*, S. B. Jaglal, G. A. Hawker. University of Toronto, Toronto, ON, Canada.

The purpose of this study was to examine predisposing, enabling and need factors related to osteoporosis screening (bone mineral density (BMD) testing), diagnosis and treatment (bisphosphonate, raloxifene or calcitonin) among community-dwelling women with arthritis at high risk for osteoporosis. A convenience sample of women participating in a longitudinal study of arthritis were consecutively recruited into the current study, N=425. Those at low risk for osteoporosis or residing in long-term care were excluded (N=6). Descriptive statistics were summarized as means or proportions. Correlates were grouped by type of factor as predisposing, enabling or need. Chi-squared analyses and unadjusted logistic regression were used in bivariate analyses. Correlations within and between the groups of factors were used to identify collinearity between variables before adjusted modeling began. Multivariable logistic regression was used in adjusted analyses. Overall, 55%, 24% and 15% reported to have been screened, have a diagnosis and were being treated respectively. Correlates of osteoporosis treatment included higher perceived calcium benefits (OR=1.04, 95%CI=1.01-1.07) and the following need factors: prior fragility fracture (OR=3.4, 95%CI=1.6-6.9), BMD testing (OR=9.5, 95%CI=3.1-29), osteoporosis diagnosis (OR=9.8, 95%CI=4.8-20), and long-term prednisone use (OR=9.7, 95%CI=3.0-31). Controlling for need factors, more frequent physician visits (OR=1.05, 95%CI=1.01-1.09) and having less than secondary school education (OR=1.9, 95%CI=1.06-3.4) were independently associated with a diagnosis of osteoporosis. Few need factors were associated with having a BMD test (fragility fracture, OR=1.7; and kg body weight, OR=.98). Rather, enabling factors such as living in metropolitan Toronto vs. a county with large rural areas (OR=2.2, 95%CI=1.3-3.6), and predisposing factors (lower general health status, fewer non-osteoporosis related conditions, younger age, fewer exercise barriers and higher perceived seriousness of osteoporosis) were independently associated with osteoporosis screening. Therefore, while need factors such as a diagnosis of, or major risk factors for osteoporosis, were correlated with osteoporosis treatment, several enabling and predisposing characteristics were found to be associated with BMD testing. These data suggest problems in access to osteoporosis screening by BMD testing, and subsequent unmet needs for osteoporosis prevention/management in asymptomatic women.

Prevalence of Low Bone Density in Older Italian Adults from the ESOPO Study. G. Crepaldi[1], S. Maggi*[1], D. de Feo[2], S. Adami[3], O. Di Munno*[4], S. Giannini[5], G. Isaia[6], L. Sinigaglia*[7], P. Filipponi[8]. [1]CNR Aging Center, Padua, Italy, [2]Procter & Gamble, Rome, Italy, [3]Rheumatology, Valeggio Hospital, Verona, Italy, [4]Rheumatology, Pisa university, Pisa, Italy, [5]Internal Medicine, Padua University, Padua, Italy, [6]Internal Medicine, Turin University, Turin, Italy, [7]Rheumatology, Gaetano Pini, Milan, Italy, [8]Internal Medicine, Umbertide Hospital, Umbertide, Italy.

Most estimates of osteoporosis in older Italians have been based on its major complications, such as hip and vertebral fractures. In the present study, quantitative ultrasound measurements were carried out with the Lunar Achilles Express apparatus in a random sample of 11,011 women 40-80 years old and 4,981 men aged 60-80 years, participating in the ESOPO Study (Epidemiological Study on the Prevalence of Osteoporosis) to estimate the prevalence of the disease in the older Italian population. Low BMD levels were defined in accordance with WHO criteria. For women, estimates indicate 22%, or 3.5 million, have osteoporosis (i.e., BMD > 2.5 standard deviations [SD] below the mean of young women) and 42%, or more than 6 million, have osteopenia (BMD between 1 and 2.5 SD below the mean of young women). For men, the prevalence rates of osteoporosis and osteopenia are 14% (about 1 million) and 34% (about 2 million) respectively. Based on this measurements and the history of fractures, we were able to calculate the OR for fractures in different sites for individuals with osteopenia and osteoporosis versus normal bone density. For hip fractures, for examples, the OR were respectively 10.8 and 28.3 in women and 2.9 and 6.6 in men and they remained highly significant even after adjusting for age. Therefore, most of the older Italians adults with low bone density are women, but the prevalence among men is substantial and their increased risk of fractures should be a major public health concern

Association between Baseline Bone Mineral Density and the Risk of a Future Osteoporostic Fracture in Elderly Women: Results from the PERF Study. Y. Z. Bagger, L. B. Tankó, P. Alexandersen, C. Christiansen. Center for Clinical and Basic Research, Ballerup, Denmark.

To investigate the relationship between the first bone mineral density (BMD) at the different skeletal sites, prevalent fractures, age and incidence of osteoporotic fractures, we have followed 5800 Danish postmenopausal women for a mean period of 10 years. BMD at the forearm, spine or hip were assessed at baseline by DEXA. Women were then stratified into normal, osteopenic and osteoporotic BMD groups according to WHO criteria. Vertebral fractures were assessed on digitalized lateral X-rays of the thoracic and lumbar spine. A more than 20% reduction of the vertebral height was considered as a radiological fracture. Non-vertebral fractures were collected by questionnaire. The mean age of women at follow-up was 71±6.5 years old. In this population, 4.1% of women had prevalent vertebral fractures detected at baseline, and 15.3% had reported prevalent non-vertebral fractures before study entry. Thus, 17.6% of women had experienced a new vertebral fracture, and 14.2% had a new non-vertebral fracture during the follow-up period. Women with BMD value of 2.5 SD below the normal mean of young adults at the spine, hip, or forearm were at significantly higher risk of osteoporotic fractures with odds ratios (OR) 2.36, 3.63, and 3.66, respectively (all p values <0.001)after adjustment for age and BMI. For any given T-score of baseline BMD measured at the different skeletal sites, the relative risk of vertebral fracture increased with increasing age. As shown in Figure 1, the risk of vertebral fracture in women between the ages of 50 and 80 years increased by 1.5 to 3.5-fold depending on T-score of BMD at the spine. Similar trends of the increased risk for vertebral fracture with increasing age were also observed at the hip and forearm BMD. Women with a prevalent fracture at baseline had a significantly increased risk for a new vertebral fracture (OR: 2.36, 95% confidence interval: 2.01-2.75, p<0.001) by the end of follow-up. In conclusion, this study further illustrates the utility of bone mass measurement at the different skeletal sites for the prediction of future fracture with slightly higher sensitivity of the peripheral sites. The results also emphasize that patients with a prevalent fracture should be instantly referred for treatment to reduce the risk of further incidences.

Major Determinants of Bone Mineral Density (BMD) at Multiple Skeletal Sites in Chinese. Y. Hsu[1], C. Chen*[1], Y. Feng[1], H. Terwedow*[1], T. Zhang*[2], D. Wu*[2], G. Tang*[2], Z. Li*[2], X. Hong*[2], B. Wang*[1], M. L. Bouxsein[3], J. Brain*[1], S. Cummings[4], C. Rosen[5], X. Xu[1]. [1]Program for Population Genetics, Harvard School of Public Health, Boston, MA, USA, [2]Institute of Medicine, Anhui Medical University, Anhui, China, [3]Beth Israel Deaconess Medical Center, Boston, MA, USA, [4]San Francisco Coordinating Center, UCSF, San Francisco, CA, USA, [5]Maine Center for Osteoporosis Research and Education, St. Joseph Hospital, Bangor, ME, USA.

The purpose of this study was to identify major environmental determinants of BMDs at different skeletal sites in Chinese population.

We conducted a community-based cross-sectional study among residents of Anhui Province, China. Body mass composition, whole body and total hip BMD were measured by DXA in 3439 men and 3304 women aged 25-65 years from 1843 families. Information on lifestyle, occupation, disease history, physical activity, reproductive characteristics was collected by standardized questionnaires. Generalized estimating equation (GEE) models were performed to access the major determinants of BMD with adjusting for potential confounders and inter-correlation within family members. Among women, 38% are postmenopausal, and 368 (11.2%) and 171 (5.2%) had a T-score less than -2.5 at whole body and total hip, respectively. Men have significantly lower percentage body fat than females (13.2%, 27.9% and 27.4% for men, pre-menopausal and post-menopausal women). The table below showed the amount of variability in BMD explained by age, weight and percentage body fat; and also showed the regression coefficient of other determinants of BMDs with significant level at least in one of the three populations (men, pre- and post-menopausal women). Our findings suggest the percentage body fat, heavy physical activity, tofu and tea consumption as well as the age, gender, body weight and cigarette smoking are important determents of BMD. Supported by NIAMS grant R01 AR045651.

	Men		Pre-menopausal women		Post-menopausal women	
	Whole Body	Hip	Whole Body	Hip	Whole Body	Hip
	R^2	R^2	R^2	R^2	R^2	R^2
Age	2.8%	4.4%	0.01%	0.04%	13.8%	10.0%
Body weight	23.9%	9.8%	16.8%	10.2%	18.7%	15.2%
Body fat %	9.5%	3.2%	8.5%	4.2%	10.0%	7.7%
Age and body weight	24.6%	12.5%	16.8%	10.3%	30.1%	23.4%
Multivariate regression models	β (SE)	β (SE)	β (SE)	β (SE)	β (SE)	β (SE)
Body fat %	-0.078 (0.030)**	-0.189 (0.049)**				
Heavy physical activity	0.008 (0.003)*	0.015 (0.006)**				
Cigarette smoking		-0.014 (0.006)*		-0.048 (0.023)*		
Tea consumption		0.014 (0.005)*				
Tofu consumption			0.009 (0.004)*			

The adjusting variables for regression models included age, BMI, body weight and occupation. *:p < 0.05; **:p < 0.01

BMD and Structure at the Proximal Femur Measured by CT in Men and Women and Blacks and Whites. M. Peacock[1], S. A. Persohn*[2], J. L. Rankin*[2], M. J. Econs[1], S. Hui[1], K. A. Buckwalter*[2]. [1]Medicine, Indiana University, Indianapolis, IN, USA, [2]Radiology, Indiana University, Indianapolis, IN, USA.

Women have higher hip fracture incidence than men and whites have higher hip fracture incidence than blacks. It is considered that these differences are due in part to men having higher BMD than women and blacks higher BMD than whites as measured by DXA. However, DXA measures areal density (aBMD). It does not provide volumetric density (vBMD). Further it cannot measure density of cortical and trabecular bone separately. Thus it is not clear which aspect of bone is responsible for sex and race differences in BMD. Similarly, differences in bone geometry at the hip between blacks and whites are considered to account for part of the difference in incidence of fracture between whites and blacks. However, bone structure from both radiographs and DXA is subject to variability from patient positioning and magnification. To overcome these problems we have used CT of proximal femur to measure and compare vBMD and structure in a sample of women and men.

325 healthy premenopausal white women, age 26-52, and 110 healthy white men, age 20-62, and 70 black men, age 20-60, were studied. Spiral CT of the lower pelvis and upper femur was performed on a multi-slice helical CT machine (MX 8000, QUAD Philips Medical Systems) with a QCT 4 bar calcium hydroxyapatite standard (Image Analysis) placed behind the proximal femur. Images of the upper femur were displayed on an image analysis work station (Philips Medical Systems). Proximal femur geometry including head width, neck width, shaft width and femoral axis length was measured from multiplanar reformatted images created from the axial images. vBMD(G/cm^3) of femoral shaft cortex and femoral neck were calculated from the Hounsfield Units corrected to the standard.

Results show that vBMD G/cm^3 was higher in white women than white men and higher in black men than white men. Women had lower values for femoral geometry. There was no difference in the femoral geometry variables between white and black men.

In conclusion a higher volumetric cortical density at the femur shaft and femur neck accounts for the difference in aBMD between white and black men. Women have a smaller skeleton than men. However, the volumetric cortical density at femur shaft and femur neck was higher in white women than white men.

group	shaft cortex vBMD	neck cortex vBMD	neck cancellous vBMD
white women	1303[a]	731[a]	315[a]
white men	1281	666	302
black men	1321[b]	698[b]	320[b]

[a] p<0.005 white women v white men [b] p<0.001 black men v white men

Bone Density Measurement Followed by Osteoporosis Education Leads to Sustained Improvement in Osteoporosis Prevention Habits. C. S. Cowgill, S. Ma*, D. Krueger, S. Zeldin*, N. Binkley. University of Wisconsin, Madison, WI, USA.

Bone mineral density (BMD) measurement identifies individuals at increased risk for osteoporotic fracture. Osteoporosis education may, or may not, be provided when BMD measurements are performed. Studies suggest that BMD measurement may favorably alter health behaviors of women. However, the long-term effects of BMD measurement with subsequent education on skeletal health behaviors are limited. We hypothesized that postmenopausal women would maintain bone preserving activities implemented as a result of BMD measurement and education.

During the months of January-March 2003, free central DXA BMD screening was offered through newspaper advertisement to postmenopausal women not receiving osteoporosis treatment. At that time, 203 women received proximal femur and lumbar spine BMD measurement utilizing GE Lunar DPX-IQ or Prodigy densitometers. All participants immediately discussed their test results with one of four physicians or a nurse practitioner specializing in osteoporosis and received counseling regarding lifestyle changes or appropriate treatment options that might maintain or improve bone health. Three months later, women who agreed to be contacted were mailed a survey that contained 25 questions about osteoporosis-related lifestyle and overall health habits before and after their BMD test. Subsequently, one year after their initial BMD measurement, those 185 participants who responded to the initial questionnaire were mailed a six-question survey that asked what lifestyle changes had been maintained. Results from 130 completed surveys received from 160 women indicate that lifestyle changes had been maintained by 92% of respondents. Specific interventions included increasing calcium intake (58%), increasing exercise (53%), using handrails to go up and down stairs (49%) increasing vitamin D (48%) and taking safety precautions at home (32%).

In conclusion, bone density screening immediately followed by osteoporosis education and individualized counseling is effective in motivating 92% of postmenopausal women to implement and maintain lifestyle changes to preserve their skeletal health. Postmenopausal women can be positively influenced by BMD testing with immediate individualized counseling.

Food Group Intake and Bone Mineral Content (BMC) during Growth from Childhood to Adolescence. H. Vatanparast*[1], S. Whiting[1], A. Baxter-Jones*[2], R. Faulkner[2], D. Bailey[2]. [1]College of Pharmacy and Nutrition, University of Saskatchewan, Saskatoon, SK, Canada, [2]College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada.

Nutrition is an important modifiable factor in the development and maintenance of bone mass particularly during peak bone mass development. The purpose of this study was to determine the role of consumption of different levels of food groups on the total body-bone mineral content (TB-BMC) accrual in boys and girls after the age of peak height velocity (PHV). Six-year longitudinal data were used from 85 boys and 67 girls (8-20 y). Biological age was defined by the age of PHV. Nutritional intake was assessed via serial 24-hour recalls. Food group intakes were classified into three levels, mostly as low, adequate and high. TB-BMC was the indicator of bone mass. The majority of subjects consumed an adequate level of milk product with more boys at the highest level than girls. In contrast, most boys and girls consumed vegetables and fruit less than the recommended amounts. As age increased, TB-BMC increased with higher magnitude in boys than girls. There was a significant difference in TB-BMC between very low and adequate levels of vegetables and fruit intake in girls (P<0.05), which was not significant after adjusting for height. Our data could not demonstrate the effect of milk product intake on bone mass during adolescence.However our subjects had an appropriate intake of milk products and consequently substantial calcium accrual during the critical years of maturity and their bone accrual data have been used as the basis for calculating calcium requirements of adolescents. Therefore, in this cohort, we are not surprised to find a lack of the effect of calcium intake on bone accrual. The data on the effect of vegetables and fruit intake on bone mass in girls should encourage continuing research on this topic.

Dietary Influences on Bone Mineral Density in Chinese Men and Women. P. A. Zalloua*[1], Y. Hsu*[2], H. Terwedow*[2], T. Zang*[3], D. Wu*[3], G. Tang*[3], Z. Li*[3], X. Hong*[3], B. Wang*[2], M. Bouxsein*[4], J. Brain*[5], S. Cummings*[6], C. Rosen*[7], X. Xu*[2]. [1]Internal Medicine, American University of Beirut, Beirut, Lebanon, [2]Harvard School of Public Health, Boston, MA, USA, [3]Anhui Medical University, Anhui, China, [4]Beth Israel Deaconess Medical Center, Boston, MA, USA, [5]Environmental Health, Harvard School of Public Health, Boston, MA, USA, [6]San Francisco Coordinating Center, UCSF, San Francisco, CA, USA, [7]Maine Center for Osteoporosis Research and Education, St Joseph Hospital, Bangor, ME, USA.

Diet choices and nutrition have proven in the last decade to be one of the major modulators of BMD in both men and women. The objectives of this study were to explore the possible environmental determinants, specifically dietary habits, of BMD by using multiple regression models in Chinese women and men living in a rural area. BMDs were measured at the hip and total body in 2127 men and 2673 women, aged 35-65. Dietary and supplement intakes were assessed by a food-frequency questionnaire. Another questionnaire was used to collect information on the subject's age, disease history, smoking, alcohol consumption, diet, physical activity as well as women's menstrual status and reproductive history. Regression models were used to assess the relationships among dietary variables and BMD, after adjusting for age, BMI, weight, occupation, smoking status and alcohol consumption. Milk consumption did not show a significant effect on BMD. Seafood consumption was significantly associated with greater BMD in both sexes (p= 0.006 for men, p=0.001 for women). Fruit consumption was also associated with higher BMD (p=0.005). High vegetables consumption, however, did not seem to positively impact BMD and, on the contrary, showed a significant association with lower BMD in pre-perimenopausal women (p=0.001). Greater consumption of preserved food was found to be associated with lower BMD in pre- and postmenopausal women (p=0.005). Finally, there was no significant association between vitamin D supplementation and greater BMD, but this lack of association may be due to the relatively small number (1.5%) of participants who took Vitamin D supplementation. Our results highlight the importance of several dietary variables as significant determinants of BMD. These results emphasize the role of dietary intake in general and show that specific foods such as fruits and seafood can positively impact BMD. This study with its large population size proves highly beneficial in identifying preventive measures, as well as some risk factors, involved in bone loss and osteoporosis. Supported by NIAMS grant R01 AR045651.

Association of Apolipoprotein E Genotypes with Bone Mineral Density and Bone Loss in Early Postmenopausal Scottish Women: No Evidence of Gene Nutrient Interaction with Dietary Vitamin K or Fat. H. M. Macdonald, F. E. McGuigan*, S. H. Ralston, D. M. Reid. Medicine and Therapeutics, University of Aberdeen, Aberdeen, United Kingdom.

We previously found an association between APOE polymorphism and bone mineral density (BMD) in women from the Aberdeen Prospective Osteoporosis Screening Study (APOSS) with carriers of E4 having lower BMD and greater bone loss compared to carriers of E2. Whether the effect of APOE is mediated through vitamin K transport, interaction with dietary fat or is independent is unknown. Gene nutrient interactions have been found between polyunsaturated fatty acids (PUFA) and APOA1 and between alcohol and APOE genotype on lipoprotein levels in subjects from the US.

A total of 3883 women from APOSS underwent bone densitometry in 1990-3 (mean ± SD

age: 48.5 ± 2.4 y) and again 6.3 ± 0.9 y later. 3239 women completed a food frequency questionnaire at the 2nd visit of whom 2481 were genotyped for APOE by DNA sequencing. Allele frequencies were: E3 78.1%; E4 14.5%; E2 7.4%. Genotypes in Hardy Weinberg equilibrium were as follows: E3/E3 1517 (61.1%), E3/E4 562 (22.7%), E2/E3 280 (11.3%), E2/E4 59 (2.4%), E4/E4 48 (1.9%), E2/E2 15 (0.6%). Subjects with E2/E4 were excluded for this analysis. We found weak positive associations between vitamin K intake and BMD at hip (FN) and spine (LS) and between alcohol intake, BMD and BMD change. There was a non-significant negative trend relating PUFA and bone loss. We found no evidence of nutrient gene interaction for APOE with either PUFA or vitamin K. The trend for BMD increasing (and bone loss decreasing) with APOE alleles 34/44 <33< 22/23 was confined to alcohol drinkers and was significant after adjustment for confounders (age, weight, height, smoking, menopausal status and HRT use) for bone loss (table). Median alcohol intake for drinkers was 7.3 g/d (range 1.2 to 79.4 g/d). We did not observe a significant interaction between alcohol consumed and APOE genotype on BMD.

APOE	Drinkers (n 1779)			Non-drinkers (n 642)		
	n	FN BMD (g/cm2)	FN BMD change (%/y)	n	FN BMD (g/cm2)	FN BMD change (%/y)

P		0.055	0.029		0.883	0.942
P adjusted		0.072	0.023		0.781	0.815

Characteristics of non-drinkers may differ from alcohol consumers, which may partly explain the differences in results. Since the effect size of nutrient variables on BMD is small, the power to detect gene nutrient interaction is limited. However, these data suggest it is unlikely that the effect of APOE genotype on BMD is influenced by intake of vitamin K or fat in healthy early postmenopausal women. The influence of alcohol requires further research.

Vitamin D Insufficiency in Canadian Aboriginal Women: The First Nations Bone Health Study. W. D. Leslie[1], J. Krahn*[1], H. A. Weiler*[2], C. J. Metge*[3], C. K. Yuen[1], M. Doupe*[1], E. A. Salamon[4], P. Wood Steiman*[5], J. D. O'Neil*[1], C. R. Greenberg*[1], L. M. Lix*[1], L. L. Roos*[1], A. Tenenhouse[6]. [1]Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada, [2]Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada, [3]Faculty of Pharmacy, University of Manitoba, Winnipeg, MB, Canada, [4]Department of Medicine, University of Manitoba, Winnipeg, MB, Canada, [5]Assembly of Manitoba Chiefs, Winnipeg, MB, Canada, [6]Department of Medicine, McGill University, Montreal, PQ, Canada.

Canadian Aboriginal women are at increased fracture risk compared with the general population (JBMR 18:S151, 2003), but the factors related to this are unknown. Obesity, insulin resistance and type 2 diabetes are also endemic in this population. The First Nations Bone Health Study (FNBHS) recruited a random age-stratified (25-39, 40-59, and 60-75) sample of Aboriginal and age-matched White women. 364 subjects underwent fasting assessments of 25OH-vitamin D (25OHD), PTH, total calcium (albumin corrected), CTX, and osteocalcin. Measures of glucose metabolism were also evaluated including serum glucose, insulin, C-peptide, IGFBP-1, IGFBP-3, and HbAlc. Aboriginal women had lower 25OHD values and higher PTH; 25OHD and PTH were negatively correlated (r=.24, P<.001). Markers of bone resorption (osteocalcin) and formation (CTX) were similar for Aboriginal and White women, but correlates of insulin resistance were all greater in Aboriginal women. 25OHD was positively correlated with IGFBP-1 (r=.24, P<.001) and IGFBP-3 (r=.17, P=.003); negatively correlated with BMI (r=-.24, P<.001), insulin (r=-.18, P=.002); C-peptide (r=-.26, P<.001), and HbAlc (r=-.12, P=.039). ANCOVA showed that ethnicity differences in 25OHD persisted after adjustment for BMI and markers of glucose metabolism. In summary, our findings show reduced vitamin D levels in Canadian Aboriginal women. Greater BMI and markers of insulin resistance (also more common in Aboriginal women) were associated with lower 25OHD levels as previously reported (JCEM 2004;89:1196), but this did not explain the ethnic difference. Further work is needed to understand the nature of the interrelationship between vitamin D metabolism and glycemic control in this population.

	Aboriginal(N=185)	White (N=179)	P
25OH-Vit D (mmol/L)	52.8±24.8	72.8±31.8	0.000001

Relationship between Vitamin D Status and Plasma Parathyroid Hormone Level in Healthy Japanese Women; Evaluation of Age-related Vitamin D Requirement. N. Tsugawa*[1], M. Shiraki*[2], K. Tanaka*[3], T. Okano[1]. [1]Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, [2]Research Institute and Practice for Involutional Diseases, Nagano, Japan, [3]Department of Nutrition, Kyoto Women's University, Kyoto, Japan.

Vitamin D is an important factor for prevention of osteoporosis and bone fracture. Subclinical vitamin D insufficiency is enhanced risk of osteoporotic fracture. Vitamin D insufficiency is characterized by mild secondary hyperparathyroidism and thus requirement for vitamin D is thought to vary with age. In the present study, in order to evaluate age-related vitamin D requirement, we measured plasma levels of 25-hydroxyvitamin D (25-OH-D) and PTH in 432 healthy Japanese women, aged 30-88 yr. Serum 25-OH-D was measured by RIA kit (DiaSorin Inc.). Serum PTH was measured by 2 immunoradiometric assays, intact PTH (1-84 and 7-84) assay and the new CAP (1-84) assay (Scantibodies Laboratory, Inc.). Data were classified into three age categories; 30-49 yr, 50-69 yr, and 70 and older than 70 yr. As the results, no correlation was observed between age and 25-OH-D level. CAP PTH and intact PTH levels correlated positively with age (r^2=0.010, p=0.0351 or r^2=0.011, p=0.024, respectively). Plasma 25-OH-D levels correlated negatively with CAP PTH (r^2=0.035, p<0.0001) and intact PTH (r^2=0.034, p<0.0001) levels in every stratified age group. Data were further classified into five subgroups according to plasma 25-OH-D level; less than 25, 25 to <37.5, 37.5 to <50, 50 to <75, 75 and more than 75 nmol/L. When plasma 25-OH-D levels were lower than 50 nmol/L, PTH levels increased significantly in any group of ages. The result suggests that 50 nmol/L of 25-OH-D is thought to be the cut-off value for vitamin D insufficiency in elderly women. PTH levels of 50-69 yr group and 70 and older than 70 yr group were significantly higher than that of the youngest group even in more than 50 nmol/L of 25-OH-D. These results suggest that 50 nmol/L of 25-OH-D is thought to be vitamin D sufficient for women younger than 50 yr, but not for women elder than 50 yr to prevent elevation of plasma PTH level, resulting in bone loss.
We conclude that Japanese elderly women might require more vitamin D and calcium intakes from diets or supplements.

Impact of Calcium Vitamin D Supplementation on Cardiovascular Parameters in Osteoporosis. G. Rajzbaum*[1], C. Chaignaud*[2], P. Bréville*[1], F. Roux*[1], M. Chauffert*[3], Y. Bézie*[2]. [1]Rheumatology, Fondation hôpital Saint-Joseph, Paris, France, [2]Pharmacie, Fondation hôpital Saint-Joseph, Paris, France, [3]Biochimie, Fondation hôpital Saint-Joseph, Paris, France.

High doses of vitamin D3, calcium and nicotine induce severe vascular calcifications in rats. Daily supplementation with calcium and vitamin D is often prescribed to osteoporotic patients to prevent fractures. Nevertheless this treatment, as in experimental pharmacology, might also have an impact on the occurrence of vascular calcification. Our aim was to investigate association of calcium vitamin D supplementation with abdominal calcifications in osteoporotic postmenopausal women.
We studied 317 post menopausal consecutive outpatients consulting for osteoporosis evaluation in a French general hospital. Presence of abdominal aortic calcifications was assessed on profile lumbar X-rays. Were noted osseous and cardiovascular parameters : age of menopause, calcium intake, osteoporotic fractures, osteodensitometry, phosphocalcic and bone turnover biochemical parameters, systolic, mean and pulse pressure, tobacco, hypercholesterolemia, previous and current treatments.
Demographic characteristics of women treated by calcium vitamin D (n=109) was not different from the controls (n=218). The treated population was characterized by a lower lumbar and femoral T score (respectively -2.51± 0.14 vs -2.05± 0.10 SD, p<0.05, and -2.17± 0.09 vs -1.86± 0.07 SD, p<0.05) associated with a higher 25OHD3 plasmatic concentration (20.5± 0.8 vs 13.1± 0.6 µg/L ; p<0.00001) and calciuria (0.46± 0.03 vs 0.36± 0.02 mmol/mmol cr ; p=0.003). The percentage of patients with abdominal aortic calcifications was identical between the two groups (45.7± 7.3 vs 53.6± 5.5 %). Nevertheless, patients treated with calcium and vitamin D were characterised by a lower aortic stiffness compared with non supplemented patients as indicated by their lower pulse pressure (51.7± 1.5 vs 55.2± 1.1 mm Hg, p=0.05).
Our results indicate that supplementation of calcium and vitamin D in osteoporotic patients is not associated with aortic calcifications, suggesting that toxic effects shown in experimental pharmacology are not relevant at therapeutic dosages in women. The lower pulse pressure observed with calcium vitamin D suggests a beneficial impact on arterial stiffness, which is an independent predictor of cardiovascular mortality in hypertensive patients.

Is Diversity More Important Than Quantity of Physical Activity In Maintaining The Fracture Resistance of The Proximal Femur? S. Kaptoge, N. Dalzell*, R. W. Jakes*, N. J. Wareham*, K. T. Khaw*, N. Loveridge, J. Reeve. Public Health & Medicine, Cambridge University, Cambridge, United Kingdom.

Hip fractures occur as a direct consequence of cortical bone instability. Biomechanical principles suggest that larger bones would have greater bending resistance as measured by the section modulus (Z), which increases in direct proportion to the bone's diameter. However, structural stability, least for the lateral/superior cortex, and measured as critical buckling stress is compromised if the bone's cortices are either thinner or located further away (d-lat) from the section's centre of gravity. We hypothesised that aging, anthropometry and physical activity may conserve Z through distribution of bone tissue, to result in an optimal placement of the bone's centre of gravity for Z rather than cortical stability.

Hip structural analysis software was used to derive structural measurements from DXA scans on 1,359 men and women in the EPIC-Norfolk population-based prospective study. Up to 4 repeat DXA scans were done in 8 years of follow-up: 2 scans(n=954, 2.9y); 3 scans(n=722, 5.4y) and 4 scans(n=78, 7.5y). Weight, height and activities of daily living (ADL) were assessed on each occasion. A standard physical activity and lifestyle questionnaire was administered at baseline. The distance from the lateral bone surface to the centroid was measured on three narrow cross-sections; narrow neck(NN), intertrochanter(IT) and shaft(S). A linear mixed model was used to assess associations with predictors.

There were significant differences in the distance to the centroid in the 3 regions (greatest at IT and smallest at S, P<0.0001). Men had greater d-lat than women (0.075cm difference, P<0.0001). Aging was associated with medial shifting of the centroid that was greater in women NN (F&M=0.010cm/y), IT (F=0.011cm/y, M=0.005cm/y) and S (F=0.003cm/y, M=0.001cm/y) P<0.0001. Increasing weight and height were associated with greater d-lat (P<0.0001). Among physical activity variables, lifetime activity (P=0.036), walking/cycling for more than 1hr/day (P=0.001), weekly time spent on weight bearing activity (P=0.009), and FEV1 (P=0.016) were associated with higher d-lat. Interestingly after adjusting for these variables, ADL scores as a measure of current activity and weekly time spent on low impact activities were associated with shorter d-lat (P<0.019). We conclude that diversity of physical activities may be superior to stereotypic walking activity in maintaining proximal femur structural stability.

Dietary Factors and Physical Activity in Low-Income Postmenopausal Osteoporotic Women. P. S. Genaro*[1], G. A. P. Pereira*[1], M. M. Pinheiro*[2], V. L. Szjenfeld[2], L. A. Martini[1]. [1]Nutrition, Sao Paulo University, Sao Paulo, Brazil, [2]Rheumatology, UNIFESP, Sao Paulo, Brazil.

Osteoporosis and related fractures represent major public health problem that are expected to increase dramatically as the population ages. Dietary risk factors and physical activity are particularly important. In a low-income population diet and physical activity could be inadequate since there is a tendency to obesity with over consumption of carbohydrates and fats, low mineral and vitamin intakes and absence of physical activity. The aim of the present study was evaluate nutrient intakes, physical activity and body composition in osteoporotic women, before nutritional advice and drug therapy. Twenty-four postmenopausal women, mean age (64 ± 7 years old) and BMI (26 ± 3 Kg/m²) assisted at São Paulo Hospital osteoporosis outpatients clinic were invited to participate. Body composition analysis was performed in all participants using DEXA technique (Lunar DPx). Diet and physical activity was assessed using three days dietary records and the Beacke questionnaire, respectively. Bone metabolism was evaluated by serum and urinary calcium. Results are presented as mean ± SD. Energy intake was 1293 ± 487 Kcal/day. Protein, total fat, carbohydrate and phosphorus intakes were 1.09 ± 0.5 g/Kg/day, 35 ± 16 g/day, 185 ± 76 and 901 ± 76 mg/day, respectively, all in accordance with proposed DRI's. However, mean calcium intake (663 ± 320 mg/day) was significantly lower than the value for this age group (1200 mg/day). Eighty-four percent of the participants had low calcium intake according to the Food and Nutrition Board (1997). Serum ionized calcium (1.19±0.10 mg/dl), total calcium (9.06±0.42) and calcium/creatinine ratio in the urine (215±128 mg/24hs) were normal. Body composition analysis demonstrated that 83% of the participants were classified as obese (mean body fat 38.0±7.8 % and mean lean mass 32±4 Kg). Most of the patients had low physical activity levels. The results demonstrate high prevalence of obesity, low calcium intake and sedentary pattern in our population. This study emphasizes the importance of proper nutritional and physical evaluation and advice in patients with osteoporosis in order to optimize adjuvant interventions to their pharmacological management.

Fracture Prevalence and Treatment with Bone-Sparing Agents: Are there Urban-Rural Differences? A Population-Based Study in Ontario, Canada. S. M. Cadarette, S. B. Jaglal, G. A. Hawker. University of Toronto, Toronto, ON, Canada.

A census of persons aged 55 or more years residing in two regions of Ontario, Canada (East York, a borough of Toronto, and Oxford County), was completed between 1995 and 1998, response rate=77%. Information including self-reported physician diagnosed osteoporosis, height loss, fracture history and treatment by a physician with bone-sparing agents (calcium, vitamin D, etidronate, fluoride and estrogen) were ascertained. The objectives of this study were to estimate the prevalence of self-reported osteoporotic fractures (arm, hip, rib, pelvis or vertebrae since age 40 years in women or 50 years in men) and the use of bone-sparing agents, and to examine if region of residence is associated with fracture or treatment prevalence. Region was coded by record linkage of residential postal codes to 1996 Canadian Census data into 4 groups: East York (urban core), and Oxford County subdivided into: urban core, small urban and rural. Respondents were excluded if they resided outside the regions of interest or were missing fracture data (5%). A total of 26,839 persons (15,541 women) were studied, of whom half resided in East York. Among those living in Oxford County, 30% lived in a rural area. Nearly 3 times as many women as men reported having had an osteoporotic fracture (14% vs. 5%), with 31% and 8% of these women and men respectively taking bone-sparing agents. Controlling for age, a diagnosis of osteoporosis, number of osteoporotic fractures and height loss, women residing in East York were more likely (OR=1.2, 95%CI=1.0-1.4) to be taking a bone-sparing agent other than estrogen, but less likely to be taking estrogen (OR=0.8, 95%CI=0.7-0.9) compared to those living in rural areas. No regional differences were observed in fracture prevalence, treatment amongst those with an osteoporotic fracture, or use of a bone-sparing agent among men. Further research should examine if regional differences in osteoporosis prevention continue to exist among women in Ontario, and if applicable, to separate physician practice patterns from individual characteristics, such as willingness to begin treatment with bone-sparing agents.

Disclosures: ***S.M. Cadarette****, None.*

Elderly Women Whose Mothers Lived to Extreme Old Age Have a Lower Risk of Hip and Non-spine Fractures than Women with Shorter-Lived Mothers. P. M. Cawthon[1], S. R. Cummings[1], T. L. Blackwell*[1], J. Zmuda*[2]. [1]Research Institute, California Pacific Medical Center, San Francisco, CA, USA, [2]University of Pittsburgh, Pittsburgh, PA, USA.

Background: We have previously shown that older women (age_65) whose parents survived to extreme old age have a survival advantage compared to women with shorter-lived parents, among participants in the Study of Osteoporotic Fractures (SOF). Additionally, these women appear to have better health overall.

Research Question: In the current analyses, we tested the hypothesis that women with long-lived parents (age ≥90 or age ≥95) experience fewer non-spine and hip fractures, and report fewer falls, than women with shorter-lived parents.

Methods: SOF women with parental death information and DXA data (N=7,862) were included in these analyses, of whom 1299 (16.6%) had mothers live past 90; 398 (5.2%) had mothers live past 95; 639 (8.1%) had fathers live past 90; and 168 (2.1%) had fathers live past 95 years of age. Fractures were adjudicated by x-ray report. Proportional hazards models were used for all analyses. Multivariate results were adjusted for age, bmd, smoking and years of education.

Results: Mothers who lived to ≥90 or ≥95 years of age had a small but significantly decreased risk of incident hip and non-spine fractures (table), compared to women whose mothers did not live as long, in age and multivariate adjusted models. In contrast, father's age at death was not significantly related to risk of fracture in age- or multi-adjusted models. Parental age at death was not significantly related to falling during follow-up (results not shown).

Conclusion: Our results suggest that there is a familial resemblance between maternal longevity and fracture resistance in women. Older maternal age at death is associated with not only extended, but also healthier survival.

Risk of Non-Spine, Hip Fracture by Parental Age at Death

Hazard Ratios (95% CI)	Non-Spine Fracture		Hip Fracture	
Parental Age at Death	Age-Adjusted	Multi-Adjusted	Age-Adjusted	Multi-Adjusted
Mother ≥ 90	**0.91 (0.83, .99)**	**0.89 (0.81, 0.99)**	**0.83 (0.69, 0.99)**	**0.77 (0.64, 0.94)**
Father ≥ 90	0.95 (0.84, 1.08)	0.93 (0.81, 1.07)	1.02 (0.82, 1.28)	1.03 (0.81, 1.31)
Mother ≥ 95	**0.83 (0.70, 0.97)**	**0.8 (0.67, 0.96)**	**0.69 (0.50, 0.95)**	**0.7 (0.49, 0.99)**
Father ≥ 95	1.11 (0.88, 1.39)	1.16 (0.91, 1.48)	0.71 (0.44, 1.15)	0.68 (0.4, 1.15)

Reduced Fracture Risk in Current Users of Thiazide Diuretics. L. Rejnmark, P. Vestergaard, L. Mosekilde. Dept of endocrinology and metabolism C, Aarhus Amtssygehus, Aarhus, Denmark.

Thiazide diuretics (TD) reduce the renal calcium excretion and may increase bone mineral density. A reduced fracture risk in subjects treated with TD has been reported in some but not all studies. The aim of the present study was to assess fracture risk in users of TD. Design: a nation-wide population-based pharmaco-epidemiological case-control study with any fracture in year 2000 as outcome and use of TD during the previous five years as exposure variable. Individual use of TD was derived from the Danish National Pharmacological Database and related to fracture data from the National Hospital Discharge Register. These data were combined with information on use of other drugs, social status, working status, income (from tax authorities), educational status (National Bureau of Statistics), contacts to general practitioners, practising specialists (The National Health Register), and comorbidity (The Charlson Index). 64,699 cases aged 40 years or more that sustained a fracture during year 2000 were compared to 194,111 age- and gender-matched controls. TD was used by 15,316 (23.7%) of the cases and by 42,647 (22.0%) of the controls (crude odds ratios (OR), 1.10; 95%CI, 1.08-1.12). However, after adjustment for potential confounders, ever use of TD was associated with a 13% (95%CI, 10%-15%) reduced risk of any fracture and a 17% (95%CI, 12%-21%) reduced risk of a forearm fracture. In current users of TD who had redeemed prescriptions for more than 1000 defined daily dosages (DDD), risk of any fracture was reduced by 29% (95%CI, 12%-42%) and risk of hip fracture was reduced by 39% (95%CI, 9%-59%). Conversely, use of less than 1000 DDD was associated with an increased fracture risk in current users. In former users, fracture risk was increased for all dosages groups. No important differ-

ences were found between men and women in either the crude or the adjusted analysis upon age- and gender-stratification. Thus, current use of TD is associated with a significantly reduced fracture risk. The reason for the reduced fracture risk in current long-term users needs further elucidation. Large long term randomized controlled studies on effects of TD on fracture risk are warranted.

Profile of Care for Hip Fracture Patients In Italy. S. Maggi*, D. Bianchi*, P. Gallina*, C. Marzari*, M. Noale*, G. Crepaldi. Aging, Italian Research Council, Padua, Italy.

Hip fracture is one of the most important causes of death and disability among older people. In spite of the increasing interest at international level, due to the clinical and functional sequelae, in Italy only limited epidemiological data are available about the incidence of hip fractures. These data vary widely across the Italian regions.

Primary aim of the present study was to ascertain the profile of hospital care for hip fractures in different geographic areas of Italy. The secondary

objectives were to determine the availability of access to community services in different regions and to evaluate the completeness and the accuracy of coding of hip fractures using ICD9 codes. The centers included in the study were in Veneto (Padova), Emilia Romagna (Parma), Liguria (Genova), Campania (Napoli), and Basilicata (Matera). The same general approach to data collection was used in all areas. Patients with pathological fractures were excluded from the study, as well as multiple hospital discharges for the same event. The frequency of hip fractures ranges from 65-75/10.000 individuals aged 65+. The accuracy of hip fractures coding using ICD9 codes is high, and the coding mistakes irrelevant. The profile of care and the availability of community services present a high variability among the different geographic areas of Italy. In particular, the timing of surgery after hospital admission varies from 2,2 ± 2,4 days in Parma to 6,2 ± 4,0 days in Napoli (mean ± standard deviation) and the percentage of patients undergoing surgery varies from 45% in Matera to about 90% in Padova and Parma. 80% of patients are discharged at home in Napoli, versus 40% in Genova, while only 1% is istitutionalized in Parma and Matera, versus 19% in Genova.

These results suggest the need for creating a national registry for hip fractures to collect data from different areas and to build the basis for standardized care in Italy.

Osteoporosis Is Significantly Underdiagnosed and Undertreated - a Nationwide Study from Denmark. P. Vestergaard, L. Rejnmark, L. Mosekilde. The Osteoporosis Clinic, Aarhus Amtssygehus, Aarhus, Denmark.

Aim: To assess the number of patients actually diagnosed with osteoporosis in Denmark with the number expected to have osteoporosis based on normative BMD data. The number of subjects with osteoporotic fractures was also assessed.

Subjects and methods: All patients diagnosed with osteoporosis and/or with osteoporotic fractures between 1995 and 1999 were retrieved from the National Hospital Discharge Register, which covers all in- and outpatient contacts to the hospitals. Based on normative values for BMD in Danish subjects and the NHANES-III data, the expected number of subjects aged 50 years or more with osteoporosis according to the WHO definition (T-score <-2.5) was calculated. The population in 1999 was 5.3 million.

Results: The estimated prevalence of osteoporosis (T-score <-2.5) was 30.7% in the hip and 27.5% in the lumbar spine (If the two sites were combined 40.8% had a T-score <-2.5 in either one or both sites) among women aged ≥50 years and 16.0% in the hip and 4.3% in the spine (combined 17.7%) among men aged ≥50 years based on normative Danish BMD values. Using the NHANES III data only 16.4%of women and 3.6% of men were expected to have a T-score <-2.5 in the hip. The expected annual incidence was 58,658/mio/yr in women ≥50 years and 23,648/mio/yr in men ≥50 years. However, the observed incidence was only 4,823 and 862/mio/yr respectively (8.2 and 3.6% of the expected). In 1999, a total of 34,691 hip, spine and forearm fractures were reported in subjects ≥50 years, and of these 18,566 were potentially attributable to osteoporosis (14,240 fractures in women and 4,326 in men equaling an incidence of 14,976 and 5,297/mio/yr, i.e. also much higher than the number diagnosed with osteoporosis). Only 0.3% of men ≥50 years were receiving a bisphosphonate while 2.2% of women received a bisphosphonate or raloxifene. Among women ≥50 years 27.7% received hormone replacement therapy.Conclusions: Osteoporotic fractures are rather frequent in Denmark, but the diagnosis of osteoporosis is rarely used. It seems that osteoporosis is markedly underdiagnosed and undertreated in Denmark as probably also elsewhere. This may have significant implications for the prevention of osteoporotic fractures.

Fracture Incidence in the City of Glasgow: Analysis by Age, Sex and Socioeconomic Deprivation. S. J. Gallacher[1], I. Baxter*[2], A. McLellan[3], C. McQuillian*[1], M. Fraser*[3], A. Gallagher*[1], F. Lovell*[4]. [1]Medical Unit, Southern General Hospital, Glasgow, United Kingdom, [2]Department of Public Health, Greater Glasgow Health Board, Glasgow, United Kingdom, [3]Department of Medicine and Therapeutics, Western Infirmary, Glasgow, United Kingdom, [4]Medical Unit, Royal Infirmary, Glasgow, United Kingdom.

The Fracture Liaison Service assesses all patients over the age of 50 presenting with an incident fracture at any site for osteoporosis risk. This service uses Nurse Specialists to link with Orthopaedic Services to identify and assess all such patients (using DXA scanning). This service covers the whole of the City of Glasgow. Glasgow has a relatively stable population of approximately 1 million people. Since the population is relatively stable and since the whole population is covered a denominator is available in order to define annual fracture incidence. This work describes all fracture incidence over the calendar year 2002 by age and sex and further describes the effects of socioeconomic deprivation on this fracture incidence. A total of 4659 fractures presented through 2002. Crude fracture rates as a percentage of the population by age group and sex are presented below.

Age	50-54	55-59	60-64	65-69	70-74	75-79	80-84	85+
Male	0.65	0.81	0.87	0.83	1.02	1.37	1.61	2.62
Female	0.92	1.44	1.73	1.92	2.54	2.87	3.91	5.03

From the above it can be seen that around 1% females age 50-54 present in 1 year with fracture compared with over 5% at age 85+. As expected incidence rates for males are lower but also increase with age - especially over age 75. Socioeconomic deprivation was then assessed for this population using UK National Census data. This allocates individuals into one of seven categories (DepCat) with DepCat 1 being the most affluent and DepCat 7 the most deprived populations. These were then grouped 1&2 (least deprived), 3,4,5 (intermediate) and 6,7 (most deprived). The effect of deprivation on fracture incidence is shown below.

Age	50-54	55-59	60-64	65-69	70-74	75-79	80-84	85+
Least Deprived	0.41	0.79	0.98	1.02	1.50	1.78	2.63	4.02
Intermediate	0.74	1.00	1.24	1.41	1.80	2.16	3.14	3.55
Most Deprived	1.02	1.39	1.53	1.62	2.15	2.61	3.42	5.28

This table demonstrates the strong relationship between deprivation and fracture incidence. This relationship was especially strong in males with fracture incidence being especially high in the most deprived group (data not shown)

Prior Foot Fracture, Current Foot Pain and Physical Function in Men and Women of the Framingham Foot Study. M. T. Hannan[1], K. E. Broe[1], M. Rivinus*[1], M. Hogan*[1], J. Murabito*[2]. [1]Hebrew Rehabilitation Center for Aged, Boston, MA, USA, [2]NHLBI Framingham Study, Framingham, MA, USA.

Despite the relatively common occurrence of foot fractures, it is not known whether a prior foot fracture (FootFx) affects physical function and foot pain. Thus, we examined the cross-sectional association of prior foot fracture with physical function and foot pain in a population-based sample. The Framingham Foot Study (2002-2006) queried participants about previous toe, ankle or foot fracture, current foot pain (e.g., present on most days in a month), and self-reported physical function (limitations using the Nagi items of walking, standing, and stair-climbing, and timed gait and chair stands). Body mass index (BMI) was calculated from measured weight and height. We used logistic regression to examine the relation of prior FootFx with current foot pain or physical function adjusting for sex, age and BMI, producing odds ratios (OR) and 95% confidence intervals (CI).

Participants included 568 men and 750 women of the Framingham Foot Study who were ambulatory and cognitively intact. Mean (±sd) age was 68y ±12 (range 40-100), and mean BMI was 28 kg/m^2 (range 17-52). FootFx was reported by 391 of the 1318 subjects (28% of men, 31% of women). 48% of those with FootFx reported that shoes hurt their feet (39% of those without FootFx, p=0.002). When shown a picture of the foot, participants with FootFx more frequently reported pain at the toes, hindfoot, forefoot, and arch than those without fracture (table). Presence of heel pain did not differ for those with and without FootFx. There were no differences between the two groups in walking or stair-climbing limitations of (p>0.42), or timed gait and chair stand items (p>0.84), however, those with FootFx more often reported limitations in ability to stand for 15 minutes than those without FootFx (table).

Foot pain remained more frequent in those with FootFx even after adjusting for effects of sex, age & BMI (table) as did difficulty in standing for 15-minutes. Timed gait and chair stands as well as limitations in walking or stair-climbing remained unassociated with prior FootFx.

Self-report of prior FootFx is associated with current foot pain and difficulty in standing but not other physical function measures in this population-based sample even after controlling for age and BMI. FootFx may have a lasting influence upon the presence of foot pain.

Prevalence of foot pain and physical function measure and adjusted OR for FootFx

(Presence/absence)	FootFx	no FootFx	adjusted OR (95%CI)
Current foot pain	31%	22%	1.4 (1.06, 1.92)
Toe pain	23%	14%	1.8 (1.28-2.50)
Hindfoot pain	14%	8%	2.0 (1.36-3.15)
Forefoot pain	14%	8%	1.6 (1.04-2.45)
Arch pain	12%	6%	1.7 (1.05-2.64)
Difficulty in standing	40%	34%	1.3 (1.01, 1.78)

Disclosures: ***M.T. Hannan****, None.*

The Incidence of Fractures at All Skeletal Sites Is Highest Among the Socioeconomically Deprived. A. R. McLellan[1], I. Baxter*[2], S. J. Gallacher*[3], M. Fraser*[1], F. Lovell*[4], C. McQuillian*[3]. [1]Division of Cardiovascular Sciences & Medicine, Western Infirmary, Glasgow, United Kingdom, [2]Department of Public Health, Greater Glasgow Health Board, Glasgow, United Kingdom, [3]Medical Unit, Southern General Hospital, Glasgow, United Kingdom, [4]Division of Medicine, Royal Infirmary, Glasgow, United Kingdom.

The impact of socioeconomic deprivation (SED)on fracture incidence is unclear; we have previously reported a possible association between SED and fracture incidence at some skeletal sites (McLellan et al JBMR2003; 18suppl.2S245abstSU275).

The Fracture Liaison Service (FLS) is a clinical service that routinely offers post-fracture assessment for osteoporosis (and treatment, where necessary) to all women and men over 50yr presenting with new fractures(McLellan et al O.I.2003;14:1028-1034); the aim is to effect optimal secondary prevention of osteoporotic fractures. Established in 1999, since 2002 the FLS has provided a unified service covering the entire City of Glasgow's urban population of ~900,000. The FLS is a unique resource for observing the epidemiology of fractures, and in particular the impact of factors such as SED on fracture incidence.

To investigate the association between SED and fracture incidence the entire cohort of 4659 women and men over 50yr who presented with fractures in 2002 were included. SED is classified according a validated 7 point scoring system (DepCat)(Carstairs 1991)based on UK National Census data linked to postcode of residence; DepCat 1 is the most affluent, & DepCat 7 the most deprived.

Annual % age/sex standardised fracture incidence rates

Depcat	Wrist (1324)	Hip (919)	Humerus (716)	Ankle (496)
1	0.38	0.27	0.21	0.15
2	0.35	0.29	0.17	0.10
3	0.5	0.24	0.24	0.17
4	0.39	0.20	0.24	0.15
5	0.53	0.33	0.21	0.24
6	0.46	0.36	0.26	0.15
7	0.62	0.47	0.36	0.25

The most deprived (DepCat 6-7) compared to the least deprived (DepCat 1-2) have age/sex standardised fracture incidence rates that are higher at all skeletal sites; the extent of the increase in fracture rates with SED ranges from 26% at hand / foot (data not shown) to 47% at the humerus. SED, however, also impacts on rates of acceptance of the offer of osteoporosis assessment by the FLS. While ~92% of patients accept assessment by the FLS after hip fracture irrespective of DepCat, for all other fracture sites there is a substantially higher refusal rate of 30% among those from Depcat 6-7 versus 19% among those from DepCat 1-2. SED is associated with higher fracture rates at all skeletal sites, and apart from after hip fracture, with higher rates of refusal to undergo assessment for the secondary prevention of osteoporotic fractures.

Measurements from Heel Bone Ultrasounds Predict Future Non-spine Fracture among Men as Well as Women. S. Fujiwara[1], T. Sone[2], K. Yamazaki[3], N. Yoshimura[4], K. Nakatsuka[5], K. Kushida[3], M. Fukunaga[2]. [1]Clinical Studies, Radiation Effects Research Foundation, Hiroshima, Japan, [2]Kawasaki Medical School, Kurashiki, Japan, [3]Hamamatsu University School of Medicine, Hamamatsu, Japan, [4]Wakayama University, School of Medicine, Wakayama, Japan, [5]Osaka City University Medical School, Osaka, Japan.

Quantitative ultrasound (QUS) is widely adopted for screening patients at risk of osteoporosis because it is an ionizing radiation-free, low-cost, simple and portable method. Although QUS measures were not well correlated with bone mineral density (BMD) by dual X-ray absorptiometry (DXA), a number of prospective studies have demonstrated that measures of QUS could predict future fracture risk in the US and Europe. To our knowledge, there has been no report based on longitudinal study if measures of QUS predict the subsequent fracture risk in Japanese, and very few studies have evaluated QUS measures in fracture prediction among men even in the US and Europe. A multi-center longitudinal study was performed to investigate the relationship between baseline heel QUS measurements and bone fracture risks.

The subjects of this study are 4,989 individuals (1,200 males and 3,789 females), 66 ±10 years (mean ± SD) of age, who underwent heel QUS (A-1000 [Lunar] and AOS-100 [Aloka]) measured at the five centers between 1993 and 2000, and responded to the questionnaire survey in 2002. In the survey they were asked their history of fracture after undergoing QUS. Average follow-up period was 5 years. The two heel QUSs measured speed of sound (SOS), and the A-1000 measured broadband ultrasound attenuation (BUA). The SOS by either QUS and BUA by A-1000 predicted self-reported hip, radius, and the other fracture except spine fracture. The relative risk (RR) of 1 standard deviation (SD) decrease of SOS by A-1000 for the fracture other than spine fracture was 1.8 (95% Confidence Interval 1.3-2.3) for women and 1.7 (95% CI 1.3-2.3) for men, and that for BUA was 1.4 (95% CI 1.2-1.7) for women and 1.6 (95% CI 1.1-2.3) for men. The RR was similar between men and women. The RR of 1SD decrease in QUS measures for the fracture was similar to that of 1SD decrease in BMD by DXA. In conclusions, SOS and BUA obtained from heel QUS predicted future fracture other than spine in both Japanese men and women with similar relative risk (RR) to that obtained from previous reports in Caucasian women.

Risk Factors for Osteoporotic Fractures in Older Women: the Leisure World Cohort. S. White[1], A. Paganini-Hill*[2], S. Service*[3], K. Atchison*[1], A. Nattiv*[3], J. Gornbein*[3]. [1]UCLA School of Dentistry, Los Angeles, CA, USA, [2]USC School of Medicine, Los Angeles, CA, USA, [3]Geffen School of Medicine at UCLA, Los Angeles, CA, USA.

Our purpose was to identify risk factors for osteoporotic fractures in older women. The Leisure World Cohort is a population-based cohort including 8,877 women from a California retirement community. The residents are mostly Caucasian and upper-middle socioeconomic class. Subjects joined the cohort by completing a questionnaire mailed to all residents in 1981-85. This survey included basic demographic information, medical history, personal habits (exercise, smoking, intake of alcohol, coffee, milk, sodas, and vitamin supplements), and menstrual/reproductive history including menopausal estrogen use. Fracture information came from follow-up surveys, hospital records, or death certificates. Subjects were followed from completion of baseline survey to date of either fracture, last follow-up survey, or, for hip fracture, death. Data were analyzed separately for fractures of hip, leg, arm, wrist, and spine. Clinical variables were first analyzed univariately to assess their influence on fracture risk. All statistically significant ($p<0.05$) variables plus those with a hazard ratio <0.8 or >1.2 were then analyzed jointly using Cox proportional hazards model and backwards elimination procedure to identify significant variables.

The mean age (SD) of women at entry was 74 (7.4) years. Risk factors and hazard ratios, in order of importance by bone, are shown in the table. For the binary variables, the hazard ratio represents the change in fracture rate for having the condition in question, compared to a person without the condition in question. For continuous variables, the hazard ratio represents the change in the fracture rate for a person at the third quartile of the variable compared to a person at the first quartile of the data. Hazard ratios >1.0 represent an increased fracture rate, hazard ratios <1.0 represent a decreased fracture rate, compared to the reference group.

Risk factors and hazard ratios for fracture by bone

Hip		Wrist		Arm		Leg		Spine	
930 fractures 6,709 subjects		376 fractures 6,391 subjects		415 fractures 7,183 subjects		339 fractures 8,237 subjects		527 fractures 6,878 subjects	
Risk Factor	Hazard Ratio	Risk Factor	Hazard Ratio	Risk Factor	Hazard Ratio	Risk Factor	Hazard Ratio	Risk Factor	Hazard Ratio
Age	2.39	Previous fracture	2.42	Previous fracture	2.41	Previous fracture	2.38	Age	2.32
Diabetes	1.69	Heart attack	1.60	Diabetes	2.32	Heart attack	0.65	Previous fracture	1.67
Current smoker	1.44	Hysterectomy	0.75	Age	1.53	Diabetes	1.31	Current smoker	1.54
Previous fracture	1.40	Age	1.27	Rheumatoid arthritis	1.36	Ever pregnant	0.81	Blood pressure meds	1.37
Body mass index	0.76	Alcohol use	0.81	Passive indoor exercise	0.80	Attitude	0.83	Active outdoor exercise	0.73
Glaucoma	1.27	Body mass index	0.84	Attitude	0.81	Age	0.84	Body mass index	0.73
Ever pregnant	0.83	Vitamin A supplements	1.15	Current smoker	0.89			Pain meds	1.28
Attitude	0.90	Cola use	0.92					Attitude	0.81
Vitamin A supplements	1.07	Diabetes	1.04					Glaucoma	0.86
Smoking pack years	1.07							Smoking pack years	1.07
								Active indoor exercise	0.94

No. of subjects vary due to missing values for some variables.

The most important risk factors for osteoporotic fracture are history of fracture after age 40, age at entry into study, diabetes, previous heart attack, and smoking. Body mass index, exercise, ever pregnant, and a positive attitude are protective.

Fracture in Stroke: Influence of BMD and Balance. M. W. J. Davie, N. J. Bainbridge*, M. J. Haddaway*. Charles Salt Centre, Robt Jones and Agnes Hunt Hospital, Oswestry, United Kingdom.

Patients with stroke are at increased risk of fracture, but many studies have used fit subjects as controls and not taken into account balance problems of stroke patients. To investigate the effect of balance and bone density on fracture risk, stroke patients were compared with subjects without stroke, but sufficiently unfit to require care in an institution (controls). Stroke subjects were matched for age and sex with controls. An “age at stroke” for a control was determined from the age at stroke of the matched stroke patient allowing comparison of fracture incidence over the same period of time. Bone density (BMD) was measured at the R and L heel with a PIXI densitometer and each subject had a Tinetti balance assessment (TBA) [range 0-16]. Dichotomous variables were compared by Chi squared, other data by ‘t’ tests or Mann-Whitney U tests and correlation by Kendall’s tau. The study was passed by the local research ethics committee.

23 female and 16 male subjects were matched (strokes age 77yr, controls age 78yr). Median time since stroke was 5.3yr (all >1yr post-stroke). No difference between R and L heel BMD for either group, nor between groups (stroke (R) 0.41: Control 0.43g/cm^2) was found. TBA was lower in stroke(med. score = 6) than controls(med. score = 9)($p<0.05$). Fractures occurred with median time post-stroke of 3.3yr in stroke subjects and 1.3yr in controls, in 33.3% of the stroke patients 12.8% of controls (p=ns). Fracture patients were

therefore pooled. TBA for stroke subjects without fracture(SNF) was lower than either control subjects without fracture(CNF) ($p<0.01$) or all subjects with fracture ($p<0.05$). Fracture subjects scored particularly badly at the 360^0 turn ($p< 0.05$ cf controls)component of TBA. Fracture subjects had lower BMD (0.34 g/cm^2) than either SNF (0.45, $p<0.01$) or CNF subjects(0.44, $p<0.01$). To investigate fracture incidence according to Tinetti score, all patients were allocated to one of 4 TBA score groups (TBA score[no. in group: no. with fracture]: 0-4[14:2]; 5-8[35:8]; 9-12[23:7];>12[6:1]). No difference in fracture incidence was evident. No relationship between TBA and BMD was found in either the stroke or control group. BMD was lower in subjects with fracture compared with non fracture patients for all Tinetti bands.

Stroke patients were not found to be at greater risk of fracture compared with institutionalised subjects. SNF subjects had the worst TBA suggesting that more active stroke patients were at greater risk of fracture. Nevertheless BMD at all Tinetti scores was lower in the subjects having fractures. Low BMD is probably more important in fracture risk than instability and should be measured in stroke patients.

Disclosures: ***M.W.J. Davie****, None.*

Characteristics of 252 Community-Dwelling Men and Women with Hip Fracture. A. E. Kearns[1], M. E. Bolander[2], L. A. Fitzpatrick[3]. [1]Division of Endocrinology, Mayo Clinic, Rochester, MN, USA, [2]Department of Orthopedic Surgery, Mayo Clinic, Rochester, MN, USA, [3]Global Development, Amgen, Thousand Oaks, CA, USA.

Hip fracture results in significant mortality and morbidity in both men and women. However, few data have compared the gender differences. We evaluated 252 community-dwelling patients admitted after a hip fracture. Patients with pathologic fracture and significant trauma were excluded. Patients were tracked through the surgical register and cases confirmed by operative reports. Baseline demographics and clinical characteristics were collected by chart review and bedside interview. There were 175 women and 77 men. On average, the men were significantly younger (77.1 ± 12.6 years) than the women (81.5 ± 9.2 years) ($p<0.002$). 25% (n=44) of women and 6% (n=5) of men had a prior diagnosis of osteoporosis ($p<0.0001$). 34 out of the 44 women who had a prior diagnosis of osteoporosis were taking antiresorptive medication (17 estrogen, 11 calcitonin, 4 alendronate, 2 raloxifene), whereas 4 out of the 5 men who had a prior diagnosis of osteoporosis were taking antiresorptive medication (2 calcitonin, 2 alendronate) at the time of the current hip fracture. Previous fracture (vertebral, ankle, pelvis, wrist, or hip) was common with 65 women (36%) and 23 men (29%) having had a prior fracture. Interestingly, in none of the men with a hip fracture prior to the current one (n= 6) had a diagnosis of osteoporosis been made as a result of the first hip fracture. In women 9 of 23 (39%) with a previous hip fracture carried a diagnosis of osteoporosis. 5 women and 6 men were taking oral glucocorticoids at the time of the fracture, but none of the 5 women and only 2 of the 6 men were taking antiresorptive medication. One third of patients had dementia/delirium/altered mental status and were unable to complete interviews during the acute hospitalization. Of those completing interviews, only 18% of women but 36% of men reported being active, 40% of both were sedentary. Only one person was bedridden. Medical conditions potentially causing balance problems were common in both men and women (36%). These data indicate that men and women in the community who sustain a hip fracture share certain characteristics but men are much less likely to be diagnosed with osteoporosis prior to the fracture. A large number of both sexes had prior fracture and highlight the many missed opportunities for earlier intervention.

Disclosures: ***A.E. Kearns****, Merck 2.*

Identification of Women at High Risk for Primary Prevention of Osteoporotic Fracture: Geelong Osteoporosis Study. M. J. Henry*[1], M. A. Kotowicz[1], J. A. Pasco[1], K. M. Sanders*[1], E. Seeman[2], G. C. Nicholson[1]. [1]Clinical & Biomedical Science, The University of Melbourne, Geelong, Australia, [2]Endocrinology, The University of Melbourne, Melbourne, Australia.

Low BMD and previous fracture are independent predictors of subsequent fracture risk. Osteoporosis trials targeting women with osteoporotic BMD and prevalent fracture have confirmed that treatment of this high-risk group is cost-effective. The aim of this case-control study was to determine T-score thresholds among women with no previous fracture that are associated with equivalent fracture risk to those with a previous fracture and femoral neck or lumbar spine BMD ≤ -2.5 (FracOP). From a low trauma fracture cohort (n=668), 291 women (mean age 72yr, range 50-93yr) were identified with fractures of the proximal femur, spine, humerus and distal forearm who had BMD measurements (median time since fracture 59 days). Controls (n=823, median age 70yr, range 50-94yr) were drawn from a random population-based sample recruited concurrently. BMD was measured at the femoral neck and spine using a Lunar DPX-L densitometer, self-reported history of fractures in adult life associated with low trauma was recorded. Optimal cut-points for fracture within the NoFrac group, stratified by age and BMD, were determined by discriminant analysis and fracture risk scores were calculated. Logistic regression determined the fracture risk score threshold that produced an equivalent odds for fracture to that of the FracOP group.

Table 1: T-Scores of equivalent fracture risk (NoFrac *vs* FracOP)

	50-54yr	55-59yr	60-64yr	65-69yr	70-79yr	≥ 80yr
Spine	-4.6	-4.2	-3.9	-3.5	-2.8	-2.0
Femoral Neck	-5.1	-4.7	-4.4	-4.0	-3.2	-2.5

Women with BMD below these thresholds without previous fracture are likely to be at high risk of fracture. Osteoporosis therapy may prove to be cost-effective in this population.

Disclosures: ***M.J. Henry****, None.*

Fractures of the Proximal Femur, Vertebrae, Distal Forearm and Proximal Humerus: Association with Bone Size, Geometry and Strength. C. M. Smith*[1], J. A. Clowes[2], N. F. A. Peel[2], R. Eastell[2]. [1]Research and Development, Barnsley District General Hospital, Barnsley, United Kingdom, [2]Bone Metabolism Group, University of Sheffield, Sheffield, United Kingdom.

We have examined the strength of association between different types of osteoporotic fracture and measurements of bone size and geometry at the proximal femur. We consecutively recruited women (age 55 - 80 years) who had sustained a distal forearm (n = 78), humeral (75), hip (53) or vertebral (73) fracture. These were compared to a population-based sample of 500 postmenopausal women from the Sheffield centre of the Osteoporosis and Ultrasound Study (OPUS study).

Total hip DXA (Hologic QDR4500A) bone mineral content (BMC) and bone area (BA) were measured. We calculated estimated bone volume (BV) using the formula BV = (BA^2 x 3.14)/4, and bone mineral apparent density (BMAD) using BMAD = BMC/BV (Henry YM et al. OI 2004). Hip strength analysis was used to measure parameters of bone size and strength in 498 women (Beck TJ, Johns Hopkins University, USA). Mean Z scores, corrected for age, height and weight were calculated using control data from the population-based postmenopausal women. The difference between fracture syndromes was compared using 1-way ANOVA with a Bonferroni correction for multiple comparisons (Table * P <0.05).

After adjusting for age, height and weight all fracture syndromes had reduced BMC and BMAD however only hip fractures had increased BV. Hip structural analysis of the narrow neck demonstrated a decreased cortical thickness, cross-sectional moment of inertia and section modulus (data not shown) and an increase in buckling ratio in vertebral and hip fractures. Only the hip fracture syndrome demonstrated an increased endocortical diameter. There was no difference in the subperiosteal diameter between fracture syndromes (data not shown).

All fracture syndromes had reduced BMC and BMAD however the pattern of structural changes at the hip differs in the different fracture syndromes. Thus both vertebral and hip fractures had a decrease in section modulus (bending strength) and an increase in buckling ratio (cortical stability) although only in hip fracture syndromes was this related to an increased endocortical diameter. These data suggest hip and vertebral fracture patients may be more at risk of subsequent hip fractures then patients with either humeral or distal forearm fractures.

	Fracture Syndrome			
Variable	Forearm	Humeral	Vertebral	Femoral
BMC ZSc	-0.53*	-0.31*	-0.79*	-0.46*
BV ZSc	-0.05	-0.07	0.12	0.54*
BMAD ZSc	-0.46*	-0.37*	-0.83*	-0.76*
Cortical Thickness ZSc	-0.37	-0.29	-0.84*	-0.75*
Buckling Ratio ZSc	0.28	0.12	1.05*	1.35*

Assessment of Bone Status and Calcium Intake in Children with Minor Trauma Fractures Using Quantitative Ultrasound Measurement at the Radius and The Tibia. S. Ish-Shalom*[1], A. Brecher*[2], G. S. Rozen*[3], N. Ish-Shalom*[4]. [1]Bone and Mineral Metabolism Unit, Rambam Medical Center, Haifa, Israel, [2]Deparment of Pediatrics, Carmel Medical Center, Haifa, Israel, [3]Department of Clinical Nutrition, Rambam Medical Center, Haifa, Israel, [4]Department of Pediatrics, Carmel Medical Center, Haifa, Israel.

Fractures are very common among children. A previous fracture is an independent risk factor for future fractures in osteoporosis. Very few studies examined the bone status in children with fractures.

The purpose of this study was to evaluate the bone status and the calcium intake of pediatric population with fractures due to minor trauma and to assess the relationship between family history of osteoporosis and low impact fractures in children.

Seventy one children that sustained wrist or forearm fractures due to minor trauma were included in our study. Patients with fractures due to a vehicle accident or falling from height were excluded. A detailed medical history was obtained including previous fractures and a family history of osteoporosis and fractures. Weight, height and BMI (body mass index) were determined. Calcium intake was calculated from a 3-days-eating diary reported by the children and their parents. Bone status at the radius and at the tibia was evaluated using a quantitative ultrasound device Sunlight Omnisense (Sunlight Medical Ltd., Tel Aviv, Israel). The measurements were compared with aged matched controls. Mean and SD for the Z-score of the radius and the tibia was -0.5±-1.1 and -2.2±-1.8 respectively. No significant differences were observed between boys and girls. Twenty one (29.6%) patients have sustained more than one fracture. A significant correlation ($r=0.43$, $p<0.001$) was observed between Z-score of the radius and Z-score of the tibia. No significant correlation was found between Z scores of the radius or tibia and the corrected BMI. Multiple fractures were more frequent in children with a family history of osteoporosis ($r=0.3$ $p<0.02$). Thirty six children completed the food diaries. The average calcium intake was 504mg/day ± 232 mg/day. None of the children reached the recommended daily intake adjusted for age, with an average deficiency of 59.3% ± 19.8%. Protein intake was 66.3 ± 20.4 gram/day, with an average excess of 14.6% ± 31.7%.

We conclude that children with a history of low trauma fracture revealed slight decrease in bone mass of the radius and marked decrease at the tibia. Children with a history of low trauma fracture consumed low calcium and a high protein diet. Multiple low trauma fractures were more frequent in children with family history of osteoporosis.

Osteoporotic Fracture Prevalence in an Area of Barcelona (Spain). Relationship with Peripheric Densitometry and Risk of Fracture Questionnary. M. Ciria*[1], L. Perez-Edo[1], J. Blanch*[1], M. Coll*[1], J. Carbonell*[1], I. Gonzalez*[2], J. Fernandez*[3], [1]Rheumatology, Institut Municipal d'Asisténcia Sanitària, Barcelona, Spain, [2]Abs baix guinardo, ICS, Barcelona, Spain, [3]Abs besos, ICS, Barcelona, Spain.

Aims: To assess the prevalence of osteoporosis (OP) and fractures in women over 65 years in an urban area through the use of AccuDEXA. To test the use of accuDEXA and the "FRACTURE" questionnaire to discriminate between patients with bone fragility fractures.

Patients and methods: Prospective population based study. Universe: women over 65 years-old attended in an Primary Care center. Data recorded: height, weight, past fractures, calcium intake, use of tobbacco and alcohol, osteopenizing drugs, maternal hip fracture, years of menarchy and menopause, use of antiresortive drugs.

The FRACTURE questionnaire was applied with no inclusion of bone density (FR1). Also, FRACTURE questionnaire was applied without the question regarding past history of fragility fractures (FR2). The cut-off point in FRACTURE score for "high risk" was 4. Bone density assessment was performed with accuDEXA. Two BMD diagnosis thresholds for OP were defined: (OP1: -2,5 SD, T-score; OP2: -1,65 SD, T-score).

Results: Target population:1.390 women. Noticed of the study:1.077. Enrolled:789. Declined to participate:75. Died:11. Unable to walk:201. Censal errors:82. Age:72.9+/-6 y.; Weight:67.8+/-11 kg; Height:1.52+/- 0.06 m; BMI:29+/-4.5; Menarchy:13.6+/-2 y.; Menopause:48.6+/-5.7y.; calcium intake:0.848+/-0.34 gr/d; BMD:0.439+/-0.076 gr/cm2; T-score:-1.25+/-1.3 SD; OP prevalence:OP1:18.3%; OP2:37.5%; Previous clinical Fx:21.9%: Colles 10.5%, humerus:4.6%, vertebrae:3.4%, ribs:1.8%, hip:1.6%. Odds ratio for fractures through diagnosis of OP (OP1 and OP2) are shown in TABLE 1. FRACTURE scores FR1 and FR2 and their Odds ratio for fracture are shown in TABLE 1. Use of antiresortive therapy:8.9%. No patients with hip fracture were treated; vertebral Fx treated:22%, Colles fracture treated:9%.

Conclusions: Prevalence of fractures was of 21.9%. A great number of patients with fractures were not treated with antiresortive drugs. AccuDEXA was able to discriminate population with a greater risk of fracture. The FRACTURE questionnaire discrimine patients with fractures to the population, also in case of excluding the previous fracture question of the FRACTURE score.

TABLE 1: CORRELATIONS WITH FRACTURES

	OP1	OP2	FR1	FR2
All Fractures	2.4 (1.8-3.2)	1.8 (1.5-2.2)	2.6 (2.1-3.1)	1.5 (1.1-1.9)
Colles Fractures	2.4 (1.8-3.3)	1.9 (1.6-2.3)	1.9 (1.5-2.4)	NS
Ribs Fractures	2.4 (1.3-4.5)	1.7 (1.2-2.6)	2.05 (1.3-3.2)	1.88 (1.1-3.43)
Humerus Fractures	NS	1.4 (1.1-2)	2.2 (1.7-2.9)	NS
Hip Fractures	2.6 (1.4-4.7)	NS	2.8 (2.2-3.7)	2.87 (1.9-4.2)
Vertebral Fracture	2.1 (1.3-3.5)	1.7 (1.3-2.3)	2.23 (1.6-3.01)	1.74 (1.1-2.78)

Predictors of Incident Appendicular Fractures in Men and Women. G. R. Haynatzki, M. R. Stegman*, R. R. Recker, R. P. Heaney. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

A rural population sample, 50+ years of age, was randomly selected for a prospective observational study (The Saunders County Bone Quality Study), consisting of 899 women and 529 men, followed for an average of 3.66 and 3.62 years, respectively. At each visit, they were measured by QUS at the patella and by SPA at distal radius and ulna, and completed a questionnaire on current and past medical history, medication use, dietary calcium intake, alcohol and caffeine consumption, cigarette smoking, fall and fracture history. Here we report the most current results from the low-trauma fracture, independently assessed by two MDs (RPH and RRR). The Cox proportional hazard model (Cox regression) was used to reveal the effect of different predictors on time to fracture. The table below shows the number of first reported low-trauma appendicular fractures (i.e. the unit is a fractured person). The analyses revealed that sex, age, radius BMD, smoking were significant predictors of time to low-trauma fracture while, for example, thyroid problem was marginally significant, at level of significance 0.05. The statistical package SAS was used in all analyses.

Low-Trauma Fracture Reported Site	**Female**	**Male**
Wrist	14	2
Hand	4	2
Ribs	4	3
Pelvis	2	0
Shoulder & Clavicle	4	1
Humerus & Elbow	6	0
Hip	9	0
Femur (distal) & Patella	3	1
Fibula (distal) & Ankle	10	2
Foot	11	3
Total Persons	67	14

Hip Fracture Trends from 1990-2001: Indirect Evidence of Improved Diagnosis and Treatment. N. Goel[1], C. H. Orces*[2], S. Lee*[3]. [1]Internal Medicine, University of Texas Medical Branch, Galveston, TX, USA, [2]South Texas Veterans Health System, Laredo, TX, USA, [3]South Texas Veterans Health System, Laredo and San Antonio, TX, USA.

As the US population ages, hip fracture rates are expected to rise. This rise may be counteracted by increasing awareness of the osteoporosis disease state as well as the availability of more diagnostic and therapeutic options. The purpose of this study is to examine trends in hip fracture hospitalization rates among persons 50 and over in the US.

Data from the National Hospital Discharge Survey were obtained covering the years 1990-2001. Only short-stay or general specialty hospitals with 6 or more staffed beds were included in the survey. Of these, only 6-8% of all eligible hospitals were represented, selected by weighted randomization based on hospital size, to represent an acute sample of the US hospitalized population. All hospital discharges among persons aged 50 years and older with a listed ICD-9 code of 820.0-820.9, corresponding to femoral neck fracture, were included. Annual hospitalization rates by age and gender were determined and then age-standardized and adjusted against the year 2000 US census data.

A total of 985,054 men and 3,014,409 women aged 50 years and older were hospitalized with a hip fracture during 1990-2001. Analyzing overall trends, the estimated number of hip fracture admissions rose 22.3% in women from 217, 813 in 1990 to 266,447 in 2001. In men they rose by 29.5% from 69, 355 in 1990 to 89, 887 in 2001. Looking at yearly data, there was evidence of an interim rise and then fall in hip fracture hospitalizations, with women reaching a peak incidence of 289,127 hospitalizations in 1996 and men, 102,541 hospitalizations in 1998. Examining age-specific rates, hip fracture hospitalization rates did not start to decline in women 65-74 and 75-84 years old until 1996 (R^2=0.52 and 0.95, respectively) and in women 85 and over until 1999 (R^2=0.93). Women under 65 experienced a slight decrease in hospitalization rates over the entire time interval (R^2=0.79). The age adjusted rates in men demonstrated a continued rise in those 65-74 (R^2=0.87), a peak in rates for those 75-84 in 1997 (R^2=0.95), and a peak in rates in those 85 and older in 1998, with a sharp decline from 1999 onwards (R^2=0.93).

Hip fracture hospitalization rates rose until the mid to late 1990's in both women and men. The subsequent decline in overall rates may speak to the Bone Mass Measurement Act and increased availability and use of densitometry and non-pharmacologic and pharmacologic therapies in this time frame. Ageism towards both genders as well as diminished awareness of the occurrence of osteoporosis-related hip fractures in men may help to explain the delay in rate downturn seen in these populations.

Study Design of the Canadian Quality Circle (CQC) Pilot Project in Osteoporosis. M. Doupe*[1], G. Ioannidis[2], A. Papaioannou[2], A. Katz*[1], B. Kvern*[1], A. Hodsman[3], A. Baldwin*[4], D. Johnstone*[5], S. Glezer*[6], J. D. Adachi[2]. [1]University of Manitoba, Winnipeg, MB, Canada, [2]McMaster University, Hamilton, ON, Canada, [3]University of Western Ontario, London, ON, Canada, [4]St. Boniface Hospital, Winnipeg, MB, Canada, [5]Procter & Gamble Pharmaceuticals Inc, Toronto, ON, Canada, [6]Aventis Pharma, Toronto, ON, Canada.

While the Osteoporosis Society of Canada (OSC) guidelines recommend evidence-based management of osteoporosis, recent studies have estimated the proportion of untreated patients in North America to be as high as 80%. A partnership of stakeholders, including the OSC, the Ontario College of Family Physicians, the University of Manitoba and Bone Metabolism Board members, initiated the CQC Project to assess the utilization of these guidelines by primary care physicians (PCP). The primary objectives are to (1) document current PCP practices of fracture prevention treatments in women at risk of osteoporosis and (2) to monitor changes in PCP practices after their participation in accredited educational interventions within a quality circle (QC) framework. This abstract highlights the unique attributes of the CQC interventions, and discusses their potential to optimize PCP care management of osteoporosis.

The CQC Pilot Project is a one year, integrated disease management project designed to assess and monitor changes in PCP's practice patterns as compared to the OSC 2002 guidelines. The 52 PCPs who participated in this initiative formed 7 quality circle (CQ) groups. Each CQ group was lead by a CQ Champion (PCP) and an Expert (specialist). Each member conducted chart reviews and completed standardized data collection forms on 30 patients during the baseline period. Patient inclusion criteria were women age 55 years and over with at least two visits to the PCP in the previous 24 months. PCPs documented their awareness of patient risk factors, and rates of BMD testing and treatment modalities. A total of 1505 data collection forms were faxed to a central database, where PCP specific practice profiles were developed, along with comparative data for each quality circle and project sample. Practice profiles were returned to each PCP, who in turn attended a CME osteoporosis workshop designed to help them understand and improve on their personal and group results. CQ members are in the process of collecting data on 30 additional patients. A second set of profiles will be developed to inform PCPs of changes in their practice patterns since the baseline period.

The Association between Osteoporosis and Oral Bone Loss in Postmenopausal Women. J. Wactawski-Wende[1], E. Hausmann*[2], K. Hovey*[1], S. Grossi*[2], R. Genco*[2], M. Trevisan*[1]. [1]Social and Preventive Medicine, University at Buffalo, Buffalo, NY, USA, [2]Oral Biology, University at Buffalo, Buffalo, NY, USA.

Epidemiological evidence supporting association between osteoporosis and oral bone loss is limited. This study investigated that association in a large cohort of postmenopausal women.

A cross-sectional cohort of 1,341 postmenopausal women aged 53 to 85 were assessed for alveolar crestal bone loss (ACH) and bone density. ACH was determined from oral radiographs with subjects dichotomized on disease severity (none/low vs. moderate/severe). Bone density was assessed using Dual Energy X-ray Absorptiometry (DXA), with severity categories determined by worst T-score measured (Normal >-1.00; Low -1.00 to -2.00; Moderate -2.01 to -2.49; Osteoporotic ≤-2.5).

Compared to subjects in the normal T-score group, the odds worse ACH increased by 39%, 59% and 330% for those with low, moderate and osteoporotic T-scores, respectively. After adjustment for weight, education, hormone use, calcium or vitamin D supplementation and smoking, the association between T-score and ACH remained appreciably unchanged. Further adjustment for age attenuated the association with osteoporotic subjects having twice the odds of being in the worst ACH group (OR=1.90; 95%CI 1.19-3.05). After age stratification, in women <70 there was a significant trend by decreasing T-score category (P<0.02). However, those in the osteoporotic group were significantly associated with worse ACH (OR=1.95; 95%CI 1.20-3.17). However, in women aged 70 and older, the odds of ACH loss was 2.5 to 4.6 fold increased for decreasing T-score category. After adjusting for all factors and age, the odds ratios (and 95% CI) for the low, moderate and osteoporotic groups were 2.66 (1.12-6.29), 2.31 (0.89-6.01) and 3.57 (1.42-8.97), respectively (P for trend=0.026).

This study is the largest to date support the finding that in postmenopausal women, there is a strong and consistent association between worsening T-score and loss of ACH, and that increasing age is an important modifier of that association.

A Meta-analysis of Milk Intake and Fracture Risk. J. A. Kanis, H. Johansson*, A. Oden*, C. De Laet*, O. Johnell, J. A. Eisman, E. V. McCloskey, D. Mellstom, H. Pols, J. Reeve, A. Silman, A. Silman. Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom.

WHO Collaborating Centre for Metabolic Bone Diseases, University of Sheffield Medical School, Beech Hill Road, Sheffield S10 2RX, UK

A low intake of calcium is widely considered to be a risk factor for future fracture. The aim of this study was to quantify this risk on an international basis and to explore the effect of age, gender and bone mineral density (BMD) on this risk.

We studied 39,563 men and women (69% female) from 6 prospectively studied cohorts comprising EVOS/EPOS, CaMos, DOES, the Rotterdam study, the Sheffield study and a cohort from Gothenburg. Cohorts were followed for 152,000 person-years. The effect of calcium intake as judged by the intake of milk on the risk of any fracture, any osteoporotic fracture and hip fracture alone was examined using a Poisson model for each sex from each cohort. Covariates examined were age and BMD. The results of the different studies were merged by using the weighted β-coefficients.

A low intake of calcium (less than 1 glass of milk daily) was not associated with a significantly increased risk of any fracture, osteoporotic fracture or hip fracture. There was no difference in risk ratio between men and women. When both sexes were combined there was a small but non-significant increase in the risk of osteoporotic and of hip fracture. There was also a small increase in the risk of an osteoporotic fracture with age which was significant at the age of 80 years (RR = 1.15; 95% CI = 1.02-1.30) and above. The association was no longer significant after adjustment for BMD. No significant relationship was observed by age for low milk intake and hip fracture risk.

We conclude that a low intake of milk is not associated with any marked increase in fracture risk and that the use of this risk indicator is of little or no value in case-finding strategies.

Parental Hip Fracture Predicts Falls, Fractures and Low Bone Density in Early Postmenopausal Women. R. J. Honkanen, H. Kröger, M. Tuppurainen*. Bone and Cartilage Research Unit, University of Kuopio, 70211 Kuopio, Finland.

Family history predicts fractures but only part of the effect seems to go through low bone mineral density (BMD). Our purpose was to determine this effect in middle-aged women and to evaluate if it is related to falling risk or bone density.

We examined the role of parental history of hip fracture in the occurrence of fractures and falls in Finnish women from a defined geographic area. The population-based cohort consisted of 11074 OSTPRE (Osteoporosis Risk Factor and Prevention Study) women born in 1932-41 who responded to three postal enquiries in 1989, 1994 and 1999. Eight hundred and seventy-eight women reported a parental hip fracture in the 1994 enquiry. Fractures during 1989-99 reported by 1915 women were validated by perusal of patient records. 4695 women reported a fall within the last 12 months either at 1994 or 1999.

Women with a history of parental hip fracture had a 29 % higher fracture risk (p=0.004) and a 22 % higher falling risk (p=0.005) than women without such a history. Adjustments did not affect these relationships. Parental hip fracture predicted also fractures (N=932) sustained after the acquisition of exposure information (+39 %; p=0.003) but did not predict subsequent falls (+14 %; p=0.119). Adjusting for age, height, weight, HRT, calcium intake, smoking, fracture history or falling at 1994 affected only slightly the association between parental fracture and fracture during 1994-1999.

In a random sample of 1244 of these women, femoral and spinal BMDs, measured thrice during the 10-year follow-up, were 3-4 % lower (p values ranging from 0.005 to 0.031) in the 105 women with a history of parental hip fracture than BMDs in other women. Adjusting for baseline age, menopausal status, height, weight, calcium intake and fracture history as well as for HRT ad 1994 and falling at 1994 slightly decreased the difference. This subsample was too small to study the effect of parental fracture on fracture incidence.

We conclude that parental fracture is a moderate predictor early postmenopausal fracture. Falling history does not considerably modulate this relationship.

M358

Improved Diagnostic Precision by Modifying 4 Decision Rules Replacing Weight by Body Mass Index (BMI) to Identify Chilean Women with Low Bone Mineral Density (BMD). C. Campusano*[1], C. Rodriguez*[1], M. Cabezas*[1], P. Viviani*[2], O. Contreras*[3], R. Pruzzo*[4], H. Amaral*[4], G. Gonzalez[1], J. Lopez*[1], E. Arteaga*[1]. [1]Endocrinology, Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Public Health, Pontificia Universidad Catolica de Chile, Santiago, Chile, [3]Radiology, Pontificia Universidad Catolica de Chile, Santiago, Chile, [4]Nuclear Medicine, Clinica Alemana, Santiago, Chile.

Decision rules developed in North America to identify women who require BMD testing have high false positive rates leading to an excess of normal subjects tested, which raises the cost of osteoporosis screening. The value of including height to improve their usefulness has not been evaluated, especially in a lower height population as the Chilean . Aim: To compare 4 international rules, modified by considering BMI instead of weight to identify low BMD Chilean postmenopausal women. Subjects and Methods: A questionnaire was performed in a cohort of postmenopausal Chilean women, followed by bone densitometry (DXA, LUNAR). Subjects using bone sparing drugs other than calcium or estrogens were excluded. We calculated scores for the following rules: National Osteoporosis Foundation (NOF), Osteoporosis Risk Assessment Instrument (ORAI), Age, Body Size, No Estrogen (ABONE) and Simple Calculated Osteoporosis Risk Estimation (SCORE), in which a 10 point cut level was used due to the absence of black race in our country. Obtained scores were analyzed versus BMD at lumbar spine and hip. Sensitivity, specificity, positive predictive value(PPV), negative predictive value(NPV) and area under the receiver operating characteristic curve (AUROC) were calculated. Subgroup analysis was performed in <65y. Results: 737 women, mean age 60.4±9.2years, were classified according to spine and/or hip BMD as osteopenic (45.5%), osteoporotic (17.2%) and below treatment threshold (T score <-2) (32.2%). Thirty nine percent were taking calcium preparations and 62% were current or former estrogen users. Diagnostic precision of classic and modified $_{(m)}$ decision rules is presented in %:

	NOF/ NOF(m)	ORAI/ ORAI(m)	SCORE/ SCORE(m)	ABONE/ ABONE(m)
Sensitivity	80.2 / 84.3	80.9 / 66.9	76.9 / 62.2	40.5 / 58.5
Specificity	35.9 / 27.5	50.5 / 70.5	31.0 / 73.2	69.3 / 73.5
PPV	19.7 / 18.6	24.3 / 30.8	17.9 / 30.7	20.6 / 29.6
NPV	90.2 / 89.5	93.1 / 91.6	83.4 / 91.0	85.6 / 90.3
False Positive	80.3 / 81.4	75.7 / 69.2	82.1 / 69.3	79.4 / 70.4
False Negative	16.4 / 10.1	6.9 / 8.4	12.6 / 15.9	14.4 / 9.7
AUROC(m) (CI)	0.58 (0.54-0.61)	0.72 (0.69-0.75)	0.73 (0.69-0.76)	0.69 (0.66-0.73)

Conclusions: In this cohort, replacement of weight by BMI in decision rules improves specificity, allowing better discrimination in whom not to test. ORAI, SCORE and ABONE had better diagnostic precision than NOF. In the subgroup of <65y ORAI and ABONE had the best specificities (data to be shown).

Disclosures: ***C. Campusano****, None.*

M359

Predictors of Osteoporosis in Young Women - a Case Population-based Control Study from BC CaMOS. J. C. Prior, C. Hitchcock*, F. Kirson & YOW*. UBC, Van Hosp CeMCOR, Vancouver, BC, Canada.

The population-based bone studies in premenopausal women show osteopenia related to age, weight, menarche, milk and lower progesterone [1-3]. Fractures occur in amenorrhea and anorexia. Cognitive dietary restraint (Restraint), perception of limiting food intake to prevent weight gain [4], is associated with lower DXA [5], higher cortisol levels [6] and ovulation disturbances [7]. The purpose of this secondary analysis from a participatory study (Young Osteoporosis Women, YOW) was to compare Restraint and reproductive variables in young women with self-identified low bone density (cases=YOW) to a similar age-stratified population-based sample with normal DXA (controls=CaMOS). YOW participants had osteoporosis (15) osteopenia (9) and 11 reported fractures (4 hip). YOW researchers met monthly, created an interviewer-administered questionnaire (IAQ) that also included items from the CaMOS IAQ [8] and interviewed 24 women. All YOW interviews were taped, blinded and transcribed. Of 123 women 25-49 years old in BC CaMOS, 44 were excluded for menopause (5/123) and DXA $\leq$-1SD (39/123) [9]. Variables include age, skipped 3 cycles (Y/N), # periods skipped (continuous), menarche age, family osteoporosis history (FHO, Y/N), Restraint (0-3 scale; assessed using 3 items from the 21-item restraint subscale of the Three-Factor Eating Questionnaire[4]) and molimina (Y/N = usually able to tell the period is coming based on axillary breast tenderness). Results compared 24 YOW cases and 79 CaMOS controls. Data reported as mean [95% confidence intervals]. The groups were similar in age (41.6 vs. 40.4), parity (0.50 vs. 0.58) and menarche (12.7 vs. 12.7). Skipped periods occurred in 46% of YOW with a mean of 12.7 [1.9,23.5] and 10% of CaMOS mean 5.4 [-0.39,11.3]. FHO was present in 76% (n=17) YOW and 14% of CaMOS participants, and Restraint scores were 1.58 [1.10,2.06] and 1.18 [0.94,1.41]. Backward stepwise logistic regression analysis of YOW including all variables except age and FHO showed that skipped periods (P=0.005) and Restraint (P=0.024) stayed in the model and explained 17.3% of the variance. This case-population control study suggests young women skipping 3 or more cycles and having higher cognitive dietary restraint are more likely to have osteoporosis and fractures than women in the general population.

Association of Increased LDL-cholesterol Levels with Osteoporosis in Postmenopausal Women. F. Tremollieres[1], J. Fillaux*[2], J. Pouilles*[1], V. Cances-Lauwers*[2], C. Ribot[1]. [1]Hôpital Paule de Viguier, Menopause Unit, Toulouse, France, [2]CHU Purpan, Department of Epidemiology, Toulouse, France.

Several studies suggest that osteoporosis is associated with increased cardiovascular morbidity and mortality in postmenopausal women. The aim or this study was to assess the relationship between BMD, bone remodeling markers and plasma lipid profile in a large cohort of early menopausal women. We selected 1961 women aged 45 to 65 years old who attended our menopause clinic for a general « menopause check-up ». According to the menstrual status and serum FSH and estradiol levels women were classified as early perimenopausal (PM), late PM or postmenopausal women. All women were free of past or current cardiovascular diseases and none had ever received ERT/HRT, lipid lowering drugs or drugs affecting bone metabolism. Fasting blood and urine samples were collected for determination of plasma lipids and lipoproteins and bone remodeling markers (osteocalcin, bone alkaline phosphatase and urinary C-telopeptide of type I collagen). Vertebral and femoral BMD were measured using DXA (GE Lunar).The relationship between BMD (categorized as normal, osteopenia and osteoporosis) and the lipid and bone remodeling variables were tested using multiple logistic regression analyses. According to the WHO classification, 914 women were considered as osteopenic (op) and 214 as osteoporotic (OP). All bone remodeling markers were significantly increased both in op and OP women ($p<0.001$) as compared to normals. Mean total cholesterol (CT) and LDL-cholesterol (LDL-C) plasma levels were also significantly increased in OP as compared to normals, but not in op women. In multiple regression analyses, all bone remodeling markers, menopausal status, time since menopause, LDL-C and BMI were independently and significantly associated with the prevalence of osteoporosis. Women with LDL-C levels $\geq$ 1,30 g/l had an odds ratio of 1.71 [95% CI 1.12-2.62] to be classified as OP compared with women with LDL-C < 1,30 g/l. The results or this study show that women with increased LDL-C levels have a greater risk of being OP compared with women whith normal LDL-C levels. Because bone remodeling markers were also significantly increased in women with increased LDL-C levels compared to women with normal LDL-C levels, it could be hypothesized that LDL-C might increased bone turnover which in turn would contribute to osteoporosis. Additional studies are needed to clarify this hypothesis.

Do Differences in Body Fat Contribute to Variation in 25-hydroxyyvitamin D Values by Age and Race in Women? A. C. Looker. National Center for Health Statistics, CDC, Hyattsville, MD, USA.

Obesity has been linked to lower serum 25 hydroxyvitamin D values, but whether this relationship is the same across age and race is not clear. To explore this question, the relationship between 25(OH)D and percent body fat (%BF) was examined by race and age in 6042 women from the third National Health and Nutrition Examination Survey (NHANES III, 1988-94). The sample consisted of 3567 non-Hispanic white and 2475 non-Hispanic black females ages 12+ years. 25(OH)D values were measured with an RIA kit (DiaSorin, Stillwater MN), while %BF estimates were calculated from bio-electrical impedance analysis. Results were compared before and after adjusting for several confounding factors: month of blood collection, dietary vitamin D intake, supplement use, milk or breakfast cereal consumption, urban/rural residence, smoking, hormone use and physical activity. Regression analyses revealed a significant age*race*body fat interaction with 25(OH)D values ($p<0.0000$). %BF was significantly negatively related to 25(OH)D levels in white females across the age range, but among blacks the relationship was significant only in the younger groups. The strength of the relationship was stronger in whites (e.g., regression coefficients were ~4 times greater on average) than in blacks within the same age group. Within race, the relationship was stronger in younger than older individuals (e.g., on average regression coefficients were ~3 times greater in those under age 50). Adjusting for confounders reduced, but did not remove, the differences in relationship strength. Differences in mean 25(OH)D by race before vs. after adjusting for %BF were also only slightly affected: 1.63 vs. 1.55 times higher in whites, respectively. In conclusion, the relationship between body fat and 25(OH)D in women varies both by age (more pronounced in younger than older persons), and race (more pronounced in whites than blacks). Differences in obesity appear unlikely to play a major role in explaining variation in 25(OH)D by age or race.

Contribution of Hip Strength Indices to Hip Fracture Risk in Elderly Women and Men. H. G. Ahlborg, N. Nguyen, T. V. Nguyen, J. R. Center, J. A. Eisman. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

This study was designed to characterize the association between hip strength indices and hip fracture risk in relation to bone mineral density (BMD) in an elderly population. From the prospective, population-based Dubbo Osteoporosis Epidemiology Study, 1902 subjects that had baseline measurements of BMD by dual energy x-ray absorptiometry (Lunar DPX-L) at the femoral neck were analysed. Of these, 71 women and 25 men aged 60 and above, sustained a hip fracture during the study period of 1989-2003. These subjects were randomly matched for age with 142 women and 50 men (ratio of case:control; 1:2) who had not sustained any fracture. Hip strength indices, including femoral neck diameter (FND), cross-sectional moment of inertia (CSMI), section modulus (Z), cross-sectional area (CSA) and compressive stress (Cstress) were estimated by reanalysis of the image files using hip strength analysis software. The association between these measures and hip fracture risk were considered in a multiple conditional logistic regression model. A Bayesian approach was used to estimate the odds ratio for each risk factor in men.

BMD-adjusted odds ratio for hip fracture for each SD difference in each parameter.

	BMD-adjusted odds ratio (95% CI)		
	Women	Men	Men (Bayesian analysis)
FND	**1.6 (1.0, 2.7)**	1.3 (0.7, 2.4)	**1.5 (1.0, 2.3)**
CSMI	**1.8 (1.0, 3.2)**	1.3 (0.6, 2.5)	**1.6 (1.0, 2.5)**
Z	**2.3 (1.1, 5.1)**	2.3 (0.95, 6.3)	**2.3 (1.4, 3.9)**
CSA	2.2 (0.7, 6.9)	1.3 (0.4, 4.6)	1.5 (0.8, 2.8)
Cstress	1.3 (0.7, 2.3)	1.7 (0.5, 5.2)	1.4 (0.91, 2.3)

In women, after adjustment for BMD, smaller FND, lower CSMI or Z were each significantly associated with hip fracture risk. In men none of these hip strength indices was significant. However, using the results in women as a prior distribution, it was estimated that the BMD-adjusted odds ratio for FND, CSMI or Z were each significantly associated with hip fracture risk in men. In the logistic regression model, BMD alone accounted for 32% and 16% of the variance of fracture liability, in women and men respectively. The addition of FND, CSMI or Z to the model increased the respective variance proportion to 34% and 19%.

These data suggest that smaller FND, lower CSMI or Z are independent risk factors for hip fracture in both women and men. However, the contribution of these measures to hip fracture prediction independent of BMD was modest in this long term prospective study in elderly women and men.

Smoking as a Major Osteoporosis Risk Factor Among Iranian Australian Women. A. Baheiraei[1], N. A. Pocock[1], J. E. Ritchie*[2], J. A. Eisman[1], T. V. Nguyen[1]. [1]Bone and Mineral Research Program, Garvan Institute of Medical Research, St Vincent's Hospital,University of New South Wales, Sydney, Australia, [2]School of Public Health and Community Medicine, University of New South Wales, Sydney, Australia.

While the prevalence and risk factors of osteoporosis in Caucasian populations have been well documented, such a profile has not been studied in Iranian Australian women. The present study was designed to estimate the prevalence and lifestyle risk factors of osteoporosis among Iranian women in Sydney, Australia.

Ninety women aged 35 years and older were recruited via a media campaign and community invitation. All subjects completed a questionnaire on socio-demographic background and lifestyle factors, including dietary calcium intake, cigarette smoking , alcohol consumption, and physical activity. Weight and height were recorded and body mass index (BMI) was calculated. Bone mineral density (BMD) was measured at the lumbar spine and femoral neck using dual-energy X-ray absorptiometry. A BMD T-score of less than -2.5 using the Australian reference database was considered as osteoporosis.

The average age of the women was 48 years, with 42% being postmenopausal. Approximately 37% of women were considered obese (body mass index $\geq$ 30 kg/m^2). Of all the anthropometric and lifestyle risk factors considered, advancing age, lower body weight and smoking were independently associated with lower BMD. These factors collectively accounted for 30 % and 38% variance of lumbar spine and femoral neck BMD, respectively. The proportion of women with osteoporosis was 12.2% at the lumbar spine and 2% at the femoral neck. These data, for the first time, indicate that the prevalence of osteoporosis in the Iranian women is comparable to Caucasian women, and more importantly, cigarette smoking is a major modifiable lifestyle risk factor of osteoporosis in this population.

Effects of Age and Gender on Bone Histomorphometry of Iliac Crest Biopsies from 89 Healthy Individuals. J. D. Sibonga[1], S. S. Cha*[2], D. E. Jewison*[1], R. T. Turner[1]. [1]Orthopedics, Mayo Clinic, Rochester, MN, USA, [2]Biostatistics, Mayo Clinic, Rochester, MN, USA.

There are few published studies investigating the effects of age and gender on bone histomorphometry in healthy humans. We performed such an analysis on 89 archived iliac crest biopsies obtained from subjects (46 women and 43 men), who were recruited specifically as healthy controls for 3 IRB-approved protocols (1981-1990). The median ages for the men and women were 48 and 56 years, respectively. Static and fluorochrome-based dynamic measurements were performed on newly prepared biopsy tissue slides. Gender-specific differences between age-adjusted means (ANCOVA, F-test) were determined for 19 indices. Gender data were correlated to age to elucidate temporal changes for each index. The effect of menopausal status was also evaluated in female data (Wilcoxon Rank Sum Test). All reported differences and correlations have p values <0.1 with significance considered at p<0.05

The age-adjusted means for osteoid width, osteoblast-osteoid interface and osteoid maturation were lower and mineralization lag time higher in men. Women had greater age-adjusted means for eroded surface, labeled surfaces (single and double), bone formation rates (surface and volume referents) and adjusted appositional rate. There was no gender difference in cancellous bone volume but trabecular separation was greater in men.

The following indices in male biopsies were negatively correlated with age: cancellous bone volume, trabecular number, osteoclast number, mineral apposition rate, adjusted apposition rate and bone formation rates (surface and volume referents). The age effect was greatest on mineral apposition rate (p<0.005). Additionally, there was a positive correlation between trabecular separation and age in men. In women, a positive correlation with age was noted for osteoid surface and volume, osteoclast number, double-labeled surfaces and trabecular thickness; there was a negative correlation with cortical thickness.

Post-menopausal women (n=33) had greater numbers of osteoclasts but reduced eroded surfaces than pre-menopausal women (n=13).

Histomorphometry suggested that sex differences in iliac crest bone biopsies were partly due to gender-specific changes in bone turnover and bone balance. Age-related bone loss seen in men was due to an unbalanced reduction in matrix production and mineralization, while an increased but balanced bone turnover maintained bone mass in the healthy women. These results indicate the importance of gender- and, to a lesser extent, age-matched reference values when using iliac crest histomorphometry to diagnose abnormalities in bone architecture, quality and turnover.

Is Nullyparity a Risk for Post-menopausal Fracture? L. M. del Rio, S. Di Gregorio*, J. Rosales*. Bone densitometry, CETIR.Centre Medic, Barcelona, Spain.

Reproductive history may affect bone mass in post menopausal women. Several authors have correlated the nulliparity with a lower bone mineral density in post menopausal women.

The aim of this study was to evaluate the parity effect on fracture incidence in post menopausal women

We included 2926 nulliparous women (61 ± 7.5 year of age) and 3306 multiparous women, who had given birth to ≥ 3 children, (60 ± 7 years of age). Lumbar spine and femoral bone mineral density were measured by DEXA (GE-Lunar). Fracture history, age of menarche, age of menopause, physical activity, smoking status and calcium intake were evaluated by a questionnaire.

T- test was used to compare means between nulliparous and multiparous group. A multiple regression test was used to determine correlations between both groups.

All results showed statisticaly differences between groups. Nulliparous women had a lower BMD in lumbar spine (0.947 g/cm2 vs 0.977g/cm2; p<0.001), femoral neck (0.787g/cm2 vs 0.822g/cm2; p<0.001), trochanter (0.656g/cm2 vs 0,694g/cm2 p< 0.001), and total femur (0.843g/cm2 vs 0.890g/cm2;p<0.001). Nulliparous and multiparous had the similar osteoporotic fracture incidence (577 vs 544), but the hip fracture incidence was higher in nulliparous women (58 vs 29) while the incidence of vertebral (213 vs 202) and wrist (306 vs 303) fracture was similar. To explain this results we studied another variables (Weight, BMI; BMD). We founded a statistical significant difference in weight, and BMD in, lumbar spine, femoral neck and total femur between both groups: nulliparous women weighing less, and had a lower BMD.

In conclusion, the nulliparity is related with a high risk to hip fracture in postmenopausal women perhaps due to physical changes related to morphological changes in femur that could explain the difference in fracture incidence only in this skeletal site.

Prevalence of Risk Factors for Osteoporosis and Rate of Bone Density Testing Among Young Menopausal Women. M. T. Connelly*[1], S. Oddleifson*[2], L. Bernstein*[2], J. Frampton*[2], J. Gifford*[2], T. Ireland*[2], M. Kelly*[2], M. Levy*[2], K. Salvato*[2], R. Shames*[2], D. Tafone*[2]. [1]Ambulatory Care and Prevention, Harvard Medical School and Harvard Pilgrim Health Care, Boston, MA, USA, [2]Women's Health Lead Team, Harvard Pilgrim Health Care, Boston, MA, USA.

The purpose of this study was to determine the prevalence of risk factors for osteoporosis among women age 50-64 who were members of a large managed care organization in New England and to evaluate the rate of bone mineral density (BMD) testing among those with risk factors. Risk factors for osteoporosis included discontinuation of hormone therapy, exposure to steroids or anti-seizure medications, fracture of bones other than skull, face, fingers, or toes, or evidence of tobacco use. Women with these risk factors who were continuously enrolled in the health plan between 2000 and 2003 were identified from the automated data systems. For the evaluation of BMD testing rate, women were excluded from the analysis if they had, between 2000-2002, a BMD test, use of medication for osteoporosis, or diagnosis of osteoporosis. The outcome of interest was proportion completing a BMD test at 6 months and 12 months after 2002. Of the 39,110 women who were members from 2000-2003, 6,852 (18%) had documentation of at least one of the risk factors of interest. Of those with risk factors, 3,371 (49%) had not had BMD testing, diagnosis of osteoporosis or treatment for osteoporosis between 2000-2002. Among these 3,371 women, evidence of tobacco use was found in more than half (53%). The second most common risk factor was fracture (26%). In the first 6 months of 2003, 454 (13.5%) of the women with risk factors had a BMD; an additional 390 (11.5%) completed a BMD test by the end of 2003. In total, 25% (844/3371) of the young menopausal women age 50-64 with risk factors for osteoporosis and no testing for, diagnosis of, or treatment of osteoporosis in the prior 2 years had a BMD during the one year window of evaluation. We conclude that strategies for improving testing among high-risk women are needed to optimize care for this population.

Height Loss: A Predictor of Low Forearm Bone Mineral Density, but not of Bone Loss in Postmenopausal Women. The Health Study of Nord-Trøndelag (HUNT), Norway. S. Forsmo[1], H. M. Hvam*[2], M. Larssen*[2], A. Langhammer*[1]. [1]Dept. of Public Health and General Practice, Norwegian University of Science and Technology, Trondheim, Norway, [2]Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, Norway.

Height loss is a predictor of osteoporosis and fractures. This particularly counts for spine fractures, but has also been shown for other fractures. Less is known concerning the relation between height loss and appendicular bone loss. The purpose of this study was to investigate the association between height loss and forearm bone mineral density (BMD) and bone loss in postmenopausal women. In 1984-86 (HUNT I) and 1995-97 (HUNT II) all inhabitants in the county of Nord-Trøndelag aged >19 years (about 92,000) were invited to the HUNT study, a multipurpose health survey. Among 2749 women born between 1924 and 1941 having participated in HUNT I, a total of 2151 underwent forearm BMD measurement in HUNT II and 1390 in a follow-up study in 2001 (mean interval 4.6 years). Baseline BMD data of 2148 (mean age 65.8) and longitudinal data of 1383 postmenopausal women (mean age 68.9) were eligible for analysis. BMD measurements were performed by single X-ray absorptiometry (Osteometer DTX 100) at the distal and ultradistal non-dominant forearm. Weight (kg) and height (cm) were measured at all three occasions with light clothing and without shoes. Mean height loss during the 11.3 years between HUNT I and HUNT II was 1.30 cm (95% CI: 1.24; 1.36), and 1.42 cm at the follow-up study (interval of 15.9 years). Age was a significant determinant of height loss, 20% of the women aged >69 at HUNT II had lost 3 cm or more compared to 5% of women <60 years ($p<0.001$). At baseline in HUNT II there was a statistically significant negative association between forearm BMD and height loss (HUNT I-HUNT II) adjusted for age, weight, smoking, years since menopause (YSM) and hormone therapy (HT). Odds ratio (OR) for forearm T-score 3 cm compared to those with height loss of 1-2 cm, (adjusted for age, weight, YSM, smoking, HT and height at HUNT I). Mean reduction in distal forearm BMD during the 4.6 years was 19 mg/cm2 (4.9%), this loss was not associated to age. No statistically significant association was found between bone loss and height loss from HUNT I to follow-up. Statistically significant predictors of forearm bone loss were weight (negative), smoking (positive), HT (negative) and BMD at baseline (positive).
In conclusion, height loss is a strong predictor of low forearm BMD in postmenopausal women. In this study, with rather short follow-up time, no association between forearm bone loss and height loss was found.

Two Cases of Obese Women With Atraumatic Fractures Associated with Normal BMD and Low Bone Turnover with Hypomineralization. T. J. Vokes[1], P. Roschger*[2], A. Nader*[3], P. Fratzl*[4], K. Klaushofer[2]. [1]Medicine/endocrinology, University of Chicago, Chicago, IL, USA, [2]Ludwig Boltzmann Institute of Osteology, 4th Med. Dept., Hanusch Hospital & UKH-Meidling, Vienna, Austria, [3]Institute for Pathology, Hanusch Hospital, Vienna, Austria, [4]Department of Biomaterials, Max Plank Institute of Colloids and Interfaces, Potsdam, Germany.

In post-menopausal women the fracture risk is increased by low BMD and high bone turnover. We encountered two subjects with extreme bone fragility and clinical presentation different form the usual patients with postmenopausal osteoporosis. A 58 year old woman with high BMI (48.1), no risk factors for osteoporosis and normal BMD (T-score +3.5 at the spine and -0.6 at the left femoral neck, but +3.3 at the right femoral neck prior to its fracture) had atraumatic fractures of the right femoral neck, left femoral shaft, 3 ribs and several stress fractures of the feet. The second patient, a 66 year old woman (BMI=30.9) with early menopause (age 38) but no other risk factors for osteoporosis, had 2 vertebral fractures with a fall at age 58 and was despite having a normal BMD started on alendronate. In the subsequent 7 years she fractured both femoral shafts and multiple ribs without trauma. In both patients serum values of calcium, Vit D and PTH were normal while the biochemical markers of bone turnover (serum osteocalcin and urinary NTx) were in the normal premenopausal range. The patients underwent tetracycline labeled transiliac bone biopsy. Histomorphometric evaluations of undecalificed 5 micron sections of plastic embedded bone biopsies revealed normal bone volume (BV/TV= 15.6 and 15.2 %, respectively), but extreme low static parameters of bone formation and resorption. The dynamic bone parameters of bone formation could not be obtained, because tetracycline labeling was undetectable. A quantitative backscattered electron imaging (qBEI) method was used to assess the bone mineralization density distribution (BMDD) and revealed a reduction on degree of mineralization of the bone matrix (CaPeak= -4.3% and -3.4%) to healthy controls (n=52). This was accompanied by a broadening of the distribution peak (CaWidth= +18.2% and +17.1%) indicating a more heterogeneous mineralization. The moderate reduction in degree of mineralization may contribute, but is not likely to account alone for the high bone fragility observed. These results suggest that some patients with extreme bone fragility may have a yet unclassified disorder characterized by a combination of low bone turnover and hypomineralization often misclassified as established osteoporosis. Recognizing this disorder may be clinically important for treatment decision.

Localization of the Cancellous Bone inside the Human Lumber Vertebra. S. Hamai*, T. Mawatari*, H. Miura*, T. Shuto*, Y. Nakashima*, H. Yamada*, K. Okazaki*, T. Kawano*, N. Tsukamoto*, Y. Iwamoto*. Department of Orthopaedic Surgery, Graduate School of Medicine, Kyushu University, Fukuoka, Japan.

Clinical evaluation of bone mineral density (BMD) is commonly performed in the lumber vertebra by dual x-ray absorptiometry (DXA), however the localization of the cancellous bone inside the lumber vertebra cannot be taken into consideration. The purpose of this study was to evaluate postmenopausal women by high-resolution computed tomography (HRCT) in vivo. We examined 20 osteoporosis subjects including 12 rheumatoid arthritis (RA) and 8 non-RA subjects and 20 non-osteoporosis subjects including 15 RA and 5 non-RA subjects. A total of those 40 (mean 61.0 years) were examined by DXA, and the whole body of the third lumber vertebra was scanned by HRCT at a spatial resolution of 351x 351 x 500 micron. All the gray-value slice images were then noise-eliminated, segmented. Preliminary experiments on the cadaveric human third lumber spine were designed specifically to select the correct threshold value. Finally, from the reconstructed 3-dimensional (3-D) volume data, arbitrary-shaped trabecular bone volume that is then divided into six parts (upper anterior, upper posterior, middle anterior, middle posterior, lower anterior, lower posterior) was extracted. Bone volume fraction (%) of each part was calculated, and 3-D image reconstruction was done. A total of those 40 were divided into four groups (Osteoporotic RA group, Osteoporosis group, RA group, and Control group). Average standard deviation of BMD by DXA were -3.162 ± 0.61, -3.158 ± 0.478, -1.379 ± 0.341, and -1.606 ± 0.853, at Osteoporotic RA group, Osteoporosis group, RA group, and Control group, respectively. In the Osteoporotic RA group, the upper and the lower anterior parts were significantly lower than the middle posterior part. In the RA group, the upper and the lower anterior were significantly lower than the upper and the middle posterior and the lower posterior was significantly lower than the middle posterior. In the Osteoporosis group and the Control group, relatively low-density areas were found in the anterior parts and the lower posterior, but the difference didn't reach statistical significance. Our study had three major findings. First, systematic density patterns inside the vertebral body were classified as the inhomogeneous pattern and the relatively homogeneous pattern. Second, regardless of the degree of osteoporosis, degree of the localization of the cancellous bone inside the vertebral body for RA subjects was more inhomogeneous than for non-RA subjects. Third, relatively low-density areas were found in the anterior parts and the lower posterior of the vertebral body.

Premenopausal Women with Idiopathic Osteoporosis Have Histomorphometric Evidence of Decreased Bone Formation. M. A. Donovan[1], H. Zhou*[2], D. McMahon*[1], D. Dempster*[2], E. Shane[1]. [1]Medicine, College of Physicians and Surgeons, Columbia University, New York, NY, USA, [2]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

Most young people with osteoporosis (OP) have an identifiable cause. Others have an idiopathic form for which no contributory etiology can be found. We have previously reported that men with idiopathic osteoporosis (IOP) have histomorphometric evidence of decreased bone formation and osteoblast dysfunction. The pathogenesis of IOP in young women is unclear. Our aim was to characterize the histomorphometric features of IOP in otherwise healthy premenopausal women. Nine such women, who presented to our clinic with OP and fragility fractures, underwent tetracycline labeled transiliac bone biopsies after secondary causes of OP were excluded by history and biochemical testing. All women were Caucasian. Mean age at diagnosis and menarche was 32.7 and 13.7 yrs respectively. Mean BMI was 21.9 kg/m^2. All had ≥1 fragility fractures and 4 had sustained hip fractures. Three were on oral contraceptives and 5 were taking calcium. Three reported a family history of OP. Mean T-score (±SD) was -2.1±1.0 at the spine and -1.7±1.3 at the hip. Compared to biopsies of age, sex and race matched controls (n=18), significant differences in bone structure and turnover were identified, particularly in cancellous bone. Although cancellous bone volume did not differ, there was a trend toward lower trabecular number (1.7±.2 *vs* 1.9±.2; p=.11) and increased separation (428.6±59.1 *vs* 387.6±73.2um; p=.16) in women with IOP. In cancellous bone, although there was no increase in osteoid thickness or surface, IOP patients had lower bone formation parameters including a 12% reduction in wall width (46.5± 4.0 *vs* 41.1±5.5 um; p<.01), an 18% decrease in mineral apposition rate (0.67±0.11 *vs* 0.82±0.09um/day; p<.01) and a 42% reduction in mineralizing surface (3.8±1.7 *vs* 6.5±3.1%; p=0.02). Similarly, the bone formation rate was 52% lower (.026±0.01 *vs* .054±.03um/um^2/day; p<.01) and the activation frequency was 38.5% lower (0.32±0.30 *vs* 0.52±0.24 cycle/year; p=.07) in IOP patients. Conversely, bone resorption was increased among IOP patients, as reflected by a markedly longer resorption period (RP) (134.2±103.9 *vs* 38.1±23.8 days; p=0.02) and increased eroded surface (ES) (5.5±2.1 *vs* 4.1±1.6%; p=.059). Similarly, wall width and mineralizing surface were significantly lower in endocortical bone and RP and ES were higher in intracortical bone. In summary, women with IOP have evidence of increased bone resorption and decreased bone formation. We conclude that women with IOP have uncoupling of resorption and formation and, like men with IOP, have evidence of relative osteoblast dysfunction.

M371

Is a Bolster Necessary to demonstrate the Dynamic Mobility of Vertebral Fractures? F. E. McKiernan, R. Jensen*. Center for Bone Diseases, Marshfield Clinic, Marshfield, WI, USA.

Dynamic mobility (DM) is a change in vertebral compression fracture (VCF) configuration between standing and supine cross-table lateral radiographs (vertebroplasty series; VpS). DM may be correlated with greater fracture severity, the presence of intravertebral clefts and predilection for the thoracolumbar junction. DM may be a mechanism by which vertebral height is restored during percutaneous vertebroplasty (PV). The best radiographic method to demonstrate DM is unknown. The purpose of this study is to determine whether an extension bolster is necessary to demonstrate DM when performing VpS.

This IRB approved protocol enrolled consecutive consented adult subjects undergoing VpS as part of their evaluation for possible PV. VpS was performed according to previously published protocol. Standing lateral X-rays centered on the index VCF were taken as usual. Supine cross table lateral X-rays were taken both before and after inflation of a sphygmomanometer bolster placed under the patient in the supine position beneath the level of the index VCF. Bolster inflation ceased when inflation pressure reached 100 mmHg or at patient request. X-rays were evaluated for the presence of DM and intravertebral clefts and manually digitized using centralized PACS system software. Dynamic mobility (DM) was said to be present when change in anterior vertebral height (ΔHa) exceeded our in vivo precision error for this measurement by 2 SD (thus, DM ≥ 0.8 mm). Using a 10-point visual analogue scale (VAS) subjects rated their fracture pain immediately before and immediately after bolster inflation.

37 subjects with 44 VCFs were enrolled. DM was demonstrated in 25/37 subjects and 28/44 VCFs prior to bolster inflation. ΔHa > 2 mm was seen in 19 and between 5 and 12.6 mm in 5/25 subjects. Bolster inflation induced or further enhanced ΔHa >0.8mm in 29/44 and > 2mm (2.1-4.5 mm) in 12/29 VCF. In 10/29 VCFs DM was only appreciated after bolster inflation (1-4.5 mm). Intravertebral clefts were appreciated in 10/37 subjects prior to bolster inflation. 3 clefts increased in size following bolster inflation. One cleft became apparent only after bolster inflation. In 4 VCF Ha decreased after bolster inflation (-0.9 to -1.6 mm). VAS in the supine position was 3.5 immediately prior to bolster inflation and rose to 6.6 immediately after bolster inflation.

Bolster inflation frequently and sometimes substantially enhances DM during VpS. Occasionally DM and rarely clefts are elicited only after bolster inflation. Bolster inflation adds minimal complexity but can add significant discomfort to the VpS. The potential significance of DM is uncertain but opportunities for pain relief and vertebral height restoration at PV may be missed if DM is not appreciated.

Spatial and Temporal Differences in Bone Loss Due to Aging and Ovx in the Tibiae of Rats. J. H. Waarsing*[1], J. S. Day*[1], A. G. H. Ederveen*[2], H. Weinans[1]. [1]Erasmus MC, Rotterdam, Netherlands, [2]N.V.Organon, Oss, Netherlands.

During the later years of life, bone mass slowly decreases. In women this loss is accelerated after menopause. In-vitro techniques like histology and conventional micro-CT have been used extensively to study bone loss. Because of limitations of the cross-sectional study design inherit to in-vitro methods it is still not clear how bone loss proceeds in space and over time. The aim of this study was to follow the process of bone loss in the tibiae of aging and ovariectomised rats in a longitudinal study using in-vivo micro-CT

Ten female 10-month old Wistar rats were divided in a sham operated and an ovariectomised group. Over one year post-operation, the right proximal tibiae of the rats were scanned at various time-points, using a prototype in-vivo micro-CT scanner (Skyscan 1076). The animals were scanned at week 0, prior to surgery, and at week 4, 14, 34 and 54. The Animal Ethics Commity approved all animal procedures.

All data sets were repositioned to exactly match the scan at week 0, using image registration software. For the metaphysical trabecular bone, we calculated volume fraction (BV/TV) and trabecular thickness (Tb.Th).

After 4 weeks BV/TV rapidly decreased by 31% in the OVX animals, which gradually proceeded to 83% after 54 weeks. Besides bone loss, also new bone formation was observed at the endosteal cortex. Non-resorbed trabecula increased in thickness (from 139 μm to 153 μm) for all animals (figure 1) and even complete new trabecular structures were formed.

In the sham operated rats, BV/TV slowly decreased at all time points reaching a loss of 37% at week 54, while the thickness of the remaining trabecula increased, again for all animals.

The changes in bone structure for both groups followed a similar pattern. Decrease in bone volume was followed by an increase in trabecular thickness. The similarity between age related bone loss and bone loss caused by OVX might indicate that similar mechanisms are at work, and that estrogen depletion resulted in an increase in the speed at which these mechanisms inflict changes in the OVX group.

The fact that some trabecula increase in thickness while at the same time their neighbors are being resorbed raises questions on how bone cells sense spatial differences. The well-known mechanical responsiveness of bone might make it plausible that the mechanism at work is an ongoing mechanical adaptation of the bone.

A High Prevalence of Vitamin D Insufficiency/Deficiency in a Minimal Truama Fracture Population. C. Simonelli[1], J. A. Morancey*[1], L. Swanson*[2], K. K. Killeen*[2], K. A. Grimm*[3], T. Weiss*[4], Y. Chen[4]. [1]Osteoporosis Services, HealthEast Clinics, Woodbury, MN, USA, [2]Department of Nursing, St. Joseph's Hospital, St. Paul, MN, USA, [3]Department of Research, HealthEast Medical Research, St. Paul, MN, USA, [4]Merck & Co., West Point, PA, USA.

Ideal vitamin D level is reported to be >30 ng/mL to allow for normal mineralization of bone, optimization of calcium absorption, and to prevent osteomalacia and secondary hyperparathyroidism. Low vitamin D is a risk factor for osteoporotic fractures that may be independent of osteoporosis by directly affecting bone mineralization, muscle strength and balance. This bone qualitative defect can only be corrected by adequate vitamin D replacement. We report the prevalence of vitamin D insufficiency/deficiency in a population of adults with non-traumatic fractures.

To evaluate the impact of nurse-practitioner consultation, 82 adults (ages 52-97 with 63% age 80+) consecutively hospitalized with hip and extremity fractures between August 2001 and January 2002 were recruited from two St. Paul, MN hospitals (latitude 42 degrees). Patients came from independent living and assisted living facilities. Demographics, medical history, and vitamin D supplementation were obtained by self-report. Blood specimens were collected during hospitalization within 48 hours of admission. Serum 25-hydroxyvitamin D [25 (OH)D] levels were performed using Diasorin 25-hydroxyvitamin D radioimmunoassay kit (RIA; normal values are 8-30 ng/mL determined in wintertime in Rochester, MN) at Mayo Clinic, Rochester, MN. Results of 25(OH)D levels were available for 78 patients and are included in the current analysis.

Patients were 99% Caucasian, 63% ≥80 years and 78% female. On admission, 9% reported using at least 800 IU per day of vitamin D through supplements (including multivitamins) and 12% were on osteoporosis medication (3 estrogen, 5 alendronate, 1 etidronate, 1 raloxifene). The mean 25 (OH)D level was 14.2 (SD 6.6) with a range of 5-39 ng/mL. The cumulative distribution of 25 (OH)D levels is shown in Figure below.

The majority (82%) of the patients had 25 (OH)D levels ≤20 ng/mL, including 19.2% < 8 ng/mL and 97.4% of patients had 25 (OH)D levels < 30 ng/mL. Mean 25(OH)D levels were not substantially different by gender, age, or osteoporosis medication use. Patients who reported vitamin D supplementation ≥800 IU/day had significantly greater mean 25 (OH)D level, albeit suboptimal, compared to those did not (19.0 vs. 13.7; p = 0.04).

Vitamin D insufficiency/deficiency is common in hospitalized fracture patients, even those who reported sufficient supplementation. Significant opportunity exists to ensure adequate and persistent vitamin D intake in patients at risk for fractures.

Serum Insulin-like Growth Factor Binding Protein-2 (IGFBP2): A Nutrient-responsive Marker of Catabolism after Hip Fracture. R. E. Rizzoli[1], P. Ammann[1], J. Burgess*[2], L. R. Donhaue*[2], C. J. Rosen[2]. [1]Div. Bone Diseases, University Hospital, Geneva, Switzerland, [2]St Joseph Hospital, Bangor, ME, USA.

Insulin-like growth factor binding protein-2 (IGFBP2) is a ubiquitous 30 kilodalton IGF binding protein which circulates in relatively high concentrations (300-500 ng/ml) and has strong binding affinity for extracellular matrices and hydroxyapatite. High levels of serum IGFBP2, inversely related to IGF-I, have been reported in catabolic states such as metastatic disease, protein calorie undernutrition, anorexia nervosa and growth hormone deficiency, although the regulatory determinants of IGFBP2 are unknown. Since hip fracture and the immediate postoperative period is a highly catabolic state, and nutritional supplementation has been shown to accelerate healing and improve functional parameters, we postulated that IGFBP2 would be increased after hip fracture, and then reduced by nutritional supplementation. We thus studied men and women (n=50) who had fracture of the hip (FH) within 10 days of surgery, and elderly unfractured controls (UC, n=28). At time of sampling FH subjects had twice the IGFBP2 concentrations as UC (1119+99 ng/ml vs 586+50 ng/ml; x±SEM, p<0.001). IGF-I was decreased in FH patients (77.1±3.7 vs 126.5±7.5 ng/ml, p<0.001), as were serum prealbumines (172±7 vs 297±7 ng/ml, p<0.001). At 6 and 12 months post surgery, IGFBP2 decreased by 14.7±5.1 and 14.9±4.7 %, respectively (p<0.05 for both). Patterns of serum IGFBP2 6 and 12 months post FH were the opposite of serum IGF-I. This suggests a marked reduction in the bioactivity of IGF-I during the immediate post FH period. Then, to further address the nutrient responsiveness of IGFBP2, we studied adult rats on a normal or an isocaloric low protein (LP) diet followed by essential amino acid supplementation (EAA) using a newly developed RIA for serum IGFBP2. Serum IGFBP2 levels were 183+25 ng/ml in controls, while those in LP fed rats were 230+36. Rats on a LP diet but supplemented either with 2.5% or 5% EAA, had a return of serum IGFBP2 concentrations to baseline (174±19 and 172±14 ng/ml, respectively) together with an overcorrection of IGF-I. In conclusion, high serum IGFBP2 is a marker of the catabolic status during and after surgery for hip fractures. Renutrition is associated with a reduction in IGFBP2. These data illuminate another mechanism whereby nutritional supplementation of hip fracture patients can positively affect functional outcome measures.

Skeletal Effects of Long-Term Marginal Zinc Supply in Aged Rats. R. G. Erben[1], K. Lausmann*[1], W. Windisch*[2]. [1]Institute of Animal Physiology, University of Munich, Munich, Germany, [2]Department of Animal Science, Animal Nutrition, Technical University Munich, Freising, Germany.

A deficient Zn supply has been implicated as a risk factor for osteoporosis in humans. The aim of the current experiment was to investigate the long-term effects of an insufficient zinc (Zn) supply on bone metabolism in aged rats, and to explore further the role of Zn in the pathogenesis of osteoporosis. Nine-month-old female Fischer-344 rats were divided into 8 weight-matched groups with 8 animals each. At the beginning of the experiment, all rats were adapted for one month to restrictive feeding (7.5 g/animal) of a semi-synthetic diet containing 8 g/kg sodium phytate and 64 ppm Zn. Thereafter, 8 animals were killed as baseline controls. For the whole duration of the experiment, control animals were pair fed to account for possible decreases in food intake in the Zn deficient rats. During the 1-month depletion phase, control animals received the Zn replete diet with 64 ppm Zn, whereas the Zn deficient rats were fed the same diet, but with a Zn content of 2.2 ppm. Eight rats in each group were killed after the depletion phase. Subsequently, the 2-month marginal phase began in which the rats on the diet with 2.2 ppm Zn received an additional daily Zn supplement of 75 µg Zn/rat by gavage. At the end of the marginal phase, 1 control and 1 Zn deficient group were killed. In the following repletion phase, 1 marginal group was switched to the Zn replete diet, while 1 group each was maintained on marginal Zn supply or on the Zn replete control diet. All remaining rats were killed after this phase. The Zn-depleted and also the Zn marginal rats showed a significant reduction in the serum concentration of Zn. Serum alkaline phosphatase was decreased by 44% relative to control animals after the depletion phase, and by 28% after the marginal phase. Zn repletion normalized the serum Zn concentrations. Bone Zn content showed a significant reduction in Zn deficient rats not before the end of the marginal phase, and did not reach control levels after the repletion phase. Using biochemical bone markers, bone histomorphometry and pQCT analysis, we found distinct age-related changes in bone metabolism and in bone mass of the appendicular skeleton during the course of the study. However, Zn deficient animals did not show decreased cancellous or cortical bone mass, increased bone resorption, reduced bone formation, or structural changes in bone architecture relative to control rats at any time point. Thus, the current study strongly suggests that Zn does not play an essential role in bone metabolism in adult rats. Based on our findings, it appears questionable whether Zn deficiency is a risk factor for osteoporosis or other bone diseases.

The Effects of Binge Drinking on Bone Turnover. K. C. Westerlind[1], R. Strange*[1], R. Story*[1], G. Evans[2], R. Turner[2]. [1]AMC Cancer Research Center, Denver, CO, USA, [2]Orthopedic Research, Mayo Clinic, Rochester, MN, USA.

Chronic alcohol (ETOH) consumption has repeatedly been shown to result in generalized decreased bone formation and locally increased bone resorption. The prevalence of binge drinking (≥ 5 drinks/session) is increasing at an alarming rate particularly in young individuals but its effect on the bone is not well studied. The purpose of this study in rats was 1) to determine whether gavaging ETOH resulted in elevated blood alcohol concentrations comparable to those in humans and 2) determine the effects of a brief period of binge drinking on histomorphometric indices of bone turnover Thirty-six 6-mos old male Sprague Dawley rats were stratified by weight and randomized to a baseline, binge drinking (gavage-fed 1.2 g ETOH/kg bw, 2x/wk on consecutive days for 2 wks), or control (gavage-fed kcal substitute, 2x/wk on consecutive days for 2 wks). Serum was collected 1 hr post-gavage. Calcein labels (10 mg/kg/bw) were given 5 and 14 days prior to sacrifice. Blood alcohol content (BAC) averaged 56 mg/dL for the binge group vs 3 mg/dL for the controls. This level is significantly lower than that observed in humans who binge drink. Despite low BACs, a significant increase in medullary area (p=0.008) was noted in the binge group (1.23mm^2) compared to controls (1.10 mm^2) and baseline (1.06 mm^2). Cortical area also tended to be reduced [4.64 mm^2 (binge) vs. 5.01 mm^2 (control) and 5.18 mm^2 (baseline); p=0.09]. No change in periosteal bone formation rate was observed. In the cancellous bone, 4 episodes of binge drinking over 2 wks resulted in no difference in mineral apposition rate but non-significant reductions in LS/BS (9.1% vs. 12.7%; p=0.10) and BFR/BS (0.13 µm^3/µm^2/d vs. 0.19 µm^3/µm^2/d; p=0.13) in the binge group compared to controls. The data suggest that binge drinking has a significant effect on bone turnover, specifically increased endocortical resorption and decreased cancellous bone formation. These effects were noted in animals with moderate BAC levels and after only 4 episodes of binge drinking. Longer-term binge drinking behavior with significantly greater concentrations of ETOH could be expected to have more deleterious skeletal effects.

Effect of Food Restriction and Hindlimb Unloading on Serum Leptin and Histomorphometric Measures of Cancellous Bone. K. Baek*, A. Currado*, M. Allen*, S. Bloomfield. Texas A&M, College station, TX, USA.

Leptin is a potential candidate responsible for linking energy metabolism to bone mass. Because astronauts are commonly in negative energy balance during spaceflight, this study was designed to assess independent effects of simulated microgravity and food restriction on bone mass and serum leptin. Male Sprague-Dawley rats (6-mo-old, skeletally mature) were randomly assigned to 4 groups (n=12 each). One group was subjected to hindlimb unloading (HU) and fed 100% of their food requirement (HU100), while another HU group was fed 70% of their food requirement (HU 70). Two cage-activity control groups were fed 100%(Con100) and 70%(Con70) of their requirement. On day 0 and day 28, peripheral computed tomography (pQCT,Stratec XCT Research M;Norland) was used to assess bone mineral density(BMD) and serum was collected to measure leptin levels by ELISA (Crystal Chem. Chicago, IL). Fluorochrome labels were given 9 and 2 days prior to sacrifice. Femurs were embedded in plastic, sectioned at 4µm and distal femoral metaphysis was analyzed, using standard histomorphometric techniques for kinetic measures (% mineralizing surface, mineral apposition rate(MAR), and bone formation rate (BFR) and static measures of bone volume (%BV/TV) and forming and resorbing surfaces. All procedures were approved by institutional animal use committee. Con 100 rats gained body weight (BW), whereas all other groups lost BW, the loss was great in HU70 vs CON70 & HU100 ($p<0.05$). We previously reported a decrease in serum leptin was observed after 28days in Con70 and HU100 (-60% and -27%,repectively) and was nondetectable in HU70 rats [Baek et al., JBMR 18:S333,2003].The change in total BMD at the proximal tibia was moderately correlated with the change in serum leptin values over 28d (r^2=.48, $p<0.01$). Percent forming surface in Con 70 and HU100 was significantly lower than that of CON100 (8.66%, 8.90% vs 10.65%, respectively; $p<0.05$) and this decrease was more pronounced in HU70 (3.33%). BFR of CC70 and HU100 was significantly lower than that of CC100 (12.2, 12.1 vs 39.4 [mm^3/mm^2/day], respectively; $p<0.0001$). MAR of CC70 and HU100 was significantly lower than that of CC100 (1.5, 1.6 vs 2.1 [µm/day], respectively; $p<0.05$) The change in BFR was strongly correlated with the change in serum leptin value over 28d (r^2=.73 $p<0.002$). We conclude that moderate caloric restriction could cause bone loss to a similar degree as does the unloading effect of microgravity. Serum leptin might be a key endocrine regulator contributing to this change in bone metabolism.

The Acute Effects of Different Dietary Phosphate Sources on Calcium and Bone Metabolism in Young Women. H. J. Karp*, K. P. Vaihia*, C. J. E. Lamberg-Allardt. Department of Nutrition, University of Helsinki, Helsinki, Finland.

A high-phosphate intake together with low calcium intake has been shown to elevate the serum parathyroid hormone concentration which causes bone resorption and increased bone turnover. The most important dietary sources of phosphate are meat, milk and grain products. Phosphate salts are commonly used as additives by food industry. Therefore, phosphate is easily achieved in a typical Western diet, and its intake exceeds the recommended amounts 2-3 fold. Dietary phosphate is considered to be easily absorbed in the small intestine. However, there have been only few studies concerning the bioavailability and metabolic consequences of dietary phosphate from different food sources.

The aim of this study was to evaluate the acute effects of dietary phosphate from three different foodstuffs and a phosphate supplement on calcium and bone metabolism. Sixteen female volunteers aged 20-30 participated in the study at five separate 24-hour sessions. At the control session both calcium and phosphate intakes were low (ca. 250 mg/day of Ca, 500 mg/day of P). At the other four sessions phosphate intake was 1500 mg/day, and 1000 mg of it was taken in from meat, cheese, wholegrains or a phosphate supplement, respectively. The foods served were exactly the same at the phosphate sessions and the control sessions, with the exception of the phosphate sources. The order of the days was randomized.

Calcium and bone metabolism was monitored for 24h by measuring the concentrations of serum ionized calcium (S-iCa), serum phosphate (S-P), serum intact parathyroid hormone (S-PTH), and the activity of serum bone specific alkaline phosphatase (S-BALP). The excretions of urinary phosphate (U-P) and urinary calcium (U-Ca) were also measured.

Compared with the control session, the S-P rose at all phosphate sessions (p=0.006-0.001). The S-P level was highest after ingesting cheese compared to all the other sessions (p=0.0001). The U-P was higher during the meat and phosphate supplement sessions as compared to the sessions when grain or cheese were given (p=0.013 and 0.0001, respectively). The S-iCa (p=0.0001) and U-Ca (p=0.003-0.0001) increased at the cheese session as compared with all the other sessions. Compared to the control day, the S-iCa declined after the phosphate supplement (p= 0.026). Due to the high calcium intake, the S-PTH was lower when cheese was given as compared with the control session (p=0.031). The S-BALP activity was higher at the meat than at the control or wholegrain sessions (p<0.045). In conclusion, there were differences in the metabolic response of phosphate from different foods. Phosphate additives had a more unfavourable effect on bone than the foods containing phosphates naturally.

Glucocorticoids Induce Changes Around the Osteocyte Lacunae That Reduces Bone Strength and Bone Mineral Content Independent of Apoptosis: Preliminary Data From A Glucocorticoid-Induced Bone Loss Model in Male Mice. N. E. Lane, M. Balooch*, J. Zhou, Y. Jiang, W. Yao. Medicine, University of California in San Francisco, San Francisco, CA, USA.

Gluococorticoids (GC) excess frequently leads to osteoporosis, with an increased fracture risk. The purpose of this study was to assess cellular, trabecular microstructure and bone strength changes within the trabecular bone of GC treated and GC naïve mice. METHODS: We administered 1.4 mg/kg prednisolone or placebo to 6 mo. old Swiss-Webster mice for 21 days. Serum was collected to assess osteocalcin (OST) by ELISA at day 21. The 5th lumbar vertebrae (LVB) was imaged by µCT for trabecular structure, and then processed for histomorphormetric assessment of bone turnover. Atomic Force Microscopy (AFM) was then used to assess elastic modulus around the osteocytes (OC) lacunae. Apoptotic osteocytes were identified by the TUNEL assay. MicroRaman spectroscopy was performed on trabecular bone of the vertebrae to assess mineral/organic peak ratio around OC lacunae.

Results: Mice treated with GCs had decreased serum OST (79%) and BV/TV (18%) in the LVB compared to GC naïve mice. These changes in GC treated mice were accompanied by decreased bone formation (35%) and increased OC apoptosis compared to GC naïve

(56%). Compared to GC naïve mice and estrogen deficient mice, elastic modulus accessed across trabecular bone regions was significantly reduced in a 40μm^2 area of around all OC lacunae in GC treated mice (67%), independent of OC apoptosis. The ratio of phosphates/ organic content around OC lacunae was significantly reduced (36%) in GC treated mice compared to GC naïve. (all comparisons $p < 0.05$).

In conclusion, we found that GC excess induced loss of trabecular bone mass and bone strength in mice. Accumulation of apoptotic OC may partly contribute to the deterioration of bone strength and structure. However, reduction on elastic modulus and changes in the mineral/collagen content was reduced independent of OC apoptosis. These findings suggest that GC-induced bone fragility arises from changes that occur around the OC lacunae that alters bone strength, independent of apoptosis and in addtion to changes in microarchitecture.

Transient Stimulation of RANKL and Persistent Inhibition of Osteoprotegerin Expression by Glucocorticoid Administration in Mice: Molecular Correlates of Glucocorticoid Effects on Vertebral Osteoclast Numbers. R. S. Weinstein, D. Jia, C. A. O'Brien, S. A. Stewart*, S. C. Manolagas. Div. of Endo/Metab, Center for Osteoporosis, Central Arkansas Veterans Healthcare System, Univ of Ark for Med Sci, Little Rock, AR, USA.

The adverse effects of glucocorticoid excess on bone result from suppression of osteoblastogenesis and osteoclastogenesis as well as promotion of osteoblast and attenuation of osteoclast apoptosis. In vitro studies indicate that these steroids act directly on differentiated osteoclasts to extend their lifespan, however, it is unknown whether effects of glucocorticoids on other cells also contribute to changes in osteoclast number in vivo. Here, we have studied the temporal relationships among a) the number of osteoclasts and osteoblasts; b) the prevalence of osteoblast apoptosis; c) mRNA expression of RANKL, osteoprotegerin (OPG) and osteocalcin (OCN); and d) the number of osteoblast and osteoclast progenitors in bone taken from mice treated with prednisolone for 3, 7, 10 and 27 days. After 3 days of prednisolone, vertebral cancellous osteoclasts decreased by 50%, as compared to placebo controls; and this change was accompanied by a 45% decrease in osteoclast progenitors. However, the decrease in cancellous osteoclasts was transient as by day 7, osteoclast number increased to 60% above controls while osteoclastogenesis remained low, suggesting that the increase was probably due to prevention of osteoclast apoptosis. Nonetheless, by day 10, cancellous osteoclasts were only 11% above controls and declined further to 60% below controls by day 27. Taqman RT-PCR of mRNA from vertebra showed increased RANKL expression on day 3, preceding the increase in cancellous osteoclasts, but in accord with the osteoclast number, RANKL returned to control levels by day 7 and 10. OPG expression, however, was decreased on day 3 and remained low. Cancellous osteoblasts were profoundly decreased to 8% of controls by day 3 and remained suppressed, due to both reduced production of progenitors and increased apoptosis of mature osteoblasts. OCN expression decreased to 2% of controls by day 3 and remained low, corresponding to the decrease in osteoblast number as indicated by a tight correlation between these two measurements ($r = 0.94$, $P < 0.0001$). The transient increase in osteoclast number and RANKL expression, in spite of a sustained decrease in osteoblast number and osteocalcin expression, strongly suggests that glucocorticoids increase osteoclast number not only by direct actions on osteoclasts but also indirectly by increasing the pro-survival effects of an increased RANKL/OPG ratio and that the cells expressing RANKL are not mature osteoblasts.

Species Specific Differences in Bone Metabolism and Osteoprotegerin Regulation During Glucocorticoid Treatment. E. G. Vajda, K. N. Griffiths*, W. Y. Chang*, L. Wang*, A. L. Hogue*, F. J. López*, O. H. Viveros*. Pharmacology, Ligand Pharmaceuticals, Inc., San Diego, CA, USA.

In humans, glucocorticoids (GCs) induce osteoporosis through two mechanisms, a transient elevation of bone resorption leading to an acute rapid loss of bone, followed by a phase of slower bone loss due to a chronic deficit in bone formation. Recent clinical studies suggest that the increase in resorption induced by GCs is the result of decreased serum levels of osteoprotegerin (OPG), an inhibitor of osteoclastogenesis. In these studies, we investigated the actions of dexamethasone and prednisolone (14 day treatment) in male Swiss-Webster mice on serum concentrations of osteocalcin (OC), OPG, and RANKL. Both dexamethasone and prednisolone significantly reduced serum levels of OC (79% and 53% reduction, respectively), increased serum OPG (72% and 35%), and decreased serum levels of free-soluble RANKL (30% and 33%) in a dose dependent manner. Subsequently, the effects of prednisolone on bone mass were examined in a 28 day treatment regimen. Prednisolone produced similar alterations in biochemical markers as observed in the shorter treatment period. In contrast, prednisolone treatment did not reproducibly decrease total body or spinal bone mineral density assessed by dual energy x-ray absorptiometry. Microcomputed tomography scans of the distal femur and histomorphometric analysis of the lumbar spine confirmed no statistically significant treatment-related decrease in trabecular bone volume. Dynamic histomorphometric analysis, however, revealed dramatically reduced lumbar spine trabecular bone formation rates (vehicle = 0.28 ± 0.05 μm^2/μm/day; prednisolone = 0.04 ± 0.02 μm^2/μm/day; $p<0.001$). Retention of fluorochrome labels administered prior to treatment, a measure of bone resorption, was increased by prednisolone, indicating suppression of bone resorption. These results clearly show that glucocorticoids dramatically suppress bone formation in mice, consistent with the findings in humans. Unlike humans, however, rapid dramatic loss of bone was not observed in the mouse. The absence of GCs effects on bone resorption in mice is probably explained by increased production of OPG and consequent reduction in bone resorption. These data suggest that the early rapid bone loss observed in humans, but not in mice, after treatment with GCs is the result of species specific differences in the regulation of the OPG/RANKL pathway.

Histomorphometric Analysis of Osteopenia Induced by Immunosuppressive Drugs in Rats. Effects of Risedronate. L. Dalle Carbonare*[1], S. Giannini[2], S. Zordan*[2], M. Valenti*[1], F. Bertoldo*[1], G. Realdi*[2], G. Crepaldi[3], V. Lo Cascio[1]. [1]Biomedical and Surgical Science, Internal Medicine D, University of Verona, Verona, Italy, [2]Internal Medicine, University of Padua, Padua, Italy, [3]CNR Aging Center, Padua, Italy.

Osteopenia is an important complication after transplantation. Corticosteroids is one of the most important pathogenic factors, while more contrasting data have been reported about the effects on bone metabolism of cyclosporin A. Bisphosphonates are a powerful therapeutic option to prevent osteoporosis and related fractures.

The aims of this study based on the rat model were: 1. to verify structural alterations on bone induced by immunosuppressive therapy with glucocorticoids (GC) and ciclosporin A (CsA); 2. to establish the efficacy of Risedronate (Ris) in the prevention of these effects.

We studied 70 female Sprague-Dawley rats, maintained at the same standard diet. The rats were divided randomly into 7 groups of treatment (10 rats each) as follows:

1.Control group: CsA vehicle + vehicle of Methyl Prednisolone (MP) + vehicle of Risedronate (Ris);
2. *Group MP*: 7 mg/Kg 3 times a week s.c. + CsA vehicle + vehicle of Ris;
3. *Group CsA*: CsA 3 mg/Kg 3 times a week s.c. + vehicle of MP + vehicle of Ris;
4. Group CsA + MP + vehicle of Ris;
5. Group CsA + Ris 5 mg/Kg body weight 3 times a week + vehicle of MP;
6. Group MP + Ris + CsA vehicle;
7. Group CsA + MP + Ris.

All the rats were weighed once a week to adjust the dose of drugs to body weight and they were treated for 30 days. Then, the rats were sacrificed. Histomorphometric evaluations on the right tibiae of 42 rats showed a reduction of bone volume (BV/TV) with a thinning of the trabeculae (TbTh), associated with decreased osteoblastic activity (BFR/TV) in GC treated group with respect to controls (BV/TV: 33±1 vs 36±1%, $p < 0.05$; TbTh: 43 vs 50mm, $p < 0.01$; BFR/TV: 15.8 vs 22.1%/y; $p < 0.01$). Risedronate seemed to counteract the effects of GC on bone (BV/TV 38±3%, $p <0.05$ vs group 2; TbTh: 53±2mm, $p < 0.01$ vs group 2; BFR/TV: 23.2 ±2.4%/y, $p < 0.01$ vs group 2). In addition, risedronate was able to preserve microarchitecture, expressed as the number of nodes (NdN/TV) and Marrow Star Volume (MSV), (NdN/TV: 27±5 #/mm^3; MSV 0.04±0.01 mm^3, $p < 0.01$ vs GC).

In conclusion, preliminary histomorphometric data of this pre-clinical rat model of secondary osteopenia, highlighted that risedronate was able to preserve bone quality in 30 days, whereas GC treated group showed that bone quality was readily deteriorated.

Bone Loss Is More Severe In Primary Adrenal Than In Pituitary-Dependent Cushing's Syndrome. M. Minetto*, G. Reimondo*, G. Osella*, M. Ventura*, A. Dovio*, M. Terzolo*, A. Angeli. Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy.

Exogenous or endogenous glucocorticoid (GC) excess is an established cause of osteoporosis and fractures. As many as 50% of patients with Cushing's syndrome suffer from osteoporosis. It is presently unknown if Cushing's disease (CD) sustained by a pituitary ACTH-producing adenoma and adrenal-dependent Cushing's syndrome (ACS) sustained by an adrenocortical adenoma have a different potential of inducing osteopenia. Aim of the present study was to retrospectively analyze bone mineral density (BMD) in 26 patients with CD (4 men, 22 women, aged 14-79 years), 12 patients with ACS (4 men, 8 women, aged 32-79 years) and 38 healthy subjects carefully matched for sex, age and body mass index (BMI). Measurement of BMD was performed by dual energy x-ray absorptiometry (DXA) using the Hologic QDR 4500 W instrument. Data were analyzed using absolute BMD values (g/cm^2), t-score and z-score referred to the manufacturer's normative data for the lumbar spine and to the NHANES III dataset for the hip. The patients with CD and ACS were comparable for age, BMI, estimated duration of disease, urinary free cortisol (UFC) levels, midnight serum cortisol and gonadal function. Lumbar DXA values were significantly different among the three groups. They were more reduced in patients with ACS (BMD, 0.76 ± 0.03 g/cm^2; t-score, -2.78 ± 0.28; z-score, -2.25 ± 0.30) while patients with CD (BMD, 0.87 ± 0.02 g/cm^2; t-score, -1.74 ± 0.24; z-score, -0.99 ± 0.32) showed DXA values between the first group and controls (BMD, 1.02 ± 0.02 g/cm^2; t-score, -0.35 ± 0.19; z-score, 0.33 ± 0.16). The difference in BMD at the spine remained statistically significant (p=0.04) after adjustment for the non-significant differences in age, UFC and fat mass between CD and ACS. Conversely, femoral DXA values were not significantly different between patients with ACS and CD, even if they were reduced with respect to controls. In patients with ACS, we observed a reduction of DHEA-S levels, expressed as standard score (z-score) to circumvent the pronounced effect of gender and age on such hormone (DHEA-S z-score: ACS -0.88 ± 1.4 vs. CD 2.25 ± 2.35, p=0.0001). DHEA-S z-score values were significantly correlated with lumbar BMD (r=0.41, p=0.02) and femoral BMD (r=0.43, p=0.01). DHEA-S z-score values were also significantly correlated with osteocalcin levels (r=0.45, p=0.01). Our data suggest that bone loss is greater in ACS than in CD. A plausible explanation comes from the reduced DHEA-S level in ACS since DHEA-S has well known anabolic actions on bone. However, this hypothesis needs to be confirmed in large, prospective series of patients with Cushing's syndrome of different etiology.

Cortical Bone Is Superior to Trabecular as an Indicator of Glucocorticoid-induced Vertebral Osteoporosis in a Murine Model. P. L. Salmon[1], O. Baeyens*[1], D. Souza*[2]. [1]Application Research, Skyscan, Aartselaar, Belgium, [2]Pharmaceutical R&D, Boehringer Ingelheim Inc., Ridgefield, CT, USA.

Glucocorticoid induced osteoporosis (GIO) has proved difficult to reproduce in a mouse model. Mice frequently gain increased trabecular relative volume in response to steroids. However murine vertebral cortical bone may be superior to vertebral trabecular bone as a model of GIO, since the cortical volume and thickness changes are in the right direction and dose-dependent. Mice were treated by injection with either vehicle or the steroid prednisolone for five weeks. Lumbar vertebral morphometry was assessed post-mortem by micro-CT. The response to prednisolone of the lumbar vertebral body volume was biphasic - first a decrease then an increase in total vertebral size with increasing prednisolone dose. Trabecular bone relative volume (BV/TV) at the mouse lumbar vertebral body showed small changes which were also biphasic, mirroring vertebral volume. BV/TV significantly increased in the group receiving 10 mg/kg prednisolone, while higher doses showed decreasing BV/TV. Bone structure thickness showed a more unidirectional response. There was a consistent dose-dependent reduction in thickness in both trabecular and cortical vertebral bone, in response to prednisolone, which was more pronounced and significant for cortical bone. The trabecular thickness decrease however was accompanied by an increased trabecular number (the density of trabecular structures) with the overall result that there was either no significant change, or a slight increase in relative trabecular volume. Structure model index also showed biphasic outcome in trabecular bone, with a decrease at low to medium doses of prednisolone reversed to no effect at high dose. By contrast, cortical thickness and volume showed dose-dependent decrease in response to steroid over the whole dose range. Thus cortical bone appears to be superior to trabecular bone, in the mouse vertebra, as a model indicator of the osteopenia in humans caused by the sharp reduction in bone formation rate resulting from glucocorticoid administration.

Lack of Significant Low Bone Density in Many Glucocorticoid Treated Children. R. P. Green. Pediatrics, Washington University School of Medicine, St. Louis, MO, USA.

Purpose: Glucorticoid treated children followed by a variety of subspecialty groups were evaluated longitudinally to characterize the natural history of glucocorticoid (GC) mediated bone disease in childhood, and as part of an effort to recruit children for a GC-induced bone disease treatment protocol.

Methods: Pediatric patients from various subspecialties, including lung transplant, pulmonary, rheumatolgy and GI clinic, who had used or were anticipated to use suprphysiologic doses of a glucocortiocid medication were invited to participate. Each participant underwent BMD assessment at approximately 6 month intervals. Because of the effect of size on BMD, both chronologic age Z scores and height age (HA) adjusted Z scores were determined at hip and spine on each scan using a Hologic QDR4500 scanner and a Hologic Research Database with gender specific normals.

Results: Based on all BMD measurements, GC treated children had bone density Z scores below the population expected mean for both chronologic age and height age [spine mean -1.19 SDS (CI -1.57 to -0.81), height age spine mean -0.64 SDS (CI -1.0 to -0.28), hip mean -1.12 SDS (CI -1.43 to -0.81), height age hip mean -0.66 SDS (CI -0.92 to -0.4). Despite this, when using -2 SD below the mean BMD for height age to define low BMD, less than 10% of BMD measurements in GC treated children met the criteria for low BMD. 4 children had clinical evidence of osteoporosis (vertebral fracture or low trauma extremity fracture). These children had BMDs significantly below children without clinical evidence of osteoporosis (spine mean Z score -3.14 vs -0.96; hip mean Z score -2.0 vs -1.0).

Conclusion: Many GC treated children do not have DEXA evidence of significantly low BMD. Children in this population who had clinical evidence of osteoporosis based on fracture did have BMDs significantly below the remainder of the population. Further research is needed to define whether DEXA BMD can be used in the clinical setting to identify those GC treated children at risk of fracture.

Low Dose Estradiol Rapidly Increases Osteoblastic Procollagen Production in Postmenopausal Women. P. Y. Liu*, K. L. Mielke*, K. A. Hoey*, J. D. Veldhuis*, S. Khosla. Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

The acute effects of estradiol on procollagen type 1 formation in postmenopausal women are controversial. Eighteen pre- and 12 postmenopausal women received two consecutive i.m. injections of 3.75 mg leuprolide acetate three weeks apart to block endogenous ovarian steroidogenesis. Transdermal estradiol therapy commenced on the night of the second leuprolide injection in an incremental stepwise fashion, with each dose of 0.05, 0.10, 0.15 and 0.20 mg per day administered for 4 consecutive days, to mimic the estradiol changes typifying the follicular phase of the menstrual cycle. Blood aminoterminal propeptide of type I procollagen (PINP), intact osteocalcin (OC), carboxyterminal crosslinked telopeptide of type I collagen (CTx) and estradiol were measured before, and then every 4 days during estradiol therapy. In the postmenopausal women, serum estradiol concentrations significantly increased from 7.1 ± 0.9 (SEM) to 150 ± 25 pg/mL (P<0.001). Furthermore, as illustrated, PINP increased by 5.7 ± 2.7 µg/L (P<0.03) from baseline after 4 days of low-dose estradiol therapy, continued to rise and remained significantly above baseline for the entire 17 day duration of estradiol therapy. Whilst PINP increased, CTx and OC did not change. Similar, but muted, alterations were seen in premenopausal women. The relationship between the changes in estradiol and PINP was further explored by multilinear regression. This demonstrated a highly significant association (P=0.001), which differed between pre- and postmenopausal women (P=0.015).

We conclude that low dose estradiol rapidly increases osteoblastic collagen synthesis in postmenopausal women at a time when collagen degradation is stable. Further analysis of the data being collected will dissect any difference in estradiol's effects on serum markers of bone turnover in pre- vs postmenopausal women.

Characterization of the Changes on Trabecular, Endocortical and Periosteal Bone in Senescence Accelerated Mouse (SAMP6) and the Effects of Testosterone. H. Z. Ke, G. Xu*, H. A. Simmons, H. Qi, D. T. Crawford*, L. C. Pan, M. Li. Pfizer Global Research and Development, Groton, CT, USA.

The SAMP6 strain (P6) has been investigated as a model of senile osteoporosis. It has been reported that P6 has lower trabecular bone mass and bone formation due to a defective osteoblastogenesis. However, the changes on different bone surfaces in P6 have not been fully characterized. The purposes of this study were to (a) characterize the changes on trabecular, endocortical and periosteal bone in P6 as compared with normal control (R1) mice in both sexes, and (b) test whether testosterone propionate (TP) can increase bone mass in P6 males and females. Ten male and 10 female R1 control mice, and 8 male and 10 female SAMP6 at 5.5 months of age were treated with vehicle, while another 8 male and

11 female SAMP6 were treated by s.c. injection with TP at 10 mg/kg/d for 8 weeks. Compared with male R1 controls, male P6 had significantly lower total mineral content (-15%), total mineral density, trabecular density, cortical content and cortical thickness, and a significantly higher marrow cavity area in the distal femoral metaphysis (DFM) by PQCT analysis. Micro-CT analysis of DFM showed male P6 had a 33% lower trabecular bone volume, while trabecular bone histomorphometry showed that male P6 have a lower mineral apposition rate and mineralizing surface. In FS, a significantly lower total mineral density (-15%) and cortical thickness with a significantly higher total bone area, marrow area (+43%), periosteal and endocortical circumferences were observed in male P6. These data indicate that the male P6 had lower bone mass on trabecular and endocortical compartments due to a lower bone formation. However, male P6 had increased cross-sectional area and marrow cavity area of long bone, indicating higher bone resorption on endocortical surface and higher bone formation on periosteal surface. TP treatment in male P6 significantly increased bone mass by further reducing bone turnover in trabecular compartment but had no effect on endocortical and periosteal compartments. Similarly, a lower bone mass in trabecular and endocortical compartments and increased cross-sectional area of long bone were found in female P6 compared with female R1 controls. However, TP failed to increase bone mass in neither trabecular, endocortical nor periosteal compartments in female P6. These results reveal that both male and female P6 had lower trabecular and endocortical bone mass due to a lower bone formation, thus can be used as senile osteoporosis models. Testosterone increases trabecular bone mass but fails to increase endocortical and periosteal bone mass in male P6, while it has no effect on female P6.

Free Serum Estradiol Levels Correlate with both Trabecular and Cortical Volumetric Bone Mineral Density in Young Adult Swedish Men. M. Lorentzon, A. Eriksson, C. Ohlsson. Department of Internal Medicine, Center for Bone Research at the Sahlgrenska Academy (CBS), Gothenburg University, Gothenburg, Sweden.

Estrogens regulate skeletal growth and mineralization in males. The aim of the present study was to determine the associations between serum levels of estradiol (E_2) and skeletal size and mineralization in young adult males. The *G*othenburg *O*steoporosis and *O*besity *D*eterminants (*GOOD*) study consists of 1075 men, age 18.9±0.6 yrs, and was initiated with the aim to find both environmental and genetic determinants for bone and fat mass. Bone parameters were measured using both DXA and pQCT. Serum levels of SHBG and E_2 were measured using RIA and free E_2 (fE_2) levels were calculated.

Regression models using physical activity, smoking, age and fE_2 as covariates showed that fE_2 was an independent predictor of areal BMD in the total body, the total femur, the femoral neck and the trochanter ($p<0.01$) but not in the spine as measured by DXA. pQCT analysis demonstrated that fE_2 was an independent predictor of both trabecular (radius β=0.13, *p<0.001;* tibia β=0.11, *p<0.001*) and cortical (radius β=0.10, *p<0.001;* tibia β=0.12, *p<0.001*) volumetric BMD but not of cortical periosteal circumference or cortical cross sectional area. The subjects with the highest tenth percentile of fE_2 (n=107) had 9.5 % ($p<0.01$) higher trabecular volumetric BMD in the radius than the subjects with the lowest tenth percentile of fE_2 (n=108). These findings demonstrate that fE_2 is a predictor of both the trabecular and the cortical volumetric BMD but not of the size of the cortical bone in young adult Swedish men.

Serum Leptin and Resistin Levels are associated with Lumbar Spine Bone Mineral Density in the Middle-aged Men. K. Oh*[1], C. Park*[1], S. Ihm*[1], S. Park*[1], E. Rhee*[2], W. Lee[2], K. Baek[3], M. Kang[3]. [1]Internal Medicine, Hallym University, Anyang, Republic of Korea, [2]Internal Medicine, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Internal Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Fat mass is an important determinant of bone mineral density (BMD), but the mechanism involved in this relation is uncertain. Several lines of evidence have suggested that the effects of fat mass on BMD may be mediated by hormonal factors, with the principal candidates being serum sex hormone, insulin, leptin, and adiponectin. Thus, the aim of this study was to investigate the relationship between serum adipocytokine and ghrelin levels, and BMD in men. Subjects were eighty men aged 42~70 (mean age, 54.5 yr). Serum concentrations of leptin and ghrelin were measured with RIA, adiponectin with ELISA, and resistin with EIA. Serum concentrations of estradiol, total testosterone, and biochemical markers of bone turnover were measured by standard methods. BMD at lumbar spine and femoral neck were measured by dual energy x-ray absorptiometry. Serum leptin levels were correlated to body mass index (BMI), waist to hip ratio (WHR), blood pressure, fasting blood sugar, serum fasting insulin, total cholesterol, triglyceride, and calcium levels. Although serum leptin levels were not significantly correlated to serum estradiol levels, but there was a weak trend in it. Serum adiponectin levels were correlated to BMI, WHR, and serum fasting insulin levels; resisitin to serum total cholesterol and low density lipoprotein cholesterol levels; ghrelin to age, WHR, and serum triglyceride levels. We observed a significant negative correlation between serum resistin levels and lumbar spine BMD. Also, there was a significant negative correlation between serum leptin levels and lumbar spine BMD. The above correlation was observed only when BMI, serum estradiol and insulin levels were included, as an independent variable, in the regression analysis model. Serum adiponectin levels were not significantly correlated with BMD, either in the presence or absence of BMI and serum insulin levels. We observed that the serum adipocytokine levels are partly associated with BMD in men. So, these data suggest that leptin and resistin may play a role on the bone mineral metabolism in men. Further studies are needed to clarify this relationship.

Hypomineralization of Bone Matrix in Male Patients with Idiopathic Osteoporosis and Fragility Fractures. S. Poetter-Lang*[1], P. Roschger[2], A. Nader*[3], P. Fratzl*[4], H. Resch*[1], K. Klaushofer[5]. [1]2nd Med.Dept., St. Vincent Hospital, Vienna, Austria, [2]Ludwig Boltzmann Institute of Osteology, 4th Med. Dept., Hanusch Hospital and UKH-Meidling, Vienna, Austria, [3]Institute for Pathology, Hanusch Hospital, Vienna, Austria, [4]Max Planck Institute of Colloids and Interfaces, Dept. Biomaterials, Potsdam, Germany, [5]Ludwig Boltzmann Institute of Osteology, 4th Med. Dept., Hanusch Hospital, Vienna, Austria.

Transiliac bone biopsies from male patients (n=24, mean age: 47 ±12) with idiopathic osteoporosis and fragility fractures (vertebral and non vertebral) were investigated for microarchitecture and bone mineralization density distribution (BMDD) to elucidate their contribution to fracture risk. Microarchitecture was described by trabecular bone volume (BV/TV), trabecular thickness (Tb.Th) and trabecular connectivity (N.Bf./B.Ar.). Mean calcium content (CaMean), the variation of calcium content (CaWidth) and the percentage of low mineralized matrix (CaLow) measured by quantitative backscattered electron imaging (qBEI) were used to characterize BMDD. The data were compared to published normative data. The clinical chemical parameters and the results of osteodensitometry (BMD measured by DXA) were compared to those of a healthy male control group (n=35, mean age: 49±9).

The clincal parameters and the biochemical markers of bone turnover of the patients did not differ from the control group. The mean value of T-score (neck: -2.2±0.8 SD, spine: -2.7±1 SD, n=24) of the patient group was significantly ($P<0.001$) different from that of the control group (neck : -0.7±1.1 SD, spine: -0.2±0.9 SD, n=35). The analysis of the biopsies revealed that patients with fragility fractures were characterized at the tissue level by reduced Tb.Th.(-12.9 %) and at the material level by decreased CaMean (-5.8 %, $P<0.0001$), increased CaWidth (+15.9 %, $P<0.0001$) and increased CaLow (+27 %). No correlation was found between BMD of lumbar spine or hip and number of clinical fractures. In contrast multiple fractures were significantly correlated ($r=0.8$; $p<0.001$) to connectivity.

We conclude from these data, that hypomineralization at the material level but not BMD is linked to fracture risk in idiopathic male osteoporosis.

Sex Hormone Binding Globulin in Primary and Secondary Osteoporosis in Men. E. Legrand, T. Couchouron*, P. Insalaco*, D. Chappard, M. Baslé*, M. Audran. Service de Rheumatologie, CHU et Inserm-EMI 0335, Angers, France.

Background: We have shown that Sex Hormone Binding Globulin (SHBG) serum concentration was increased in men with osteoporosis (OP) and was correlated with hip bone mineral density. However the cause of high serum SHBG has not been investigated (*Legrand, Bone 2001, 29: 90-95*). .

Aim: To compare SHBG and bioavailable steroids serum levels in men with primary or secondary OP.

Methods: 341 men (mean age 57.1 years) with a spine or a hip low BMD (T-score< -2) and 50 controls were included in a cross sectional and prospective study. Age, BMI and risk factors for osteoporosis were checked. Fasting serum samples were assayed for total and free testosterone, total and bioavailable estradiol and SHBG. Men without risk factors and with normal total testosterone (n= 137) were categorized as Primary OP. Spinal X rays films were analysed independently by 2 trained investigators and vertebral fracture was defined as a reduction of at least 20% in the anterior, middle or posterior vertebral height.

Results: In the total cohort, SHBG concentration was higher (38.8 vs 24.4 nmol/l, p< 0.001) and bioavailable estradiol (75.5 vs 128.2 %) and testosterone (14.7 vs 25.4%) were lower in patients compared with controls. After adjusting for age and BMI, there was no significant difference between primary and secondary OP for SHBG, total and bioavailable estradiol. Furthermore, SHBG and bioavailable estradiol levels were not correlated with tobacoo smoking, alcohol consumption or corticosteroids use. In contrast, total testosterone (4.2 vs 4.9 microg/l, p< 0.01) and bioavailable testosterone(12.9 vs 17.23 %) were lower and LH (6.1 vs 4.4 IU/l) was higher in men with secondary OP.

After adjusting for BMI, total testosterone and estradiol, hip BMD was correlated with SHBG in primary OP (r = 0.34, p< 0.001) and in secondary OP (r = 0.17, p< 0.01). Finally, logistic regression analysis showed that after adjusting for BMI, SHBG was strongly associated with the presence of vertebral fracture in men with primary OP (1SD increase, Odds ratio = 2.4, CI 1.3-4.5) or secondary OP (1SD increase, Odds ratio = 2.2, CI 1.4-3.5)

Conclusions These results confirm that SHBG serum level is higher in men with OP, correlates with hip BMD and vertebral fracture, *independently* of classical risk factors such as tobacco smoking, alcohol abuse or corticosteroid therapy. In contrast these factors inhibit the secretion of testosterone, which could worsen bone loss. Family and genetic studies are needed to elucidate the over expression of SHBG in men with low BMD.

Rapid Bone Loss at the Hip in HIV-infected Postmenopausal Women. M. T. Yin*, J. Dobkin*, V. Addesso, J. Zadel*, K. Brudney*, E. Shane. Medicine, Columbia College of Physicians & Surgeons, New York, NY, USA.

Low bone mineral density (BMD), a complication of HIV infection and antiretroviral therapy (ART), has been reported both in HIV-infected men and premenopausal women, although increased rates of bone loss have not been observed consistently in these groups. The incidence of HIV infection is increasing among postmenopausal (PM) women, in whom the risk for fractures and the need for intervention may be much greater. In this regard, we have reported that that the prevalence of osteoporosis (T<-2.5) at the lumbar spine (LS) was significantly greater in Hispanic and African-American HIV+ than HIV- PM women (41% vs 22%; p< 0.05). HIV status remained a significant predictor of LS BMD after controlling for age, body mass index (BMI) and ethnicity.

Hypothesizing that rates of bone loss would be more rapid in HIV+ than normal PM women, we measured BMD by DXA and biochemical indices of mineral metabolism in 32 HIV+ PM women at baseline and 1 year. Because comparable data have not been published for African-American and Hispanic women, annual % change in BMD in the HIV+ women was compared with data from healthy white PM women after stratification for early (<5 years) and late (>5 years) after menopause. Correlates of annual % change in BMD were evaluated by t-tests and simple regression. Data are reported +/- SEM.

Subjects were aged 56 +/- 2 and were PM by 10 +/- 2 yrs. 72% were Hispanic and 28% African American. Time since HIV diagnosis was 8 +/- 2 yrs; 79% were currently on ART and of those, the mean duration of ART was 5 +/- 1 yrs. Annual % change in femoral neck BMD was -2.5 +/- 0.9% in the early menopause group (N=10) and -2.7 +/- 1.6% in the late group (N=19), both higher than the upper limit of annual rates reported in healthy PM women (-0.6%). Annual % change in total hip (TH) BMD was positively correlated with time since HIV diagnosis (r=0.38, p=0.04), and baseline levels of bone turnover markers: osteocalcin (r=0.51, p<0.01), bone specific alkaline phosphatase (r=0.43, p=0.02), and N-telopeptide (r=0.41, p=0.04). Annual % change in TH BMD was not significantly correlated with age, time since menopause, BMI, nadir CD4, duration or class of ART, or serum levels of 25-OH vitamin D. Annual % change in lumbar spine BMD was within the range reported for healthy women.

In summary, the higher prevalence of osteoporosis in PM Hispanic and African American PM women with HIV is also associated ongoing bone loss that is greater than expected at the hip and associated with biochemical evidence of increased bone remodeling. We conclude that Hispanic and African American PM women with HIV may be at increased risk for hip fracture and should be evaluated and treated for osteoporosis.

OPG Polymorphism, Serum RANKL, Serum OPG and Bone Metabolism in Men. D. Merlotti, L. Gennari, G. Martini, A. Calabrò*, V. De Paola*, N. Dal Canto*, S. Salvadori*, R. Valenti*, B. Franci*, S. Campagna*, B. Lucani*, R. Nuti. Dept. of Internal Medicine Endocrine Metabolic Sciences and Biochemistry, University of Siena, Siena, Italy.

Osteoprotegerin (OPG) is a soluble decoy receptor that binds to the receptor activator of NF-kB ligand (RANKL), the final effector molecule for osteoclastogenesis. Both OPG and RANKL are present in the circulation in detectable amounts, however their relationship with bone mass and bone turnover in men has not been completely established. We conducted a study aimed at evaluating serum OPG and RANKL levels and their correlation with OPG polymorphism (C/T), bone turnover markers, cytokine levels, sex hormones and BMD in 100 elderly men. Serum OPG levels increased with age (r=0.26; p<0.05), while RANKL levels did not significantly varied with age (r=-0.02). OPG correlated inversely with serum bioavailable testosterone (r=-0.28; p<0.05) and estradiol levels (r=-0.26; p<0.05) and positively with LH levels (r=0.31; p<0.01). In contrast, there was no correlation between OPG or RANKL and biochemical markers of bone turnover. RANKL levels were positively correlated with circulating IL-6 (r=0.39; p<0.01) and TNF-alpha (r=0.23; p<0.05), while no relationships between OPG and cytokine levels were observed. Interestingly, even though no correlations were observed with baseline BMD (lumbar spine and femoral neck) or quantitative ultrasound (QUS) parameters at calcaneous and phalanxes, both OPG and RANKL levels appeared slightly and negatively correlated with rates of bone loss at the femoral neck (r=-0.20 and r=-0.23, respectively; p<0.05). No major differences were observed in markers of bone turnover, baseline BMD, QUS or rates of bone loss in subjects grouped according to either serum OPG or RANKL above or below the median value. However, subjects with serum RANKL levels below the median value showed higher bioavailable estradiol levels and lower IL-6 and TNF-alpha levels. Even though osteoporotic subjects showed higher OPG and RANKL levels with respect to non osteoporotic subjects these differences were not statistically significant. Finally, no significant differences in bone turnover markers, BMD and rates of bone loss were observed according to the C/T polymorphism in the OPG gene, except for OPG levels that were higher in men homozygous for the C allele. In conclusion, our data confirm that age and sex hormones are important determinant of serum OPG levels in men. While the increase in circulating RANKL may reflect an increase in bone remodeling, the rise in circulating OPG could represent an homeostatic mechanism to limit bone loss.

Posturographic Evaluation of the Effects of Alfacalcidol and Active Absorbable Algal Calcium (AAA Ca) on Sway Parameters with Eyes Opened and Closed. T. Fujita[1], S. Nakamura*[2], M. Ohue*[2], Y. Fujii[1], A. Miyauchi*[3], Y. Takagi*[3], H. Tsugeno*[4]. [1]Calcium Research Institute, Kishiwada, Japan, [2]Katsuragi Hospital, Kishiwada, Japan, [3]National Sanatorium Hyogo Chuo Hospital, Sanda, Japan, [4]Tsuyama Chuo Hospital, Tsuyama, Japan.

Swaying and postural in stability frequently seen in elderly subjects representing one of the risk factors has been difficult to evaluate accurately until the introduction of computerized posturography. In view of the effects of vitamin D derivatives and active absorbable algal calcium (AAA Ca) preventing fracture in addition to moderately increasing bone mineral density (Journal of Bone and Mineral Metabolism 22: 32-38, 2004), 30 subjects without specific disorders of mineral metabolism or neurological disorders were randomly selected and divided into 3 groups of 10 subjects each. After baseline posturography, group A was given 1μg alfacalcidol daily, group B 900 mg calcium as AAA Ca and group C nothing in addition to continued daily food. Mean age (61± 2, 62 ± 2 and 63 ± 2 years in groups A, B and C respectively) and lumbar bone mineral density was indistinguishable among these groups. After 2 months, posturography was repeated. Paired t-test before and after treatment revealed significant decrease of the area covered by the tract of the center of gravity indicating the extent of sway (p=0.0039) and significant increase of the tract density per unit area indicating sway-control efficiency (p=0.0054) in group A but not B and C, with eyes opened. With eyes closed, however, significant decrease of sway area (p=0.0169) and significant increase of tract density (p=0.0245) occurred only in group B and not in A and C. Analysis of variance with multiple comparison by Fisher's PLSD method of after/ before ratio of sway area revealed significant decrease in both A and B but not C. With eyes closed, only B showed significant increase of tract density. Both alfacalcidol and AAA Ca alleviated swaying, the former especially with eyes opened and the latter with eyes closed, suggesting a difference in the mechanism of action.

Immobilization Induces a Widespread Loss of Bone Integrity and Impaired Sensory Neurohumoral Signaling. W. S. Kingery[1], S. Offley*[1], T. Guo*[1], T. Wei*[1], D. Lindsey*[2], C. Jacobs[2]. [1]PM&R service (117), VAPAHCS, Palo Alto, CA, USA, [2]Rr&d, VAPAHCS, Palo Alto, CA, USA.

Recently we observed that unilateral sciatic nerve transection in rats caused a reduction in cancellous bone density and substance P content in the contralateral intact hindlimb. Chronic administration of a substance P receptor antagonist after sciatic section further enhanced bone loss in the intact contralateral hindlimb, therefore we postulated that reduced neuropeptide release in bone could contribute to the remote bone loss. It has long been recognized that immobilization alone can cause a loss of trabecular mass, structure, and strength, but the remote effects of immobilization alone have not been previously investigated. In the current study we tested the hypothesis that prolonged unilateral limb immobilization has deleterious effects on cancellous bone and neuropeptide signaling in the contralateral limb. The right hindlimbs of skeletally mature Sprague Dawley male rats were casted for 4 weeks. Immobilization caused a reduction in bone mineral density (measured by DXA scanning at 4 weeks after cast removal) in the metaphyses of the ipsilateral and to a lesser extent contralateral femur. There was no effect on diaphyseal bone density in either limb. Microcomputed tomography (μCT) in the distal femur demonstrated bilateral loss of trabecular bone volume and connectivity after unilateral immobilization. On biomechanical testing bone strength was also reduced bilaterally. No changes were observed in body weight or 24-hour grid-crossing activity at 4 weeks after immobilization and there was no reduction in weight bearing or gastrocnemius and soleus muscle mass in the non-immobilized left hindlimb, data indicating that skeletal unloading did not contribute to the loss of cancellous bone integrity the contralateral femur. Substance P and calcitonin gene-related peptide (CGRP) levels in the sciatic nerve were reduced bilaterally after unilateral immobilization. Sciatic nerve stimulation evoked extravasation responses were also diminished bilaterally after immobilization. These results support the hypothesis that the remote osteoporotic effects of unilateral limb immobilization are a consequence of impaired sensory neurohumoral signaling in the cancellous bone.

In Postmenopausal Women, Femoral Neck BMD Is Positively Correlated to Circulating Levels of Soluble RANKL and Negatively Correlated to Levels of IL-7. S. Walker*, M. B. Finch*, D. Marsh*, G. Li. Trauma Research Group, Queen's University Belfast, Belfast, United Kingdom.

Increased T cell expression of receptor activator of nuclear factor-κB ligand (RANKL) and its binding to receptor activator of nuclear factor-κB (RANK) on osteoclasts and their precursors plays a major role in osteoclastogenic bone loss in mice. IL-7, a potent stromal cell derived cytokine, can also stimulate T cell RANKL expression and induce osteoclastogenesis in murine models.

We investigated the relationship of plasma soluble RANKL (sRANKL) and IL-7, and T cell RANKL expression in 60 post-menopausal women: 30 with osteoporosis and 30 with 'normal' BMD. BMD measurement by DXA (Lunar DPX), giving T score readings at the femoral neck and L2-L4, enabled categorisation. Osteoporosis was defined as a T score of ≤ -2.5 at femoral neck or L2-L4 or both. Plasma from each subject was banked and levels of each cytokine were determined using commercially available ELISAs. Applying a whole blood technique, mononuclear cells were dual-labelled with FITC-conjugated CD3 antibody (Dakocytomation, UK) and RPE-conjugated RANKL antibody (R&D Systems,

Europe). The percentage of CD3+RANKL+ cells was calculated using flow cytometry (EPICS Elite, Beckman Coulter).
Between the osteoporotic and non-osteoporotic groups, there was no difference in the mean plasma levels of either sRANKL or IL-7, or RANKL positive T cells (using student's t test after log transformation). However, a significant negative correlation was seen between the hip BMD and IL-7 (Pearson r = -0.24, p=0.034) which persisted after adjustment for age (r = -0.19, p = 0.043). There was a significant positive correlation between hip BMD and sRANKL (r = 0.4, p= 0.03) which persisted after adjustment for age (r=0.33, p=0.05).There was no correlation between spinal BMD and either sRANKL or IL-7 levels. When the subjects were divided into two groups; those with hip T score ≤ -2.5 and those with hip T score > -2.5, the mean sRANKL between the groups was significantly different (0.055 pmol/l v 0.125 pmol/l respectively, p = 0.008). There were no significant correlations between RANKL positive T cells and sRANKL, IL-7, hip or spinal BMD. In summary, sRANKL levels are significantly lower in those with femoral neck T scores ≤ -2.5; T cell RANKL expression does not appear to be correlated to either hip or spinal BMD, nor to plasma sRANKL or IL-7 levels. Plasma IL-7 is positively and significantly correlated with hip BMD.
In conclusion, these results suggest sRANKL and IL-7 are altered in post-menopausal femoral neck bone loss. Low levels of plasma sRANKL and high levels of IL-7 may prove useful tools in identifying those with femoral neck osteoporosis and preventing future hip fractures.

Institutionalized Elderly Type II Diabetics Have Higher Bone Mass, Lower Bone Turnover Markers and PTH Levels Compared to Non-diabetics: Evidence for Decreased Calcium Sensing by Parathyroid Glands. M. Roth*, A. Fahrleitner*, C. J. Piswanger-Sölkner*, B. Obermayer-Pietsch*, A. Tiran*, G. Leb*, E. Maier*, H. Dobnig. Internal Medicine, Medical University Graz, Graz, Austria.

Introduction: There is evidence that patients with type I diabetes mellitus (DM) have low and those with type II DM higher BMD levels when compared to controls. Little is known whether bone status and calcium regulation of elderly type II diabetics differ from non-diabetics.
Patients and methods: We compared 301 female residents with DM with 1398 non-diabetic individuals living in 95 homes for elderly. Patients´ age was between 70 and 100 years. Exclusion criteria were known malignancies, hypercalcemia and predefined significant impaired liver- and kidney function. We performed quantitative bone ultrasound measurements at the calcaneus, radius and the proximal third phalanx. Biochemical measurements included among others osteocalcin, serum cross laps (sCTX), PTH and vitamin D levels in 177 patients as well as PTHrP and amylin concentrations in a smaller subgroup. Patients were prospectively followed for the occurrence of fractures over two years. All analyses were performed after adjustment for age, BMI and renal function.
Results: Patients with DM had significantly higher BUA and SOS readings at the calcaneal- (0.5 SD in Z-score, p<0.0001) and radial site (0.3 SD, p<0.01). In diabetic subjects serum PTH, osteocalcin and sCTX levels were significantly *lower* and protein-normalized serum calcium levels *higher* when contrasted with non-diabetic patients. These differences were seen in all three decades. For defined serum calcium categories mean PTH levels were consistently lower by 15% in diabetic individuals when compared to non-diabetic patients. There was no difference in serum amylin and PTHrP levels between the two groups. A total of 110 prospective hip- and 242 non-vertebral fractures occurred. Incidence rates for non-vertebral fractures were 15% (DM) and 14% (non-DM) and for hip fractures 6% (DM) and 7% (non-DM), respectively. None of these differences were significant.
Conclusion: Bone ultrasound measurements were significantly higher in elderly residents with DM throughout all age groups. This difference was likely attributable to lower PTH secretion due to impaired calcium-sensing by the parathyroids and consecutive decreased bone turnover rates in patients with DM. This beneficial change in bone metabolism was, however, not reflected by fracture rates and may have been offset by a higher propensity of falls in diabetic residents.

Decreased Cortical Bone Mineral Density in Type2 Diabetes Mellitus. K. Tanaka[1], K. Shide*[2], K. Ishida*[1], S. Tsugawa*[1], S. Kido*[1], Y. Seino*[2]. [1]Kyoto Women's University, Kyoto, Japan, [2]Kyoto University Hospital, Kyoto, Japan.

Although type1 diabetes is associated with decreased BMD, it is controversial whether type2 diabetes causes decreased BMD or not. Obesity is common in type2 diabetes, and body weight greatly affects BMD at weight-bearing sites such as lumbar spine and hip, but not at non-bearing sites such as radius. These facts, however, do not seem to be fully taken into account by the previous researchers, which is likely to be responsible for the large discrepancies on the effects of type2 diabetes on BMD.
Fortytwo hospitalized patients with type2 diabetes were recruited in the study (62 +/- 12 years old). BMD was measured at lumbar spine, hip, radius, and whole body using QDR2000 (Hologic). As shown below, more than half of the patients had T score above -1SD at lumbar spine and total hip according to the WHO criteria. In contrast, two third of the patients were considered osteoporotic at distal one third of radius.

DXA Results at Various Skeletal Sites

	L2-4	Total Hip	Radius (distal one third)	Radius (ultradistal)
Normal	23	31	6	15
Osteopenia	15	11	8	12
Osteoporosis	4	7	28	15

Next, the patients were classified according to the skeletal site showing the lowest T score. As shown below, T score was the lowest at distal one third of radius in most of the patients.

Skeletal Site Showing the Lowest T Values

	L2-4	Total Hip	Radius (distal one third)	Radius (ultradistal)
Number of Patients	2	0	35	5

Our results suggest that type2 diabetes is associated with decreased BMD, which is obscured at weight-bearing sites. Preferential decrease of BMD at distal one third of radius suggests that BMD is decreased at cortical bone, and suggests that the pathogenesis of osteoporosis in type2 diabetes is different from that in postmenopausal osteoporosis.

Chronic Bone Pain Following Femur Fracture in the Rat: Modeling the Osteoporotic Pain Experience. M. P. Roudier, J. S. Wiley*, T. L. Panzitta*, M. D. Brot*, S. D. Bain. SkeleTech, Inc., Bothell, WA, USA.

Chronic bone pain associated with osteoporotic fractures is a commonly encountered clinical problem. However, there are no established preclinical models to investigate the nature and source of the enduring pain observed in osteoporotic patients. In order to explore this question, we have evaluated nociceptive responses in a rat bone fracture model. Experimentally, male Sprague-Dawley rats received either a closed fracture of the right femur stabilized by an intramedullary pin (IM pin) or a sham procedure which involved insertion of the IM pin only. An untreated control group was also included. Pain associated with the bone fracture was determined beginning 3 weeks post-fracture using tests for thermal and mechanical hyperalgesia. The test of thermal hyperalgesia measures the withdrawal latency when a heat source is directed at the hind paw, while mechanical hyperalgesia uses Von Frey filaments to assess somatosensory responses to pressure stimuli. Testing for thermal and mechanical hyperalgesia continued until the rats were sacrificed at 6 weeks post-fracture. Compared to intact and IM pin controls, the analyses of the thermal and mechanical hyperalgesia revealed that the animals experienced significant pain in the fractured limb (p<0.01), which, in the case of the mechanical hyperalgesia, persisted for the duration of the 6-week experiment (p<0.01). Furthermore, the mechanical hyperalgesia was inhibited dose-dependently by gapapentin, an agent prescribed for neuropathic pain, but not by salmon calcitonin or the non-specific cyclo-oxygenase inhibitor, ketorolac. Finally, immunostaining of the dorsal horn of the spinal cord for the astrocyte marker, glial fibrillary acidic protein (GFAP) revealed a significant upregulation of GFAP immunostaining in the ipsilateral cord that was at least partially abrogated by gabapentin treatment. In summary, the persistent mechanical hyperalgesia and GFAP upregulation in the spinal cord observed post-fracture is indicative of chronic pain conditions. Moreover, the inhibition of persistent pain by gabapentin but not by calcitonin or ketorolac suggests that the fracture pain in this model may be neuropathic in nature. Therefore, these findings demonstrate the potential of this model to investigate and characterize the mechanisms associated with the development of chronic bone pain following fracture.

Association between 8-Hydroxydeoxyguanosine Levels in Bone Marrow and Bone and Mineral Metabolism. M. I. Kang, K. H. Baek*, H. J. Tae*, J. H. Han, W. Y. Lee*, K. W. Oh*, C. S. Cho*, H. S. Kim*, K. W. Lee*. Internal medicine, The catholic University of Korea, Seoul, Republic of Korea.

Reactive oxygen species (ROS) have been shown to be responsible for the aging process and osteoporosis. Several lines of evidence have found a tight association between oxidative stress and pathogenesis of osteoporosis. We studied the relationship between oxidative stress in the bone marrow and bone and mineral metabolism. Little is known about the oxidant status in the bone marrow, and its direct measurement from the bone marrow may establish the effect of oxidative stress on the local milieu of the bone metabolism within the bone microenvironment. The main aim of this study is to investigate whether oxidative stress in bone marrow may have an impact on bone metabolism and bone mass. Oxidative stress was evaluated in bone marrow serum by measurement of 8-hydroxy-2'-deoxyguanosine (8-OHdG) in 39 patients (48.2±13.5 years, 24 men, 15 women). The biochemical markers of bone formation (bone specific ALP) and resorption (ICTP) were measured from the same specimen. Bone mineral density (BMD) of the lumbar spine, and proximal femur were measured by dual energy X-ray absorptiometry. In the age-, sex-, weight- and smoke status- adjusted model, the marrow 8-OHdG level showed a positive correlation with marrow ICTP level (r=0.36, p<0.05). Although statistically not significant, the 8-OHdG levels tended to be negatively associated with the BMD at lumbar spine and proximal femur. Taken together, theses results suggest for the first time that increased oxidative stress in bone marrow could be involved in negative balance in the bone metabolism

Osteoprotegerin and RANKL Serum Levels in Primary and Secondary Osteoporosis. G. Martini, S. Salvadori*, L. Gennari, R. Valenti*, B. Franci*, S. Campagna*, A. Avanzati*, B. Galli*, D. Merlotti, B. Lucani*, R. Nuti. Dept. of Internal Medicine Endocrine Metabolic Sciences and Biochemistry, University of Siena, Siena, Italy.

Osteoprotegerin (OPG), a secreted member of tumor necrosis factor superfamily, has been identified as an osteoblast-derived regulator of bone resorption: it acts neutralizing the receptor activator of nuclear factor κβ ligand (RANKL), a cytokine required for osteoclast formation and activation. The aim of the study was to evaluate both age-dependent changes of these cytokines with age in healthy women and men and their relationships with bone mass and bone metabolism. Moreover we examined the behaviour of serum OPG and RANKL in patients with postmenopausal osteoporosis or chronic glucocorticoid treatment.
The population studied was: 150 healthy women aged 59.9±10.2 years, 87 healthy men aged 68.4±8.7 years, 103 women with postmenopausal osteoporosis aged 65.2±8.5 years, and 36 subjects with myastenia (18 females and 18 males aged 61.8±18.1) on glucocorticoid treatment for at least one year.
Sera were assayed for OPG and RANKL using a sandwich enzyme immunoassay (Osteoprotegerin and RANKL, Biomedica, Austria). Precision intra and interassay was lower than 10%. Bone metabolism was evaluated by serum cross linked C-telopeptides of type I collagen (sCTX, Serum CrossLaps, Osteometer, Denmark), serum parathyroid hormone (PTH intakt MTPL, Germany, and vitamin D status (25-OH RIA Kit, DiaSorin, USA).
Osteoporotic women and patients on glucocorticoid showed significantly higher values of OPG (7.6±4.8 pmol/L and 8.6±6.1 pmol/L, respectively) compared to healthy women and men (6.5±3.4 pmol/L and 5.4±3.2 pmol/L, respectively). High levels of RANKL were found in steroid-osteoporosis (7.04±4.4 pmol/L) while in the other groups RANKL ranged from 0.97 pmol/L to 1.24 pmol/L. Serum OPG was positively correlated to bone mass expressed as T-score in all the studied population except in osteoporotic women. The only significant relationship regarding bone turnover was found between RANKL and CTX in healthy women ($r=0.22$, $p<0.01$). No correlations were found as regards OPG, RANKL, PTH and 25-OHD. We conclude that OPG increase with age both in women and men. The high values of OPG in primary and secondary osteoporosis suggest an attempt to counteract the increased rate of remodeling although serum levels of OPG and RANKL were unrelated to bone turnover, parathyroid function and vitamin D status. The increase of RANKL in steroid-induced osteoporosis have to be better clarified.

Iliac Crest Biopsy Chemical Composition Differentiates Fractured from Non-fractured Women and Exhibits Change with Age. B. R. McCreadie[1], T. Chen*[2], D. S. Rao[3], M. D. Morris*[2]. [1]Orthopaedic Surgery, University of Michigan, Ann Arbor, MI, USA, [2]Chemistry, University of Michigan, Ann Arbor, MI, USA, [3]Bone and Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA.

It is currently unclear whether chemical composition of bone tissue changes with age or influences osteoporotic fracture risk.
Archival iliac crest biopsies from subjects without fractures (n=10, mean age 56 y, range 43-70 y) and patients with osteoporotic fractures (n=5, mean age 63 y, range 50-72 y) were studied. Separate regions 220 x 330 microns were scanned in trabecular and cortical regions of each specimen using Raman spectroscopy, resulting in datasets of 18,900 pixels each. From pixels containing bone, average carbonate/phosphate and phosphate/amide I band area ratios were obtained separately for trabecular and cortical regions of each specimen. No corrections were made for multiple comparisions.
Both carbonate/phosphate ratio and phosphate/amide I ratio were higher in cortical than trabecular bone for all specimens ($p=0.005$ and $p=0.01$, respectively, paired t-tests). This suggests that mineralized matrix chemistry differs between bone types. Whether this is a fundamental difference or a result of differing average tissue age is unclear.
Chemical composition of cortical bone mineralized matrix changes with age, as demonstrated by a decrease in phosphate/amide I ratio ($p=0.005$, linear regression model). Neither carbonate/phosphate ratio in cortical bone nor any measure in trabecular bone showed significant change with age.
The phosphate/amide I ratio in non-fractured subjects was greater in cortical than trabecular bone until age 55 (in all 6 subjects), but greater in trabecular bone in those 55 y or older (in all 4 subjects). In all 5 fractured patients, the phosphate/amide I ratio was greater in cortical bone. Thus, fractured patients demonstrated the pattern seen in younger (under 55) non-fractured subjects, as opposed to the pattern of non-fractured subjects of similar age. It is possible that failure to alter mineralized matrix chemistry results in increased fracture risk.
Comparing fractured to non-fractured individuals, trabecular bone from fractured patients had lower phosphate/amide I ratio ($p=0.03$, t-test). No differences were found in cortical bone or in carbonate/phosphate ratio in trabecular bone. This lower mineral/matrix ratio (decreased mineral) in trabecular bone suggests a systemic increase in remodeling prior to or following fracture, and is likely demonstrated more clearly in trabecular bone because of its more rapid turnover. If this increase in remodeling occurs prior to fracture, chemical composition from iliac crest biopsy specimens may improve fracture risk assessment.

A Comparison of Estrogen, Calcitriol or Both Therapies on the Relationship between Serum Parathyroid Hormone and 25 Hydroxy Vitamin. J. C. Gallagher, P. B. Rapuri, G. Haynatzki*. Bone Metabolism Unit, Creighton University, Omaha, NE, USA.

Estrogen deficiency , decreased serum calcitriol and secondary hyperparathyroidism have been implicated in the pathogenesis of osteoporosis.It has been proposed that estrogen prevents the age-related increase in parathyroid hormone (PTH) either directly or indirectly by suppressing PTH secretion. In the present study, we compared the effects of calcitriol and conjugated estrogens or the combination of both on the relation between PTH and 25OHD. In a double blind, placebo randomized study, 489 elderly women were randomized to HRT, CEE.625 mg +MPA2.5mg daily (ERT only in hysterectomized), calcitriol 0.25 mg. b.i.d., HRT & calcitriol, or placebo for 3 years .Serum 25OHD levels were measured by competitive protein binding assay and serum intact PTH was measured with an Allegro immunoradiometric assay both at baseline and end of study (36 months). The differences between slopes and intercepts between the regression lines of serum 25OHD and PTH in the four treatment groups was compared by SAS. There was no significant difference between the regression slopes of placebo and the hormone therapy/estrogen therapy ($p=0.77$) groups. However there was a significant ($p<0.006$) difference between the placebo ($y=65.78-0.81x$) and the calcitriol ($y=39.6-0.32x$) treatment groups.
After 3 years treatment with estrogen there was no decrease in serum PTH and no change in the relationship between serum 25OHD and PTH whereas calcitriol treatment significantly decreased serum PTH by sixty percent compared to placebo.In estrogen treated women serum 25OHD remains the primary determinant of serum PTH. In contrast on calcitriol treatment there was no significant relationship between serum 25OHD and PTH.In summary,calcitriol is more effective than estrogen in reducing secondary hyperparathyroidism in elderly women.

Valproic Acid Inhibits Osteoblast and Osteoclast Activity in Therapeutic Dose Ranges. B. L. Gracious*[1], R. P. Bossert*[2], J. Puzas[3]. [1]Psychiatry and Orthopedics, University of Rochester Medical Center, Rochester, NY, USA, [2]University of Rochester Medical Center, Rochester, NY, USA, [3]Orthopedics, University of Rochester Medical Center, Rochester, NY, USA.

Cross-sectional studies have demonstrated reduced bone mineral density in children or adults receiving anticonvulsant treatment with valproic acid (VPA). Mechanisms for such action have not been determined. We examined direct effects of VPA on osteoblast viability, proliferation, and activity and on osteoclast cell function.
Osteoblasts from neonatal mouse calvaria were isolated and plated in standard solution. Media from the cells was replaced with plating media +/- VPA in 1:5 dilutions from 1000-0.32µg/ml in triplicate. Exposure concentrations for all components of the study were 0.0µg/ml, 0.32µg/ml, 1.6µg/ml, 8µg/ml, 40µg/ml, and 200µg/ml. Cells were harvested after 24 or 48 hours in VPA media for determinations of viability, proliferation or alkaline phosphatase activity evaluation. Viability was assessed using an MTT assay system with absorbance measured at 595nm. Proliferation was measured via de novo DNA synthesis after incorporation of radiolabeled thymidine. Radioactivity was determined by liquid scintillation spectrometry. Alkaline phosphatase activity was measured after adding p-nitrophenylphosphate solution for up to 30". Absorbance was read at 410nm. Osteoclast function was measured by lacunae formation on bovine bone wafers incubated for 14 days with neonatal rat osteoclast cells at concentrations of either no VPA or 0.32µg/ml - 200µg/ml VPA in 1:5 dilutions. Number and area of osteoclast lacunae were quantified with Osteometrics software.
Osteoblast alkaline phosphatase activity decreased significantly at 48 hours at VPA levels from 4-200ug/ml corrected for viability ($p < 0.05$ for VPA at 8, 40, and 200ug/ml). Osteoblast viability and proliferation were unaffected by VPA through 200ug/ml with evidence of decreased proliferation at 1000ug/ml. Osteoclast lacunae formation trended downward as VPA concentration increased.
Human therapeutic ranges of VPA (50-100µg/ml) appears to inhibit osteoblast alkaline phosphatase activity in a rodent cell model. Osteoclast lacunae formation may decrease as valproic acid concentration increases. Replication of these findings, determination of the specific cellular/genetic pathways of inhibition, and an animal model to examine for potential histologic and clinical changes are needed.

The Rate That Family Physicians Prescribe Pharmacological Treatment to Their Patients: Canadian Quality Circles (CQC) Project. B. Kvern*[1], G. Ioannidis[2], M. Doupe*[1], A. Katz*[1], A. Papaioannou[2], A. Hodsman[3], A. Baldwin*[4], D. Johnstone*[5], M. Baranci*[6], J. D. Adachi[2]. [1]University of Manitoba, Winnipeg, MB, Canada, [2]McMaster University, Hamilton, ON, Canada, [3]University of Western Ontario, London, ON, Canada, [4]St. Boniface Hospital, Winnipeg, MB, Canada, [5]Procter & Gamble Pharmaceuticals Inc, Toronto, ON, Canada, [6]Aventis Pharma, Laval, PQ, Canada.

The CQC Pilot Project is a one year, integrated disease management project to improve family physicians' adherence to the OSC 2002 guidelines through the use of standardized documentation and sequential quality QC meetings. There were 449 family physicians approached to participate. Among these, 52 formed 7 quality circles. The 52 physicians conducted chart reviews for a total of 1505 patients. These patients were women age 55 years and over, were known to the physician and had attended at least 2 visits in the past 24

months. Data were gathered using the quality circle project data collection form.
Our baseline analysis examined the rate that family physicians prescribe drug treatment to their patients depending on the likelihood that they had osteoporosis. A patient likely to have osteoporosis was one who was perceived by the physician to have the disease or the physician interpreted the patient's BMD test results as osteoporosis. A patient not likely to have osteoporosis was one who was perceived by the physician not to have the disease or the physician interpreted the patient's BMD test results as not osteoporosis. We examined rates of drug therapy for patients likely and not likely to have osteoporosis. For those patients who received drug therapy, we evaluated the rate that physicians were prescribing their drug of choice.
Results indicated that of those patients who were likely to have osteoporosis, 70% were and 30% were not treated for the condition. Of the patients not likely to have osteoporosis, 11% were and 89% were not given therapy. For those patients that received therapy, approximately 73% of patients were taking the physician's drug of choice. The reasons why some patients were not taking the physician's drug of choice included the price of medication to the patient, treatment side effects, formulary restrictions, patient refused treatment, and patient compliance.
In conclusion, a high proportion of patients with osteoporosis are being treated, much higher than has previously been reported. However, 30% of patients that were eligible for treatment did not receive therapy. In addition, a portion (27%) of patients on therapy are not taking the physician's drug of choice. Future research should focus on education approaches that address the barriers identified by family physicians in prescribing therapy to their patients with osteoporosis.

Alendronate Treatment Prevents Periprosthetic Bone Loss Following Total Hip Arthroplasty. G. M. Blake[1], A. I. A. Rahmy*[2], A. Tonino*[3], I. Fogelman[1]. [1]Nuclear Medicine Department, GKT School of Medicine, London, United Kingdom, [2]Nuclear Medicine Department, Atrium Medical Centre, Heerlen, Netherlands, [3]Orthpaedics Department, Atrium Medical Centre, Heerlen, Netherlands.

Historically periprosthetic bone losses of up to 25% have been reported in patients undergoing total hip arthroplasty (THA). We report a pilot study to investigate whether treatment of THA patients with alendronate (70 mg once a week) starting before their operation can prevent these losses. Twenty-eight consecutive patients (23F,5M) (mean age 62 y, range 41-77 y) undergoing THA with a cementless hip prosthesis (ABG2, Howmedica International, Rutherford, NJ) commenced alendronate treatment one month before surgery. Twenty-six untreated patients (14F,12M) (mean age 62 y, range 48-69 y) also receiving the ABG2 prosthesis served as a control population. Both groups were operated on by the same team of surgeons and followed an identical regime after THA. Postoperative DXA scans were performed to measure BMD in periprosthetic bone at 10 days (treated as baseline for the subsequent follow-up), 6 weeks, 3 months and 6 months in the 7 Gruen zones (GZ) and the total periprosthetic region of interest (total ROI). For the total ROI the mean percentage change (SEM) in BMD at 6 months was +0.7 (1.3) % in alendronate treated patients compared with -5.2 (1.2) % in untreated patients ($p = 0.002$). The trend for alendronate treatment to prevent postoperative bone loss was found in both female (+0.9 (1.7) % vs -4.6 (1.7) %, $p = 0.032$) and male patients (+0.2 (1.1) % vs -5.7 (1.7) %, $p = 0.051$). A repeated measures ANOVA test showed a highly statistically significant treatment effect in the total ROI ($p = 0.002$), GZ1 ($p = 0.002$), GZ2 ($p = 0.014$), GZ3 ($p = 0.010$), GZ4 ($p = 0.001$) and GZ5 ($p = 0.008$), but not GZ6 ($p = 0.60$) or GZ7 ($p = 0.59$). In conclusion, alendronate treatment was effective in preventing periprosthetic bone loss in patients undergoing THA with the ABG2 prosthesis in the total periprosthetic ROI and in 5 out of 7 Gruen zones.

Bisphosphonate Effects on the Program of Gene Transcription During Osteoclastogenesis. L. Sun*[1], G. Gross*[2], A. Varbanov*[2], R. Phipps*[2], M. Zaidi[1], B. R. Troen[3]. [1]Mount Sinai School of Medicine, New York, NY, USA, [2]Procter & Gamble, Cincinatti, OH, USA, [3]Miami VAMC GRECC, University of Miami School of Medicine, Miami, FL, USA.

To investigate the impact of bisphosphonates upon gene expression during osteoclast formation, we performed micro array transcriptional profiling of osteoclast precursors (RAW 264.7 cells) *in vitro*. We analyzed the 5-day time point following induction of osteoclastogenesis with RANK ligand (RANKL), with or without risedronate (RIS) (10^{-6} M) or alendronate (ALN) (10^{-7} M). Cells were also treated with RIS or ALN alone, without RANKL. cRNA was prepared from duplicate samples of each treatment condition and hybridized to Affymetrix U74Av2 mouse genome arrays. Eliminating probe sets with absent calls across all conditions removed 5678 of the 12422 probe sets on the chip. Of the remaining 6744, the probe sets where the NLOGP values were >3 (NLOGP=log10(P-value)) were considered differentially expressed. Of a total of 629 differentially expressed probe sets identified through this analysis, RANKL versus untreated cells exhibited 479, and RANKL + RIS versus control exhibited 523. In contrast, RIS versus untreated, and RANKL + RIS versus RANKL exhibited only 17 and 2 differentially expressed probe sets, respectively. The addition of RIS to RANKL thus resulted in only 2 differentially expressed genes in comparison to RANKL alone, indicating a minimal effect of RIS on transcription during osteoclastogenesis. Initial analyses suggested that ALN did alter transcription, but we cannot, at this point, exclude the possibility of technical artifacts resulting from "bright chips". RANKL treatment expectedly stimulated the expression of osteoclastic genes, including MMP-9, calcitonin receptor, TRAP, cathepsin K, integrin β3, and carbonic anhydrase, but inhibited cathepsins L, S, C, and B. Genes such as VEGF-C, chemokine receptor 1, and M-Ras, were newly identified as RANKL inducible. Interestingly, RANKL potently suppressed expression of a large group of interferon-γ regulated genes, including interferon-γ-induced proteins with tetratricopeptide repeats 1 and 2 and IFN regulatory factor 7. Quantitative real-time RT-PCR of a subset of genes confirmed the transcriptional profiling data. Thus, utilizing powerful transcriptional profiling technology, we demonstrate (a) the divergent regulation of cathepsin, interferon-γ-regulated, and growth factor (VEGF-C and IGF-1) genes, and (b) that the potent bisphosphonate, risedronate, at least *in vitro*, appears to act by mechanisms other than by altering gene transcription during osteoclast formation.

Evaluation of BMD in Patients with Graves' Disease and Its Change during Anti-thyroidal and Aminobisphosphonate (Alendronate or rIsedronate) Therapy. S. Wada[1], S. Yasuda*[2], M. Kogawa*[2], S. Kamiya*[1], S. Katayama*[2]. [1]Dept of Clinical Science, Josai International University, Chiba, Japan, [2]Dept of Endocrinology and Metabolism, Saitama Medical School, Saitama, Japan.

It is recognized that loss of bone mineral density (BMD) and risk of fractures are associated with endocrine disturbances. Although hyperthyroidism has been considered as one of the risk factors for osteoporosis, it is not well established whether hormone excess due to Graves' disease (GD) actually reduces BMD or whether effective treatment can reverse the decrease of BMD in these patients. The aim of this study was, therefore, to evaluate BMD in GD, and its change by treatment. We examined 44 GD patients (14 males and 30 females), and 45 with Hashimoto's disease (HD), as a reference. GD patients were treated with anti-thyroidal drugs, radioisotope, or subtotal thyroidectomy and patients of HD were treated with lT4. In patients with GD, BMD did not correlate solely with duration of disease, body mass index, the titers of TSH receptor antibodies, or the amounts of anti-thyroidal drugs. There was no significant difference between BMD in premenopausal GD women or women with HD. In postmenopausal women treated for GD, however, lumbar BMD was reduced significantly in comparison with healthy controls and with the HD patients. The age of disease onset correlated significantly with BMD ($p<0.01$, $r=-0.88$), suggesting that the age of onset could be an important factor in the eventual loss of BMD or development of osteoporosis. We further examined the changes of BMD during the treatment of hyperthyroidism in 26 patients (4 males and 22 females). 22 out of 26 patients were successfully treated and regained euthyroid status; their lumbar BMD increased in response to therapy (T score -0.72 vs. -0.26). In contrast, patients whose treatment was unsuccessful lost ~5% of lumbar BMD over ~2yr . After the follow up period (when BMD was largely unchanged), GD patients with low BMD (<-2.5SD) received alendronate (5mg/day) or risedronate (2.5mg/day). This medication effectively increased lumbar BMD by 6.95±7.33%/yr. Although bone loss associated with hyperthyroidism is regarded as a transient event, this study indicates that patients who develop hyperthyroidism after menopause hardly ever retain BMD. GD could be a significant risk for osteoporosis, but effective therapy for this, as well as aminobisphosphonate administration, can significantly increase BMD in these patients.

Risedronate Therapy reduces the Risk of New Vertebral Fractures by 60% in Osteoporotic Men with osteoporosis within 1 year. J. Ringe[1], H. Faber*[1], M. Salem*[1], A. Grauer[2], G. Möller[3]. [1]Medizinische Klinik IV, Klinikum Leverkusen, University of Cologne, D-51375 Leverkusen, Germany, [2]Medical Affairs, Procter & Gamble Pharmaceuticals USA, Mason, OH, USA, [3]Medical Affairs, Procter & Gamble Pharmaceuticals Germany GmbH, D-65824 Schwalbach, Germany.

Background: In postmenopausal osteoporosis clinical studies with Risedronate have shown rapid fracture reduction at vertebral and non-vertebral sites after only 6 months of treatment. Rapid reduction of vertebral fracture risk with Risedroante has also been shown in glucocorticoid-induced osteoporosis and interestingly, the risk reduction observed in male and female subgroups was not different. Purpose of the study: In the current study, we examine the effects of Risedronate on vertebral fractures and BMD mean change in lumbar spine, femoral neck and total hip BMD only in men with primary and secondary osteoporosis. Secondary endpoints include non-vertebral fractures, height loss, pain, safety, and tolerability. Methods: In this single center, open label, prospective, conrolled trial, patients were randomized by stratum. 316 male patients were recruited with T-score values of lower than -2.5 SD at lumbar spine (LS) and lower than -2.0 SD at the femoral neck (FN) with or without prevalent vertebral fractures (vert-fx). Patients in Group A (n=158; 81 with, 77 without prevalent vert-fx) received Risedronate 5 mg plus calcium 1000 mg and 800 IU Vit. D daily. Group B comprised equally 158 men. Those with a prevalent vert-fx (subgroup B1 n=81) were treated with alfacalcidol 1 mg plus calcium 500 mg daily, whereas patients without prevalent vert.-fx (subgroup B2, n=77) were treated with 800 IU plain vitamin D plus calcium 1000 mg daily. In group A 64 patients (41%) and in group B 66 (42%) had secondary osteoporosis. BMD measurements and x-rays were performed at baseline and 12 months thereafter. Results: After this first year of treatment men receiving Risedronate showed a mean LS-BMD increase of 4.7% compared to a mean increase of 1.0% in Group B patients ($p<0.001$). The mean change of total hip BMD was 2.7% and 0.4% for groups A and B, respectively ($p<0.001$). Corresponding changes at the FN were 1.8% and 0.3% for the respective groups ($p<0.001$). During the 12 months of therapy in 5% (8/158) of patients of Group A and in 12.7% (20/158) of Group B new vert-fx were recorded (RR 0.4, Fisher' exact test; $p<0.028$). The corresponding incidences for patients with new non-vert-fx were 10 and 17, (RR 0.59, n.s due to insufficient power). Both therapies were well tolerated. Conclusions: We conclude that Risedronate therapy within one year reduces the risk of new vertebral fractures by 60% and significantly increases BMD at all measurement sites in men with osteoporosis.

Effects of Continuous Combined HRT and Clodronate on Bone Mineral Density in Osteoporotic Postmenopausal Women: 5-Year Follow-Up. K. Hänninen*[1], M. Tuppurainen[1], M. Komulainen*[1], J. Jurvelin*[2], H. Kröger[3], E. Alhava*[3], S. Saarikoski*[1]. [1]Obstetrics and Gynecology, Kuopio University Hospital, Kuopio, Finland, [2]Clinical Physiology and Nuclear Medicine, Kuopio University Hospital, Kuopio, Finland, [3]Surgery, Kuopio University Hospital, Kuopio, Finland.

Recent Studies suggest, that adding bisphosphonates to hormone replacement therapy (HRT) may improve the antiresorptive effects of HRT. In this 5-year randomized study we examined the effects of HRT with or without bisphosphonate. In the Kuopio Osteoporosis Study (OSTPRE) a sample of 3200 women were selected for BMD measurement by Lunar DPX in 1995-97. In all 167 women aged 61±2.7 years (11±4.9 years postmenopausal), with a T-score ≤ -2.5 SD at either the lumbar spine or femoral neck were recruited. They were randomized to receive daily estradiol hemihydrate (E2) 2mg + noretisterone acetate (NETA) 1mg (Kliogest®, Novo Nordisk, Denmark) + Boneplac, which consisted of either 800mg clodronate (Bonefos®, Leiras Ltd, Finland) (n=48) or placebo(n=47). In case of contraindications or refusal from HRT, the women were offered clodronate 800mg/day (n=50). The multivariate ANOVA analyses for repeated measurements were used. The results are based on an intention to treat analyses.BMD was measured at 0,1,3 and 5-year intervals. The baseline characteristics were similar in all treatment groups, including BMD. After one year treatment the lumbar BMD increased in all treatment groups: 4.9%±3.4% in the HRT group, 4.6%±4.5% in the combination group and 1.8%±4.3% in the clodronate group. After three years the HRT and combination groups showed increases of 2.9%±4.3% and 2.1%±5.5% from the baseline, while the clodronate group showed a decrease of -3.4%±4.6% ($p<0.001$). After 5-years lumbar BMD had increased by 3.9±5.1% in the HRT group and by 4.2±7.0% in the combination group. The clodronate group showed a decrease of -1.4±5.3% ($p<0.01$).In the femoral neck, after one year, the HRT and combination groups showed increases in BMD of 3.0%±2.9% and 3.1%±3.8% respectively, while BMD in the clodronate group decreased by -0.08%±4.6% . After three years the HRT and combination groups increased 2.7%±5% and of 2.3%±5.6%, while the clodronate group decreased -2.9%±5.2%. After five years, BMD benefit was 1.2%±12.9% and 2.8±5.9% in the HRT and combination groups, while net loss of BMD in the clodronate group was -3.3±5.7% ($p<0.01$).In conclusion, E2 2mg combined with NETA 1mg increased spinal and femoral BMD in postmenopausal women with severe primary or secondary osteoporosis.The addition of clodronate 800mg did not further increase the BMD values in combination with HRT. In contrast, clodronate 800mg /day could not preserve BMD in five years.

Effect Of Bisphosphonate In Insufficiency State Of Vitamin D. Preliminary Experimental Study. S. N. Zeni[1], S. R. Mastaglia*[1], P. Mandalunis*[2], M. C. Degrandi*[1], M. B. Oliveri[1], J. Somoza*[1]. [1]Sección Osteopatías Médicas, Hospital de Clínicas, University of Buenos Aires, Buenos Aires, Argentina, [2]Catedra de Fisiología, School of Dentistry, University of Buenos Aires, Buenos Aires, Argentina.

It is known that vitamin D insufficiency or deficiency has negative effects on skeletal metabolism. Experimental bone loss is achieved by ovariectomy (OVX) in rats by increasing bone turnover. Bisphosphonates (BPs) are useful antiresortive agents to inhibit resorption in several bone diseases. Hypothetically vitamin D insufficiency could affect bisphosphonate therapy. The aim of the present preliminary study was to investigate whether bone mass recovery due to olpadronate (OPD) treatment is affected by Vitamin D status- i.e. normal or insufficiency, using OVX rats with established osteopenia. A total of 16 female Wistar rats (280-300 g) were OVX: 8 rats were fed a synthetic diet that covered all adequate requirements (+VitD); 8 rats were housed under red light and fed the same synthetic diet lacking of Vitamin D (-VitD). During 60 days rats lost approximately 15% of bone mass, after that (To) 8 rats of +VitD group and all rats of -VitD group received during a 45-day period (Tf) 16ug OPD/100g rat weekly. Simultaneously, 8 OVX and 8 SHAM rats were fed the synthetic diet throughout the study and only received placebo treatment. Bone mineral density (BMD) (mg/cm2), 25OHvitamin D (ng/ml), bone alkaline phosphate (mUI/ml) and serum CTX (ng/ml) were assessed at To and Tf and tibia histomorphometry was made at Tf. (Table).Different letters indicated a $p<0.05$. Bone recovery by OPD treatment was greater in +VitD than in -Vit D. At Tf sCTX was lower and 25OHVitD was higher than in -VitD group. The +VitD group presented greater bone volume and lower erosive surface than -VitD group. Conclusion: These results suggest that OPD effects may be less beneficial in vitamin D deficient state.

Delta: Changes (Tf-To) in total skeleton (TE) and lumbar spine (LS).

The Point-Of-Care Device and Actonel® (risedronate) Once-a-Week Dosing Satisfaction Trial (POWER). W. P. Olszynski[1], A. Jovaisas*[2], W. Bensen*[3], S. Morin*[4], J. Stewart*[5], M. Baranci*[5], K. S. Davison[3]. [1]Medicine, University of Saskatchewan, Saskatoon, SK, Canada, [2]Med., Univ. of Ottawa, Ottawa, ON, Canada, [3]Med., McMaster Univ., Hamilton, ON, Canada, [4]Int. Med., McGill Univ. Health Centre, Montreal, PQ, Canada, [5]Aventis Pharma Inc., Laval, PQ, Canada.

The Point-of-Care device and Actonel® Once-a-Week dosing satisfaction trial (POWER) is a 24-week, multi-centre, prospective, open-label, randomized, controlled community practice-based study. The primary objective was to determine whether feedback on response to therapy using bone resorption results will improve subject satisfaction with therapy, a surrogate measure of persistence. Secondary objectives included: (1) comparing subject satisfaction of those previously treated for osteoporosis with those who were treatment-naïve; (2) documenting the response of bone turnover markers to Actonel (risedronate) 35mg Once-a-Week after 12 weeks of treatment; and (3) evaluating the correlation between subject satisfaction on Actonel 35mg Once-a-Week and bone turnover marker results after 12 weeks of treatment.

Patients (mean age of 63-71 yrs) were enrolled from 556 primary care centres in Canada and included postmenopausal women with osteoporosis, stratified into two groups: (1) osteoporosis treatment-naïve (n=1341); or (2) treated for osteoporosis within the past two years with either alendronate (n=157), etidronate (n=552), hormone replacement therapy (n=136), or calcitonin (n=33), but discontinued prior to enrolment due to lack of effect or intolerance.

All patients received Actonel 35mg Once-a-Week and were randomly assigned to either the bone turnover marker (n=1065) or no bone turnover marker group (n=1154). For the bone turnover marker group, urinary NTX was assessed at baseline and after 12 weeks using Osteomark® NTX Point-of-Care devices, which are registered by Health Canada as a rapid, one-step, in-office, disposable medical device for this purpose. Feedback and interpretation on response to therapy will be provided to patients in the bone turnover marker group at 12 weeks. Patients in the no bone turnover marker group will receive standard care at both time points. Patient satisfaction will be measured in both groups at 24 weeks with a self-administered questionnaire.

The POWER trial will help determine whether feedback on response to therapy using bone resorption results will improve subject satisfaction with therapy, a surrogate measure of persistence, and will describe the effect of Actonel 35 mg Once-a-Week on the level of bone turnover markers at 12 weeks of treatment.

Differential Gene Expression in Bone Tissue of Postmenopausal Osteoporotic and Healthy Women. I. Takacs[1], J. P. Kosa*[1], G. Speer*[1], A. Tabak*[1], Z. Nagy[1], J. Kiss*[2], P. Lakatos[1]. [1]I.st Department of Medicine, Semmelweis University, Budapest, Hungary, [2]Department of Orthopedics, Semmelweis University, Budapest, Hungary.

The central role of estrogen deficiency in the pathogenesis of osteoporosis in postmenopausal women is well established, however, its effect on gene expression is not fully understood. The recently developed DNA macroarray technique allows analysis of changes in expression of genes related to bone metabolism. In this study, we examined the difference in bone-related gene expression of 9 osteoporotic (age range: 75-88) and 5 healthy (age range: 58-78) postmenopausal women. The bone samples were collected in the course of total hip arthroplasty. The bone samples were cryo-grinded, and total RNA was isolated by a column-based method. Following cDNA synthesis, biotin labeling by linear polymerase reaction and hybridization were carried out. Gene expression values were normalized to GAPDH and analyzed by unpaired Student's t-test. Among the 96 genes examined, the expression patterns of five genes were significantly different in the osteoporotic and healthy postmenopausal groups. The expression of matrix metalloproteinase 10 (MMP-10) and platelet-derived growth factor alpha polypeptide (PDGFα) genes was increased while the collagen type I receptor (CD36), insulin-like growth factor 2 (IGF-II), and transforming growth factor beta receptor I (TGFβR1) genes exhibited a decreased expression in osteoporotic subjects compared to that of the control group. These results may provide further insight into the pathomechanism of postmenopausal osteoporosis.

Alendronate Is More Effective than Alphacalcidol in Preventing Glucocorticoid-induced Osteoporosis. R. de Nijs*[1], J. Jacobs*[1], A. Algra*[1], E. Buskens*[1], A. Huisman*[1], R. Laan*[2], C. de Laet*[3], W. Lems*[4], J. Bijlsma, on behalf of the STOP study group[1]. [1]University Medical Center, Utrecht, Netherlands, [2]University Medical Center, Nijmegen, Netherlands, [3]Erasmus Medical Center, Rotterdam, Netherlands, [4]Free University Hospital, Amsterdam, Netherlands.

Treatment with glucocorticoids (GCs) is associated with bone loss initiated already early in therapy, causing an increased fracture risk. The most important mechanism is decreased bone formation. Alendronate blocks bone resorption, but alphacalcidol stimulates bone formation.

The aim of the study: to determine which treatment is the most effective in prevention of glucocorticoid-induced osteoporosis.

We performed a randomized, double-blind, double-placebo clinical trial of 18 months dura-

tion in patients with a rheumatic disease, starting treatment with GCs in a dosage of 7.5 mg prednisolon equivalent daily or higher for 6 months or longer. Patients were allocated to treatment with either alendronate 10 mg and alphacalcidol-placebo daily or alphacalcidol 1 microgram and alendronate-placebo daily. In case of insufficient dietary calcium intake patients received calcium 500 mg daily and whenever vitamin D deficiency existed suppletion with inactive vitamin D 400 IU daily. Primary outcome was change of bone mineral density (BMD) of the lumbar spine (LS) in 18 months. Secondary outcomes were change of BMD in 18 months of the hips and symptomatic vertebral fractures. Evaluation of the incidence of vertebral deformities will take place at a follow-up of 3.5 years after start of the study.

Included were 201 patients in 23 outpatient departments of rheumatology in the Netherlands. One hundred patients received alendronate, 101 alphacalcidol; 163 patients completed the study. The BMD of the LS in the alendronate group increased with 2.3 ± 4.6%, in the alphacalcidol group the BMD decreased with 1.9 ± 5.7%. After 18 months the difference between both groups was 4.2% (95% confidence interval (CI) 2.6 to 5.8). In the alendronate group the BMD of the total hip increased with 0.7 ± 5.9%, in the alphacalcidol group it decreased with 2.5 ± 6.3%. After 18 months the difference in BMD between both groups was 3.2% (95% CI 1.0 to 5.5). No new symptomatic vertebral fractures were reported in the alendronate group, but in the alphacalcidol group 6 new symptomatic vertebral fractures occurred in 3 patients. Two non-vertebral fractures in 2 patients occurred in the alendronate group and 3 in 3 patients in the alphacalcidol group. No serious side effects were observed. We concluded that in this 18-month study concerning patients with rheumatic diseases treated with GCs, alendronate was more effective in preserving bone than alphacalcidol.

One-year Follow-up of 27 Patients With Osteoporosis Treated With a Single Intravenous Dose of Zoledronate. G. J. Paz-Filho*[1], C. A. M. Kulak[1], J. Kaminski*[1], S. C. Radominski[2], J. P. Bilezikian[3], V. Z. C. Borba[1]. [1]Endocrinology, SEMPR, Curitiba, Brazil, [2]Division of Rheumatology, UFPR, Curitiba, Brazil, [3]Departments of Medicine, College of Physicians & Surgeons, Columbia University, New York, NY, USA.

Zoledronate is a potent intravenous bisphosphonate with potential to be effecticious in postmenopausal women and men with osteoporosis. We studied the effects of zoledronate on bone mineral density in 27 patients (6 men and 21 women, aged 59±17 years) with osteoporosis (mean T score, -3.18±1.4). Thirty-three percent of the subjects had history of at least one fragility fracture. All subjects received 4 mg of intravenous zoledronate in a single dose. Lumbar-spine and total hip bone mineral density were measured at baseline , 6 months (T6) and 12 months (T12) after drug administration. At T6, mean lumbar-spine bone density increased from 0.699±0.149 g/cm^2 to 0.727±0.104 g/cm^2, a mean increase of 4%. Mean total hip density increased from 0.643±0.147 g/cm^2 to 0.659±0.136 g/cm^2, a mean increase of 2.4%. At T12, nineteen patients, evaluated so far, showed a 6.3% increase in lumbar-spine density and a 4.6% increase in total hip density, as compared to baseline. These changes in bone mineral density were not statistically significant because not all patients had yet completed the protocol. Adverse effects were limited to mild and self-limited myalgias, pyrexia and paresthesias. No one developed clinical hypocalcemia. Biochemical markers of bone resorption and formation were obtained at baseline and T12. The plan for this study is to continue to follow these patients for at least 2 years after the single dose of zoledronate in order to answer a key question: how long does a single dose of zoledronate maintain reduced indices of bone turnover? The answer to this question, not previously available from other cohorts, will help to guide an approach to the use of this agent in women and men with osteoporosis.

Disclosures: ***G.J. Paz-Filho****, None.*

Early Changes in Urinary Cross-linked N-terminal Telopeptides of Type I Collagen Level Predict One-year Response of Lumbar Bone Mineral Density to Alendronate in Japanese Elderly Women with Osteoporosis. J. Iwamoto[1], T. Takeda*[1], M. Uzawa*[2]. [1]Department of Sports Medicine, Keio University, Tokyo, Japan, [2]Department of Orthopaedic Surgery, Keiyu Orthopaedic Hospital, Gunma, Japan.

The purpose of this study was to determine whether the early changes in urinary cross-lined N-terminal telopeptides of type I collagen (NTX) level would predict the one-year response of lumbar bone mineral density (BMD) to alendronate in Japanese elderly women with osteoporosis. One hundred and five postmenopausal women with osteoporosis, 54-88 years of age, were treated with alendronate (5 mg daily) for 12 months. Urinary NTX level was measured by enzyme-linked immunosorbent assay at the baseline and months 3, 6, and 12, and lumbar (L1-L4) BMD was measured by dual energy X-ray absorptiometry using a Hologic QDR 1500W instrument (Bedford, MA, USA) at the baseline and month 12. The mean percent reduction in urinary NTX level at months 3, 6, and 12 was 36.8 %, 49.5 %, and 49.0 %, respectively, with a more significant reduction at months 6 and 12 than at month 3, and the mean percent increase in lumbar BMD at month 12 was 8.2 %. Single regression analysis showed a significant correlation between the percent reductions in urinary NTX level at months 3, 6 and 12 and the percent increase in lumbar BMD at month 12 (r=0.200, P<0.05; r = 0.341, P<0.001; and r = 0.338, P<0.001, respectively). Thirty percent of patients were thought to be poor responders at month 3, with a reduction in urinary NTX level of less that minimum significant change (MSC), and 61 % of them showed a greater reduction in urinary NTX level exceeding MSC at month 6. These results suggest that the change in urinary NTX level at 3 and 6 months after the start of alendronate treatment at 5 mg daily could be a predictor of the one-year response of lumbar BMD, followed by a steady state level of urinary NTX after 6 months of treatment, in Japanese elderly women with osteoporosis.

Disclosures: ***J. Iwamoto****, None.*

M418

Comparative Study of Bone Turnover and BMD Responses to Treatment with Risedronate, Vitamin D, or Vitamin K in Japanese Osteoporosis Patients: Results of a 24-Week Interim Analysis. H. Iwata*, S. Yamada*, H. Takagi*. Rheumatism and Prosthesis Center, Nagoya Kyoritsu Hospital, Nagoya, Japan.

The Japanese have the world's longest average life span (84 years for women, 77 years for men) and the elderly population of Japan is rapidly rising. Measures to counter diseases specific to the elderly, particularly osteoporosis, are important. We compared changes in bone turnover markers and BMD with the administration of risedronate (RIS), the latest bisphosphonate treatment available in Japan, with those of vitamin D and vitamin K, currently the most common treatments for osteoporosis in Japan.

120 Japanese patients with primary osteoporosis (11 men, 79.5 yrs; 109 women, 70.7 yrs; overall age, 71.7 yrs) were enrolled at Nagoya Kyoritsu Hospital between May 2002 and May 2003 and were randomly assigned to one of three treatment groups (n=40/arm). They received 2.5 mg/d of oral risedronate (Actonel®, RIS), 1.5μg/d of vitamin D3 (Alfarol®, VD_3), or 45 mg/d of vitamin K (Glakay®, VK_2).

The mean (SD) changes in bone turnover markers and BMD from baseline to 24 weeks are shown in the table below:

Variables	% Change from Baseline			*P*-value	
	RIS	VD_3	VK_2	RIS vs VD_3	RIS vs VK_2
Urinary NTX	-43.8 (28.9)	1.3 (83.1)	6.2 (59.4)	0.006	<0.001
Serum NTX	-32.4 (14.4)	-20.5 (21.8)	-6.6 (22.2)	0.033	<0.001
Urinary DPD	-28.4 (35.4)	-2.5 (43.8)	1.2 (36.2)	0.013	0.003
Serum OC	-37.9 (23.4)	-12.4 (26.6)	14.8 (48.6)	<0.001	<0.001
Serum BAP	-26.3 (24.0)	-24.7 (18.4)	-4.3 (44.7)	0.772	0.029
BMD	4.7 (2.48)	1.7 (4.97)	0.5 (4.89)	0.029	0.001

NTX = cross-linked N-telopeptides of type I collagen; DPD = deoxypyridinoline; OC = osteocalcin; BAP = bone alkaline phosphatase; BMD = bone mineral density.

The decreases from baseline in urinary and serum NTX, and urinary DPD were significantly greater with RIS compared with both VD_3 and VK_2, from 4 weeks (data not shown) to 24 weeks of drug administration. RIS resulted in a greater reduction from baseline in serum OC than both vitamin groups. For serum BAP, similar decreases were observed for RIS and VD_3; the decrease was greater for RIS compared with VK_2. At 24 weeks, the BMD increase was significantly greater with RIS compared with both VD_3 and VK_2.

After 24 weeks of treatment in Japanese patients, risedronate is a more effective treatment for osteoporosis than VD_3 or VK_2 alone.

Role of Alendronate in Therapy of Post-Traumatic Complex Regional Pain Syndrome I of the Lower Limb. D. H. Manicourt*, J. P. Brasseur*, Y. Boutsen, G. Depresseux*, J. P. Devogelaer. Rheumatology Unit, St-Luc University Hospital, Brussels, Belgium.

Introduction: As complex regional pain syndrome I (CRPS I) is associated with regional osteoclastic over-activity, the effect of the anti-resorbing agent alendronate (ALN) at the daily oral dose of 40 mg was evaluated in patients with post-traumatic CRPS I of the lower limb.

Methods: Forty patients were enrolled in this 8-week randomized, double-blind, placebo-controlled study with an optional 8-week open extension (week-12 to week 20) with ALN after a non therapeutic time period of 4 weeks. Clinical parameters included joint mobility (JM), limb edema as well as pressure tolerance (PT) and spontaneous pain (SP). Urinary levels of type I collagen N-telopeptides (NT x) were assessed by using an ELISA. Patients were examined at week-4, -8, -12, -16, -20 and -24. Statistical analysis included two-way factorial ANOVA.

Results and conclusions: In contrast to placebo-treated patients (n = 20), all patients of the ALN-treated group (n = 19) exhibited a marked and sustained improvement in SP, PT and JM as well as a significant reduction in urinary NT x levels at week-4 and -8. The improvement was maintained at week-12. Twelve patients from the ALN-treated group and 12 patients from the placebo-treated group volunteered for the 8-week open trial and they all responded positively to ALN, therefore supporting the use of oral ALN in post-traumatic CRPS I . By reducing local bone accelerated remodeling, ALN might relieve pain by effects on nociceptive primary afferents in bone and pain associated changes in the spinal cord, and also possibly through a central mechanism.

Osteoporosis Treatment Using Reinforcement With Bone Turnover Marker Data Reduces Fracture Risk: The IMPACT Study. P. D. Delmas*[1], B. Vrijens*[2], C. Roux*[3], A. Le-Moigne-Amrani*[4], R. Eastell*[5], A. Grauer*[6], N. B. Watts*[7], H. A. P. Pols*[8], J. D. Ringe*[9], L. van de Langerijt*[10], D. Cahall[11]. [1]INSERM Research Unit 403, Lyon, France, [2]AARDEX Ltd, Zug, Switzerland, [3]University René-Descartes, Paris, France, [4]Aventis Pharmaceuticals, Bridewater, NJ, USA, [5]University of Sheffield, Sheffield, United Kingdom, [6]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [7]University of Cincinnati, Cincinnati, OH, USA, [8]Erasmus University, Rotterdam, Netherlands, [9]Klinikum Leverkusen, Leverkusen, Germany, [10]Aventis Pharmaceuticals, Hoevelaken, Netherlands, [11]Aventis Pharmaceuticals, Bridgewater, NJ, USA.

With effective agents available for treatment of postmenopausal osteoporosis, patient persistence with treatment is necessary to sustain beneficial results. The IMPACT study assessed the effect of physician reinforcement using bone turnover marker (BTM) data on persistence with risedronate treatment. Eligible patients included postmenopausal women aged 65-80 years with spine/hip T-score ≤-2.5 or T-score ≤-1.0 with a low-trauma fracture after age 45 years. All subjects received risedronate 5 mg/d for 1 year and were pretreated with calcium 500 mg/d and vitamin D 400 IU/d for 20 days (median) prior to BTM baseline and initiation of risedronate. Centers were randomized into either reinforcement (RE+; verbal feedback based on urinary N-telopeptide of type I collagen [NTX] change from baseline) or nonreinforcement (RE-) groups. Electronic monitoring caps were used to assess daily compliance. Persistence was defined as the number of days from first dose intake until treatment discontinuation. A total of 2302 women from 171 centers in 21 countries were enrolled into the study. Lumbar and thoracic spine X-rays were performed at baseline and at 52 weeks for assessment of vertebral fractures and assessed using semi-quantitative techniques. Of these, vertebral fracture data were available for 1317 patients (RE+ n=676, RE- n=641). A total of 390 (30%) women had a prevalent vertebral fracture at baseline. Treatment was associated with a low incidence of new vertebral fractures during treatment (1.9%). In total, 8 (1.2%) new vertebral fractures were observed in the RE+ group compared with 17 (2.7%) in the RE- group (p=0.049). In summary, reinforcement of osteoporosis treatment using BTM data correlated with increased benefits on fracture reduction. This benefit could be explained partially by the significant increase in persistence observed in the subgroup of patients that was reinforced with a positive message based on a ≥30% decrease of urinary NTX. We conclude that reinforcement of osteoporosis treatment using BTM data might be beneficial for obtaining optimal fracture reduction.

Increased Osteoclast Number and Size in C57bl Mice with Calcium Deprivation and Treatment with a Single Dose of Zoledronic Acid. C. Gaudin*, H. Libouban*, M. Moreau*, M. F. Basle*, M. Audran, D. Chappard. LHEA Faculté de Médecine, INSERM EMI 0335, Angers, France.

The objective of this study is to evaluate the efficacy of a single dose of zoledronic acid (ZOL) in preventing bone loss and the associated mechanism in a calcium deprived mice. ZOL dosage was calculated to mimic the annual dose regimen used in human.

In animals, a low calcium diet induces: a significant increase in bone remodeling markers, an increase in osteoclast (Oc) number, and a reduction in the bone mineral density. Histomorphometric studies have confirmed that both trabecular and cortical bone are altered in animals fed with a low calcium diet. Recently, a single annual zoledronic acid (ZOL) infusion was reported to be as efficient as daily oral dose of bisphosphonate in the treatment of osteoporotic patients. Similar to other bisphosphonates ZOL has been shown to reduce Oc activity and induce Oc apoptosis.

Thirteen groups of nine C57BL mice (6-10 weeks old) were given laboratory food (either standard or calcium deprived), and water ad libitum (either tap or distilled). ZOL+ animals received at day 0, a single injection of ZOL in the tail vein (78µg/kg) and were fed with either a low calcium (ZOL+Ca-) or a normal diet (ZOL+Ca+); animals used as control (ZOL-Ca+) or fed with a low calcium diet (ZOL-Ca-) received a single saline injection by the same route. Animals were euthanized at 0, 2, 4 and 8 weeks and the effect on bone of calcium deficiency with/without ZOL was quantified by X-ray microcomputed tomography. Oc were histochemically identified by TRAcP staining.

Calcium diet induced a rapid trabecular bone loss in Zol-Ca- mice with reduced Tb.N and increase in Tb.Sp. ZOL+Ca- animals had an increased bone volume and preserved Tb.N. Surprisingly, Oc number was dramatically increased in ZOL+Ca- animals with calcium-deficient diet. This was associated with an increased of the Oc length in ZOL+Ca- mice (45.1 ± 2.1 µm vs. 17.9 ± 1.1 µm A normal calcium diet seemed to be required to induce Oc apoptosis by ZOL although Oc activity was impaired as evidenced by the preserved bone mass.

In conclusion, ZOL has been efficacious in preventing bone loss in calcium deprived mice through a significant reduction in Oc activity while their number increased.

Effect of Alendronate in a Lapine Model of Estrogen Deficiency. B. Pennypacker, T. Cusick*, P. Masarachia, D. B. Kimmel. Bone Biology and Osteoporosis, Merck Research Laboratories, West Point, PA, USA.

The adult ovariectomized (OX) rat is the most oft-used *in vivo* model for testing agents to prevent estrogen deficiency bone loss. Despite its cancellous bone remodeling, the adult rat lacks Haversian remodeling of cortical bone. The smallest, most ubiquitous adult animal with significant Haversian remodeling, that develops OX-induced bone loss, is the rabbit. We further characterized the OX rabbit by evaluating bone remodeling after OX and the minimum dose of the anti-resorptive, alendronate (ALN) that fully blocks OX-induced bone loss.

Two experiments are reported. In #1, adult (7.5 months old, 3.9kg) rabbits were OX'd (N=22) or Sham-OX'd (N=11) during early June. 11 OX rabbits were given ALN (0.2mg/kg; subcutaneous (SC), 3X/wk) for 27 weeks. After in vivo dual calcein labeling, all were necropsied. Lumbar vertebrae (LV) 2-4 were fixed in 70% ethanol. Bone mineral density (BMD, mg/cm^2) of LV3 was determined (DXA); LV4 was embedded in methacrylate, sectioned parasagitally (6µm), and analyzed for cancellous (c) mineralizing surface. 100µm sections of the mid-femur were analyzed for endocortical (e) and periosteal (p) mineralizing surface (MS/BS; double+half-single, %), and number of labeled Haversian systems (HS)/mm^2. In #2, adult rabbits were OX'd (N=44) or Sham-OX'd (N=11) during early July. OX rabbits (11/grp) were given ALN (0, 0.03, 0.1, or 0.3mg/kg; SC, 2X/wk) for 13 weeks and necropsied. BMD of LV2-4 was determined ex vivo. Kruskal-Wallis plus Student-Neuman-Keuls post-hoc testing was applied.

OX-induced bone loss (9-13%) occurred in the LV of both experiments. In #1, bone loss was accompanied by increased formation rate at all four measured sites. ALN (0.6mg/kg/wk) completely blocked OX-induced bone loss in both experiments. In #2, ALN (0.2mg/kg/wk, LVBMD=409±29) was fully efficacious, while ALN (0.06mg/kg/wk, LVBMD=389±19) was partially efficacious for blocking bone loss.

These results suggest that the OX rabbit is an accurate, though seasonal, model of OX-induced bone loss, when considering behavior of bone mass and bone formation rate. These results also show that ALN inhibits bone formation at the cancellous, endocortical, and Haversian surfaces, but not at the periosteal surface. They further indicate that the minimum dose of ALN that fully inhibits vertebral bone loss in the OX rabbit is 0.2mg/kg/wk SC.

Impact of Non-Compliance and Non-Persistence With Daily Bisphosphonates on Longer-Term Effectiveness Outcomes In Patients With Osteoporosis. R. J. Sebaldt*[1], L. G. Shane*[2], B. Z. Pham*[2], R. J. Cook*[3], L. Thabane*[1], A. Petrie*[4], W. P. Olszynski[5], D. A. Hanley[6], J. Brown[7], J. D. Adachi[1], T. Murray[8], R. Josse[8], A. Papaioannou[1]. [1]McMaster University, Hamilton, ON, Canada, [2]Outcomes Researcher, Toronto, ON, Canada, [3]University of Waterloo, Waterloo, ON, Canada, [4]Research Associate, Hamilton, ON, Canada, [5]University of Saskatchewan, Saskatoon, SK, Canada, [6]University of Calgary, Calgary, AB, Canada, [7]University of Laval, Quebec, PQ, Canada, [8]University of Toronto, Toronto, ON, Canada.

This study aims to measure the impact of patient non-compliance and non-persistence with daily-regimen bisphosphonate treatment on longer-term treatment effectiveness outcomes, including changes in BMD and fracture rates.

We studied patients with OP treated with daily BP regimens in routine clinical care. All patients were being treated by tertiary care specialists collaborating in a systematic, prospective, observational, clinical data collection program. We report program follow-up rates and inconsistent use of BP therapy i.e. early discontinuation of BP or self-report of taking BP less than 80% of the time over the follow-up interval. We compared longer-term clinical outcomes between patient groups who reported inconsistent and consistent use of BP therapy: change in BMD (analysis of covariance) and incidence of fracture (Poisson regression).

From 1990 to 2002, 4,405 patients with OP (t-score < -2.5) (mean age 64, 86% female) were treated with BP. Cumulative follow-up rates in the program after 1, 2, and 3 years were 78%, 63% and 52%, respectively. Complete data for analysis of longer-term clinical outcomes were available for 1,041 patients (23.6%). This subset excludes patients who did not return for follow-up and is considered significantly enriched for patients who adhere to therapeutic advice rather than representative of the average patient population. In consistent BP users (CU) (n = 920, 88%), lumbar spine BMD increased significantly from baseline after 1, 2 and 3 years: 3.3% (95% CI: 0.6%, 6.1%), 4.9% (2.2%, 7.7%) and 6.5% (3.7%, 9.3%), respectively. In inconsistent BP users (IU) (n = 121, 12%), no significant improvement in BMD occurred until Year 3, at which time a modest gain of 3.2% (0.03%, 6.3%) was achieved relative to baseline (p = 0.002). The differences in BMD increase between the CU and IU were statistically significant after 1, 2 and 3 years: 1.4% (0.5%, 2.3%), 2.4% (1.2%, 3.6%) and 3.3% (1.5%, 5.2%), respectively. In addition to BMD, there was a trend of a 27% greater 10-year fracture risk in IU compared with CU (adjusted relative risk 1.27 (0.9, 1.8), p = 0.18).

This study demonstrates that patients who use BP inconsistently do not attain the proven clinical benefits of BP therapy.

New Approach to Simplify Osteoporosis Treatment Regimen for Bisphosphonate and Calcium. J. D. Ringe[1], S. van der Geest*[2]. [1]Klinikum Leverkusen, Leverkusen, Germany, [2]Procter & Gamble Pharmaceuticals, Geneva, Switzerland.

All large bisphosphonate trials have added calcium in amounts ranging from 500 to 1000 mg/day above individual dietary intake. Accordingly, calcium supplements or calcium/vitamin D combinations are recommended today as co-medication to antiresorptive therapy in all recently published national or international guidelines on the care strategy for osteoporosis. This consistent use of calcium may be hampered and impaired by several factors in the individual patient: low prescription rate or advice to purchase calcium; reduced compliance due to complex regimen; incorrect administration (e.g. calcium together with bisphosphonates). Therefore, treatment can be simplified by offering the two compounds in an integrated package, developed to facilitate the intake of this complex regimen. A new blister strip was developed containing one tablet of risedronate 35mg and 6 calcium carbonate tablets for a week of therapy. The package contained dosing instructions for the two products on one patient information leaflet. In a cohort of 164 patients, mean age 68.5 years, we studied in a cross over design, the impact of the new pack versus separate packages on the patients understanding of intake instructions. The understanding of five instructions was tested: intake of risedronate 35mg in the morning, only with water, without food, without other medication, separate from calcium. Adherence to all 5 instructions increases the likelihood of obtaining maximal therapeutic response to bisphosphonate treatment. Analysis of cross-over data (n=164) showed high understanding of instructions for the separate packaging (70%, n=115) but improved significantly with the combination pack (82% n=134) (p<0.05). In this cohort, 83% of participants preferred the new combination pack over separate packs (p<0.05). Reasons for this preference are shown in table 1.

TABLE 1

Reasons for preference*(n=164)	%
Prefer one pack over two packs	49
Easy/convenient to use/ practical handy	39
Easy to understand/less confusion	36
Easier to remember/ less likely to forget	19

* multiple reasons possible

These data support that the integrated combination packaging of risedronate with calcium can lead to simplification of therapy. Simplification of therapy can lead to improved adherence to treatment and consequently the likelihood to meet therapeutic goals of the therapy.

Zoledronic Acid Counteracts Bone Loss in the Spinal Cord Injury Model of Microgravity. J. R. Shapiro[1], T. J. Beck[2], B. Mustapha*[3], C. B. Ruff*[4], P. Ballard*[5], J. Caminis[6]. [1]Medicine, Uniformed Services University, Bethesda, MD, USA, [2]Radiology, Johns Hopkins University, Baltimore, MD, USA, [3]Neuroscience Research, National Rehabilitation Hospital, Washington, DC, USA, [4]Cell Biology, Johns Hopkins University, Baltimore, MD, USA, [5]Spinal Cord Injury, National Rehabilitation Hospital, Washington, DC, USA, [6]Novartis Pharmaceutical, East Hanover, NJ, USA.

Although mechanical consequences are not well known, exposure to microgravity causes significant lower-limb bone loss; similar patterns have been seen in tetra- or paraplegic spinal cord injury (SCI). In a double-blind placebo-controlled randomized study, we evaluated effects of intravenous 4 or 5 mg of zoledronic acid on SCI bone loss. Subjects included 12 males and 3 females (8 placebo, 7 zolendronate) evaluated within 10 weeks of injury and followed for 1 year. SCI lesions were located between C-5 and T-12 and were classified as ASIA A or ASIA B depending on motor/sensory deficit. DXA scans of the LS spine and hip were obtained at 0, 6 and 12 months using Hologic QDR 1000 and GE Lunar Prodigy densitometers standardized with a special phantom. Hip Structure Analysis was used to derive BMD, cross sectional area (CSA), periosteal diameter, section modulus (Z), and estimates of endocortical diameter, mean cortical thickness and buckling ratio. Zoledronic acid maintained femoral neck CSA and had significant positive effects (p= <0.05) on BMD, CSA, periosteal diameter, Z, and buckling ratio in the intertrochanteric region. Overall, treatment effects were most evident at the shaft. Compared to placebo, treatment significantly reduced the decline in BMD, CSA, Z, and cortical thickness and attenuated the increase in endosteal diameter, and buckling ratio. Lumbar spine BMD rose 13.3 % in controls and 5.2% in treatment group: each group sat erect daily. Urinary n-telopeptide excretion was decreased following treatment. SCI, as a model for microgravity exposure, causes major losses in bone mass and structural strength at the proximal femur. Despite the small sample size, this study showed that zoledronic acid had significant positive effects on some structural parameters of the femoral neck and intertrochanteric region, and on all structural parameters in the femoral shaft, thus counteracting the negative effects of non-weight-bearing, and potentially that of microgravity, on BMD and bone strength.

Bone Mineral Density Response to Pamidronate in Adult Osteogenesis Imperfecta. J. R. Shapiro[1], C. Hickman*[1], M. Shindle*[1], K. BrintzenhofeSzoc*[2], P. Sponseller*[3]. [1]Osteogenesis Imperfecta Program, Kennedy Krieger Institute, Baltimore, MD, USA, [2]School of Social Service, Catholic University, Washington, DC, USA, [3]Orthopedic surgery, Johns Hopkins University, Baltimore, MD, USA.

We report the response to treatment with pamidronate in adults with osteogenesis imperfecta (OI). Pamidronate is reported to induce a robust increase in bone mineral density and a significant decrease in fracture rate in children with OI. An assessment of pamidronate treatment for one year in adults with type IA OI was reported to improve bone biopsy morphology, with positive, but statistically non-significant, increases in bone density.

Factors influencing treatment results in adults include: fracture incidence, is significantly less than in children, bone turnover is lower, adults are less compliant with treatment and testing schedules, the presence of rodding, scoliosis and greater limb deformity alters DXA readings.

This cohort includes 59 patients, 17 males and 42 females having OI types I (n = 34) , III (n=18) and IV (n=7) between the ages of 16-64 years. 24 patients were treated with IV bisphosphonate. Bisphosphonate treatment regimens in 35 patients included: IV pamidronate (n=24) : 1.5 mg/kg body wt. to a maximum of 60 mg every 3-4 months. 24 patients were non treatment controls. 11 subjects received oral bisphosphonate (data not included). Diets were supplemented with calcium, 800-1200 mg/day and 400 U vitamin D daily. DXA scans were obtained at 6-12 month intervals on the same machine and are reported comparing baseline to months 12 and 18.

After treatment of type I OI for18 months, mean L1-L4 BMD changed from 0.830 gm/cm2 to 0.805 gm/ cm2 (p=>0.10) total hip changed from 0.739 gm/cm2 to 0.808 gm/cm2(p > 0.10). In type III OI, L1-4 changed from 0.607 gm/cm2 to 0.648 gm/cm2, total hip changed from 0.804 to 0.652 gm/cm2 (p=>0.01) . In type IV patients mean L1-L4 changed from 0.671 gm/cm2 to 0.697 gm/cm2, total hip changed from 0.423 to 0.558 (n=1, p=> 0.10). For treated type I patients, urine NTX (nMBCE/mM creatinine) was 49, at baseline, 28 at 6 mo., and 33 at 12 mo. For treated type 3 patients, urine NTX (nMBCE/mM creatinine)= 98 at baseline, 93 at 3 mo., 82 at 6 mo., 87 at 9 mo. and 103 at 12 mo.

Bisphosphonate treatment of adults with mild or severe OI for 18 months has non-significant effects on BMD in the lumbar spine or proximal femur. Patients may show a small increase in spine BMD after 1 year of treatment, which then plateaus. Adult OI patients treated with bisphosphonates remain susceptible to sporadic fractures particularly with mild trauma. Urine NTX values decline in treated type I patients but not in treated type 3 patients. Bone morphology is required to assess treatment effects in the individual patient.

Evaluation of Alendronate Therapy in a Murine Model of Male Idiopathic Osteoporosis. J. E. Zerwekh, R. Millsaps*, A. Thomas*, E. Simpson*, O. Oz. Center for Mineral Metabolism and Clinical Research, University of Texas Southwestern Medical Center at Dallas, Dallas, TX, USA.

Up to 50% of men with osteoporosis have no identifiable etiology and are defined as having primary or idiopathic osteoporosis (IO). Clinical trials have shown such men respond favorably to bisphosphonate treatment, an antiresorptive agent, despite the low bone-turnover remodeling pattern that is usually seen in male IO. These observations raise the possibility of an anabolic effect of bisphosphonate in male IO. In order to clarify the mechanism(s) of bisphosphonate action in low turnover states of bone remodeling, we evaluated the effect of alendronate therapy on bone density, histomorphometry, biochemical markers of turnover, and ex-vivo osteoprogenitor cell studies in 12 adult male aromatase-deficient mice (ArKO) and compared the response to that in 12 placebo-treated ArKO male mice and 12 placebo-treated wild-type littermates. This murine model has been found to have a similar histological and biochemical presentation as seen for men with IO. Following 1 month of alendronate therapy (70 µg/kg, twice per week), lumbar BMD increased by 7.7% in ArKO males (p=0.00002) but decreased by 0.9% and 3.2% in placebo-treated ArKO and wild-type animals, respectively. Both bone histomorphometry and biochemical markers of bone turnover disclosed further reductions in bone turnover following alendronate treatment. Placebo-treated ArKO males had significant reductions in cancellous bone volume, trabecular thickness, osteoid volume and surface, and osteoblastic surface as compared to wild-type mice. Alendronate administration to ArKO males further reduced eroded surface and mineralizing surfaces as compared to ArKO-placebo, resulting in a significant reduction in bone formation rate. Alendronate also resulted in a significant decline in 24 hr urinary calcium, deoxypyridinoline and in serum osteocalcin when compared to the pre-treatment baseline values. Compared to wild-type littermates, ArKO mice had significant reductions in the number of bone marrow osteoprogenitors. Alendronate treatment did not affect osteoblast progenitor number or the number of osteoblasts undergoing apoptosis. Taken together, these findings suggest that alendronate's ability to raise bone density in males with idiopathic osteoporosis is the result of further reduction of bone turnover and that there is no apparent effect on osteoblastogenesis.

Predictive Value of Biochemical Markers of Bone Turnover in the Treatment of Japanese Postmenopausal Women with Alendronate. K. Kurasawa*[1], O. Chaki[1], K. Mochizuki*[1], Y. Arata*[1], H. Yoshikata*[1], R. Kikuchi[1], I. Gorai[2], F. Hirahara*[1]. [1]Obstetrics and Gynecology, Yokohama city University School of Medecine, Yokohama, Japan, [2]Obstetrics and Gynecology, International University of Health and Welfare Atami Hospital, Atami, Japan.

We aimed to evaluate the effect of alendronate on bone density and biochemical markers of bone turnover in postmenopausal Japanese women with osteoporosis or osteopenia.Sixty eight postmenopausal Japanese women (64.9+/-7.1 years old) diagnosed as osteopenia or osteoporosis were enrolled in this study. After giving informed consent, the subjects were treated with arendronate 5mg per day. Lumbar and femoral neck bone mineral density(BMD) were determined at the start of this study and every six months. Biochemical markers of bone formation were measured intact osteocalcin (IOC) after 1, 3, 6,12,18,24 months. And biochemical markers of bone resorption were measured urinary deoxypyridinoline (DPD) and crosslinked N-telopeptide of type I-collagen (NTX) after 1, 3, 6,12,18,24 months. The predictive value of biochemical markers of bone turnover for bone density was evaluated by using the minimum significant change (MSC). Lumbar spine BMD was increased by 6.76+/-4.95% 2 years after treatment. Femoral neck BMD was increased by 4.21+/-4.90% 2years after treatment. The percent changes of each biochemical marker at 3 and 6 months after treatment were significant as compared with baseline values; DPD -24.9% and -26.0%, IOC -25.0 and 34.4%, NTX -32.0% and -34.4%. In addition, the percent changes of NTX at 1 month after treatment were greater than MSC. The results suggest that treatment alendronate 5mg daily significantly increased lumbar BMD and reduced biochemical markers, especially IOC and NTX are useful for predicting the effect of alendronate in postmenopausal Japanese women. In addition, it was recognized that an effect of treatment with alendronate continued during an observation period.

Monthly Oral Ibandronate Is Well Tolerated in Women with Postmenopausal Osteoporosis: 1-Year Results from MOBILE. E. M. Lewiecki[1], P. D. Miller[2], R. Lorenc[3], C. Hughes*[4], B. Bonvoisin[4], M. R. McClung[5]. [1]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA, [2]Colorado Center for Bone Research, Lakewood, CO, USA, [3]The Children's Memorial Institute, Warsaw, Poland, [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [5]Oregon Osteopor**osis Center, Portland, OR, USA.**

As with other chronic, asymptomatic conditions, adherence to osteoporosis therapies is poor. Adverse events (AEs) are often cited as a reason for treatment discontinuation. A convenient, monthly-dosed oral bisphosphonate with good safety and tolerability may enhance adherence, thereby optimizing therapeutic outcomes in postmenopausal osteoporosis (PMO). Ibandronate (Boniva®) is a potent, nitrogen-containing bisphosphonate. In a recent clinical study, oral ibandronate, administered daily or intermittently with an extended between-dose interval of more than 2 months, significantly reduced the risk of new vertebral fractures (3-year vertebral fracture risk reduction: 52% and 50%, respectively).[1] A safety profile similar to placebo was also reported, independent of the administration schedule. The MOBILE study is investigating the efficacy and safety of a convenient monthly oral ibandronate regimen. MOBILE is a randomized, double-blind, phase III, non-inferiority study comparing monthly oral ibandronate (100mg given as 50mg per day on two consecutive days, 100mg, or 150mg) with 2.5mg per day in 1,609 women with PMO. The safety and tolerability of ibandronate was assessed at 1 year, with a confirmatory analysis after 2 years. The 1-year safety analysis showed oral ibandronate to be well tolerated, with no numerical imbalances between arms in the overall number of AEs or overall number of AEs by body system. Importantly, no difference in the incidence of upper gastrointestinal AEs was observed in the 50/50mg, 100mg, 150mg monthly oral regimen, compared with daily arm (15.9%, 21.7% and 16.9% vs 18.0%, respectively). More specifically, the incidence of dyspepsia was similar across the study arms (6%, 9% and 6% vs 7%, respectively). In conclusion, monthly oral ibandronate was well tolerated with no apparent unexpected safety concerns. By providing greater patient convenience and excellent tolerability, monthly oral ibandronate may enhance therapeutic outcomes in PMO through improved long-term therapeutic adherence.

Evidence for a Specific Recognition Step Involved in Cellular Uptake of Bisphosphonates. K. Thompson, M. J. Rogers, F. P. Coxon*, J. C. Crockett*. Medicine & Therapeutics, University of Aberdeen, Aberdeen, United Kingdom.

The exact mechanism by which bisphosphonates (BPs) are internalised into cells remains unclear. Cellular uptake of BPs has been shown to be dependent on calcium in RAW264 macrophages. We have previously shown that the non-nitrogen-containing BP (non-N-BP) clodronate (CLO) antagonises the effects of nitrogen-containing BPs (N-BPs) in J774 macrophages *in vitro* and postulated that BP uptake takes place via a membrane-bound transport protein. To investigate this further, we synthesised a fluorescently-labelled analogue of alendronate (FL-ALN).

Using confocal microscopy, uptake of FL-ALN by J774 macrophages was detected in intracellular vesicles within 5 minutes of treatment. We compared the pattern of uptake of

FL-ALN to specific markers of fluid-phase endocytosis (TRITC-dextran), adsorptive endocytosis (wheat germ agglutinin-TAMRA) and receptor-mediated endocytosis (transferrin-TAMRA). Only TRITC-dextran showed a marked degree of co-localisation with FL-ALN, suggesting that a major component of BP uptake is mediated by fluid-phase endocytosis.

Using flow cytometry, J774 cells were found to markedly accumulate FL-ALN within 4 hours. Consistent with our previous findings, molar excess of the non-N-BP CLO dramatically inhibited the vesicular uptake of 100μM FL-ALN. Co-treatment of J774 cells with FL-ALN and 250μM CLO inhibited uptake of FL-ALN by 90%. This inhibitory effect of CLO was not due to inhibition of fluid-phase endocytosis, since CLO did not affect the uptake of FITC-dextran.

Since BPs are non-hydrolysable analogues of pyrophosphate (PP_i) we hypothesised that PP_i may also compete with BPs for cellular uptake. Co-treatment of J774 cells with 250μM PP_i decreased FL-ALN uptake by 76%. Due to the high affinity of BPs for divalent ions (such as Ca^{2+}), we investigated whether the inhibitory effect of CLO or PP_i was due to Ca^{2+} chelation. Whilst molar excess Ca^{2+} ions stimulated FL-ALN uptake, 500μM EGTA (a Ca^{2+} chelator) inhibited FL-ALN uptake by 96%, which was reversed in the presence of 2mM Ca^{2+}. Supplementation of 250μM CLO or PP_i with molar excess (1mM) Ca^{2+} partially prevented the inhibitory effect of CLO, but not PP_i, on FL-ALN uptake.

These observations show that cellular uptake of BPs can occur by fluid-phase endocytosis. However, there appears to be a specific recognition step prior to endocytosis that is dependent on Ca^{2+} and can be blocked by competition with PP_i or other BPs, such as CLO.

Fluvastatin Prevents Bisphosphonate-Induced Vγ9Vδ2 T-Cell Activation and Proliferation *In Vitro*. K. Thompson, M. J. Rogers. Medicine & Therapeutics, University of Aberdeen, Aberdeen, United Kingdom.

An acute phase response is the major adverse effect of intravenously-administered nitrogen-containing bisphosphonates (N-BPs) and is associated with the activation (TNFα and IFNγ release) and proliferation of the major subset of γ,δ-T cells in humans ($Vγ9Vδ2^+$ subset). We, and others, have recently reported that the stimulatory effects of N-BPs on γ,δ-T cell proliferation in cultures of human PBMCs are most likely due to inhibition of FPP synthase, an enzyme in the mevalonate pathway. By this mechanism, N-BPs cause the accumulation of upstream isoprenoid lipids such as IPP, which then directly activate $Vγ9Vδ2^+$-T cells. N-BPs, such as zoledronic acid (ZOL), stimulate γ,δ-T cell proliferation in human PBMC cultures with a similar order of potency to the order of potency for inhibition of FPP synthase. Mevastatin, by inhibiting HMG-CoA reductase, can abrogate the stimulatory effects of N-BPs on γ,δ-T cells by preventing the N-BP-induced accumulation of IPP.

Treatment of PBMC cultures with 1μM ZOL for 7 days caused an ~8-fold increase in the proportion of γ,δ-T cells in the $CD3^+$ population. This proliferative effect of ZOL was decreased by >75% when PBMCs were simultaneously treated with 1μM fluvastatin (FLU). Consistent with this, 1μM ZOL caused a marked increase in the proportion of $Vγ9Vδ2^+$-T cells in the γ,δ-T cell population from ~70% (+/-9.1%) in naïve cultures to 98.6% (+/-1.6%) after 7 days treatment. Simultaneous treatment with FLU reduced the ZOL-induced increase in the proportion of $Vγ9Vδ2^+$-T cells to 86% (+/- 2.9%). The inhibitory effect of FLU could be abolished by replenishing cells with mevalonate, suggesting that FLU prevents $Vδ2^+$-T cell proliferation by inhibiting HMG-CoA reductase and preventing ZOL-induced accumulation of IPP.

Although the concentration of ZOL used in this study is similar to the C_{max} following intravenous administration to patients *in vivo* (1μM), plasma concentrations decrease rapidly with a $t_{½}$ of <2hrs. Therefore, the effectiveness of a short pulse of ZOL for inducing IFNγ release in PBMC cultures was investigated. A 2hr pulse of 1μM ZOL induced a 10.3-fold (+/-0.7) increase in IFNγ release from PBMCs after 48hrs. A simultaneous 2hr pulse with 1μM FLU markedly decreased ZOL-induced IFNγ release by >70%. When FLU was present for the entire 48hr period, FLU was only slightly more effective at preventing the ZOL-induced IFNγ release than when present only for the 2hr ZOL pulse, suggesting that sufficient FLU is internalised by PBMCs within a 2hr period to prevent the accumulation of IPP resulting from a clinically relevant exposure to ZOL. Co-administration of FLU with intravenous N-BPs may therefore provide a means for preventing the acute-phase response *in vivo*.

Studies of antiresorptive agents indicate that 1-year threshold values for treatment-induced increases in BMD and decreases in BCM predict for antifracture efficacy.[1] Ibandronate (Boniva®) is a potent, nitrogen-containing BP with antifracture efficacy when given daily or intermittently.[2] A 2-year, randomized, double-blind, phase III, non-inferiority study (MOBILE) is comparing the efficacy and safety of 50/50mg (single doses on consecutive days), 100mg (single day) and 150mg (single day) monthly oral ibandronate with oral daily ibandronate (2.5mg; 3-year vertebral fracture risk reduction: 52%) in 1,609 women with PMO. After 1 year, a prespecified analysis examined the proportion of patients in each arm achieving increases in: lumbar spine (LS) BMD above baseline or 6%; total hip (TH) BMD above baseline or 3%; both LS and TH BMD above baseline. The proportion of patients achieving decreases in sCTX below defined threshold values was also examined. After 1 year, the majority of patients achieved increases in LS or TH BMD above baseline (**Table**). Compared with the daily arm, significantly more patients achieved increases above baseline in the 150mg arm for LS BMD and the 100mg and 150mg arms for TH BMD. Likewise, more patients in the 100mg and 150mg arms achieved substantial increases in LS BMD (>6%) and TH (>3%) BMD than in the daily arm. In addition, most participants achieved increases in both LS and TH BMD above baseline ($p \leq 0.001$ for 100mg and 150mg vs 2.5mg). In the analysis of sCTX, a significantly greater proportion of patients in the 150mg arm consistently achieved decreases in sCTX of >30%, >50% and >70%, respectively, compared with the daily arm. In summary, a larger proportion of women receiving 100mg and 150mg monthly oral ibandronate achieve increases in LS and/or TH BMD after 1 year versus those receiving daily ibandronate. Moreover, compared with daily, significantly more patients receiving 150mg ibandronate achieve threshold values for sCTX.

Relative Change in Bone Mineral Density Is a Valid Surrogate for Antifracture Efficacy with Ibandronate. S. Epstein[1], H. Huss*[2], K. M. Wilson*[3], R. C. Schimmer[3]. [1]Mt Sinai Medical Center, New York, NY, USA, [2]., Levekusen, Germany, [3]F. Hoffmann-La Roche Ltd, Basel, Switzerland.

Predefined statistical analyses of the findings from recent antifracture studies of oral and intravenous ibandronate in postmenopausal osteoporosis demonstrate a reduction in risk of vertebral fracture that is significantly associated with improvements in BMD.[1,2] In light of these positive findings, an additional statistical analysis[3] was performed to validate relative change (%) from baseline in BMD as a surrogate marker for predicting 3-year VF RR with ibandronate (using total hip and lumbar spine BMD after 1, 2 and 3 years). The following criteria were used to evaluate surrogacy: (1) BMD is affected by treatment; (2) fracture incidence is affected by treatment; (3) BMD is prognostic for fracture; and (4) the proportion (ρ) of the 3-year antifracture effect explained by relative change (%) from baseline in BMD at each time point. For criteria 1-3, parameter estimates were produced using simple logistic regression models. When the studies were considered separately, findings were variable due to the small sample sizes. However, when the data were pooled, robust findings were reported. Notably, the criteria for surrogacy (outlined above; 1-3) were fulfilled for all analyzed surrogate endpoints for 3-year VF RR (**Table**). In addition, values for ρ (criterion 4) indicated that relative change (%) from baseline in total hip and lumbar spine BMD after 2 and 3 years explained a substantial proportion of the 3-year antifracture effect with ibandronate (**Table**). Importantly, values were similar to those obtained for other widely accepted surrogate endpoints. In summary, while not providing a complete explanation for antifracture efficacy, these findings highlight the utility of using relative change (%) from baseline in total hip and lumbar spine BMD after 2 and 3 years as surrogate markers for 3-year VF RR with ibandronate.

Does Dosing Regimen Impact Persistence With Bisphosphonate Therapy Among Postmenopausal Osteoporotic Women? J. A. Cramer*[1], M. M. Amonkar*[2], A. Hebborn*[3], N. Suppapanya*[2]. [1]Yale University, West Haven, CT, USA, [2]GSK, Collegeville, PA, USA, [3]Roche, Nutley, NJ, USA.

Although bisphosphonates are effective in the management of osteoporosis, patients often omit doses or discontinue treatment for a variety of reasons. This study assessed treatment adherence with daily and weekly bisphosphonates among postmenopausal osteoporotic women. Administrative claims data (from 1997-2002) from 30 health plans were used to identify postmenopausal osteoporotic women (>45 years) newly-prescribed (no bisphosphonate Rx at least 6 months prior) a once-weekly (QW - alendronate 35 or 70 mg) or once-daily (QD - alendronate 5 or 10 mg or risedronate 5 mg) bisphosphonate. The QW and QD cohorts were followed for 12 months from the date of fill of the index prescription. Medication possession ratio (MPR) was used to estimate compliance and cumulative bisphosphonate exposure during follow-up while persistence was calculated as the number of days from the initial prescription to a lapse of >30 days after completion of the previous refill. A total of 2741 women met the inclusion criteria (alendronate QW = 731; alendronate or risedronate QD = 2010). Mean age was 63.7 years. Overall MPR was 60.6% but QW users had a significantly higher MPR than QD users (69.2% vs 57.6%, t = -7.51, p<0.0001). Overall treatment persistence during the 12 months of follow-up was 196 days but significantly longer persistence was observed for QW users when compared with QD users (227 vs 185 days to discontinuation, respectively, log-rank X^2 = 30.3, p<0.0001). Kaplan-Meier analysis (Fig. 1) showed that at the end of 12 months, 44.2% of women on the QW regimen and 31.7% of women on the QD regimen persisted with therapy. Median duration of persistence was substantially higher in the QW cohort than the QD cohort (269 vs 134 days respectively). Also, 31% of QD users had ≤2 fills as compared to 21% of QW users (X^2= 23.11, p < 0.0001). Results indicate that postmenopausal osteoporotic women prescribed a weekly bisphosphonate regimen had significantly higher rates of compliance and longer persistence compared with those taking a more frequent, daily dosing regimen. However, rates for both regimens were less than desirable in terms of MPR, time to discontinuation and refill rates. These data demonstrate that less frequent dosing increases persistency, which is needed to obtain maximal long-term therapeutic benefits.

Figure 1: Time to discontinuation

The Response to Bisphosphonates and No Treatment Varies on the Concave and Convex Sides of the Scoliotic Spine. R. H. Routh*[1], A. L. Burshell[1], E. A. Nauman*[2]. [1]Endocrinology, Ochsner Clinic Foundation, New orleans, LA, USA, [2]Department of biomedical engineering, Tulane University, New orleans, LA, USA.

Adult scoliosis is estimated to be present in 5-10% of the population and its etiology may be related to adolescent scoliosis, degenerative disease or osteoporosis. Previous studies from our laboratory showed that the lumbar spine Z-Score is +1.5 S.D. greater than the femoral neck and the concave side is 15-20% denser than the convex side (SPINE, 2004).
The higher BMD on the concave side may be related to compression of the vertebrae, accretion of bone on the concave side, or greater bone loss on the convex side. In order to differentiate between these possibilities, we compared the repeat BMD to the original BMD in patients with scoliosis taking no therapy (N) or a bisphosphonate (B).
Scoliosis was identified by a single certified BMD interpreter and included in the study if they had a previous BMD scan and were taking either no N or B using the Hologic Delphi DXA. There were 35 patients in the N group and 27 patients in the B. The average time between scans was approximately 2 years. The L1-L4 vertebrae were divided vertically in two equal areal segments. The BMD of the concave and convex sides was determined.
The concave BMD increased significantly more than the convex side in the N group (See Figure). Similarly, the concave BMD increased more than the convex in the B group. The B group density was greater than the N on both the concave and convex sides. There did not appear to be any change in the angles of deformity between the repeat and baseline DXA scans.
This is the first study to show in scoliosis that the concave BMD increases without therapy. Bisphosphonates increase the lumbar BMD in both the concave and convex scoliotic spine, but greater on the concave. Finally, at least some of the increase in lumbar concave BMD is due to new bone formation.

Improving Compliance with Oral Bisphosphonate Therapy in a Pharmacist-managed Osteoporosis Clinic. E. N. Griffin*[1], V. I. Petkov*[2], M. I. Williams*[1], R. A. Adler[2]. [1]Endocrinology and Bone Metabolism, McGuire VA Medical Center/Virginia Commonwealth University School of Pharmacy, Richmond, VA, USA, [2]Endocrinology and Bone Metabolism, McGuire VA Medical Center/Virginia Commonwealth University School of Medicine, Richmond, VA, USA.

Bisphosphonates (BIS) are effective for osteoporosis. Patients discontinue therapy due to adverse events, cost, or problems with administration. Pharmacists can play a significant role in compliance. We hypothesized that a Bone Pharmacotherapy Clinic (BPC) could improve compliance with osteoporosis treatments.
In a single Veterans Affairs Medical Center we compared compliance with oral BIS in BPC patients to those followed by other providers (OTH). Compliance was calculated as the cumulative months of oral BIS prescribed divided by the months the BIS prescription was actually refilled. A retrospective electronic medical record review was conducted of 63 patients who had ≥ 4 visits to the BPC and 63 patients monitored by OTH, matched by BIS start date (± 3 months).
The 2 groups had similar age, weight, body mass index, gender, race, and fracture history distribution. BPC patients had significantly shorter exposure to oral BIS because 12 (19%) were switched to intravenous formulations. A greater proportion of BPC patients had follow-up BMD tests and documented adverse events than OTH patients. Compliance with oral BIS was greater in the BPC patients as compared to OTH patients. Alendronate had a compliance rate of 82.6 % vs. 70.1 % (p-value 0.016) while risedronate had a rate of 71.8 % in the pharmacotherapy group as compared to 62.3% in the OTH group (p-value NS). The difference in alendronate compliance remained significant after adjusting for the length of treatment, BMD test follow-up, and treatment related adverse events. Least square means from the ANCOVA model were 80.1% [74.9, 89.2] for BPC patients and 70.7% [63.1, 78.2] for OTH patients. A larger number of OTH patients (n=16) discontinued therapy as compared to BPC patients (n=10). Characteristics of patients who discontinued therapy in both groups were not significantly different with respect to age, BMI, gender, race, BMD follow up, fracture history, length of treatment or the number of active medications, but 37% of patients who discontinued therapy had a documented fracture (27.3% of BPC and 43.8% of OTH). Only 30% of patients who discontinued therapy had documented side effects from BIS.
In the BPC patients, factors associated with continued therapy were older age and having a recent BMD test follow-up (logistic regression model). Patients enrolled in a Bone Pharmacotherapy Clinic are more likely to be compliant with oral BIS therapy as compared to those patients followed by other healthcare providers.

Effect of Change in Dietary Acid-base Balance on Bone Turnover and Urine Calcium Excretion. R. Jajoo*[1], L. Song*[2], H. Rasmussen*[3], B. Dawson-Hughes[2]. [1]Division of Rheumatology, Tufts-New England Medical Center, Boston, MA, USA, [2]Bone Metabolism Laboratory, JM USDA Human Nutrition Research Ctr on Aging at Tufts University, Boston, MA, USA, [3]Metabolic Research Unit, JM USDA Human Nutrition Research Ctr on Aging at Tufts University, Boston, MA, USA.

We conducted this study to determine whether net acidity of the diet influences the rate of bone turnover and urinary calcium excretion. Forty subjects, age 50 years and older, with low usual protein and calcium intakes, were given supplemental protein at 0.75g/kg, 600 mg of elemental calcium and 400 IU of vitamin D3 daily. They were randomly assigned to fruit and vegetable supplements to neutralize the acid load from the added protein or to supplements containing carbohydrates and fat that were isocaloric to the fruits and vegetables. Net endogenous acid production was assessed by 24-hour urine net acid excretion (NAE). Urinary NAE, N-telopeptide (NTX) and calcium excretion and serum PTH and osteocalcin were measured at baseline, day 30 and day 60. Neither group had a significant change in weight during the study. This study was approved by the Investigation Review Board. There were no significant differences in NAE or in markers of bone turnover or urinary calcium excretion in the two groups by ANOVA. However, in all sub-

jects, baseline NAE was significantly correlated with 24-hour urine NTX (r = 0.428, P = 0.006). Baseline NAE was not significantly associated with serum PTH (r = 0.264, P = 0.100), serum osteocalcin (r = -0.017, P = 0.917), or urine calcium excretion (r = 0.281, P = 0.079). An increase in NAE from baseline to day 60 was significantly associated with an increase in urine NTX (r = 0.367, P = 0.020), and adjustment for change in serum PTH modestly altered this correlation (rp = 0.304, P = 0.060). Change in NAE was also significantly correlated with change in serum PTH (r = 0.358, P = 0.023); however, there was no association between change in serum PTH and change in urine NTX (r = 0.260, P = 0.106). Change in NAE was not significantly associated with change in serum osteocalcin (r = -0.128, P = 0.431) or with change in urine calcium excretion (r = 0.231, P = 0.152). We conclude that in healthy elderly men and women, a diet-induced increase in NAE over 60 days was significantly associated with an increase in urine NTX, indicating that acidogenic diets promote bone resorption. This association appears to be partially mediated by PTH. Increasing diet acidity did not appear to alter serum osteocalcin or urine calcium excretion. Because there was no difference in NAE between groups, it was not surprising to see no group difference in markers of bone turnover or urine calcium excretion.

Influence of Iron and Calcium on Change in Bone Mineral Density Differs by HRT Status in Postmenopausal Women. J. Maurer*[1], M. Harris*[2], T. Lohman[3], V. Stanford*[1], E. Cussler*[3], S. Going*[1], L. Houtkooper*[1]. [1]Nutritional Sciences, University of Arizona, Tucson, AZ, USA, [2]Pediatrics, Center for Applied Research and Evaluation, University of Arkansas, Little Rock, AR, USA, [3]Physiology, University of Arizona, Tucson, AZ, USA.

Hormone Replacement Therapy (HRT) has been used to prevent osteoporosis related bone mineral loss, yet, little research is known about how HRT may influence the nutrient-bone mineral density (BMD) interaction. This study was conducted to determine if dietary iron (iron) and dietary plus supplemental calcium (calcium) were associated with 1 year changes in BMD of postmenopausal women and if HRT use influenced these associations. Subjects were healthy nonsmoking postmenopausal women (n =228, mean age 55.6 ±4.6 years) from the Bone, Estrogen, Strength Training (B.E.S.T.) Study who completed the first year of this partially randomized clinical trial were examined. Women were stratified by HRT use status (HRT n =116, No HRT n =112). BMD was measured at five sites (lumbar spine L_2-L_4, trochanter, femur neck, Ward's triangle and total body) using dual energy X-ray absorptiometry (DXA) at baseline and 1 year. Mean nutrient intakes were assessed using 8-day diet records. All women received 800 mg a day of elemental calcium as calcium citrate. Regression analyses were conducted examining the effects of iron and calcium on BMD change adjusting for the effects of years past menopause, baseline BMD, weight change, exercise, and energy intake. Further associations of iron and BMD change adjusting for the same covariates and calcium were also examined, and vice versa. Tertiles were created for iron and calcium intake and then graphed against estimated marginal mean change in BMD to assess the interaction of iron with calcium on BMD change. Iron was associated ($p \leq .05$) with greater positive change in BMD at the trochanter and Ward's triangle in women taking HRT. Calcium was associated ($p \leq .05$) with change in BMD at the trochanter and femur neck for women not taking HRT. In women taking HRT in the lowest tertile of calcium intake (900-1400 mg), change in femur neck BMD increased linearly as tertile of iron intake increased. Conversely, in women not taking HRT, increase in BMD was seen only in the women in the highest tertile of calcium intake (1600-2600 mg). For both groups combined, change in BMD at the trochanter and Ward's triangle increased with increasing intakes of dietary iron in women at the lowest tertiles of calcium intake (HRT: 900-1400 mg; No HRT: 500-1300 mg). We concluded that HRT influences the associations of iron and calcium on change in BMD.

Calcaneal Ultrasound Change Rates In Girls From Age 10 To Age 13. K. M. Davies, J. M. Lappe, G. Lypaczewski*, J. Stubby*. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Two cohorts of girls aged between 9 and 10 were recruited for longitudinal studies of the effects of calcium nutrition and exercise on bone acquisition from 9 to 13. Those with more than 3 sessions/wk in organized sports were excluded. At semiannual visits, heel speed of sound (SOS) and attenuation (BUA) were measured by the Osteometer DTU-One. Graphs of group averages of these variables by visit or age appeared linear, so linear regressions over visits covering age 10 through 13 were done for individuals to obtain rates of change of SOS and BUA relative to baseline. In the CalKids study, participants were randomized into "normal diet" as controls and "calcium" with diet enhanced by foods richer in or supplemented with calcium. In the ExKids study, the groups were controls "C", 3 times a week exercise sessions "EX", and exercise sessions with more calcium food intake "EXHC". There was no difference between the studies in baseline values. Pooled for the 58 CalKids and 102 Exkids in this analysis, they are: SOS 1551.8 (SD 6.5) m/s and BUA 37.3 (SD 4.8) dB/MHz. In each study there was no difference between groups for the rates, but for the ExKids the rates were not different from zero, while for the CalKids they were positive: SOS 0.07%/y, P <0.002; BUA 3.3%/y, P < 0.0001. We believe the difference may be due to the effect of menarche. In the CalKids study, 37 of 58 girls (64%) had menarche within the interval of analysis, while for the ExKids only 44 of 102 (43%) had menarche. Conclusion: Hormonal status affects the change of calcaneal Ultrasound SOS and BUA in girls age 10 through 13.

Effects of Calcium-fortified Soy Milk Supplementation on Bone Mineral Density in Chinese Adolescent Girls Aged 14-16. S. C. Ho[1], G. Guldan*[2], J. Woo*[3], R. Yu*[1], M. Tse*[2], A. Sham*[1], J. Cheng*[4]. [1]Community & Family Medicine, Chinese University of Hong Kong, HK, Hong Kong Special Administrative Region of China, [2]Food & Nutritional Sciences Programme, Department of Biochemistry, Chinese University of Hong Kong, HK, Hong Kong Special Administrative Region of China, [3]Department of Medicine & Therapeutics, Chinese University of Hong Kong, HK, Hong Kong Special Administrative Region of China, [4]Department of Orthopaedics & Traumatology, Chinese University of Hong Kong, HK, Hong Kong Special Administrative Region of China.

Purpose: We aim to study the effect of calcium-fortified soy milk supplementation on change of bone mineral density (BMD) and content (BMC) in Chinese adolescent girls aged 14-16 y. **Methods:** This one-year study was conducted in 210 adolescent girls recruited from 6 secondary schools with comparable academic status, and assigned randomly to the intervention or control groups. Girls of the intervention group were supplied daily with 375 ml of calcium fortified soymilk (Calciplus) supplementation containing 142.5 kcal, 6.75 g protein, 4.1 g fat, 600 mg Ca and 54 mg isoflavones. At baseline, all participating subjects were ascertained the pattern of dietary intake based on 3-day self-administered food diary. BMD was measured at baseline and at 12 months with a Delphi QDR series, Hologic Dual-energy X-ray densitometre (Walthan, MA) at the spine (L1-L4), and hip (femoral neck, trochanter, and intertrochanter, and total hip). We compare the percentage change in BMD/BMC of the spine and hip region between the intervention (N=104) and control group (N=95). **Results:** The mean percentage changes of BMD/C and standard deviation (SD) over the followup for the intervention and control groups are: neck of femur BMD 2.7± 2.94%, 1.8±3.49% (p = 0.08); trochanter BMD 3.3±3.27%, 1.6±2.94% (p = <0.001); intertrochanter BMD 3.6±3.05%, 2.32±2.95% (p = 0.002); total hip BMD 3.1±2.39%, 2.05±2.22% (p = 0.001); total hip BMC 3.8±3.05%, 2.6± 2.96% (p = 0.006). The percent difference between the two study groups [100x (soymilk-control)/control] ranged from 45% to 113%. We observed no difference in the spine BMD/C between the two groups. Analysis of covariance controlling individually for height, weight, growth stage, dietary energy, calcium from usual diet yielded similar results. Stepwise multivariate regression analysis also showed that the supplementation group was significantly associated with increase in % BMD/C at the hip after simultaneously controlling for the covariates. **Conclusion:** 375 ml calcium fortified soymilk supplementation is among the effective strategies in increasing hip BMD and BMC and the optimization of peak bone mass in Chinese adolescent girls.

Effect of Choline Stabilized Orthosilicic Acid on Bone Density in Ovariectomized Rats. M. Calomme[1], J. Sindambiwe*[1], P. Cos*[1], C. Vyncke*[2], P. Geusens[3], D. Vanden Berghe*[1]. [1]Pharmaceutical Sciences, University of Antwerp, Antwerp, Belgium, [2]Bio Minerals nv, Destelbergen, Belgium, [3]Limburg University Center, BIOMED, Limburg, Belgium.

Silicon (Si) deficiency in animals results in bone defects. Orthosilicic acid is a bioavailable form of Si and was found to stimulate collagen type 1 synthesis[1] in human osteoblast-like cells. Choline stabilized orthosilicic acid (ch-OSA) was reported to increase the femoral BMD in chicks[2].

The effect of ch-OSA supplementation on bone loss was investigated in mature ovariectomized rats. The study was approved by the local Ethical Committee. Female Wistar rats (n=58, age: 9 months) were randomly divided in 3 groups. One group was sham operated (SHAM, n=21) and bilateral ovariectomy (OVX) was performed in the other 2 groups. One group (OVX1, n=20) was supplemented orally with ch-OSA (1 mg Si/kg BW) starting immediately after OVX whereas rats in the second group (OVX0, n=17) were controls. Rats were pair fed a standard diet and were sacrificed after 30 weeks supplementation. BMC and BMD were analyzed by DEXA. Scans were recorded for total femur, 4 regions of interest in the femur (H1: midshaft, H2, H3, H4: distal metaphysis), and lumbar vertebrae. Si concentration was measured by ETAAS. Comparison between groups was evaluated with the Mann-Witney U test.

The serum Si concentration of supplemented rats (mean: 253 µg/l) was significantly higher compared to SHAM (113 µg/l, p<0.0001) and OVX controls (147 µg/l, p=0.001). The 24 hour urinary Si excretion of supplemented OVX rats (165 µg) was significantly higher compared to SHAM (120 µg, p=0.001) and OVX controls (94 µg, p<0.0001).

Bone mineral content was significantly decreased by OVX in the femur (-15 %, SHAM vs. OVX0, p=0.0001) and spine (-17 %, SHAM vs. OVX0, p<0.0001). Ch-OSA supplementation increased significantly the femoral BMC in the distal region (H3: +9.4 %, OVX1 vs. OVX0, p=0.01) and total femoral BMC (+6.4 %, OVX1 vs. OVX0, p=0.025). Lumbar BMC was marginally increased by ch-OSA supplementation (+3.5%, vs. OVX0, p=0.17).

OVX significantly decreased bone mineral density in the femur (-15 %, SHAM vs. OVX 0, p<0.0001) and spine (-14 %, SHAM vs. OVX0, p=0.0005). Ch-OSA supplementation increased significantly the femoral BMD at two sites in the distal region (H2: +4.2 %, H3: +7.2 %, OVX1 vs. OVX0, p<0.05). Total lumbar BMD was marginally increased by ch-OSA supplementation (+4.6 %, vs. OVX0, p=0.11).

In conclusion, ch-OSA supplementation partially but significantly prevents femoral bone loss in the aged ovariectomized rat model. These results confirm earlier studies suggesting an essential role of Si in bone metabolism.

An Investigation into the Effects of Calcium Carbonate Supplementation on Markers of Pubertal Status and Leptin in 8-12 Year Old Gambian Girls. F. Ginty[1], A. Prentice[1], L. McKenna*[1], J. Bennett*[1], B. Dibba*[2]. [1]MRC Human Nutrition Research, Cambridge, United Kingdom, [2]MRC, Keneba, Gambia.

It has been suggested that menarcheal age may be inversely associated with calcium intake, but the mechanistic basis for this remains uncertain. The aims of the present study were to investigate, in a population where delayed puberty is common, whether calcium supplementation of prepubertal Gambian girls aged 8-12 years modified markers of pubertal status including, luteinising hormone (LH), follicle-stimulating hormone (FSH), and sex-hormone binding globulin (SHBG). Since dietary calcium has been postulated to indirectly affect fat mass, which in turn may modify the rate of pubertal development, leptin was also measured. Eighty girls were randomised, double-blind to receive either 714 mg/d of supplemental calcium (as calcium carbonate (Calcichew)) or a matching placebo for 12 mo. Fasting blood samples were collected from all subjects at baseline and at the end of the intervention period. Plasma from sixty subjects (n=28 and 32, respectively, for calcium and placebo groups) was analysed for LH, FSH and SHBG by Immulite immunoassay analyser (DPC, UK). Leptin was analysed by enzyme-linked immunoassay (Quantikine Human Leptin R&D Systems, UK). At baseline, the majority of subjects were in Tanner stage 1, with the exception of two subjects from the placebo group, who were at Tanner stage 2. No significant differences were found between groups for any of the markers. Conditional regression analysis was conducted to determine differences between groups at the end of the supplementation period, after adjustment for baseline value, age, body weight, height and number of supplementation days. At the end of the study, two subjects from the calcium group and three subjects from the placebo group had moved from Tanner stage 1 to 2. There were two further subjects in the placebo group who had moved to Tanner stage 3. There was a non-significant trend for higher LH (+28.7 (SE 20.2)%, p=0.16) and FSH (+39.1 (23.9)%, p=0.11) in calcium-supplemented subjects. Significant differences were not found for SHBG (+1.8 (8.9) %, p=0.84) or leptin (-13.0 (11.0)%, p=0.60). A significant difference in body weight was not found (+1.23 (1.26)%, p=0.37 for calcium vs placebo subjects), nor was there a significant difference in triceps skinfold measurement (-5.88 (4.76)%, p=0.22). These findings do not provide convincing evidence that calcium supplementation of prepubertal Gambian girls modifies markers of pubertal status or leptin. This may be due to the slower maturation rate of Gambian children compared to Caucasians. Further research is required to investigate the mechanisms by which calcium might affect the rate of pubertal maturation.

Evaluation of the Clinical Use of Vitamin K Supplementation in Postmenopausal Women with Osteopenia (The EKCO Trial): Study Design and Baseline Data. A. Cheung[1], L. Tile*[1], Y. Lee*[1], G. Hawker*[2], L. Thompson*[3], R. Vieth*[4], P. Massicotte*[5], T. Murray*[6], R. Josse*[6]. [1]University Health Network, Toronto, ON, Canada, [2]Sunnybrook and Women's Health Sciences Centre, Toronto, ON, Canada, [3]University of Toronto, Toronto, ON, Canada, [4]Mount Sinai Hospital, Toronto, ON, Canada, [5]University of Alberta, Edmonton, AB, Canada, [6]St. Michael's Hospital, Toronto, ON, Canada.

In recent years, vitamin K has been postulated to play an important role in bone health. Epidemiologic studies suggest that fracture patients have lower serum vitamin K levels when compared to non-fracture controls. As well, those with low vitamin K intake are at higher risk of fractures.

We are currently conducting a 2-year double-blind placebo-controlled randomized trial of 5mg oral vitamin K_1 daily supplementation in 430 postmenopausal women with osteopenia. Our primary hypothesis is that 5mg of vitamin K_1 daily will attenuate the natural BMD loss in postmenopausal women with osteopenia. We included postmenopausal women with T-scores between -1 and -2 in the lumbar spine (L1-L4), total hip, and femoral neck. We excluded women with osteoporosis, Paget's or other metabolic bone disease, and those on chronic oral steroids, coumadin, antiresorptive medications in the past 3 months, or megadoses of vitamin A or E. All women will have baseline, 1-year and 2-year measurements of BMD, as well as bone turnover markers. Each has a dietary assessment for calcium and vitamin D intake and is supplemented to 1500mg of calcium and 800IU of vitamin D a day. This protocol was approved by the ethics review boards of all participating centers, and informed consent is obtained prior to participants enrolling in the study.

As of May 2004, we have screened 729 women, and 386 have been randomized. Mean age at baseline was 59 years. Natural menopause was at age 50, and surgical menopause was at age 43. Mean height was 161.7 cm, mean weight was 68.4 kg, and mean BMI was 26.1. Mean BMD for lumbar spine (L1-L4) was 0.923 g/cm^2 (T-score = -1.2), total hip was 0.869 g/cm^2 (T-score = -0.6), and femoral neck was 0.712 g/cm^2 (T-score = -1.2). 88.6% of participants were Caucasian, 2.3% African-Caribbean, 6.2% Asian and 2.8% other. 55.8% were married or cohabiting. 35.0% had a family history of osteoporosis. 65.8% used some alcohol. 6.2% are current smokers, 46% ex-smokers, and 47% never smoked. 66% rated their health as very good or excellent, and 34% good or fair. Overall, our participants are relatively healthy.

The ECKO trial is one of three ongoing large-scale randomized trials to examine the effect of vitamin K supplementation on bone health in North America. We expect to complete this study by 2006.

Dose-dependent Effects of Vitamin E on Bone in an Orchidectomized Rat Model of Osteoporosis. S. Chai*[1], E. A. Lucas[1], B. J. Smith[1], A. Patade*[1], L. Devareddy*[1], D. Y. Soung[1], K. Korlagunta*[1], C. Wei*[1], D. Marlow*[2], B. H. Arjmandi[1]. [1]Nutritional Sciences Department, Oklahoma State University, Stillwater, OK, USA, [2]Laboratory Animal Resources, Oklahoma State University, Stillwater, OK, USA.

In a previous study we demonstrated that a moderately high dose of vitamin E in the diet improves biomechanical and biochemical properties of bone in old male mice. The present study was conducted to evaluate whether vitamin E can exert bone-sparing effects on osteopenic male bone. Forty 12-mo old male Sprague-Dawley rats were either sham-operated (sham) or orchidectomized (orx) and fed a control diet for 120 days to establish bone loss. Thereafter, rats were assigned to their corresponding treatment groups (n=10): Sham + 75 IU vit E; ORX rats received 75, 250, or 500 IU vit E per kg diet for 90 days. To date, whole body as well as 4th lumbar and femoral bone mineral density (BMD) and content (BMC) have been evaluated using dual energy x-ray absorptiometry. Data are presented below:

Parameters	Sham + 75 IU vit E	Orx + 75 IU vit E	Orx + 250 IU vit E	Orx + 500 IU vit E
BMC, *g*				
Whole Body	15.863±0.26 [a]	14.548±0.25[b]	14.709±0.25 [b]	14.432±0.25 [b]
Femur	0.717±0.017 [a]	0.625±0.016 [b]	0.635±0.016 [b]	0.608±0.016[b]
BMD, *g/cm^2*				
4th Lumbar	0.203±0.005[a]	0.1733±0.005 [b]	0.1658±0.005[b]	0.1632±0.005[b]
Whole Body	0.187±0.002 [a]	0.177±0.002 [b]	0.174±0.002 [b]	0.174±0.002 [b]
Femur	0.277±0.004[a]	0.249±0.004[b]	0.252±0.004[b]	0.242±0.004[b]
4th Lumbar	0.256±0.004[a]	0.223±0.004 [b]	0.224±0.004[b]	0.219±0.004[b]

Values presented are mean ± SE. Within each row, values with different superscript letters are significantly different from each other (P<0.05).

Although vitamin E has been shown to have some osteoprotective properties in other animal models, the findings of the present study indicate that vitamin E is unable to restore bone mass once the loss has occurred in this rat model of male osteoporosis.

Disclosures: ***E.A. Lucas****, None.*

Does Vitamin E Affect Microarchitectural Properties of Osteopenic Female Rats? E. A. Lucas[1], D. A. Khalil[1], B. J. Smith[1], L. Devareddy*[1], D. Y. Soung[1], V. Peddireddy*[1], S. Juma[2], M. P. Akhter[3], D. Chakkalakal*[4], B. J. Stoecker[1], B. H. Arjmandi[1]. [1]Nutritional Sciences Department, Oklahoma State University, Stillwater, OK, USA, [2]Department of Nutritional Sciences, University of Cincinnati Medical Center, Cincinnati, OH, USA, [3]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [4]Department of Orthopedic Surgery, Creighton University Medical Center, Omaha, NE, USA.

In the present study, the dose-dependent effects of vitamin E in improving bone microarchitectural properties was investigated using osteopenic ovariectomized rat model. Seventy-five 12-month old female SD rats were divided into 5 groups and were either ovariectomized (ovx; 4 groups) or sham-operated (1 group). Rats were fed standardized laboratory diet (AIN-93M) containing 75 mg vitamin E per kg diet for 120 days to allow occurrence of significant loss in bone mineral density (BMD) due to ovx. Thereafter, the diet of rats in sham and one ovx group was maintained on the 75 mg vitamin E per kg diet while three ovx groups was supplemented for 100 days with one of the vitamin E dose: 300, 525, or 750 mg vitamin E per kg diet. Animals that received 750 mg vitamin E had enhanced 4th lumbar vertebral bone quality as evident by improved yield force and yield stress in comparison with ovx controls. However, neither histomorphometric (proximal tibia) nor micro-structural (5th lumbar vertebra) data indicated that vitamin E supplementation results in higher bone volume over total volume (BV/TV), an index of bone mass. Additionally, micro-computed tomography (μCT) findings including finite element analysis showed no effects of vitamin E on trabecular region of 5th lumbar vertebral bone. The improvement in biomechanical properties of 4th lumbar may not be due to enhanced trabecular bone mass or micro-structural properties.

Effects of Soy Isoflavones on Bone Mineralization and Milk Mineral Concentration in Lactating Rats. C. A. Peterson*, J. Schnell*, L. Hillman. Nutritional Sciences, University of Missouri-Columbia, Columbia, MO, USA.

Although research has shown that soy isoflavones increase bone density during periods of chronic estrogen deficiency (e.g. surgical or natural menopause), scarce data exists on the skeletal effects or safety of soy isoflavone intake during acute estrogen deficiency (e.g. lactation). Our hypothesis is that soy isoflavone consumption will attenuate the bone loss associated with lactation. Further, we want to determine if isoflavones affect milk quality or quantity. Immediately after parturition, lactating rats were randomly assigned to one of four nutritionally complete diets (n=12/group) in which casein-based diets were supplemented with different levels of soy isoflavone extracts (ADM Novasoy, Decatur, IL): 0, 2, 4, or 8 mg total aglycone isoflavone/g protein. At day 12-15 of lactation, milk was col-

lected once from each dam. At weaning (day 21), bones and serum were harvested from 6 animals per group (lactation groups). The remaining 6 rats from each group continued on their respective diets for 4 weeks when bones and serum were collected (recovery groups). There were no differences in dam age or weight among all groups. Animals consumed significantly more food during the lactation phase than during the recovery phase. Serum genistein concentration was higher in lactating, high isoflavone diet dams; likewise, milk genistein concentration was higher in high isoflavone diet dams. Histomorphometry revealed that lactation results in losses in cancellous bone volume, mineralized bone volume, trabecular thickness and growth plate volume and thickness. Isoflavone treatment had no effect on any of these indices. Despite a trend for increased total tibia calcium in animals receiving the high isoflavone diet (p=0.1), isoflavone treatment did not affect milk calcium or phosphorus concentration or litter weight. This is the first report on the bone effects of isoflavone intake using an intact lactating rat model. Results provide support that consumption of soy isoflavones, in levels that can be readily attained through moderate consumption of soy foods, have neither protective effects on bone nor deleterious effects on milk quality or quantity during lactation.

Dried Plum Prevents Bone Loss in Animal Model of Male Osteoporosis. B. J. Smith[1], M. Franklin*[1], E. A. Lucas[1], E. A. Lancaster*[1], D. Y. Soung[1], L. Devareddy[1], D. Bellmer*[2], D. Marlow*[3], B. H. Arjmandi[1]. [1]Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, [2]Food & Agricultural Products Research & Technology Center, Oklahoma State University, Stillwater, OK, USA, [3]Laboratory Animal Resources, Oklahoma State University, Stillwater, OK, USA.

Among the dietary approaches for improving skeletal health, dried plum has been found to both prevent and reverse bone loss in female rat models. The effectiveness of dried plum in preventing bone loss in males, however, has not been examined. Therefore, the present study was undertaken to investigate the osteoprotective effects of dried plum in a male model of osteoporosis. Sixty, 6-month old male Sprague Dawley rats were either sham-operated (Sham=1 group) or orchidectomized (ORX=4 groups) and randomly assigned to dietary treatments: standard semi-purified diet (Control) with either LD=5%, MD=15%, or HD=25% (w/w) dried plum for 90 days. All diets were isocaloric, isonitrogenous, and had similar calcium and phosphorus content. Both the MD and HD dried plum completely prevented the ORX-induced decrease in whole body, femur, and 4th lumbar vertebra bone mineral density (BMD). Biomechanical testing of the femur mid-diaphysis indicated that ultimate load values for the MD and HD groups were also similar to that of the Sham group. Analyses of the distal femur metaphysis revealed that compared to the ORX-Control group, trabecular bone volume (BV/TV) was increased by the HD, while trabecular number (TbN) and separation (TbSp) were improved by all doses of dried plum. We conclude that that dried plum can prevent osteopenia in male rats of gonadal hormone deficiency, similar to that observed in females. Further studies are planned to investigate the bone-sparing mechanisms of dried plum and its bioactive components, e.g. polyphenols.

Low Adherence with External Hip Protectors Due to Both Hip Protector Itself and Garment. T. Koike, H. Toyoda*, R. Sugama*, M. Tada*, Y. Orito*, K. Takaoka. Orthopaedic Surgery, Osaka City University Medical School, Osaka, Japan.

External hip protectors appear effective for preventing hip fracture in nursing home residents with osteoporosis. However, compliance with use of hip protectors has been poor. The following factors may negatively influence compliance: cerebral disorders; adverse effects such as skin irritation; hip protector experienced as too hot in summer, uncomfortable in bed or necessitating assistance with toilet functions. We have therefore designed a new hip protector using softer porous materials, which is “open” so as to not interfere with toilet functions. To assess the benefits of this newly designed garment, a cluster randomized intervention-control design was used to examine the acceptability of hip protectors worn by residents at high-risk of falls (n=140) in nursing homes for 6 months. No previous studies have used sham hip protectors. Participants were divided into four groups: conventional garment with hip protector (Safehip, n=27); conventional garment without protector (n=27); open garment with protector (n=44); and open garment without protector (n=42). The four groups were alike in age (mean 81.3 y), body weight (45,7 Kg), body height (145.7 cm), and activities of daily living. Only one hip fracture occurred in the group of open garment without protector and no fracture in other groups. Compliance with hip protectors was very low for both garment types (Table). We accepted the use of hip protectors only during the daytime, and defined it as full adherence. Although compliance was slightly higher for conventional garments than for open garments, low compliance was largely attributable to the use of a hip protector in itself. Furthermore, we were surprised at low adherence with use of garments without protector. To achieve adequate adherence with use of external hip protector, we should reform not only the protectors but also hip protector underwear.

Month	0	3	6
Open garment w/ protector	44 (100%)	7 (15.9%)	5 (11.4%)
Open garment w/o protector	42 (100%)	24 (57.1%)	14 (33.3%)
Conventional garment w/ protector	27 (100%)	5 (18.5%)	6 (22.2%)
Conventional garment w/o protector	27 (100%)	15 (55.6%)	15 (55.6%)

Factors Related to Spinal Mobility in Patients with Postmenopausal Osteoporosis. N. Miyakoshi, M. Hongo, S. Maekawa, Y. Ishikawa*, E. Itoi*. Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

We have shown that the quality of life (QOL) in patients with spinal osteoporosis is impaired by the spinal mobility. However, factors related to the spinal mobility in these patients are still unclear. We evaluated the possible factors affecting spinal mobility in patients with postmenopausal osteoporosis. A total of 128 postmenopausal women with osteoporosis aged over 50 years (mean, 70 years) were included in this study. The thoracic and lumbar kyphosis angles and range of motion (ROM) of the total spine (thoracic and lumbar spine) were measured in the upright position and at maximum flexion/extension with a computer-assisted device (SpinalMouse®) for determination of shape and mobility of the spinal column. The paravertebral muscle (PVM) thicknesses of thoracic and lumbar spine in upright position were measured using ultrasound. The number of vertebral fractures was evaluated with lateral radiographs of the spine. Isometric back extensor strength was evaluated with a dynamometer in 91 patients. Age (r=-0.412), lumbar kyphosis angle (r=-0.284), back extensor strength (r=0.369), PVM thickness at lumbar spine (r=0.227), and the number of vertebral fractures (r=-0.260) showed significant correlations with total spinal ROM ($p<0.05$). However, no significant correlations were observed between the total spinal ROM and PVM thickness at thoracic spine (r=-0.069) or thoracic kyphosis angle (r=-0.138). Multiple regression analysis revealed that the back extensor strength was the most significant contributor to the total spinal ROM. We conclude that the back extensor strength is an important factor to maintain spinal mobility in patients with postmenopausal osteoporosis. The present study suggests a possible effect of back extensor exercise on maintaining the QOL in patients with postmenopausal osteoporosis.

Bone Density, Bone Biomarker and Serum IGF-1 Responses to 80 Weeks of Resistance Training in Older Adults. D. Bemben, M. Bemben*, I. Palmer*, J. Baker*. Health and Exercise Science, University of Oklahoma, Norman, OK, USA.

The purpose of this study was to examine the effects of 80 weeks of resistance training on bone metabolism and serum IGF-1 levels in older men (n=15) and women (n=25), 57-70 years of age. The training programs involved 3 sets of 12 isotonic resistance exercises performed either 2 or 3 days per week, at low (40%1RM) or high (80% 1RM) intensities. Muscular strength was assessed at 5 week intervals to determine progression. Dual Energy X-Ray Absorptiometry (GE Lunar DPX-IQ, version 4.7b) was used to measure BMD at the lumbar spine, proximal femur and total body sites at baseline, 40 and 80 weeks of training. Serum levels of bone-specific alkaline phosphatase (BAP, Metra Biosystems) and cross-linked N-telopeptide of Type I collagen (NTx, Ostex International) were measured at the same time points using ELISA kits. IGF-1 and IGF Binding Protein 3 (BP3) levels were measured by RIA kits (Diagnostic Systems Laboratory). Significant increases in BMD ($p<.05$) from baseline to 80 weeks of training were observed for the spine, trochanter, and total hip sites. Total body BMD showed a transitory increase ($p<.05$) from baseline to 40 weeks of training. There were significant ($p<.05$) trial x training group effects for the trochanter and total body BMD sites. There were gender differences in the bone biomarker responses to training as BAP significantly increased ($p<.05$) approximately 20% from baseline to 40 weeks in men and NTx significantly decreased ($p<.05$) 18% in women from baseline to 80 weeks. There were significant ($p<.05$) trial, gender, trial x gender, and trial x training group effects for serum IGF-1. Men had significant increases ($p<.05$) in IGF-1 from baseline to 40 weeks and the high intensity training groups showed the same pattern of response. BP3 significantly decreased ($p<.05$) from baseline to 80 weeks of training in both men and women. In conclusion, resistance training significantly improved BMD in men and women with the high intensity programs exerting greater effects at the trochanter and total body sites. The bone biomarker responses suggest the mechanisms for increasing BMD may differ between men and women. The decrease in the BP3 indicates that there may be greater bioavailability in circulating IGF-1 by the end of the 80 weeks of resistance training.

Treadmill Exercise on the International Space Station: The Effects of External Loading. K. O. Genc*[1], C. C. Maender*[2], A. J. Rice*[1], R. S. Ochia*[3], J. G. Snedeker*[4], P. R. Cavanagh[1]. [1]The Cleveland Clinic Foundation, Cleveland, OH, USA, [2]NASA-Johnson Space Center, Houston, TX, USA, [3]Rush Presbyterian-St. Luke's Medical Center, Chicago, IL, USA, [4]ETH, Zurich, Switzerland.

Providing Earth-like gravity replacement loads (GRL) during exercise on long duration space missions may be critical to the maintenance of bone mass. Two devices are currently used on the International Space Station (ISS) to provide a restoring force to return the astronaut to the treadmill surface during treadmill exercise: a subject load device (SLD) and various bungee cord (BC) configurations. In this experiment, the loads on the feet during treadmill exercise on the ISS were measured while all combinations of GRLs were used. The results were compared to similar exercise protocols on Earth. In-shoe forces were monitored using modified Pedar insoles (Novel Gmbh, Munich, Germany) placed inside the shoes of a single astronaut, who gave his informed consent to participate in the IRB-approved experiment. Data were recorded at 128 Hz on a wearable computer and downlinked via satellite. Thirty seconds of exercise data during 10 different loading conditions on orbit were collected and low-pass filtered using a 50 Hz cutoff frequency. All on-orbit loading profiles showed a marked decrease in peak ground reaction force when compared to 1g loading. The mean push off force (MPF) was significantly larger in 1g compared to 0g (Fig. 1). Daily load stimulus (DLS), a mathematical model used to relate changes in bone mineral density to daily loading histories, was also calculated from the force data for each loading condition using an exponent, m, of 5. During treadmill running the ratio of DLS for a 30 second period of activity in 0g to that in 1g varied from 0.50 to 0.78 over the range of loading configurations. Thus, treadmill exercise in space provided a maximum of only approximately 75% of the stimulus to bone experienced during typical exercise on Earth.

Figure 1: The mean push off force (MPF) from 30 seconds of walking and running at varying loading configurations on earth (1g) and on-orbit (0g). The dashed lines are used to illustrate the difference in MPF in 1g compared to 0g. All Running MPFs are significantly different from one another ($p < 0.05$) and all walking MPFs are significantly different from one another except for SLD 170 and 1Bungee ($p<0.05$).

Stimulation of Cortical Bone Formation Using Extremely Low-Level, High-Frequency Mechanical Signals. S. Judex[1], L. Karim*[1], R. Garman[1], L. Donahue[2], C. Rubin[3]. [1]Biomedical Engineering, State University of New York at Stony Brook, Stony Brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA, [3]Center for Biotechnology, State University of New York at Stony Brook, Stony Brook, NY, USA.

The osteogenic potential of mechanical signals indicates that a biomechanical modality, if it can be applied safely, would constitute a unique, non-pharmacologic intervention for osteoporosis. While preliminary work demonstrates that trabecular bone can be augmented by low-level, high frequency loads, the response in cortical bone remains unclear. Eighteen adult (4m), female, BALB/cByJ mice were randomly assigned to one of two groups: Loaded (10min/d of 45Hz @ 0.3g, induced non-invasively using a vibrating platform) and Long-Term Control. Bone labels were administered on days 10 & 20, and histomorphometric parameters measured at the diaphyseal midshaft of the tibia. Following a 21d experimental period, mineralizing (periosteal) surface (MS/BS) in loaded animals was 25% greater than controls (p=0.19), with a 33% increase at the endosteal surface (p=0.17). Loading increased mineral apposition rate (MAR) by 46% (p=0.03) and bone formation rates (BFR/BS) by 93% (p=0.06).

	Endocortical MS/BS (%)	Periosteal MS/BS (%)	Periosteal MAR (μm/d)	Periosteal BFR/BS (μm/y)
Control (Mean ± sd)	36.0 ± 16.4	37.7 ± 17.5	0.41 ± 0.10	61.2 ± 38.3
Load (Mean ± sd)	48.0 ± 18.0	47.1 ± 24.2	0.60 ± 0.19	118.0 ± 91.5
% Difference	33%	25%	46%	93%
p-value	0.17	0.19	0.03	0.06

These data indicate that extremely low-level mechanical signals, inducing cortical strains well below ten microstrain, can effectively augment cortical bone formation. When considered together with the ability of such signals to stimulate trabecular bone, it suggests that an amalgam of high-frequency signals may help regulate both cortical and trabecular bone physiology. As these strain levels are two orders of magnitude below those generated by functional activity, they may represent a safe and efficacious means of augmenting bone quantity and quality in the clinic. This work supported by NSBRI.

Long-Term Changes in Body Composition Predicts Bone Change in Postmenopausal Women. J. Choi*, E. C. Cussler*, S. B. Going, L. L. Metcalfe*, H. G. Flint-Wagner*, T. G. Lohman. Department of Physiology, University of Arizona, Tucson, AZ, USA.

The aim of this study was to examine changes in bone mineral density (BMD) in relation to 4-yr changes in weight and body composition in exercising postmenopausal women at four bone sites: femoral trochanter and neck, lumbar spine, and total body. Both lean tissue mass and percent body fat were assessed. One hundred sixty-six postmenopausal women, 45-66 yr old, who completed annual 4-yr dual-energy x-ray absorptiometry (DXA) and anthropometric measurements were included in the analyses of this study. At baseline, subjects were blocked into hormone replacement therapy (HRT) or no-HRT groups and randomized into exercise or no-exercise groups. Exercise training involved 3 days per week completing two sets of 6 to 8 repetitions in resistance exercises at 70-80% of one repetition maximum. During the four years of data collection, 32.9% in no-HRT crossed over to take HRT and 72.7% in no-exercise crossed over to participate in exercise. Therefore, the variables used in 4-yr analyses were years on HRT during the four years of the study and mean exercise attendance. Using multivariate linear regression, change in body weight was a significant predictor of change in BMD at all four bone sites; it was the strongest predictor of BMD at the femoral trochanter and neck bone sites. Mean exercise attendance was also a significant predictor of BMD, stronger at the lumbar and femoral trochanter bone sites. Multivariate regression models including changes in lean tissue mass and percent body fat showed both were significant predictors of BMD. Femoral trochanter BMD was associated most strongly with change in lean tissue mass ($p < 0.01$). Subgroup analyses included covariance analysis (ANCOVA) among tertiles of change in lean tissue mass. Changes in BMD among the tertiles were only significant at the femoral trochanter bone site, where the reduced BMD seen in the lowest tertile was significantly different from gains in BMD within the middle and highest tertiles ($p < 0.01$). We conclude that there is a positive relationship between long-term change in body weight and change in BMD. Long-term change in lean tissue mass, change in percent body fat, and mean exercise attendance are all significant predictors of BMD in postmenopausal women. Lean tissue mass changes had the greatest effect at the femoral trochanter bone site.

Change in Walking Endurance Among Women with Prevalent Vertebral Fractures: Associations with Concurrent Change in Impairment, Functional Status, and Disability. K. M. Shipp[1], C. F. Pieper*[2], D. T. Gold[3], K. W. Lyles[4]. [1]Community and Family Medicine, Duke University, Durham, NC, USA, [2]Biostatistics and Bioinfomatics, Duke University, Durham, NC, USA, [3]Psychiatry and Behavioral Sciences, Duke University, Durham, NC, USA, [4]Medicine, Duke University, Durham, NC, USA.

Osteoporotic vertebral fractures are associated with functional limitations and disability. We tracked changes in functional performance (walking endurance as measured by six minute walk [SMW] distance) over six months in 142 older women (age 80.9 ± 5.6 years) with prevalent vertebral fractures (number=2.4 ± 1.8) who were subjects in an exercise/coping skills clinical trial. Although the exercise intervention did not target endurance walking, and, therefore, did not significantly improve SMW distance, we conducted exploratory analyses to determine whether a change in SMW over six months was related concurrently to change in other parameters along the disability model.

Using Spearman's correlation coefficients, change in SMW was correlated significantly ($p < 0.05$) to change in 7 parameters, including impairment: trunk rotation range of motion 0.24, psychiatric symptoms -0.20, confidence in mobility 0.29; functional performance: gait velocity 0.59; functional status: Functional Status Index (FSI) -0.22, MOS-36 physical function subscale 0.25; and disability: MOS-36 physical role subscale 0.25. Linear regression analyses, controlling for age and number of vertebral fractures, estimated that 33% of the variance in change in SMW distance was explained by change in the impairments and gait velocity. In turn, change in SMW distance accounted for 9% (FSI) and 7% (MOS-36 physical function subscale) of the variance for change in functional status and 4% of the variance for change in role disability (MOS-36 physical role subscale).

Walking endurance, the construct measured by the SMW, has been shown to improve with targeted exercise in older adults with chronic medical problems. The results presented here support the premise that an exercise regime that targets and improves walking endurance could lead to better functional status and less disability in older women with prevalent vertebral fractures.

Weight Lifted in Strength Training Predicts Four-Year Bone Changes in Postmenopausal Women. E. C. Cussler*, S. B. Going, H. G. Flint-Wagner*, R. B. Blew*, J. Choi*, T. G. Lohman. Physiology, University of Arizona, Tucson, AZ, USA.

The aim of this study was to examine the relationship between weight lifted over four years of progressive strength training and change in bone mineral density (BMD) in a group of calcium-replete, postmenopausal women.

As part of a large clinical trial, 89 calcium-supplemented postmenopausal women (55.4±4.5 years), randomized to a progressive strength training program, were followed for four years. Fifty-four percent of the women were using hormone replacement therapy. Three times weekly, subjects were asked to complete two sets of six to eight repetitions in eight core exercises at 70-80% of one repetition maximum. Women recorded weights and repetitions of all exercises throughout the four years. Total and regional BMD was measured at baseline and thereafter annually using dual-energy x-ray absorptiometry (DXA). Hormone replacement therapy (HRT) use was calculated as continuous years on HRT through the fourth year.

Women using HRT (48) and not using HRT (41) had similar baseline age, body mass index, percent fat, and lean soft tissue(LST). HRT users had fewer years past menopause and had higher initial lumbar spine BMD ($p<.01$ and $p<.05$, respectively) than non-users. Exercise compliance averaged 75.2±18.3%, 54.3±33.9%, 38.9±33.8%, and 33.2±32.8% for sequential years. The mean weight lifted in the dumbbell or military press (MP), used as a surrogate for exercise compliance, was 26,223.8±17,734.1kg over four years. In multiple linear regression, increases in lumbar spine(LS), total body(TB), and ulna(U) BMD were positively and significantly related to weight lifted in the military press after adjusting for age, baseline BMD and weight, HRT use, and weight and LST change. LS BMD increased 0.016g/cm^2 (1.6%) ($p<.01$), TB, 0.006g/cm^2 (0.6%) ($p<.01$), and U, 0.003g/cm^2 (1.5%) ($p<.05$) for every standard deviation of weight lifted in the MP. While hips sites (femur neck, trochanter, and wards) and ultradistal radius models did not reach significance, gains at all these sites were found with higher levels of weight lifted. Only TB BMD change was independently associated with HRT use ($p<.01$). No interaction was found between HRT use and weight lifted.

Evidence of an independent, linear relationship between regional and total BMD change and weight lifted in the military press during a four-year strength training program supports the positive, long-term usefulness of this type of exercise for the prevention of osteoporosis in postmenopausal women.

Adapting a Vibration-Based Countermeasure for Bone Loss for use in Microgravity Conditions. X. Lei*, Y. Qin, W. Lin, S. Judex, C. T. Rubin. Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA.

Osteoporosis, the progressive loss of bone density and strength, is both common and severe in astronauts subjected to long-term space flight; yet effective countermeasures have proven elusive. Recent work has shown that brief exposure to 30Hz, 0.3g whole-body vibration can effectively inhibit disuse osteopenia, and thus potentially applicable in microgravity conditions. The device consists of a base plate which uses an electromagnetic actuator to drive the top platen, which remains coupled via connecting springs. Due to the absence of gravity, an elastic restraint secures the subject to the vibration platform, and thus transmits the loads from the shoulders through to the weight bearing skeleton. To avoid disrupting other experiments, the base plate cannot be fixed to the space station, and thus it must be determined if the mechanical signal, in the free floating system, will reach regions of interest (i.e., hip), a challenge which was not anticipated in a previous ground-base model of transmissibility [Fritton et al. 1997]. The objective of this study is to determinate the appropriate parameters needed to produce sufficient but not excessive vibrations to the hip. A simple mass-spring-dashpot model with 3 degrees of freedom was first applied to study the system responses to harmonic excitations. The mass of the base plate and the stiffness of the support spring were considered as major design parameters. Noting that the rigid-body mode is not of concern, the two natural frequencies of the system were analytically obtained. The preliminary results reveal that the higher natural frequency of the system can be dramatically altered by adjusting the above two design parameters, while the lower natural frequency is relatively unaffected.

In a first-order approximation, a 50% body weight restraint and an 8kg device weight, an 18N, 30Hz load applied to an 80kg astronaut in microgravity will deliver 4.4N to the femoral neck. Displacement of the plate would be less than 1mm. Mechanical responses can be modulated by optimizing the base plate and connection springs as shown in the figure. The results using the vibration models found to match ground-base experimental data reasonably. The model predictions provide a better understanding of human body responses to vibration treatment in the weightless environment and a guideline for an optimal design of the vibration apparatus as well. This work was supported by NASA.

Post Study Follow up in a Group of Women Completing Osteoporosis Treatment Drug Trials. K. M. Hill*, E. A. Mossman, M. R. McClung. Oregon Osteoporosis Center, Portland, OR, USA.

Little is known regarding follow-up care of participants completing osteoporosis treatment research trials. The purpose of this study was to determine if participants completing such trials at our center saw a health care provider at study end and if osteoporosis medications were prescribed.

Local institutional review board approval was obtained. Questionnaires were sent to all women completing osteoporosis treatment trials at the Oregon Osteoporosis Center between April 2002 and January 2004. One reminder telephone call was made to non-responders. Quantitative descriptive statistics were used to analyze the questionnaire responses.

49% of questionnaires were returned (91/187). 39% (16/41) of initial non-responders returned the questionnaire after a reminder call. 58% of respondents (53/91) saw their health care provider at study end and 74% (39/53) of those were given a prescription for osteoporosis medication. Of those given a prescription, 90% (35/39) filled the prescription, and 80% (28/35) were still taking the medication at the time of this study. The majority of respondents were prescribed a bisphosphonate when a prescription was written. Of those not seeing a provider at study end, 24% (7/29) indicated inability to afford medication, 17% (5/29) indicated they didn't think they needed the medication, 3% (1/29) listed no provider, 3% (1/29) listed concerns regarding side effects, and 41% (12/29) listed a variety of other reason with no trend identified in these responses.

Following participation in an osteoporosis drug treatment trial, just over half of questionnaire respondents had a follow up visit with their health care provider. Of those, the majority received an osteoporosis medication prescription, filled the prescription and continued taking the medication up to 2 years post study. Our results indicate the need to determine ways to better promote post study follow up care.

Analysis of First Events vs. Multiple Outcomes. A. L. Oberg*, E. J. Atkinson*, S. J. Achenbach*, L. J. Melton. Mayo Clinic, Rochester, MN, USA.

There is controversy in the clinical trial literature about the appropriateness of considering multiple outcomes. While a single endpoint (e.g., death or recurrence) may be reasonable in cancer trials, it makes less sense for studies of osteoporosis treatments where patients are at risk of multiple fractures of diverse types. The traditional time-to-first event Cox models have been extended by Anderson & Gill to permit evaluation of time-to-multiple events (A-G). We undertook to determine what is gained or lost in the assessment of fracture risk when using all fractures experienced by each patient rather than just the first one. We analyzed the risk of additional fractures at multiple sites among 225 postmenopausal women from an age-stratified sample of Rochester, MN residents gathered in 1980 with median follow-up of 16.2 years. Altogether, 110 subjects subsequently had at least one moderate trauma fracture and 245 moderate trauma fractures were observed in total. We used Cox and A-G analyses to examine age, baseline femoral neck BMD, and dietary protein as predictors of subsequent fracture. The information gain was assessed by examining the ratio of standard errors (SE) of the parameter estimates from the two models. If each subsequent fracture provides completely new information (is independent), first and subsequent fractures would contribute equal amounts of information. However, the assumption of complete independence is generally not met. In this sample, 135 additional fractures were actually worth 31, 73, and 14 first fractures, respectively, for age, BMD and dietary protein. The table indicates the detectable hazard ratio (HR) in a study with risk factor prevalence of 50%. With proportions of first and subsequent fractures approximately equal, as is true in this study, and subsequent fractures worth 45% of a first fracture, the detectable HR with 90% power is improved by 9%-14%. The largest gain is realized for the smaller sample sizes.

Expected # 1st fractures (fxs)	Expected # subsequent fxs	%Worth, subsequent fxs	Detectable HR 80%/90% power
50	50	0%*	2.21/2.51
		15%	2.10/2.36
		30%	2.01/2.24
		45%	1.94/2.15
100	100	0%*	1.76/1.92
		15%	1.69/1.84
		30%	1.64/1.77
		45%	1.60/1.72
200	200	0%*	1.49/1.59
		15%	1.45/1.54
		30%	1.42/1.50
		45%	1.39/1.47

* Results for Cox analyses.

Although it remains to be determined whether the worth of additional subsequent fractures is consistent across differing study populations and/or variable types, including multiple fractures per subject allows use of all information from a patient and permits sample size or follow-up time to be decreased at substantial cost savings.

Disclosures: ***A.L. Oberg****, None.*

Outcome of Balloon Kyphoplasty with PMMA and Calcium Phosphate Cement in Patients with Painful Vertebral Fractures due to Primary Osteoporosis: A Comparative Prospective Controlled Trial. C. Kasperk[1], I. Grafe*[1], K. DaFonseca*[2], U. Liegibel*[1], U. Sommer*[1], U. Hilscher*[1], G. Noeldge*[3], M. Libicher*[3], P. Nawroth*[1], P. Meeder*[2]. [1]Endocrinology and Metabolism, University of Heidelberg, Heidelberg, Germany, [2]Trauma Surgery, University of Heidelberg, Heidelberg, Germany, [3]Radiology, University of Heidelberg, Heidelberg, Germany.

Medical treatment of primary osteoporosis does not entirely solve the clinically severe complications of osteoporosis: pain and impaired mobility due to vertebral fractures. This study analyses changes in radiomorphology, pain, mobility, number of new vertebral fractures and health care utilization one year after augmentation of vertebral fractures by balloon kyphoplasty.

60 patients with primary osteoporosis and more than 12 months old painful vertebral fractures were included in this cohort study selected by an interdisciplinary team of osteologists/endocrinologists, trauma surgeons and radiologists. 40 patients were treated with balloon kyphoplasty (20 received PMMA and 20 calcium phosphate cement) while 20 served as controls. The groups were analyzed prior to treatment and 3 and 6 months later. All patients received standard medical treatment (1g calcium, 1000 IE vitamin D3, standard dose of an oral aminobisphosphonate, pain medication, physical therapy).

Balloon kyphoplasty increased midline vertebral height of the treated vertebral bodies by 12.1 % while in the control group vertebral height decreased by 8.2 % (p=0.001). Augmentation and internal stabilization by balloon kyphoplasty resulted in a 70 % (p=0.007) reduction of back pain, while mobility increased by 24 % (p=0.031). There is no significant change in control patients with regards to pain and mobility during the 6 months follow up. The number of back-pain-related doctor visits within the 6 months follow up period decreased significantly after kyphoplasty compared to controls: 3.3 visits/patient in the balloon kyphoplasty group and 8.6 visits/patient in the control group. There is no significant difference with regards to the clinical outcome between the patients treated with PMMA or calcium phosphate cement.

Balloon kyphoplasty improves quality of life for elderly patients with primary osteoporosis suffering from chronic pain caused by vertebral fractures. Therefore, balloon kyphoplasty appears to be a promising addition to evidence-based medical osteoporosis treatment in selected patients with chronic pain due to old vertebral fractures.

The Effect of anti-TNFa Therapy on Spinal Bone Mineral Density in Patients with Crohn's Disease. A. D. Rhim*[1], G. R. Lichtenstein*[1], A. M. Weinberg*[1], C. Su*[1], M. Pazianas[2]. [1]Gastroenterology, Medicine, Univ of Pennsylvania, Philadelphia, PA, USA, [2]Medicine, Univ of Pennsylvania, Philadelphia, PA, USA.

Pro-inflammatory cytokines might be, at least partially, responsible for the development of osteopenia or osteoporosis in Crohn's Disease. We investigated whether anti-TNF therapy for Crohn's Disease could have any positive skeletal impact. Hence, we studied the effects of Infliximab, a monoclonal antibody against TNFa without or with bisphosphonates, on spinal bone mineral density (BMD). The effect of corticosteroids was also analyzed. A retrospective cohort analysis was performed on 61 patients with Crohn's and low BMD. Twenty three (23) patients were on Infliximab and 36 patients were on bisphosphonates. Mean duration between DXA scans was 2.2 $\pm$ 0.99 years. After controlling for corticosteroid use, patients with concurrent Infliximab and bisphosphonate treatment exhibited a greater increase in BMD compared to those on bisphosphonates alone (+6.7%/y vs +4.46%/y, $p<0.05$); corticosteroids inhibited this effect ($p<0.05$). However, Infliximab alone had no effects on BMD. Patients receiving bisphosphonates showed a significant increase in lumbar spine BMD compared to those not on bisphosphonates (+3.97% change in T-score/y vs -3.68%/y, $p<0.001$). Concurrent corticosteroid use significantly inhibited this effect. Concurrent Infliximab use may confer an additional benefit to that already documented for bisphosphonate use alone; bisphosphonates are beneficial in the treatment of low BMD in patients with Crohn's disease, though corticosteroids may partially inhibit this effect.

A Practical Stepwise Flow Sheet for Pharmacologic Treatment of Low Energy Fractures in a Department of Orthopaedic Surgery. H. Christoffersen[1], S. N. Holmegaard*[2]. [1]Orthopaedic, Thisted Hospital, Thisted, Denmark, [2]Department of medicine, Thisted Hospital, Thisted, Denmark.

Patients with low energy fractures (LEF) are at high risk for new fractures, but orthopaedic surgeons primarily focus attention on operative procedure and ignore preventive measures of established value.

Adequate prevention is especially important in the elderly patient with LEF of the hip, in whom a new fracture carriers a considerable risk of fatal consequences. However, only 5-25% of patients with LEF are evaluated and treated for osteoporosis. This state can probably only be improved by standardized and automatically initiated procedures for evaluation and pharmacologic treatment of LEF where the patients primarily are treated. We have therefore developed a stepwise strategy for clinical evaluation and appropriate pharmacologic treatment of patients with LEF.

For patients admitted to the orthopaedic department due to LEF of the hip, screening tests for secondary osteoporosis are done immediately after admission and all patients are started on treatment with 1200 mg calcium and 20 mcg vitamin D daily.

Patients with positive screening tests are referred for evaluation by an endocrinologist. The remaining majority is evaluated for propensity to fall, estimated life expectancy and for males palpation of the testes.

When fall is the dominant problem, possible contributory factors in the home and effects of drug treatment, e.g. glucocorticoids, sedatives and antihypertensive drugs, are evaluated.

All patients are discharged with calcium and vitamin D (1200mg/20 mcg), and if estimated life expectancy is > 2 years therapy with biphosphonate (Alendronate 70 mg once weekly) started before discharge.

Patients with LEF seen in the OPD are also treated with calcium and vitamin D, given information about the possible relation between LEF and osteoporosis and encouraged to contact their general practitioner for screening tests and measurement of BMD.

This simple program can increase awareness amongst orthopaedic surgeons, general practitioners and patients about prevention of new osteoporotic fractures in a high risk population.

Drug Compliance in Glasgow: A Year Following Hip Fracture. A. P. Gallagher*, S. J. Gallacher, C. A. McQuillian*, M. Harkness*. Medical Unit Southern General Hospital, Glasgow, United Kingdom.

As the population ages, orthopedic surgeons worldwide are seeing an increasing number of hip fractures. Our Fracture Liaison Service was introduced in November 2000 to put in place a system which would identify and treat, automatically, all hip fractures following admission to the orthopedic unit.

More than 1200 fractured neck of femur patients have been identified to date.

An osteoporosis treatment algorithm was integrated into the hip fracture pathway.

To audit compliance with the medications prescribed, and to assess the incidence of side effects experienced, a postal survey was undertaken in 112 patients (aged over 70 and with AMT>7) who had been commenced upon osteoporosis therapy a year earlier.

65 questionnaires were returned complete: 20% male and 80% female.

1.5% were recommended calcium/vitamin D alone however 15.4% were commenced upon this.

27.5% were recommended bisphosphonate alone however only 21.5% received this.

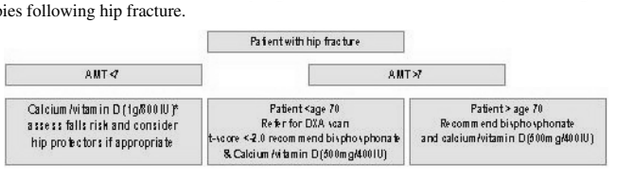
71% were recommended bisphosphonate and calcium/vitamin D although it was only prescribed in 56.9%.

Thankfully 95% of patients were given some form of osteoporosis medication.

90% stated medication was being taken as directed (10% leaving this question blank).

7.8% of patients experienced side effects (bisphosphonates being the main source), 4.7% stopped the medication whilst the other 3.1% stopped and restarted.

This simple study emphasizes the very high continuance rates in all osteoporosis drug therapies following hip fracture.



recommended medication / which medication are you taking (crosstabulation)

		which medication are you taking

Barriers to Effective Management of Osteoporosis in Minimal and Moderate Trauma Fractures: A Prospective Study. D. Bliuc*, C. R. Ong, J. A. Eisman, J. R. Center. Bone and Mineral, Garvan Institute of Medical Reasearch, St Vincent's Hospital, University of NSW, Sydney, Australia.

Osteoporosis is suboptimally investigated and treated even in high-risk people with a history of prior fracture. In addition, there is some evidence that individuals with moderate trauma fracture have a lower bone density and are at higher risk of subsequent fracture. The aim of this study was to define the factors influencing the management of individuals at risk of osteoporosis and the risk profile of individuals with minimal and moderate trauma fractures. Consecutive fracture patients (n=218) treated in the outpatient fracture clinic of a teaching hospital in Sydney over an 18 month period (February 2002-July 2003) were interviewed. Risk factors for osteoporosis, type and circumstance of fracture, prior investigation and treatment for osteoporosis were collected and participants were contacted by telephone 3 months after enrolment to ascertain follow up.

Risk factors for osteoporosis including family history, low dietary calcium intake, glucocorticoid use and conditions associated with bone loss occurred with similar frequency in the minimal and moderate trauma groups and between the sexes. Overall, half of the participants (50% of women and 48% of men) had had a prior fracture independent of whether their current fracture was due to minimal or moderate trauma. Even among those with a prior fracture, only 37% had a bone density scan, and 14% were on specific osteoporosis

treatment. There was only a minimal (5%) increase in the rates of investigation and treatment after 3 months. The proportion of people investigated and treated was lower in the moderate trauma group and particularly in males. In multivariate analysis, independent predictors for being investigated for osteoporosis were age over 50, presence of prior fracture and female gender. The only independent factors influencing treatment were age over 50 and having been investigated.
This study has confirmed the low rates of investigation and treatment of low trauma fractures even in the group who already have suffered a prior fracture. Osteoporosis is even more poorly managed in males and in those under the age of 50. People with moderate trauma fractures have the same risk factors for fracture as those with minimal trauma fractures including a similarly high proportion of prior fractures. These findings support the concept that people with moderate trauma fractures are at higher subsequent fracture risk, yet are neither investigated nor treated. This study highlights the need for further exploration of barriers to appropriate osteoporosis management.

Osteoporosis Identification and Treatment After Fragility Fracture in an Inner City Orthopaedic Unit. E. R. Bogoch[1], V. I. M. Elliot-Gibson*[2], D. E. Beaton*[2], S. A. Jamal[3], R. G. Josse[3], T. M. Murray[3]. [1]Department of Surgery, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada, [2]Mobility Program Clinical Research Unit, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada, [3]Department of Medicine, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada.

The orthopaedic unit at St Michael's Hospital, a university hospital in Toronto, Ontario, has a program to identify, educate, refer, treat, and evaluate fragility fracture patients for osteoporosis (OP). An OP Exemplary Care Program was designed to address system and individual barriers to identification and treatment of OP. System modifications included coordination between the orthopaedic, endocrinology and nuclear medicine units to provide a continuum of care for fragility fracture patients with suspected OP. Individual barriers were addressed through ongoing education of physicians, staff and patients to increase knowledge and awareness of OP. A coordinator is responsible for daily program operations. Criteria for inclusion into this program were: male ≥ 50; female ≥ 40; fracture resulting from low trauma; fracture sites: distal radius, proximal humerus, proximal femur, vertebrae. Increased awareness of OP among surgeons led to the additional inclusion of patients with suspected OP but were either below age criteria, sustained a high trauma fracture, and/or had an atypical fracture site. Data presented is from the period December 1, 2002 to November 30, 2003 (n = 430).

	Inpatients n = 154		**Outpatients n = 276**	
	Female n = 123	Male n = 31	Female n = 210	Male n = 66
Mean age	80.36	72.55	67.70	65.47
Fracture Site: Hip	95	29	48	13
Wrist	2	0	96	26
Shoulder	11	0	42	19
Vertebra/Other#	15	2	24	8
Previous Dx/Rx of OP	43	6	88	9
Referral or Rx initiated#	72 of 80	18 of 25	103 of 122	51 of 57
No referral or rx intiated*	8 of 80	7 of 25	19 of 122	6 of 57

*# Minimum Rx initiated was vitamin D and calcium. *No referral/rx due to refusal, contraindications, death, normal BMD.*

Over 90% of fracture patients received appropriate OP attention demonstrating a positive change in clinical behaviour by physicians and staff and unprecedented success in OP care. Anticipated outcomes are an increase in preventive health behaviours in fracture patients and a decreased rate of subsequent fractures and related health care costs. Six-month follow-up will be completed for all patients to assess compliance with referral and medications which may demonstrate those groups most amenable to treatment. An orthopaedic leader, motivated staff, an assigned OP coordinator and stable resources are required to maintain an intensive clinical program.

Temporal Trends in Prevention of Glucocorticoid-Induced Osteoporosis. K. G. Saag*[1], S. H. Gehlbach*[2], J. R. Curtis*[1], K. Worley*[3], T. E. Youket*[3], J. L. Lange*[3]. [1]University of Alabama at Birmingham, Birmingham, AL, USA, [2]University of Massachusetts at Amherst, Amherst, MA, USA, [3]Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The 1996 American College of Rheumatology (ACR) recommendations for prevention and treatment of glucocorticoid-induced osteoporosis (GIOP) suggest bone mass measurement (BMM) and anti-resorptive medications for at risk patients. We investigated changes in the proportion of chronic glucocorticoid (GC) users who received these tests or medications from 1996 - 2001. The data source was a random sample from a medical and pharmaceutical claims database (Protocare), representing a health plan with 7 million covered lives in 20 states. The study population (denominator) included patients initiating chronic oral GCs (average > 7.5 mg/day prednisone equivalent for > 6 months) in a biennial period. Numerators were patients receiving BMM within 12 months before and after initiating GC therapy and those who received a non-estrogen anti-resorptive pharmaceutical (bisphosphonate, calcitonin, raloxifene) within 12 months after initiating GC therapy. 3,125 adults initiated chronic GC therapy over 1996-2001 and were: 62% women; 18 - 49 years old: 30%, 50-64: 23%, 65+: 47%. The proportion of women ages 50+ who received BMM increased from 10% in 1996-7 to 19% in 2000-2001. Anti-resorptive pharmaceutical use similarly increased from 7% to 23%. In contrast, among all men and women ages 18 - 49, the proportions receiving BMM and/or anti-resorptives were less than 6% for all biennial periods. Besides demographics, factors that increased the likelihood of receiving BMM were prior fracture in the 12 months before GC therapy (OR 2.5, 95% CI 1.0 - 2.5) and treating physician specialty (OR 1.8 specialist vs. generalist; 1.0 - 3.4). Factors associated with increased likelihood of receiving anti-resorptive medications included prior fracture (OR 6.0; 3.3 - 10.9), physician specialty (OR 2.2 specialist vs. generalist; 1.3 - 3.8), and cumulative dose of GC (OR 1.7 for highest tertile of use compared to lowest; 1.0-1.9). In contrast to the 1996 ACR recommendations for prevention and treatment of GIOP, the proportion of patients initiating chronic GC therapy between 1996 and 2001 who received BMM or non-estrogen anti-resorptive pharmaceutical was low. However, trends seem to be improving somewhat over time, especially among post-menopausal women.

Beta-blocker Use, Bone Mineral Density and Fracture Risk in Older Women: Results from the EPIDOS Prospective Study. R. Levasseur[1], P. Dargent-Molina*[2], J. P. Sabatier*[3], C. Marcelli*[1], G. Bréart*[2]. [1]Rheumatology CHU, Caen, France, [2]INSERM U149, Villejuif, France, [3]Nuclear Medicine CHU, Caen, France.

Recent experimental studies in mice suggest that beta-blocker use may be associated with a reduced risk of osteoporosis (Takeda et al. Cell 111:305, 2002). To verify this hypothesis, we assessed the association between non cardio selective beta-blocker use and both bone mineral density (BMD, g/cm²) and fracture risk in a large cohort of elderly French women who participated to the EPIDOS (Epidemiologie de l'Osteoporose) study. BMD was measured by DXA (Lunar DPX-Plus) at the hip (femoral neck, ward triangle, trochanter) and total body. Out of the 7598 women (mean age 80.5 ± 3.8 years) included in the cohort, 283 (3.7%) were taking a beta-blocker at baseline. The average duration of use was 13.9 (± 10.1) years.The drugs most frequently used were sotalol (n=97) and propranolol (n=93). All beta-blocker users were taking the drug 5 to 7 days a week. Women who were taking a beta-blocker were slightly younger than non users (79.8 vs 80.6 years; p=0.0002). Women were asked how they would judge their health compared to other women of their age. Compared to non-users, beta-blocker users declared more often that they were as healthy as other women of their age (69.9 vs 60.9%), and less often that they were either in worse health (26.1 vs 32.5%) or in better health (4.0 vs 6.6%) than other women of their age (p=0.009). There were no significant difference in mean weight between beta-blocker users and non users (60.7 vs 59.8 kg, p=0.18). After adjustment for age and subjective health status, there was no significant difference in hip or total body BMD between beta-blocker users and non users. During an average of 3.6 (± 1.2) years of follow-up, 1311 women suffered at least one non-vertebral osteoporotic fracture. After adjustment for age and health status, there was no significant association between beta-blocker use and risk of fracture (hazard ratio = 1.2; 95% CI: 0.9 - 1.5). We conclude that beta-blocker use is not associated with a reduced risk of osteoporosis in older women. Thus, there is a controversy about the beta-blocker effect on bone between animal studies and human studies and between human studies that show the same results than our study (Reid et al. JBMR 18(Suppl2):SU327 2003) and other that show a positive effect on BMD and fracture risk (Pasco et al. JBMR 19:19 2004).

AC-100, a Fragment of MEPE, Promotes Fracture Healing in a Femoral Closed Fracture Model in Rats. M. Lazarov*[1], M. Shih*[2], A. Negron*[2], R. Blacher*[1], Y. Kumagai[1], D. M. Rosen[1]. [1]Acologix, Inc, Emeryville, CA, USA, [2]Skeletech, Bothell, WA, USA.

MEPE, a protein originally cloned from tumors associated with hypophosphatemic osteomalacia, increases renal phosphate excretion and is expressed in normal human bone cells. **AC-100 (Dentonin)**, a central 23-amino acid fragment of MEPE, conserved among species, contains motifs that are important in regulating cellular activities in the bone microenvironment including an integrin-binding, a glycosaminoglycan-binding, and a calcium binding motif and has demonstrated potent anabolic activity on osteoblast precursor cells *in vitro*. Here we report that AC-100 exhibits bone anabolic activity *in viv*o as well as *in vitro* and promotes fracture healing in a femoral closed fracture model in rats.

Methods: Sprague Dawley female rats, approximately 3 months old, were randomly assigned to different treatment groups (n=12 per group) by body weight at the commencement of the study. All rats received a unilateral closed fracture femoral defect created in the right femur. Radiographs were taken to confirm the fracture. Following the fracture, all animals received daily local subcutaneous injections (approximately 0.3 mL) of saline (vehicle control) or the treatment compound at or near the fracture site. The positive control group received subcutaneous injections of PTH. After euthanasia using carbon dioxide asphyxiation, the right and left femurs were excised and tested by a mechanical device for strength in 3-point bending. In addition, histopathological assessments were performed on the toluidine blue stained sections of the femoral defect region without knowledge of treatment group.

Results: By comparison of the biomechanical properties, AC-100, 5 mg/mL showed significantly higher ($p < 0.05$) normalized (value from the test side divided by value from the intact side) absorbable strain energy (improved material properties) from the 3-point bending test, as compared to the vehicle control group. By histopathology evaluation on the amount of callus and its mineralization (calcein labeling), the AC-100 5 mg/mL group was significantly greater ($p < 0.05$) than the vehicle control group, and not significantly different from the PTH-treated group (positive control).

Conclusion: These data suggest that AC-100 does promote fracture healing in this experimental model and may have potential as an anabolic drug to increase bone mass.

Treatment Initiation after Osteoporosis Screening Varies by Skeletal Site of Diagnosis and Disease Severity. R. M. Brennan, J. Wactawski-Wende, K. M. Hovey*. Social and Preventive Medicine, University at Buffalo, Buffalo, NY, USA.

The objective of this study was to assess variations in treatment initiation among postmenopausal women determined to have osteoporosis. Dual-energy x-ray absorptiometry (DXA) screening was conducted as part of a larger study of osteoporosis and periodontal disease. Copies of DXA results were provided along with a summary cover sheet reporting T-scores for the lateral spine, antero-posterior spine, femoral neck, and total forearm. Subjects were followed after one year to assess treatment initiation. The study was approved by the Health Sciences Institutional Review Board at the University at Buffalo. Subjects included in this analysis (n = 230) had no previous knowledge of their bone density, were newly determined at screening to have osteoporosis (T-score <= -2.5), reported discussing DXA results with a health care provider, and were not missing data on study variables. Overall, 129 (56.1%) women initiated new treatment for osteoporosis. Ninety-four (55.6%) women with osteoporosis at the lateral spine, 51 (62.2%) women with osteoporosis at the antero-posterior spine, 40 (71.4%) women with osteoporosis at the femoral neck, and 55 (61.1%) women with osteoporosis at the total forearm initiated new treatment. Many women had osteoporosis at more than one skeletal site, with 68 (67.3%) initiating new treatment. In univariate logistic regression analyses, osteoporosis at the femoral neck (OR = 2.39; 95% CI: 1.25, 4.58), more than one skeletal site with osteoporosis (OR = 2.30; 95% CI: 1.34, 3.94), and T-score of -3.0 or less (OR = 2.57; 95% CI: 1.50, 4.40) compared with greater than -3.0 were significant predictors of treatment initiation. Other skeletal sites of diagnosis and other risk factors for fracture (age, hormone therapy use, previous fracture, family history of fracture, and body mass index) were not significant univariate predictors of treatment initiation. After stratifying by osteoporosis at the femoral neck, multivariate modeling showed that severity of disease (T-score of -3.0 or less) only predicted treatment initiation for those without osteoporosis at the femoral neck (OR = 2.13; 95% CI: 1.13, 4.03), and number of sites with osteoporosis was not statistically significant for either group. Treatment after osteoporosis screening was more likely for postmenopausal women determined to have osteoporosis at the femoral neck compared to other skeletal sites. Among women who did have osteoporosis at other skeletal sites, those with more severe disease were more likely to be treated.

Diagnosis and Treatment of Osteoporosis in Vertebral Fracture Patients Who Have Undergone Vertebroplasty or Kyphoplasty: The Importance of Clinical Pathways. A. Fang*[1], A. Abdelmalek*[2], M. Weisman*[3], S. L. Silverman[4]. [1]Cedars-Sinai, Los Angeles, CA, USA, [2]Kaiser Permanente West Los Angeles, Los Angeles, CA, USA, [3]Cedars-Sinai, Beverly hills, CA, USA, [4]Cedars-Sinai/UCLA/OMC, Los Angeles, CA, USA.

Osteoporosis is often underdiagnosed and undertreated in hospitalized patients with hip fracture. We studied the diagnosis and treatment of osteoporosis in hospitalized patients with acute vertebral compression fracture who underwent vertebroplasty (VP) or kyphoplasty (KP) in two different institutions in Los Angeles: a closed model HMO (Kaiser West Los Angeles) and a community academic hospital (Cedars-Sinai Medical Center or CSMC).

We performed a retrospective chart review of patients admitted with a primary diagnosis of vertebral fracture to CSMC in May and June 2003 and to the HMO from January 2002 to April 2003. Cases were identified by diagnostic codes for osteoporosis, fracture and vertebral body augmentation (VBA).We excluded vertebral fracture associated with significant trauma, malignancy or bone disease. Patients hospitalized for reasons unrelated to vertebral fractures were also excluded from this study.

At CSMC we identified twenty patients . Of these twenty patients all underwent a VBA procedure: ten patients had KP and ten patients had VP. Only 1/20 of the patients had a DXA during hospital stay. At hospital admission, 6/20 patients were on an osteoporosis treatment medication other than calcium. At discharge 9/20 of the patients were on osteoporosis medication.

At the HMO we identified 32 patients: 20 female ,12 male with vertebral fracture who received VP. The HMO has a mandatory clinical pathway requiring a physical medicine consultation prior to surgical authorization.30/32 patients were on an osteoporosis medication other than calcium prior to discharge. 8/32 had a DXA during hospitalization.

In summary, our data show marked differences in OP diagnosis and treatment between an HMO and a community academic hospital for patients with surgically treated osteoporotic vertebral fracture. We conclude that patients with vertebral fracture who are surgically treated may not have a DXA or treatment during hospitalization. Our data suggests that clinical pathways may be helpful in increasing diagnosis and treatment of osteoporosis in surgically treated patients with vertebral compression fracture.

A Single-Dose Pharmacokinetic Study of Lasofoxifene in Japanese and Caucasian Postmenopausal Women. M. Gardner*[1], Y. Nishizawa*[2], G. Wei*[1], L. Dogolo*[1], A. Calcagni*[1]. [1]Pfizer Inc, Groton, CT, USA, [2]Pfizer Inc, Tokyo, Japan.

Lasofoxifene, a next generation selective estrogen receptor modulator (SERM), is in late stage development for the treatment of osteoporosis. Lasofoxifene is extensively metabolized via both oxidative and conjugative pathways in the liver. Since ethnic differences in drug metabolism between Asian and Western populations have been reported for other drugs, the pharmacokinetics (PK) of lasofoxifene in postmenopausal women of Japanese (J) heritage were compared to those of Caucasians (C).

This was a double-blind, placebo controlled, parallel group, single oral dose study. Twelve J subjects living in the West and 12 age-matched (within 5 years) C subjects were studied at the projected therapeutic dose of 0.25 mg. Six of the J subjects were first-generation (FG) and six were second-generation (SG). At the 0.1 mg and 0.5 mg dose levels, 6 J and 6 age-matched C subjects were studied. The J subjects at these doses were a mixture of FG and SG. Lasofoxifene was administered after an overnight fast. Serial plasma samples for determination of lasofoxifene PK were obtained up to 480 hours postdose. ANOVA was used to calculate 90% confidence intervals (CI) for the ratios of least-squares mean Cmax and AUC(0-∞) values (based on log transformation). PK comparisons were made between first generation and second generation Japanese subjects at the 0.25 dose and between Japanese (FG & SG) and Caucasians at all doses.

All subjects completed the study and the treatments were well tolerated. Lasofoxifene PK in FG subjects were similar to those of SG subjects at the 0.25 mg dose. The SG/FG treatment ratio (90% CI) of log-transformed Cmax and AUC(0-∞) was 96% (83% to 111%) and 94% (73% to 122%), respectively. Lasofoxifene was absorbed and eliminated slowly in both groups with the mean Tmax and t½ values of approximately 11 and 150 hours, respectively. Overall the PK of lasofoxifene was similar for J and C subjects. The J/C treatment ratio of log-transformed Cmax and AUC(0-∞) at the 0.25 mg dose was 105% (93% to 118%) and 100% (85% to 119%), respectively. Exposure to lasofoxifene increased predictably with dose in both populations over the range of 0.1 to 0.5 mg. Differences in body weight between J and C subjects did not affect exposure to lasofoxifene.

Lasofoxifene PK in Japanese and Caucasian postmenopausal women are similar, with predictable increases in exposure following single doses ranging from 0.1 to 0.5 mg.

Effect of Toremifene on Orchiectomy-Induced Osteopenia in the Male Rat. S. Raghow*[1], J. Okolicany*[2], V. Shen[3], K. Veverka*[2], M. Steiner*[2]. [1]GTx, Inc., Memphis, TN, USA, [2]GTx, Inc, Memphis, TN, USA, [3]SkeleTech, Inc., Bothell, WA, USA.

Osteopenia, osteoporosis and bone fractures are common complications of androgen deprivation therapy (ADT) in men with prostate cancer. Selective estrogen receptor modulators (SERMs) are known to reduce bone loss in females and may prevent osteoporosis and fractures in males as well. We tested the efficacy of a SERM, toremifene (Tor), to prevent bone loss in the orchiectomized (Orx) male rat. In a 12-wk study, fifty skeletally mature male rats were either sham-operated or orchiectomized (Orx) and divided into 5 groups (n=10) as follows: Sham + vehicle, Orx + vehicle, Orx+Tor (5mg/kg/d), Orx+Tor (10 mg/kg/d) and Orx+Estradiol (E, 0.2mg/kg/ml control). Treatment was initiated at castration via s.c. pump. Calcein fluorochrome was administered by injection at 12 and 2 days before necropsy for static and dynamic histomorphometric analysis. Serum bone biomarkers osteocalcin (OC) and C-terminal telopeptides (CTX) were measured at 0, 1.5, 4, 6 and 12 wks by ELISA. Prostate was weighed at necropsy. Lumbar vertebrae (LV4 and LV5) were excised at the end of the treatment period. LV5 was subjected to DXA scan for bone mineral density and LV4 was fixed in buffered formalin for histology and histomorphometry. Prostate weight of the Orx rats was 22% of the sham controls. Orx increased OC levels significantly and both E and Tor reversed this effect. Serum CTX levels showed no mean-

inful difference between groups. Orx induced reductions in bone mineral density of L5 and trabecular bone volume (TBV) in L4 of male rats due to significantly elevated bone turnover as evidenced by increase in BFR and osteoclast surface and number. Tor prevented the Orx-induced loss in BMD and preserved TBV at the lumbar vertebral body. The mechanism of action of Tor appears to be anti-resorptive in nature as Tor reduced BFR and osteoclast parameters significantly ($p < 0.05$) below the sham-operated animals. The use of estradiol similarly exerted an anti-resorptive effect on Orx rats and the protection of bone mass in the lumbar vertebrae was quite evident. Tor had no effect on prostate weight in the Orx rat. In conclusion, both estrogen and toremifene were able to combat androgen deficiency-induced bone loss in male rats and their protective effects on bone microarchitecture appeared to be due to suppression of bone turnover. Our studies suggest the possibility that toremifene may prevent vertebral bone loss, protect bone quality and prevent vertebral fractures in prostate cancer patients treated by androgen-deprivation therapy.

Raloxifene Modulates IL-6 and TNF-alpha Synthesis in vivo: Results from a Clinical Pilot Study. S. Migliaccio. Fisiopatologia Medica, University La Sapienza, Rome, Italy.

Walter Gianni1, Andrea Ricci2, Paola Gazzaniga3, Marina Brama2, Maria Pietropaolo4, Sergio Votano5, Francesco Patanè3, Anna Maria Aglianò3, Stefania Falcone6, Giovanni Spera6, Vincenzo Marigliano4, Sergio Ammendola2, Donato Agnusdei7, Roberto Scandurra2 and Silvia Migliaccio6 Unità Geriatria Oncologica, INRCA, Rome; Departments of 2Biochemical Sciences, 3Experimental Medicine, 4Geriatrics, 6Medical Physiopathology, University of "La Sapienza", Rome; 5Hospital San Carlo-IDI Sanità, Rome; 7University of Siena & Eli Lilly & Company, Italy.

Raloxifene (RAL), a selective estrogen receptor modulator, is indicated for prevention and treatment of postmenopausal osteoporosis. RAL, by decreasing bone turnover, prevents bone loss and microarchitecture damage, significantly reducing the incidence of osteoporotic fractures. Our previous in vitro data demonstrated that RAL modulates osteoclast activity by, at least in part, an Interleukin-6 (IL-6) and Tumor Necrosis Factor-alpha (TNF-alpha)-dependent mechanism. In this study we evaluated the effects of RAL treatment (60 mg/day) on these two cytokines circulating levels in 14 postmenopausal women with osteoporosis. Lumbar bone density (DEXA), IL-6 and TNF-alpha blood levels were measured before and, after 6, and 24 months of therapy. In this small group of postmenopausal women RAL, 60 mg/day for 24 months, induced a significant increase in lumbar bone mineral density as compared to baseline before therapy (Tscore -2.8 ± 0.1 baseline vs Tscore -2.57±0.1 after 6 months and Tscore -2.0±0.1 after 24 months), as previously demonstrated in larger cohort of postmenopausal women. IL-6 and TNF-alpha expression, elevated before tratment, significantly decreased (50% and 30%, respectively) after 6 months. This effect was sustained up to the end of the treatment period (75% and 35% respectively). Thus, our data show that RAL treatment can significantly modulate circulating levels of cytokines involved in osteoclastogenesis and bone resorption, suggesting that the modulation of soluble factors could play a pivotal role in the mechanisms of the osteoprotective effect of RAL.

Significant Bone Loss Following Cessation of Estrogen Replacement Therapy in Postmenopausal Women. S. B. Broy, L. G. Jankowski*. Center for Arthritis and Osteoporosis, Illinois Bone and Joint Institute, Park Ridge, IL, USA.

Since publication of the Women's Health Initiative (WHI), many women have discontinued estrogen replacement therapy (ERT). Review of 2 large national databases estimated a 66% national decline in Prempro prescriptions 1 year following the July 2002 publication of WHI[1]. The NORA study suggests that women who have recently discontinued estrogen have an increased risk for hip fracture compared to women who have never taken estrogen[2].

The purpose of this study was to evaluate the effect of estrogen cessation on bone mineral density (BMD). Bone densitometry (Hologic 4500A) records from 1/1/2000 - 5/1/2004, in a large rheumatology/orthopedic practice and osteoporosis center, were reviewed. Postmenopausal women who had been on ERT for at least 2 years and then discontinued ERT for 6 months to 5 years were included and divided into Group I: patients on no osteoporosis medication, Group II: patients who continued ongoing (>1 year) osteoporosis medication and Group III: patients who began a new osteoporosis medication when ERT was discontinued. Patients in renal failure or on >5mg prednisone were excluded. Change in BMD was considered significant if it exceeded the least significant change in the spine, total hip or femoral neck.

Group I: 52 patients, age 49-83 (mean 64), no osteoporosis medication.

44/52 patients (84.6%) lost bone, 4 gained and 4 had stable BMD.

Bone loss ranged from 2.6-14.9% in the spine (SP), 2.4-12.4% in the total hip (TH) and 3.0-13.3% in the femoral neck (FN). Mean change was -2.9% ±4.5 SP, -3.3% ±3.3 TH and -3.4% ± 4.5 FN. Bone loss was seen whether patients had stopped ERT for 6-12 months (11 of 12), 1-2 years (17 of 22) or 2-5 years (15 of 18).

Group II: 7 patients, age 61-86 (mean 74), continued osteoporosis medication, alendronate (4), risedronate (3).

6/7 patients lost bone (up to 8.7% SP, 10.6% TH, 10.4% FN), 1 had stable BMD.

Group III: 16 patients, age 40-79 (mean 65) who started raloxifene (5), alendronate (7) or risedronate (4).

6/16 patients lost bone (up to 10.7% SP, 7.6% TH, 9% FN), 7 gained, 3 had stable BMD.

This study documents that significant bone loss is common when ERT is discontinued. Without other therapy, most patients (84.6%) lost a statistically significant amount of bone in at least one area whether ERT was discontinued 6 months, or up to 5 years previously. Even patients on medication for osteoporosis can loose bone: 6/7 (85.7%) who continued ongoing therapy for osteoporosis and 6/16 (37.5%) who began a new osteoporosis medication lost bone. Women who discontinue estrogen at any age should be carefully monitored following cessation of ERT.

Patients Profile on Hormonal Replacement Therapy and Raloxifene to Treat Post Menopausal Osteoporosis: Are There Any Clinical Differences? The Switch from Hormonal Replacement Therapy to Evista Study; The SHE Study. J. Oliveira*[1], M. Kayath[1], M. Escander*[2], P. Beltrame*[3], R. Bertazzo*[4], W. Weissheimer*[5], P. Basso*[1], O. L. Bracco*[1]. [1]Medical Division, Eli Lilly Brazil, São Paulo, Brazil, [2]No disclosure, Campo Grande, Brazil, [3]No disclosure, Santa Maria, Brazil, [4]No disclosure, São José do Rio Preto, Brazil, [5]No disclosure, Chapecó, Brazil.

The Women's Health Initiative (WHI) Study publication has raised concern about the indication and length of estrogen replacement therapy. Raloxifene is an option to prevent and treat osteoporosis in women with postmenopausal osteoporosis. The Switch from Hormonal Replacement Therapy to Evista (SHE) Study was an observational study designed to evaluate tolerability and treatment satisfaction associated with raloxifene treatment after hormone replacement therapy in postmenopausal women in a naturalistic setting in Brazil. Twenty-nine gynecologists participated in the study. The study involved two groups of patients, both previously on HRT: one group maintained HRT to prevent or treat osteoporosis (Group 1, n=70), while the second group switched to raloxifene from HRT (Group 2, n=164) after a 4-8 week washout period, each according to the gynecologist's recommendation. Twice as many patients were included in the raloxifene group according to the protocol. We present data regarding the clinical features of both groups. Student t-test or Mann-Whitney was used for statistical analyses, and results are expressed as mean ± standard deviation.Statistical significance was set at $p \leq 0.05$. Results: Patients advised to maintain HRT were significantly younger than patients who switched to raloxifene; the chronological age was 58.3 ± 5.1 vs 62.7 ± 6.3, respectively, $p<0.001$. Time since menopause was shorter in group 1 than group 2 (9.2 ± 5.7 years vs 12.7 ± 6.9 years, respectively, $p=0.001$). Mineral bone density measurement was the most common clinical reason to switch from HRT to raloxifene (95.7% of patients). Only 1.2% of the patients who stopped HRT presented vasomotor symptoms during the "wash-out" period. There was no difference between the 2 groups regarding presence of vasomotor symptoms. In conclusion, Brazilian physicians prescribe raloxifene to treat postmenopausal osteoporosis for older women with a longer time since menopause, in comparison to women in whom they continue HRT. Physicians reported raloxifene's bone efficacy as the most common reason to switch from HRT. The transition from HRT to raloxifene did not result in significant vasomotor symptoms. Raloxifene, due to its bone efficacy, is an important option to prevent or treat postmenopausal osteoporosis after HRT in a naturalistic setting in Brazil.

Vitamin K2 and Raloxifene Combine to Improve the Femoral Neck Strength of Ovariectomized Rats. J. Iwamoto*[1], J. Yeh[2], A. Schmidt*[3], E. Rowley*[3], T. Takeda*[1], M. Sato[3]. [1]Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan, [2]Dept. Medicine, Winthrop University Hospital, New York, NY, USA, [3]Bone and Inflammation, Lilly Research Labs, Indianapolis, IN, USA.

We evaluated the skeletal effects of two therapies available in Japan, vitamin K2, raloxifene, as well as the vitamin K2 plus raloxifene combination, in a rat model of post-menopausal osteoporosis. Six-month-old rats were ovariectomized, except for sham-ovariectomy controls (Sham), and dosed orally with vehicle, 30 mg/kg vitamin K2 (K), 1 mg/kg raloxifene (Ral), or the combination of K+Ral for 6 weeks following surgery.K had no effect on serum estrogen, low-density lipoprotein cholesterol (LDL-C), or urinary deoxypyridinoline (DPD) levels, but slightly increased osteocalcin (OC) compared to Ovx. Ral lowered total cholesterol, LDL-C, OC, and urinary DPD levels to below Ovx levels, while having no effect on estrogen levels. Ral, but not K, prevented ovariectomy-induced loss of bone in the distal femoral metaphysis and proximal tibial metaphysis, as did the K+Ral combination. Ral, but not K, partially prevented loss of vertebral vBMD, while K+Ral had vBMD greater than Ovx. K increased bone formation rate (BFR/BS) to above Ovx, while Ral and K+Ral reduced BFR/BS to Sham levels. K had no effect on eroded surface (ES/BS) compared to Ovx, while Ral and K+Ral reduced ES/BS to Sham levels. Groups were not different in the vBMD of femoral midshaft; however K was observed to increase periosteal mineralizing surface (MS/BS) of the tibial shaft to above Ovx, while Ral reduced periosteal MS/BS toward Sham levels. Femoral neck strength was not different between groups, except K+Ral was reproducibly stronger than Ovx or Sham. Ral, but not K, partially prevented loss of lumbar vertebra strength; but K+Ral was not different from Sham or Ovx. Therefore, K and Ral had complementary effects on bone formation and resorption activities, respectively, resulting in a reproducible, additive improvement of femoral neck strength. These rat data suggest interesting therapeutic possibilities that may require clinical verification.

Preliminary Infra-Red Analysis of Biopsies from the MORE Study. D. Faibish*[1], S. M. Ott[2], A. L. Boskey[1]. [1]Mineralized Tissues Laboratory, Hospital for Special Surgery, New York, NY, USA, [2]Medicine, Division of Metabolism, University of Washington, Seattle, WA, USA.

The selective estrogen receptor modulator raloxifene reduced the risk of vertebral fracture in postmenopausal women with osteoporosis in a large clinical trial (Multiple Outcomes of Raloxifene Evaluation - MORE) conducted in 7705 post-menopausal women [Ettinger et al., JAMA 282:637, 1999]. Quantitative microradiographic analyses of bone biopsies from this trial showed an increase in mineral content with treatment. It was hypothesized that the changes in the bone mineral content reflect changes in the "quality" of bone in patients treated with raloxifene.

Randomly selected iliac crest biopsies from 3 groups of patients (n=5 per group) enrolled in the MORE study were analyzed; 2 experiment groups, treated with 60 or 120mg of raloxifene, and a placebo group. All were given calcium and vitamin D. Biopsies, obtained at baseline and two years after treatment were embedded in polymethyl methacrylate (PMMA) and cut in two µm-thick sections (Microm) and scanned using a FTIRI spectrometer (Spotlight, Perkin Elmer). For each biopsy, spectra from six 200 X 200 µm regions were collected, 3 in the cortical bone and 3 in the trabecular at a spectral resolution of $8cm^{-1}$. The spectra were linearly baselined and the contribution of the embedding media spectrally subtracted (Isys, Spectral Dimensions). Spectroscopic parameters examined were previously established as sensitive to bone quality: mineral to matrix peak area ratio (ash weight), 1660/1690 cm^{-1} peak intensity ratio (collagen maturity), 1030/1020 cm^{-1} peak intensity ratio (mineral crystallinity). The change in pixel population means for each of the parameters was compared with one-way ANOVA**.**

All three groups showed increases in the mineral-to-matrix ratio in trabecular and cortical bone, but no significant changes were found in the examined parameters. Collagen maturity and crystallinity did not vary significantly from baseline in any of the groups.

In conclusion, two-year treatment did not show a marked improvement in the bone quality as determined by infra-red analyses in the group analyzed. Both longer term studies and a larger sample size might be needed to detect any effect of raloxifene on bone quality.

Influences of Intermittent Administration of Human Parathyroid Hormone on Bone Marrow Cells after Cancellous Bone Osteotomy in Ovariectomized Rats. K. Nozaka, N. Miyakoshi, Y. Kasukawa, S. Maekawa*, E. Itoi. Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

Osteosynthetic surgeries for patients with osteoporosis frequently results in delayed or non union. It is well known that intermittent administration of human parathyroid hormone (hPTH) acts on osteoblasts and their precursor cells and exerts anabolic effects on bone in osteopenic animals and humans. We therefore hypothesized that intermittent hPTH administration would facilitate osteosyntesis in patients with osteoporosis. To test this hypothesis, proximal tibial osteotomy was created in mature osteopenic rats induced by ovariectomy (OVX) and effects of intermittent administration of hPTH on bone marrow at the surgery site were evaluated. After OVX or sham-operation, hPTH(1-34) 100µg/kg or its vehicle solution was administered subcutaneously once a week for four weeks. The animals were killed one week after the last injection, and their tibiae were harvested. Conventional bone histomorphometry and the measurements of adipocyte number and size were performed using the decalcified hematoxylin and eosin stained sections. Furthermore, using the immunohistochemical technique, the percentages of proliferating cell nuclear antigen (PCNA) positive cells in bone marrow cells were evaluated. OVX-vehicle group showed high turnover osteopenia compared to sham-vehicle group. PTH increased bone volume per tissue volume (BV/TV) compared to vehicle treatment both in sham-operated and OVX rats by increasing bone formation. The quantity of adipocyte and the number of adipocyte per marrow volume (AV/MV and N.A/MV) were significantly increased in OVX-vehicle group and decreased in OVX-PTH group compared to those in sham-vehicle group. The percentages of PCNA positive cells were increased in sham-PTH and OVX-PTH groups compared to those in corresponding vehicle treated groups. These results support the view that intermittent administration of hPTH could exert the anabolic effects on bone by differentiating marrow stromal cells to osteoblasts more than adipocytes. The increased PCNA positive cells in bone marrow at the osteotomy site revealed that the PTH might have a potential role of affecting cell kinetics at osteotomy site.

Once-weekly Sustained-Duration PTH (PTH-Fc) Exerts Potent Anabolic Effects on Bone by Activating ß-arrestin2. S. L. Ferrari[1], D. Manen*[1], P. J. Kostenuik[2], M. L. Bouxsein[3], R. Rizzoli[1], D. Pierroz[1]. [1]Division of Bone Diseases, Geneva University Hospital, Geneva, Switzerland, [2]Amgen Inc., Thousand Oaks, CA, USA, [3]Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Med Center, Harvard Med School, Boston, MA, USA.

Twice-weekly injections of a fusion molecule of PTH(1-34) with human IgG-Fc fragment (PTH-Fc), which confers sustained duration to PTH, increases bone mass in rodents (1). However, the mechanisms of action of PTH-Fc remain to be elucidated. PTH activity is normally regulated by ß-arrestin2 (ß-arr2), a cytoplasmic protein interacting with the PTH/PTHrP receptor (PTH1Rc). Thus, we hypothesized that PTH-Fc anabolic activity could depend on ß-arr2 activation. We characterized ß-arr2-GFP and PTH1Rc-GFP trafficking in HEK293 cells, as well as cAMP signaling in response to PTH-Fc. Moreover, we compared bone mineral density (BMD, by pDXA) and skeletal micro-architecture (by µCT) in ovariectomized (OVX) wild-type (WT) and ß-arr2 KO adult female mice (n=4-11/group) treated with PTH-Fc once weekly (150 nmol/kg/wk, equivalent to PTH(1-34) 80 mg/kg/wk), daily PTH(1-34) (80 mg/kg/d) or vehicle (VEH) s.c for 4 wks.

PTH-Fc recruited ß-arr2-GFP from the cytoplasm to the membrane and internalized PTH1Rc-GFP within minutes, a pattern indistinguishable from cells exposed to PTH(1-34). Maximal acute cAMP response to equimolar concentrations of PTH-Fc and PTH(1-34) was similar, but residual cAMP accumulation 2 hrs after exposure to agonist was significantly higher (2x) with PTH-Fc compared to PTH(1-34). Yet, rechallenge with either agonist induced a maximal cAMP response, indicating that PTH-Fc did not cause major desensitization. In OVX WT mice, vertebral trabecular bone volume fraction (Tb.BV/TV) and trabeculae thickness (Tb.Th) were significantly higher with PTH-Fc compared to both VEH and PTH(1-34) (all $p<0.0001$). Moreover, PTH-Fc was slightly superior to PTH in increasing cortical thickness (C.Th.) ($p=0.048$, and $p<0.0001$ vs VEH). In OVX ß-arr2 KO mice, PTH-Fc was also marginally better than PTH in increasing C.Th. ($p=0.08$, and $p<0.0001$ vs VEH) and vertebral Tb.Th ($p=0.017$, and $p<0.0001$ vs VEH). In contrast, PTH-Fc failed to significantly increase Tb.BV/TV (NS vs either PTH or VEH) and it decreased Tb. number compared to PTH ($p=0.05$). Altogether, total body BMD gain with either PTH or PTH-Fc was greater in WT than ß-arr2 KO mice, and significantly better with PTH-Fc in WT ($p=0.04$ vs PTH), but not in ß-arr2 KO mice.

These data indicate that PTH-Fc activity is normally regulated by ß-arr2, which allows for the potent anabolic effects of PTH-Fc on cancellous bone despite its prolonged circulating half-life.

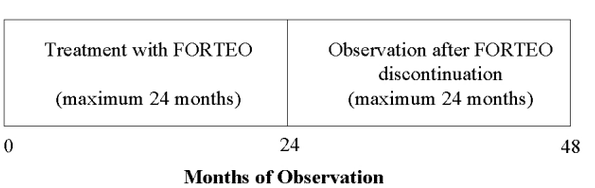
DANCE: Direct Analysis of Non-vertebral Fracture in the Community Experience Study Overview. P. D. Miller[1], S. L. Silverman[2], D. T. Gold*[3], P. Chen*[4], K. A. Taylor[4], R. B. Wagman[4]. [1]Colorado Center for Bone Research, University of Colorado Health Sciences Center, Lakewood, CO, USA, [2]OMC Clinical Research Center and the Department of Medicine, University of California Los Angeles, Los Angeles, CA, USA, [3]Duke Aging Center, Duke University Medical Center, Durham, NC, USA, [4]Lilly Research Laboratories, Indianapolis, IN, USA.

The Fracture Prevention Trial established that Forteo® [rhPTH (1-34); generic name, teriparatide] treatment substantially reduced the risk of vertebral and non-vertebral fractures after a median 19 months of therapy (Neer et al., 2001). Overall, vertebral fracture risk was reduced by 65%. Non-vertebral fragility fracture risk, measured at over six sites (including wrist, rib, and hip), was reduced by 53%. The experience in randomized placebo-controlled clinical trials may differ from that in community practice. The DANCE study is a prospective observational study designed to evaluate the long-term effectiveness, safety, and tolerability of FORTEO in a larger, more diverse patient population than studied in clinical trials. The primary objective is to evaluate the occurrence of non-vertebral fragility fractures in subjects treated with FORTEO for up to 24 months. Secondary objectives include determination of clinical vertebral fractures, serious adverse events, new or worsening pain and back pain, adherence to therapy, bone mineral density changes, and criteria used to initiate FORTEO therapy. Subjects will be followed through a course of FORTEO therapy for up to 24 months and for an additional 24 months after cessation of treatment (Figure). Therefore, subjects may participate in this study for up to 48 months. All aspects of patient care, including diagnostic and therapeutic interventions, will be chosen and conducted at the discretion of the participating study physician according to their clinical judgment and the local standard of medical care.

DANCE Study Design: Summary



Two study periods:

1) FORTEO treatment phase, maximum 24 months

2) Post-treatment phase, maximum 24 months

Approximately 200 sites, 4000 subjects

Defining the Maximal Tolerable Does of PTH-related Protein(1-36) in Humans. M. J. Horwitz, M. Tedesco*, S. Sereika*, A. Bisello, A. Garcia-Ocana*, A. F. Stewart. U Pittsburgh, Pittsburgh, PA, USA.

Once daily hPTHrP(1-36) administered subcutaneously to postmenopausal women with osteoporosis in very high doses (6.56 ug/kg or ~ 400 ug/day) causes a rapid (3 months) and marked (4.7%) increase in lumbar spine density. These results compare favorably to those reported for PTH. However, PTHrP differs from PTH in that whereas markers of bone formation are increased with both PTH and PTHrP, markers of bone resorption increase with PTH, but do not change with PTHrP. Thus, PTHrP appears to have pure anabolic effects. Surprisingly, despite the 20-fold higher doses of PTHrP vs. PTH employed {20 ug/d for hPTH(1-34) vs. 400 ug/d for PTHrP(1-36)}, subjects receiving PTHrP experienced no acute or subacute hypercalcemia, hemodynamic changes, or other objective or subjective adverse effects.

Given this absence of dose-limiting adverse effects or toxicity, the current study was designed to explore the maximal tolerable dose of PTHrP given as a single one-time injection to healthy young adults. Thus, hPTHrP(1-36) was given under close observation to healthy young (22-35 y.o.) volunteers, in groups of three, in escalating (approximately 30%) doses of 9 ug/kg, 12 ug/kg and 16 ug/kg (or approximately 600 ug, 900 ug and 1.2 mg). These doses correspond to 30, 45 and 60 times the approved dose for hPTH(1-34). Despite the large doses and meticulous objective and subjective monitoring for the 10 hours following administration of the dose, no adverse effects have been identified. Orthostatic pulse and blood pressure, serum calcium, serum ionized calcium, and serum creatinine were all completely normal. The highest serum calcium observed was 9.9 mg/dl in one subject.

To confirm that the hPTHrP(1-36) employed was fully active, its structure was confirmed using amino acid analysis and mass spectroscopy, and its biological activity was confirmed using adenylyl cyclase assay in human SaOS-2 osteosarcoma cells. Finally, when administered intravenously to normal volunteers in far lower doses, prompt increases in serum calcium were observed.

Thus, despite employing doses of hPTHrP that are some 60 times higher than those tolerated for PTH, no hypercalcemia or other adverse effects have been observed, and further dose escalation continues. These studies suggest that while the 4.7%, 3 month increment in lumbar BMD described in earlier studies is appealing, the maximal therapeutic dose, and maximal efficacy of PTHrP have not been defined. Further studies are in progress to define the maximal tolerable dose, the pharmacokinetics that underlie these observations, and longer term efficacy. Given the tolerability of large doses and the anabolic efficacy of smaller doses, once or twice per week dosing of PTHrP may be a therapeutic option.

hPTH (1-34) Treatment Increased Serum FGF2 Levels in Glucocorticoid Induced Osteoporosis Patients. M. M. Hurley[1], W. Yao[2], C. D. Arnaud[2], N. E. Lane[2]. [1]Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Medicine, University of California at San Francisco, San Francisco, CA, USA.

Basic fibroblast growth factor (bFGF or FGF2) is a potent bone anabolic agent in experimental animals in vivo and Fgf2-/- mice develop low bone mass with aging (Montero et al, JCI 2000). Although intermittent administration of parathyroid hormone (PTH) stimulates new bone formation in rodents and humans, the mechanism of this effect is not established. Previous studies showed that PTH increased FGF2 mRNA and protein expression in osteoblasts and that the hypercalcemic and anabolic effects of PTH are diminished in Fgf2-/- mice. We therefore assessed whether PTH modulated FGF2 in humans. Daily injections with hPTH (1-34) are associated with increases in both biochemical markers of bone formation and bone resorption (JCI 1998). In addition, previous studies showed that changes in levels of biochemical markers predicted increases in bone mass associated with hPTH (1-34) treatment (Lane et al, OST. Int 2000). We determined the changes in the serum level of FGF2 in patients treated with hPTH (1-34) for 12 months and at 12 months off treatment. All studied subjects (n=51) had post-menopausal osteoporosis, were treated chronically with glucocorticoid + estrogen (HRT) and were randomized to hPTH (1-34) 40 mg/d (n=28) or a control group (n=23). In addition, all study subjects were also treated with 1000 mg/d calcium and 800 IU/d vitamin D3. Biochemical markers of bone formation [osteocalcin (OST), and bone-specific alkaline phosphatase (BSAP)] and FGF2 (ALPCO Diagnostics, Windham, NH) were monitored at the baseline, every 3 months for 18 months and at 24 months. All of these were assayed by ELISA in duplicate. In the hPTH (1-34) group, osteocalcin increased by more than 150% above baseline at 3 month ($p<0.05$ from time 0) and was maintained at this level throughout the treatment period. BSAP increased more than 80% over the baseline level at 3 months and was maintained at 90% above baseline for the next 9 months ($p<0.05$). FGF2 levels increased at a slower rate than OST and BSP, with an increase of about 45% by 3 month, an increase of 60% above baseline from 6 to 9 months ($p<0.05$) and increased more than 90% from baseline by 12 months ($p<0.05$). In the control group, no significant changes were observed in any biochemical markers of bone formation or FGF2 levels. In summary, we found that daily hPTH (1-34) injections increase FGF2 levels. These results support the hypothesis that hPTH (1-34) daily injections increases osteoblast activity by stimulating osteoblast production of FGF2.

Effects of PTH on Bone Architecture and Bone Mass in Orchidectomized Rats. S. Gomez*[1], M. Diaz-Curiel[2], C. de la piedra[3], d. serfaty*[4], M. Lefort*[3], M. Montero*[3], F. Perez Martinez*[5], S. Luna*[6], J. Garcia*[7]. [1]Facultad de medicina, Universidad De Cadiz, Cadiz, Spain, [2]Medicina interna, Fundacion Jimenez Diaz, Madrid, Spain, [3]Fisiopatologia Ósea, Fundacion Jimenez Diaz, Madrid, Spain, [4]Fisiopatología Ósea, Fundacion Jimenez Diaz, Madrid, Spain, [5]Medicina Experimental, Fundacion Jimenez Diaz, Madrid, Spain, [6]Facultad de Medicina, Universidad De Cadiz, Cadiz, Spain, [7]Facultad de Medicina, Universidad De Granada, Granada, Spain.

The aim of this work was to determine the effects of PTH administration (1-34 rat PTH, SIGMA, $4x10^{-6}$ g/kg/day, subcutaneous daily injection) to rats, in order to avoid the development of osteopenia due to orchidectomy. Twenty-four nine month-old male Wistar rats were orchidectomized: 12 were treated with PTH during 72 days (OQX+PTH) and 12 were untreated (OQX). Twelve age- and sex-matched rats were sham operated (SHAM). After that time, rats were sacrificed. Bone mineral density in lumbar spine (L2-L4) was measured by DEXA. Bone Volume/Total Volume (BV/TV), Trabecular Thickness (Tb.Th), Trabecular Separation (Tb.Sp), Trabecular Number (Tb.N) in L4. The following results were respectively found in SHAM, OQX and (OQX+PTH) groups: BMD (0.311+/-0.019; 0.308+/-0.022; 0.331+/-0.008 g/cm2); BV/TV (29.3+/-3.7; 22.7+/-2.4; 36.1+/-8.1 %); Tb.Th (124.2+/-49.3; 127.3+/-48.2; 145+/-60 microm); Tb.Sp (263.2+/- 155; 337.2+/-277; 260.8+/-166 microm); Tb.N (2.35+/-0.29; 1.78+/- 0.19; 2.48+/-0.55 number/mm).

In summary, orchidectomy produced a significant decrease on bone mass (expresssed by BV/TV) in male rats, due to a decrease in the number of bone trabecula with a higher separation between them, but with the same thickness than those of control rats. PTH treatment, not only avoid bone mass decrease development in OQX rats, but also increase BMD in treated rats with respect to SHAM group. This fact was due to a significant increase in trabecular thickness without changes in number or trabecular separation. BMD determination by DEXA was not enough sensitive to detect changes between SHAM and OQX rats after 72 days from orchidectomy, but it was able to detect the BMD increase produced by the PTH treatment to OQX rats.

Should the National Guidelines for Mineral and Vitamin D Supplements Be Modified for Patients Using Teriparatide: Some Clinical Observations. D. A. Licata. Endocrin, Cleve Clinic, Cleveland, OH, USA.

Teriparatide has opened a new modality for treatment of primary osteoporosis and has so far proven to safe and effective. No long lasting metabolic alterations in mineral metabolism are found in the original pivotal study. In its clinical use, however, unexpected changes were found in mineral metabolism of some patients. The present report describes results from a retrospective survey undertaken to understand the mechanism of these observations. The study evaluated changes in mineral metabolism in patients(n=12) using teriparatide for 3-6 months. Serum calcium, PTH, 25 vitamin D, 1,25 vitamin D, bone turnover markers (serum osteocalcin [OSC], and urinary NTX) were measured using standard clinical procedures. Patients were using supplemental calcium and vitamin D per standard published guidelines. The average daily calcium supplement was 1080 mg and the vitamin D 2025 IU. During treatment, serum calcium increased 5-6% and PTH decreased 16-17% ($p<0.05$). All changes, however, were within the normal reference interval. Seventy-five percent of calcium values were between 10 and 10.5 mg/dL. OSC and NTX increased 3.5 ($p<0.05$) and 4.2($p<0.1$) -fold, respectively. 25 vitamin D did not significantly change. 1,25 vitamin D increased 2-3 fold ($p<0.05$) from baseline. Sixty-six percent of values were greater than the 95% reference value (upper reference cutoff 66 pg/mL vs. patients average 98.8 pg/ml). Patients experienced no symptoms during this period of treatment. Adjustment of the daily mineral supplement corrected the serum calcium changes when seen. Comparing these patients and those with documented hyperparathyroidism showed several interesting differences. Higher calcitriol levels and lower PTH levels were noted in the treated osteoporotic patients. Summary: teriparatide increases serum 1,25 vitamin D and calcium, the later change reflecting the amount of daily mineral supplement used. Conclusion: For patients using teriparatide, clinicians may need to adjust the mineral and vitamin D doses recommended in published guidelines.

Intermittent PTH and Propranolol Have Synergistic Effects on Vertebral Trabecular Bone in Ovariectomized Mice. D. D. Pierroz[1], M. L. Bouxsein[2], V. Glatt*[2], R. Rizzoli[1], S. L. Ferrari[1]. [1]Div of Bone Diseases, University Hospital, Geneva, Switzerland, [2]Orthopedic Biomechanics Laboratory, Harvard Medical School, Boston, MA, USA.

Adrenergic system stimulation decreases bone mass, and adrenergic blockade with propranolol has been shown to prevent ovariectomy-induced bone loss in mice. Intermittent PTH administration increases bone formation and resorption, resulting in improved bone mass and architecture. We thus hypothesized that propranolol and PTH could have synergistic effects on bone. For this purpose, 15 wk-old mice were ovariectomized (OVX) and were pair-fed to a non-ovariectomized group (Sham). Propranolol (PRO, 0.5 g/L in drinking water) was immediately administered to one group of OVX mice, whereas another group remained untreated. After 4 weeks, mice with and without PRO were further assigned to daily hPTH(1-34) (80 µg/kg/d) or vehicle VEH for 4 weeks (n=5-7/group). Changes in total body bone mineral density (TB BMD) were evaluated by pDXA, trabecular (Tb) and cortical (Cort) bone architecture were measured by µCT at the end of the experiment. Osteocalcin (OC) and a bone resorption marker (TRAP) were also evaluated.

As expected, OVX significantly reduced TB BMD gain compared to Sham (P=0.014). Intermittent PTH significantly increased TB BMD gain compared to VEH (P<0.0001) in OVX mice. More specifically, PTH increased femur Cort thickness (Th) and vertebral Tb Th compared to VEH (both P<0.0001), whereas vertebral Tb Number (N) and Tb bone volume fraction (BV/TV) did not significantly change with PTH alone. PRO significantly increased TB BMD gain (P=0.01), vertebral Tb Th and Tb N (both P=0.007), and Tb BV/TV (p=0.001) compared to OVX mice without PRO, but did not affect Cort Th. Most importantly, the combined treatment of PRO plus PTH significantly increased TB BMD over PTH alone (P=0.003). This synergistic effect was seen particularly on Tb BV/TV (+17%, P=0.0025 vs PTH), Tb N (+11%, P=0.01), and marginally on Tb Th (+4%, P=0.05), but not on Cort Th. PTH significantly increased OC (+46% vs VEH, P<0.0001), whereas PRO did not modify OC levels in the PTH or VEH groups. In contrast, PRO decreased TRAP levels significantly compared to VEH (-53%, P=0.03) and marginally compared to PTH (-18%, ns).

Altogether, these data confirm that propranolol confers some protection against OVX-induced bone loss, particularly in trabecular bone, and this possibly by inhibiting bone resorption. Moreover, propranolol and PTH in combination exert a synergistic anabolic action on trabecular bone. In contrast, cortical bone remodeling does not appear to be prominently affected by adrenergic blockade. Hence, the development of combined therapies might be of interest for the treatment of osteoporosis.

Administration of ThPTH to Humans Using Macroflux® Transdermal Technology Results in the Rapid Delivery of Biologically Active PTH. V. Gopalakrishnan*[1], S. Hwang*[1], H. Loughrey[2], B. Alexandre*[2], D. Desai*[1], L. Haiying*[1], T. Abribat*[2], L. Vachon*[2], P. Daddona*[1]. [1]Alza Corporation, Mountain View, CA, USA, [2]Theratechnologies Inc, St Laurent, PQ, Canada.

Purpose of Study: The objective of this first-in-human study was (i) to evaluate the general safety, and (ii) to determine the pharmacokinetic (PK) and pharmacodynamic (PD) profile of Macroflux-PTH transdermal patch delivery.

Clinical Trial Design: In this 2-part crossover study, a total of 31 female subjects (age range 20 to 40) received a single 1-hour application of a 2 cm^2 Macroflux-PTH patch in the upper arm and a subcutaneous (SC) injection of teriparatide (FORTEO®) into the thigh. Macroflux patches were loaded with 30 µg of synthetic human PTH (1-34) and the comparator teriparatide doses used were 20 and 40 µg in part I and part II respectively. Human PTH (1-34) was measured over a 24 h period using an optimized commercially available enzyme immunoassay (EIA) that was shown by the vendor to have 100 % cross reactivity with hPTH (1-34) and 0 % cross reactivity with hPTH (1-84). Urinary biomarkers (cyclic AMP (cAMP) and phosphate), and plasma biomarkers (total and ionized Ca^{++} and phosphate levels) were measured over an 8-hour and 24-hour period respectively.

Results: The preliminary results indicate that the 30µg Macroflux-PTH patch delivered hPTH (1-34) at blood levels in the range of that obtained with a 40 µg teriparatide dose. The plasma PK profiles of hPTH (1-34) were comparable for both SC and Macroflux delivery (see Figure). Urinary cAMP increased markedly within two hours for both routes of administration indicating that the delivered hPTH (1-34) was biologically active. Changes in plasma biomarkers were also comparable between the two routes of administration. On the whole the frequency of adverse events (AE) reported between the two groups were comparable and typical of those seen with teriparatide. No serious AE's were reported and the majority of AE's were mild in severity.

Conclusion: The results of this proof-of-concept study in humans demonstrate the feasibility for the efficient transdermal delivery of hPTH (1-34) by Macroflux technology. This delivery approach warrants further development and investigation as a convenient alternative to SC administration of hPTH (1-34) for osteoporotic patients.

Parathyroid Hormone and 1,25-Dihydroxyvitamin D_3 Exert Independent but Co-operative Effects on Bone Anabolism. D. S. Miao, Z. L. Zhang*, R. Samadfam*, J. R. Li*, I. Bolivar*, Q. W. Xia*, G. N. Hendy, D. Goltzman. Medicine, McGill University, Montreal, PQ, Canada.

Parathyroid hormone (PTH) is required for bone anabolism in the fetus and is a potent stimulus for bone formation when administered intermittently to post-natal animals. We previously reported that when mice with targeted deletion of the 25-hydroxyvitamin D 1α hydroxylase [1α-(OH)ase$^{-/-}$] are fed a "rescue" diet (2% calcium, 1.25 % phosphorus, 20% lactose), they normalize their serum calcium and PTH levels and exhibit reduced bone volume. Consequently, 1,25-dihydroxyvitamin D [1,25-$(OH)_2$D] is required for optimal bone formation. To determine the requirement for 1,25-$(OH)_2$D for the anabolic effect of exogenous PTH, we administered PTH-(1-34), 40 µg /kg body weight subcutaneously, either once daily or three times-a-day to 1α-(OH)ase$^{-/-}$ mice fed a rescue diet and to wild-type (WT) animals on the same diet. PTH administration was begun at three months of age and continued for 1 month. Animals were examined at 4 months. In vehicle-treated animals serum calcium and PTH levels were not significantly different in 1α-(OH)ase$^{-/-}$ and in WT. On the rescue diet, however, bone mineral density (BMD), bone volume and osteoblast numbers were reduced in vehicle-treated 1α-(OH)ase$^{-/-}$ versus WT controls. Administration of once daily or thrice daily PTH did not significantly raise serum calcium above vehicle-treated levels in either group. Serum PTH levels were slightly increased in both groups after once daily administration and markedly increased after injection three times-a-day. Serum 1,25-$(OH)_2D_3$ levels were undetectable in 1α-(OH)ase$^{-/-}$ mice and raised slightly by once daily PTH and more dramatically by thrice daily injections in the WT mice. BMD, bone volume, osteoblast numbers and IGF-1 immunoreactivity in osteoblasts were increased in both mutant and WT mice after once daily PTH administration but these anabolic indices remained lower in the 1α(OH)ase$^{-/-}$ mice than in the WT. Thrice daily PTH administration produced even greater increases in trabecular and cortical bone in both WT and 1α-(OH)ase$^{-/-}$ mice but the levels reached were still slightly lower in 1α-(OH)ase$^{-/-}$ than in WT mice. The results: 1) Confirm that 1,25-$(OH)_2D_3$ exerts an anabolic effect on bone 2) Show that PTH, even when given three times-a-day to murine models, produces a strong anabolic effect 3) Show that the anabolic effect of exogenous PTH can occur in the absence of 1,25-$(OH)_2D_3$ and 4) Show that both hormones are required for optimal bone anabolism.

PTH Increases Bone Mineral Density and Resistance to Mechanical Load in a Rat Model of Osteoporosis. Z. Henriksen*[1], C. Thorkildsen*[2], J. E. B. Jensen[1], N. R. Jørgensen[1]. [1]The Osteoporosis and Bone Metabolic Unit, Departments of Endocrinology and Clinical Biochemistry, Copenhagen University Hospital, Hvidovre, Denmark, [2]Zealand Pharma A/S, Glostrup, Denmark.

Parathyroid hormone (PTH) is an anabolic agent that stimulates cancellous and compact bone formation and reduces fractures in patients with osteoporosis. Thereby PTH represents an important new advance in the therapy of osteoporosis. In this study we looked at the effects of PTH on bone in mature female rats.

Six months old female nullipara Fisher rats were ovariectomized (ovx) or sham operated (sham). Three months after the operation, ovx rats were randomized to 4 month of treatment with either saline (veh) or PTH 40 µg/kg/day 5 days a week. At the end of the dosing period, blood was collected for measurement of the following markers of bone formation: alkaline phosphatase (ALP) and osteocalcin (OCN) as well as the bone resorption marker C-telopeptide collagen type I fragment (RatLaps). Right femur and tibia were collected for measurement of bone mineral density (BMD) and left femur was collected for bone strength (max-load) measurements. Data were analyzed by one-way ANOVA followed by Fisher's LSD for posthoc comparison.

	veh/sham (n=21)	veh/ovx (n=20)	PTH/ovx (n=19)
Femur BMD (g/cm2)	0.199±0.002**	0.167 ±0.001	0.254 ± 0.003**§§
Femur max-load (Newton)	108 ± 2**	89 ± 1.	154 ± 3**§§
ALP (nmol/ml)	193 ± 7**	245 ± 11	303 ± 12**§§
OCN (ng/ml)	136 ± 6 $^{p=0.07}$	178 ± 8	453 ± 20**§§
RatLaps (ng/ml)	15.1 ±1.4*	20.1 ± 1.4	24.1 ± 1.1*§§

Values are mean ±SEM. *: p<0.05, **p<0.001 relative to veh/ovx treated animals, §§: p<0.001 relative to veh/sham treated animals

PTH treatment dramatically increased femoral BMD and bone strength as compared to both ovx/vehicle and sham/vehicle treated animals. In addition, all measured bone markers were significantly increased in PTH/ovx rats compared to veh/ovx rats and veh/sham. Thus, the ovx induced bone loss was not only reversed by the PTH treatment, but the ovx/PTH treated group also had significantly stronger bones than the sham-operated group.

In conclusion PTH treatment results in a dramatically increased bone formation as well as an increased bone resorption, indicating an increased bone turnover. The data demonstrates a net bone formation leading to increased BMD and bone strength.

Optimizing Patient Selection for Recombinant Parathyroid Hormone Therapy. M. Casey*, J. Walsh*, M. Healy*, N. Maher*, C. Kirby*, C. Connolly*, C. Cunningham*, D. Coakkey*. St. James Hospital, Dublin, Ireland.

Introduction: The recent availability of anabolic therapies for osteoporosis necessitates a thorough investigation for this treatment to our rule the recognised contra indications as well as potential complicating factors such as idiopathic hypercalcuria which substantially increased the patients' risk of renal calculi whilst on PTH therapy.

Methods: We review the first 84 patient referrals to a specialist osteoporosis clinic for PTH therapy and we report the results of a comprehensive clinical investigation of these subjects.

Results: The mean age of the referrals was 74.9 ± 11 years with 71 females and 12 males. All had severe osteoporosis and 70% had addition of vertebral fractures (≥1). Nine patients were excluded from PTH Therapy because of monoclonal gammopathy and / or Bence Jones Proteinuria. One was also excluded because of a history of breast cancer with radiotherapy. Four males with elevated PSA could not immediately commence PTH and were referred for Prostatic biopsy. Two patients were in advanced CRF (creatinine clearance of < 30mls / min). Five patients had hypercalcuria (24 hours U. Ca of > 7.5mmol) and this is under active management at present prior to PTH. On patient was treated for thyrotoxicosis and two for coeliac disease prior to commencing PTH Therapy. Six patients were unable / unwilling to self inject.

Conclusion: In older age groups there is a high prevalence of secondary causes for osteoporosis and these must be thoroughly investigated prior to consideration for PTH Therapy

Disclosures: ***M. Casey****, None.*

Basic FGF Increases Trabecular Bone Connectivity and Improves Bone Strength in the Lumbar Vertebral Body of Osteopenic Rats. W. Yao[1], T. Hadi*[1], J. Zhou*[1], Y. Jiang[1], T. J. Wronski*[2], N. Lane[1]. [1]University of California in San Francisco, San Francisco, CA, USA, [2]University of Florida, Gainesville, FL, USA.

Recently, basic fibroblast growth factor (bFGF) has been found to increase trabecular bone mass (BV/TV) and connectivity (CD)in the proximal tibial metaphyses (PTM) in osteoporotic rats. The purpose of this study was to determine the bone anabolic effects of bFGF in the lumbar vertebral body (LVB), a less loaded skeletal site with a lower rate of bone turnover than the PTM.

METHODS: 6-month old female SD rats were ovariectomized (OVX) or sham-operated and untreated for 8 weeks to induce osteopenia. Then G 1 (Sham) and G2 (OVX) were treated SC with vehicle and OVX; G 3 and G4 were treated SC with PTH [hPTH (1-34) at 40ug/kg, 5×/wk] and bFGF (1 mg/kg daily, 5×/wk), respectively, for 8 wks. At sacrifice, the 5th LVB was removed, subjected to μ-CT for determination of trabecular bone structure, and then processed for histomorphometry to assess bone turnover. The 6th LVB was used for mechanical compression testing (MTS, Bionix 858). The data were analyzed with the Kruskal Wallis test followed by post-hoc testing as needed.

RESULTS: After 16 wks of estrogen deficiency, there were significant reductions in BV/TV, trabecular thickness (Tb.Th), and bone strength. Treatment with either bFGF or hPTH (1-34) increased BV/TV in OVX animals. However, hPTH (1-34)-treated animals had a significant increase in BV/TV, and trabecular and cortical thickness compared to bFGF-treated animals. Treatment of OVX rats with hPTH (1-34) also significantly increased bone strength compared to OVX + Vehicle animals (maximal load and stiffness). Treatment with bFGF increased Tb.N more than hPTH (1-34). Basic FGF also significantly increased Tb.Th, and maximum load compared to OVX + Vehicle animals.

SUMMARY. These results suggest that both anabolic agents increase trabecular bone volume in the LVB of osteopenic rats. However, they alter trabecular structure differently with hPTH(1-34) predominantly increasing trabecular thickness whereas bFGF increases trabecular number and connectivity density. Although both anabolic agents improved bone strength by compressive testing compared to OVX + Vehicle animals, hPTH (1-34) appeared to be more potent at this skeletal site.

Treatment Groups	N	BV/TV (%)	CD (1/mm^3)	Tb.N (1/mm)	Tb.Th (μm)	Max. Load (N)	Stiffness (10^{2}N/mm)
1. Sham + Vehicle	12	37.6 ± 5.0	51.3 ± 12.7	3.8 ± 0.2 ^{d}	98.5 ± 11.1	266 ± 47 ^{c}	7.9 ± 3.7 ^{c}

Administration of Vitamin K2 (Menatetrenone: MK4) Improves Bone Strength by Promoting Bone Formation in Diabetic Rats. S. Wada[1], S. Yasuda*[2], M. Kobayashi*[3], K. Omura*[3], K. Hara*[3], M. Kogwa*[2], Y. Akiyama*[3], S. Katayama*[2]. [1]Dept of Clinical Science, Josai International University, Chiba, Japan, [2]Dept of Endocrinology and Metabolism, Saitama Medical School, Saitama, Japan, [3]Eisai Co. Ltd, Tokyo, Japan.

A subanalysis of large-scale clinical studies demonstrated that not only type 1 but type 2 diabetes showed an increased incidence of fractures. To examine the underlying mechanisms for bone fragility in type 2 diabetes, we have studied the effects on bone of chronically elevated serum glucose levels in Goto-Kakizaki (GK) rats. The results suggested that continuous elevation of serum glucose leads to skeletal fragility and that administration of MK4 partially protects against the decline of bone strength. In the present extensive analysis, we focused on skeletal morphology to identify the factors involved in these processes. The experimental animals included 111 GK rats and 44 non-diabetic Wistar rats. The rats, eight weeks of age at the start of the experiment, were fed a normal diet until they were 40 weeks of age, during which time their blood glucose and HbA1c levels and body weight were measured every two weeks. At 40 weeks of age, they were divided into two groups: those to be given MK4 (30 mg/kg b.w./day) and those to receive no active drug treatment; and were further fed for an additional 24 weeks. The results of vertebral compression tests showed increased bone elasticity and stiffness of lumbar vertebrae in the MK4 group (elasticity: 240±12.5 N/mm2 in the control diet vs. 326.9±16.3 N/mm2 in the MK4, p<0.01; stiffness: 538±29 in the control diet vs. 669±34 N/mm in the MK4, p<0.01). These beneficial effects were further assessed by bone histomorphometry, where significantly increased new bone formation was recognized in the MK4 group with respect to the following measurements: BV/TV (4.75±0.39% in the control diet vs. 6.49±0.49% in the MK4, p<0.01) and Tb.N (0.76±0.06/mm in the control diet vs. 1.00±0.07/mm in the MK4, p<0.05). The Ob.S/BS was 2.04±0.25% in the control diet and 4.85±0.46% in the MK4 (p<0.01) and Oc.S/BS was 2.73±0.20% in the control diet and 3.42±0.27% in the MK4 (p<0.05). The MAR, an index reflecting bone formation obtained by double labeling with calcein, was significantly higher in the MK4 group (0.512±0.076 micro m/day in the control diet vs. 0.716±0.066 micro m/day in the MK4, p<0.05). Similar effects of MK4 on skeletal morphology were observed in Wistar rats. These findings suggest that administration of MK4 ameliorated low bone turnover and remodeling in diabetes and that this treatment increased bone formation and improved bone strength. These results provide evidence that support the usefulness of MK4 in the treatment of diabetic osteopathy.

A Selective EP4 Agonist Stimulates Fracture Healing. Y. Shinagawa*, T. Maruyama, H. Oida*, K. Sakata*, A. Seki*, H. Yoshida*, K. Oda*, M. Naka*, K. Kondo*. Research and Development Headquarters, ONO Pharmaceutical Co., Ltd, Osaka, Japan.

The morbidity and mortality associated with impaired/delayed fracture healing remain high. Since fracture healing requires reparative phase and remodeling phase, prostaglandin E_2 (PGE_2), which has been reported to stimulate both bone formation and resorption, seems to be an appropriate intervention for fracture healing. However, due to side effects, PGE_2 is an unacceptable therapeutic option. We have recently demonstrated that the bone anabolic action of PGE_2 is mimicked by the activation of EP4 receptor, which is a subtype of PGE_2 receptor, and that the selective EP4 agonist ONO-4819·CD restores bone mass and strength in rats subjected to ovariectomy or immobilization at doses without severe side effects (*). The aim of this study was to examine the effect of ONO-4819·CD on fracture healing in rats at tolerable doses. Rats were prepared by making a surgical osteotomy on the fibula and sacrificed at 21 days after surgery. The strength and bone mineral content of the callus area in the fibula was assessed by means of three-point biomechanical testing and radiographic analysis. ONO-4819·CD was injected intravenously for 2 hours twice a day from the day after the surgery until the end of the experiments. In vehicle-treated animals, the strength of the fractured fibula recovered around 50% compared with the untreated fibula at 21 days after osteotomy. Administration of ONO-4819·CD enhanced the strength of the callus area in a dose dependent fashion. In addition, the radiographic analysis revealed that bone mineral contents and closure of fracture line in the callus area was more pronounced in rats treated with ONO-4819·CD than those obtained with vehicle. These results indicate that ONO-4819·CD enhanced the fracture healing by the activation of both bone formation and bone remodeling. Since no obvious adverse effect was observed in rats treated with ONO-4819·CD in this study, the activation of EP4 receptor with ONO-4819·CD may be a therapeutic intervention for fracture healing. Its usefulness in patients will be clarified by clinical trial on-going in Japan.

A Single Intraosseous Injection of rhBMP-2/CPM Improves Structure and Strengthens the Distal Radius of Ovariectomized Nonhuman Primates in 6 Months. H. J. Seeherman, E. A. Smith-Adaline, J. D. Parkington*, X. J. Li, J. M. Wozney. Women's Health and Bone, Wyeth Research, Cambridge, MA, USA.

Recombinant BMP-2 (rhBMP-2) is a potent osteoinductive factor with the potential to lower fracture risk in osteoporotic patients by inducing anabolic bone formation following local injection. This study evaluated intraosseous (IO) delivery of 0.2 mL of 1.5 mg/mL rhBMP-2 administered in a calcium phosphate matrix (CPM, ETEX Corporation, Cambridge, MA) into one distal radius of 11 adult female cynomolgus monkeys that had been ovariectomized 5 years previously. The contralateral radii remained untreated. Animals were euthanized at 1 month (n = 1) and 3 months (n = 1) for histologic evaluation and 9 animals were euthanized at 6 months either for histology (n=3) or pQCT and biomechanics (n=6).

Radiographs demonstrated new bone formation as early as 2 months after treatment. The majority of the carrier appeared to be resorbed by 3 months. At 6 months, there was substantial new bone formation leading to an increase in the circumference of the distal radius. At 1 month, histology demonstrated increased marrow cellularity, vascularity, appositional and new trabecular bone formation, along with an increase in endosteal and periosteal bone formation compared to the untreated limb. Marrow activation and anabolic bone formation persisted at 3 months and was still ongoing at 6 months. Ex-vivo pQCT analysis at 6 months demonstrated BMP/CPM significantly increased cross-sectional area (17 ± 12%, p = 0.015), trabecular bone area fraction (23 ± 14%, p = 0.013) and cortical thickness (23% ± 17%, p = 0.05) in the radial metaphysis (paired t-test). Cross-sectional area of the distal radial shaft increased (25% ± 28%, p = 0.08) and cortical thickness remained unchanged. BMP/CPM increased maximum compressive load (23% ± 22%, p = 0.05), yield load (45% ± 25%, p = 0.01) and energy (68% ± 64%, p = 0.069), but not stiffness.

In summary, a single IO administration of BMP/CPM resulted in a marked and rapid increase in cortical and trabecular bone in the distal radius leading to increased mechanical properties at 6 months. The anabolic effect of BMP/CPM was still present at 6 months. The combination of rhBMP-2/CPM represents a promising anabolic therapy for prevention of osteoporotic fractures, particularly for patients undergoing surgical treatment for vertebral or contralateral wrist or hip fractures.

Glucose-Dependent Insulinotropic Peptide Regulates Bone Turnover In Vivo. D. Xie[1], K. H. Ding[2], M. Hamrick[3], A. L. Mulloy[2], K. Insogna[4], C. M. Isales[2]. [1]Institute of Molecular Medicine and Genetics, Medical College of Georgia, Augusta, GA, USA, [2]Medicine, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA, [3]Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA, USA, [4]Medicine, Yale University School of Medicine, New Haven, CT, USA.

Glucose-dependent insulinotropic peptide (GIP) is an incretin hormone whose release from the small intestine is stimulated by nutrient ingestion. We previously reported that GIP receptors are present in osteoblastic cells and GIP increases collagen type I synthesis and alkaline phosphatase activity in isolated osteoblasts. To further define GIP's role as an anabolic hormone in vivo we utilized two genetically altered mouse models, a transgenic mouse over-expressing GIP under the control of the metallothionein promoter (Tg+/+) and a GIP receptor knockout mouse (GIPR -/-). Tg +/+ mice were fed zinc (25 mM) in their drinking water beginning at one month of age and all measurements were taken at five months of age and compared to age-matched wild-type (C57/Bl6) and GIPR -/- mice. Tg +/+ mice had significantly higher mean GIP levels (wild-type: 251 pM, Tg +/+: 606 pM, GIPR -/-: 261 pM, (n=26 animals, p<0001 control vs. Tg +/+). Tg+/+ animals also had a significant increase in markers of bone formation (serum alkaline phosphatase activity, wild-type: 104 U/L, Tg+/+: 136 U/L, GIPR -/-: 86 U/L, (n=30 animals, p<0.003 control vs. Tg+/+) and a decrease in pyridinoline (GIPR -/-: 1.9, Tg+/+: 1.3 nM; n=26 animals, p<0.001 GIPR -/- vs. Tg +/+). Consistent with these biochemical data, GIP transgenic mice had a significant increase in bone density and GIPR -/- mice a significant decrease when compared to wild-type by PIXImus (wild-type: 0.0492, Tg+/+: 0.0534, GIPR -/-: 0.0480 g/cm2, n=30 animals, p<0.007 wild type vs. Tg+/+; p<0.028 wild type vs. GIPR -/-).

These data are consistent with the conclusion that: 1. GIP inhibits bone breakdown and stimulates bone formation. 2 Loss of GIP signaling results in significant bone loss. Since GIP receptor is known to be downregulated in humans with increasing age, our data suggest that attenuation of the GIP signal in bone may contribute to aging-related bone loss.

The Novel Vitamin D Analog ED-120 Inhibits Bone Resorption and Stimulates Periosteal Apposition in Overiectomized Rats. Y. L. Ma, Q. Zeng*, S. Smith*, H. W. Cole*, H. U. Bryant, M. Sato. Bone and Inflammation, Eli Lilly and Company, Indianapolis, IN, USA.

Skeletal effects of ED-120, an oral vitamin D analog, were examined in ovariectomized (Ovx) rats. In study 1, ED-120 (provided by Chugai) at 0.008, 0.04 or 0.1μg/kg/d was given to 6 month old rats for 6 weeks starting at two weeks post-Ovx. ED-120 significantly increased serum calcium over Ovx controls (up to 7%) at 0.04 and 0.1μg/kg/d doses; but micro-CT analysis showed that all 3 doses of ED-120 increased bone mineral density (BMD) of the distal femur relative to Ovx controls (13-73%). Histomorphometry analysis showed that trabecular area of the proximal tibiae in the two highest dose groups was greater than Ovx (89% and 168%, respectively) and not different from Sham. In study 2, ED-120 at 0.03, 0.1 or 0.3 μg/kg/d (po) and PTH (1-38) 40 μg/kg/d sc were given for 3 months to 7 month-old rats that were permitted to lose bone for 1 month prior to treatment. Compared with Ovx, ED-120 significantly increased serum calcium (up to 15%) at 0.1 and 0.3 μg/kg/d, but ED-120 completely restored BMD at 0.03μg/kg/d, and increased BMD over Sham at 0.1 and 0.3μg/kg/d in vertebrae L-5. Trabecular area in the proximal tibia was 280% and 502% higher than Ovx controls, respectively. The bone mass increase was accompanied by thickening trabeculae and increased trabecular connectivity. The high dose effect was not different from PTH 40μg/kg/d treatment. ED-120 also significantly increased mid-femur BMD and tibial shaft cortical area over both Ovx and Sham controls at 0.1μg/kg/d or higher. The efficacy of ED-120 was due to lower bone resorption and reduced turnover rate on trabecular and endocortical surfaces, with increasing mineralizing surface, mineral appositional rate and bone formation rate on the periosteal surface. To determine the bone efficacy of ED-120 in the absence of intestine or renal effects, ED-120 was given through a cannulae into the tibial marrow cavity of Ovx rats daily for 10 days. Up to 50% more new bone formation was seen in ED-120 treated tibiae compared to vehicle controls. These data suggest that ED-120 compares favorably to PTH in restoring lost bone due to Ovx in rats and could have therapeutic potential for the treatment of osteoporosis, if hypercalcemia is monitored closely.

A Higher Dose of Vitamin D Reduces the Risk of Falls in Nursing Home Residents: A Randomized, Placebo-Controlled, Multiple Dose Study. D. P. Kiel[1], K. E. Broe[1], T. C. Chen*[2], L. A. Cupples*[3], H. Bischoff-Ferrari[4], M. F. Holick*[2]. [1]Hebrew Rehab Ctr for Aged & Harv Med Sch, Boston, MA, USA, [2]Boston Med Ctr, Boston, MA, USA, [3]BU Sch Pub Hlth, Boston, MA, USA, [4]Brigham & Women's Hosp, Boston, MA, USA.

Although a recent meta-analysis of randomized, controlled trials reported that vitamin D (vit D) supplementation reduced the incidence of falls, there was insufficient data to formally test which dose of vit D would be most beneficial. Therefore we analyzed results of a five-arm, double-blinded, placebo-controlled trial involving 125 residents (89 women, 36 men) from a 725-bed long-term care facility in Boston, MA. Eligible residents had none of the following: severely limited mobility; fx within past 6 mo; use of glucocorticoids or anti-seizure drugs; disorders associated with abnormal calcium metabolism; use of pharmacologic doses of vit D; expected death within the next five mo. These 125 residents were randomly assigned to one of four dose groups of daily vit D supplementation (200, 400, 600, or 800 IU) or placebo from January-May, 1995. At baseline, subjects were evaluated for age, wt, ht, 25 hydroxy vit D (ng/ml), functional and cognitive status, falls in prior year, and facility multivitamin use (400 IU of vit D). Falls were ascertained using the facility's computerized incident reporting system.

We examined risk of falls across all intent to treat dose groups using Cox proportional hazards adjusting for age and multivitamin use (y/n) and then compared the risk of falls in the 800 IU group to the other four groups combined. Additionally we looked at multiple falls using negative binomial regression and repeated these across quintiles of total vit D supplement intake (study tablet + multivitamin).

Of the 125 participants, 72% were female, mean age 89±6 years, 63% were taking a daily multivitamin, and 115 completed the trial. There were no baseline differences across groups with the exception of age. The number of falls over the 5 mo period in the placebo, 200, 400, 600, and 800 IU groups were 31, 37, 33, 41, and 9 respectively. The percentage of participants with > one fall during follow up were 32%, 42%, 36%, 36%, and 9% respectively.

Compared to the 800 IU group, participants in the other groups had a 3 to 4-fold increase in the hazard ratio (HR) for first fall. Participants in the 800 IU group had a 71% reduction in the risk of falls (HR 0.29; 95% CI: 0.11-0.72) compared to the other four groups combined. Similar results were obtained when considering all falls or when using quintiles of total vit D

intake.
In conclusion, nursing home residents taking at least 800 IU of vit D daily have a lower risk of falls than those taking lower daily doses. To maximally reduce the risk of falls in nursing homes, vit D doses of 800 IU or higher may be needed.

Disclosures: ***D.P. Kiel****, None.*

Importance of the Understanding of the 25-hydroxyvitamin D Status for the Alendronate Treatment of Postmenopausal Osteoporosis. M. Yamanaka*[1], M. Ishijima[1], A. Tokita[2], K. Kitahara[1], F. Enomoto*[3], M. Sawa*[3], M. Nozawa*[3], H. Kurosawa*[1]. [1]Dept. of Orthopaedics, Juntendo Univ. School of Medeicine, Tokyo, Japan, [2]Dept. of Pediatrics, Juntendo Univ. School of Medeicine, Tokyo, Japan, [3]Orthopaedic Surgery, Juntendo Tokyo-Kouto Geriatric Medical Center, Tokyo, Japan.

The aim of this study is to investigate the relationship between the vitamin D status and the effect of the treatment of alendronate in postmenopausal osteoporotic Japanese women. Seventy-eight Japanese women who were all outpatients for our hospital were included in this study. Subjects were ranged from 52 to 82 years of age. Serum levels of 25(OH)D3, 1,25(OH)2 D3, intact-PTH and bone specific alkaline phosphatase (BAP) and urinary levels of NTX were measured at the first medical examination and every three months thereafter. In those, eighteen patients who were diagnosed as primary osteoporosis were treated with alendronate (5mg, daily). BMD of the lumber spine was measured every six months. Serum levels of 25(OH)D3 at the first medical examination were correlated negatively with that of intact-PTH (intact PTH=64.8-0.87*25(OH)D, r=-0.29, p=0.01). Insufficient levels of 25(OH)D3 (<15 ng/ml) at the first medical examination were recognized in nine patients (12%). In addition, five patients (7.2%) in residual 69 patients were increased in levels of intact-PTH (>65 pg/mL) at the first medical examination. One of those patients was diagnosed with primary hyperparathyroidism. In eighteen patients who were treated with alendronate for primary osteoporosis, insufficient levels of 25(OH)D3 at the first medical examination were recognized in five patients. In two of them the levels of 25(OH)D3 were not improved after six months from the first examination despite of dietary education. The increase in the BMD in lumber spine and the decrease in urinary levels of NTX of the two patients after six months of alendronate treatment was insufficient compared to those of residual sixteen patients. These results indicate that patients with secondary hyperparathyroidism are not rare in postmenopausal outpatients. In addition, insufficiency of vitamin D status in postmenopausal osteoporotic women may inhibit the effect of alendronate that suppresses osteoclastic bone resorption. Therefore, understandings of the vitamin D status in postmenopausal women are really important not only to understand their nutritive status but also to obtain a satisfactory effect using alendronate for treatment of osteoporosis.

Disclosures: ***M. Yamanaka****, None.*

Bone Histomorphological Examination Reveals ED-71, 1α,25-dihydroxy-2ß-(3-hydroxypropoxy)vitamin D_3, and Human PTH(1-34) Activate Bone Formation in A Different Way in Aged Ovariectomized Rats. K. Tsunemi*, S. Takeda*, A. Sugita*, F. Takahashi, H. Saito, N. Kubodera*, F. Makishima*. Chugai Pharmaceutical Co.,Ltd., Gotemba, Japan.

ED-71 (1α,25-dihydroxy-2ß-(3-hydroxypropoxy) vitamin D_3) is a novel orally active vitamin D analog for the treatment of osteoporosis, currently under Phase 3 clinical trials in Japan. We previously reported ED-71 dose-dependently increased both bone mineral density (BMD) as well as bone strength of both lumber vertebrae and femur in aged ovariectomized (OVX) rats. In present study, we examined effects of ED-71 on bone formation by bone histomorphometry in compared with human parathyroid hormone (hPTH(1-34)) in aged OVX rats. Seven-month old female rats were ovariectomized and kept untreated to lose bone mass for three months prior to the treatment. OVX rats were given either vehicle, ED-71 (0.08μg/kg) or hPTH (1-34) (20 nmol/kg), five times a week. Sham-operated animals were given vehicle. Rats were sacrificed at day 7, day 14, day 28 and day 56. In all groups, serum calcium was within normal range. Both ED-71 and hPTH(1-34) restored lumber spine BMD comparable to Sham group at day 28, and continued to increased BMD to overcome the Sham group at day 56. ED-71 increased serum osteocalcin, however, did not affect serum alkaline phosphatese. ED-71 decreased urine deoxypyridinoline throughout the treatment period.
In bone histomorphometry, both ED-71 and hPTH(1-34) groups restored bone volume (BV/TV) comparable to the Sham group at day 28 and day 56. The ED-71 group maintained high mineral apposition rate (MAR), bone formation rate (BFR/BS), and obteoblast surface (Ob.S/BS) as observed in OVX group, however, significantly decreased eroded surface (Er.S/BS), osteoclast surface (Oc.S/BS) and osteoclast number (Oc.N/BS). On the other hand, hPTH(1-34) significantly activated both bone formation (MAR, OV/BV, Ob.S/BS, BFR/BS) and bone resorption (ES/BS, Oc.S/BS, Oc.N/BS) compared to OVX group.
Bone histomorphological analysis revealed that both ED-71 group and hPTH(1-34) group had thick trabecular bones, in which lamellar bones were added to the trabeculaes, observed at day 7 and day 14. After reaching Sham level, ED-71 started to form convexed shape of trabecular contour and increased trabecular connectivity, without showing any bone resorption figures, which observed at day 28 and day 56. On the other hand, hPTH(1-34) still continued to add lamellar bones to trabecularae as well as activating bone resorption at day 28 and day 56. These data suggested that both ED-71 and hPTH(1-34) increased bone mass, however the time-course and the way of bone formation of the two agents were not identical.

Effect of Long Term Antiepileptic Therapy on Bone Density and Response to Different Doses of Vitamin D: Two Randomized Trials in Children and Adults. M. Mikati*[1], L. Dib*[2], B. Yamout*[2], R. Sawaya*[2], G. El-Hajj Fuleihan[2]. [1]Pediatrics Department, American University of Beirut, Beirut, Lebanon, [2]Internal Medicine Department, American University of Beirut, Beirut, Lebanon.

Antiepileptic drugs (AEDs) are risk factors for low bone density[1], possibly due to a deleterious effect on vitamin D metabolism. To date, there are no randomized trials assessing the efficacy of vitamin D supplementation on bone parameters in patients on AEDs.
We conducted two parallel randomized controlled trials, both in adults and children, to test the efficacy of vitamin D supplementation over one year in maintaining bone mineral density. The two doses were a maintenance dose (400 IU vitamin D/day) versus a higher dose (2000 IU/day for children and 4000 IU/day for adults); a placebo was not used for ethical reasons. The adult study group included 78 subjects, 40 women and 33 men, age 28.7±9.7 years, duration of AED therapy 10.8±9.5 years. The pediatrics group included 78 subjects, 41 boys and 37 girls, age 13.2± 2 years, duration of AED therapy 5.2± 4.6 years. Serum 25 hydroxy vitamin D (25 OHD) and spine hip and forearm BMD in adults and spine and total body BMD/bone mineral content (BMC) in children were measured at baseline and at one-year.

Vitamin D levels in study groups before and after study entry

	Adults		Children	
	Low Dose	High Dose	Low Dose	High Dose
Baseline 25 (OH)D (ng/ml)	13.4 (6.4)	13.7 (8.0)	18.2 (7.1)	18.0 (9.1)
One year 25(OH)D (ng/ml)	17.5 (7.3)*	26.3 (8.9)*	21.2 (8.5)*	22.9 (8.4)*

*Implies significant changes compared to entry values, p< 0.05.

At baseline, bone density in epileptic adults, but not in children, was significantly lower than that of age, gender and ethnic-matched controls[2] at the spine and hip in men (p=0.05 and p=0.023 respectively) and women (p=0.038 and p=0.013). At one-year, no significant difference in percentage change BMD/BMC was observed between the two treatment arms, both in the adult and in the pediatric studies. When compared to a longitudinal study of age, gender and ethnic-matched healthy controls, epileptic boys, but not girls, had significantly lower total body BMC increments at one year (10.9±11.2% versus 15.8±8.4%, p=0.016), with a trend for lower increments at the spine.
Adults, but not children, on AED had lower BMD compared than age-gender and ethnic matched controls, as we previously reported[1].Particular attention to skeletal health is warranted in ambulatory subjects on chronic antiepileptic therapy. Although Vitamin D supplementation seems to maintain BMD, the optimal dose is however still unclear and necessitates larger dose-ranging multicenter trials.

One-year Vitamin D Supplementation of Adolescent Girls Influenced only Serum 25-hydroxyvitamin D. H. T. Viljakainen[1], A. Natri*[1], M. M. Huttunen[1], A. Palssa*[1], J. Jakobsen*[2], K. D. Cashman*[3], C. Mølgaard*[4], C. Lamberg-Allardt[1]. [1]Department of Applied Chemistry and Microbiology, division Nutrition, University of Helsinki, Helsinki, Finland, [2]Danish Institute for Food and Veterinary Research, Söborg, Denmark, [3]Department of Food and Nutritional Sciences, Cork, Ireland, [4]Research Department of Human Nutrition, The Royal Veterinary and Agricultural University, Frederiksberg C, Denmark.

Exposure to sunlight is the major source of vitamin D for adolescent girls in the summer, even in Finland, a country with hardly any UVB-light in the winter. However, body stores of vitamin D with inadequate dietary intake do not maintain serum 25-hydroxyvitamin D (s-25-OHD) concentrations through out the winter, which leads to increased parathyroid hormone (s-iPTH) secretion and may sabotage bone mineral accretion.
The purpose of this one-year study was to determine in a randomised, double-blinded, placebo-controlled setting the effect of vitamin D3 supplementation on s-25-OHD, s-iPTH concentration and bone markers in adolescent girls.
Altogether 225 girls, mean aged (SD) 11.4 (0.4) y, participated the study between September 2001 and March 2002. They were randomly assigned into three groups receiving 0, 5, or 10 μg of vitamin D3. Subjects with a compliance of at least 80% were included in the final analysis. Fasting blood and second void urinary samples were collected during month 0, 6 and 12 of the intervention. S-25-OHD was measured by a HPLC method, S-iPTH by OSTEIA assay and s-osteocalcin by ELISA. Deoxypyridinole from urine samples was analysed by HPLC. Statistical analyses were performed by ANOVA by SPSS.
At baseline, mean S-25-OHD concentration was 47.8 (17.3) nmol/L and median dietary intake of vitamin D and calcium was 4.4 (4.0) μg and 1230 (540) mg, respectively. S-25-OHD was influenced by supplementation (p<0.0001) and season (p=0.008), and an interaction of these two (p=0.03). The concentration of S-25-OHD increased in groups receiving 5 and 10 μg by 5.7 (15.7) nmol/L and 12.4 (13.7) nmol/L, respectively, over the year, while it decreased by 6.7 (11.3) nmol/L in the control group. Increase in S-25-OHD differed between groups (p<0.001). Supplementation influenced neither S-iPTH nor the bone markers, but higher concentrations of all bone markers were seen in autumn than in winter (p=0.04), indicating an effect of season.
In conclusion, there is an interaction between season and vitamin D supplementation in determining the variation of S-25-OHD. Serum 25-OHD concentration was maintained only in the group receiving 10 μg throughout the year. The total dietary vitamin D intake (including supplement) in this group was 14.8 μg, which is more than the DRI.

Bone Mineral Density Determinations by DXA in the Management of Marfan Syndrome Patients. Some Factors Which Affect the Measurement. P. F. Giampietro*[1], M. G. E. Peterson*[2], R. Schneider*[3], J. G. Davis*[4], C. Raggio*[5], E. Myers*[6], S. W. Burke*[5], O. Boachie-Adjei*[7], C. M. Mueller*[8]. [1]Medical Genetic Services, Marshfield Clinic, Marshfield, WI, USA, [2]Center for Clinical Outcome Research, Hospital for Special Surgery, New York, NY, USA, [3]Radiology, Hospital for Special Surgery, New York, NY, USA, [4]Pediatrics, Weill Medical College, New York, NY, USA, [5]Pediatric Orthopedics, Hospital for Special Surgery, New York, NY, USA, [6]Biomechanics, Hospital for Special Surgery, New York, NY, USA, [7]Adult and Pediatic Spine Surgery, Hospital for Special Surgery, New York, NY, USA, [8]Nutrition Services, Weill Medical College, New York, NY, USA.

The purpose of this study was to statistically compare bone mineral densities (BMD) in a series of 30 patients with Marfan syndrome to those patients reported in the literature. We hypothesized that agreement between values, hence the degree of osteoporosis or osteopenia reported, was dependent on the instrumentation used. Dual-energy x-ray absorptiometry (DXA) was performed using a pencil-beam Lunar DPXL instrument on a sample of 30 adult patients with diagnosed Marfan syndrome from 1993-2000. The results were compared with those of studies studies published from 1993-2000 that used either Lunar or Hologic bone densitometry instrumentation. The differences of our results compared with those made on other Lunar machines were not statistically significant, but did differ with statistical significance with published results from Hologic machines. Before progress can be made in the assessment of BMD and fracture risk in Marfan patients, and in the evidence-based orthopedic management of these patients, standardization of instrumental bone density determinations will be required along with considerations of height, obesity, age and sex.

Effect of 3 Years of Pamidronate on the Functional, Radiographic, Densitometric and Biochemical Outcomes of Infants with Severe Osteogenesis Imperfecta. C. F. J. Munns, F. Rauch, F. H. Glorieux. Genetics, Shriners Hospital for Children, Montreal, PQ, Canada.

In children with severe osteogenesis imperfects (OI), cyclical intravenous pamidronate treatment may be of greatest benefit when started at a very young age. We evaluated 29 children with OI types I (n=3), III (n=14) or IV (n=12) who started pamidronate therapy at 2 years of age or less (mean 0.7 ±SD 0.6 years), and had completed 3 years of treatment. They were compared to an historical control group of 29 untreated children with severe OI matched for OI type and age at the three year time point. The total annual pamidronate dose was 9 mg/kg. At analysis, the mean age of the pamidronate and control cohorts were similar (3.6 vs 3.7 years; p>0.05, paired t-test). The pamidronate cohort were heavier (12.1 vs 10.7 kg; p=0.05) but were of similar height (84.1 vs 80.1 cm; p>0.05). Bone age did not differ significantly between the pamidronate and control groups (3.7 vs 3.2 years; p>0.05). Morphometry of L1-4 vertebral bodies showed a significant improvement of vertebral shape (p<0.05). There was no difference in the incidence of popcorn epiphysis or scoliosis (p>0.05 by chi squared test). The age at the first lower limb rodding procedure was significantly lower in the pamidronate cohort (2.5 vs 4.0 years; p=0.003), suggesting that they were pulling to stand at a younger age. Insufficient data was available to allow for meaningful comparisons of fracture incidence. Serum parathyroid hormone levels did not differ significantly between the groups. The table summarizes other significant findings.

Clinical feature	Pamidronate	Control	P
PEDI gross motor score	36.2 ±13.1	23.9 ±12.3	<0.001
Mobility score	2.3 ±0.9	0.8 ±1.0	<0.001
2nd metacarpal cortical thickness (mm)	0.86 ±0.09	0.67 ±0.28	0.02
Volumetric BMD (mg/cm^3)	88 ±12	45 ±11	<0.001
Ionized calcium (mmol/l)	1.29 ±0.05	1.31 ±0.04	0.05
Alkaline phosphatase (U/l)	185 ±45	274 ±63	<0.001
Urine NTx (μmol/min/l)	339 ±132	850 ±301	<0.001

This study, in infants with severe OI, demonstrates that 3 years of cyclical pamidronate is safe with regards to growth, bone age advancement and calcium homeostasis, while decreasing bone turnover. More over, it was associated with significant improvements in gross motor function, vertebral morphometry, cortical thickness and volumetric BMD. Further follow-up is required to evaluate its effects on scoliosis, popcorn epiphysis and final height.

Musculoskeletal Manifestations of Mild Osteogenesis Imperfecta in the Adult. F. E. McKiernan. Center for Bone Diseases, Marshfield Clinic, Marshfield, WI, USA.

The musculoskeletal manifestations of mild Osteogenesis Imperfecta (OI) in the adult are not well described. Scant available literature suggests variable hypermobility, rare tendon rupture, occasional Reflex Sympathetic Dystrophy (RSD), infrequent fracture and little overall disability.

The objective of this study is to better characterize the musculoskeletal manifestations of mild OI in adults and to estimate their degree of impairment. An anonymous, 32-question survey designed to meet the study objective was hosted on the OI Foundation (OIF) web site for 6 weeks ending 4/9/04. Unduplicated adult respondents constituted the registry. IRB analysis determined that registry analysis was exempt from their review.

111 respondents (33M /78F) were of mean age 42.1yM/40.2yF (range 20-70). 73.9% considered their OI mild, 23.4% moderate and 2.7% severe. Fracture number and morphometrics did not differ among these 3 groups and all fit the descriptive term mild. Peak height was 65.6"M/61.1"F. 91% of sclera were blue or not white. 49%M/87.2%F considered bruising abnormal. 48.8% M/87.2%F considered dental health abnormal. There were 3410 lifetime fractures; 27.6% of these occurred after age 18y. 44.4% reported an established diagnosis of "arthritis". Of those, 66.7% reported osteoarthritis, 37.5% unknown arthritis, 6.25% fibromyalgia, 4.2% inflammatory arthritis. Pain and stiffness scores dominated at the low back and large weight bearing, lower extremity joints. 82.7% reported some functional impairment based on articular issues; 46.3% requiring some assistance with ADL. 65.7% reported hypermobility, 55.8% prior joint dislocation and 38.9% prior tendon rupture. Instability dominated at the knees. 52% reported some functional impairment based on ligament and tendon issues. Back pain was reported to be common in 70.1%. 72.5% reported some impairment from back pain. 46.8% reported scoliosis. 5.5% reported RSD. In spite of this 60.9 % rated overall physical health as good or excellent. 72% had previously used NSAID/COX II-inh, 47% anti-remodeling agents and 24% systemic/IM/articular steroids.

In conclusion, the majority of adults with mild OI report some functional impairment due to musculoskeletal concerns. 30-50% require some assistance with ordinary ADL. 5-15% require assistance with light physical tasks and personal ADL. Pain and stiffness were dominant in the low back and large weight bearing LE joints. Instability was dominant at the knees. Tendon rupture was not uncommon. RSD was rare and may be over-represented in the literature. This population frequently uses NSAID/COX II-inhibitors, glucocorticoids and anti-remodeling agents. This and fluoroquinolone use may be of some concern for these persons.

X-Linked Hypophosphatemia: Favorable Outcome of Joint Replacement. M. P. Whyte. Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA.

X-linked hypophosphatemia (XLH) is the most common heritable form of rickets (prevalence ~ 1:20,000). Affected children are treated with 1,25-dihydroxyvitamin D_3 and inorganic phosphate (Pi) supplementation during childhood to overcome renal Pi wasting and to prevent skeletal deformity and to improve stature. Whether medical treatment should continue during the adult years is considered on an individual patient basis. Radiographic surveys have shown that osteoarthritis (OA), especially in the knees but also in the hips, is a common complication of XLH during adulthood reflecting the previous eras of suboptimal medical treatments (Medicine 68: 336 '89). The likelihood and severity of OA in the knees correlates positively with the degree of bowing of the lower limbs. However, the utility of joint replacement for XLH, and whether patients should be receiving perioperative medical therapy, is uncertain.

Having treated 186 children with XLH during the last 20 years, we have also encountered a significant number of affected adults with this X-linked dominant disorder. To assess the outcome of joint replacement for XLH in adults, we contacted all 10 patients known to us who have undergone either knee or hip replacement. The 10 patients had 12 knees and 3 hips replaced by different surgeons at different medical centers. Age at surgery ranged from 41 - 65 years. Only 5 of these individuals received medical therapy [1,25$(OH)_2D_3$ and Pi] perioperatively. Postoperative follow-up ranged from 1-20 years.

None of the patients reported a complication from surgery. One individual had reduced flexion after knee replacement. All experienced considerable reduction in pain and improvement in mobility.

Knee or hip replacement for adults with XLH, with or without perioperative medical treatment, is well tolerated and associated with significant clinical improvement including reduction in pain and increase in mobility.

High Bone Mass Disease with Fragile Dentition In A Kentucky Kindred: A New Autosomal Dominant Disorder. D. Wenkert[1], S. Mumm[2], W. H. McAlister*[2], M. P. Whyte[1]. [1]Shriners Hospitals for Children, St. Louis, MO, USA, [2]Washington University School of Medicine, St. Louis, MO, USA.

Genetic analyses of high bone mass phenotypes in patients have revealed critical mechanisms for human skeletal remodeling. Examples are activating mutations of exons 2-4 of *LRP5* leading to benign or symptomatic osteosclerosis and hyperostosis and defects in genes that regulate acidification by osteoclasts causing osteopetrosis.

We have studied 10 affected individuals of a 4-generation kindred from Kentucky with a unique high bone mass disease with prominent dental manifestations. Clinical and laboratory features are distinct from Albers-Schönberg disease ("benign" osteopetrosis) and from LRP5 high bone mass phenotypes. Family members recognize affected individuals in infancy by their head shape (high forehead and squared-off parietal occipital region). Later, and more striking, there is eruption of small translucent primary teeth. Affected teenagers and adults develop mandibular prominence and bone aches and pains.

Growth: Linear growth is normal. Pre-adolescents appear proportional in weight although BMI percentiles can be elevated perhaps due to high bone mass. Excessive weight gain and hyperlipidemia begin in adolescence.

Neurologic: Affected individuals first complain of severe "migraine" headaches in their teens. Some have early impaired hearing and one developed tunnel vision.

Teeth: Primary and secondary teeth are small, brittle, abscess-prone, and have translucent edges. Both are generally "lost" early through wear, although prolonged retention of pri-

mary teeth affected one patient. Worn secondary teeth are removed due to uncontrollable abscesses. Most affected adults are edentulous by age 30.
Bone: Small facial sinuses lead to frequent sinusitis beginning in childhood. In some patients, progressive bone pain becomes intermittently incapacitating in adulthood. Dentists and surgeons describe the teeth and skeleton as hard but brittle. X-rays show neither the rugger-jersey spine nor the basilar skull sclerosis characteristic of Albers-Schönberg disease. Furthermore, iliac crest biopsy of one affected woman (age 39) showed no cartilage bars.
Biochemistry: Screening for *LRP5* mutations in exons 2, 3 and 4 was negative. Fasting serum phosphate levels were normal in children, however, 3 affected adults had low concentrations (2.2-2.3 mg/dl) yet a normal level of 1, 25-dihydroxyvitamin D. Serum calcium, magnesium, bone alkaline phosphatase, osteocalcin, serum tartrate resistant acid phosphatase and creatine kinase fractionation (brain isoform) and urinary NTX were unremarkable.
The chromosomal location and gene defect causing this unique disorder of bone and teeth are as yet unknown.

Vertebral Morphometry During Pamidronate Treatment for Pediatric Osteogenesis Imperfecta. S. Sahebjam*, C. Munns, F. Rauch, F. H. Glorieux. Shriners Hospital, Montreal, PQ, Canada.

There is anecdotal evidence that long-term treatment with intravenous pamidronate improves vertebral shape in children and adolescents with osteogenesis imperfecta (OI), but detailed analyses are lacking. In this study we measured the height of vertebral bodies L1 to L4 of patients with moderate to severe OI before and during pamidronate treatment. Anterior, posterior and midpoint height was determined on lateral lumbar spine X rays and results were related to the length of the vertebral bodies in the antero-posterior direction. Before pamidronate treatment, there was evidence of continued compression of vertebral bodies L1 to L3, where mid-height decreased significantly during an average follow-up period of 3.3 years (n = 22 patients). After an average of 3.3 years of pamidronate treatment, the height of all vertebral bodies had increased significantly at all measurement sites (n = 46 patients). This reshaping of vertebral bodies continued during the fourth and fifth year of treatment. Thus, vertebral bodies have a tendency to progressively crush in untreated children with moderate to severe OI. During pamidronate treatment considerable reshaping of vertebral bodies occurs.

Restoration of Bone Resorption Causes Down-Regulation of CTGF Expression in Osteopetrotic Rats. R. A. Aswad*[1], C. A. MacKay*[2], J. M. Aubin*[2], P. R. Odgren[2], F. F. Safadi[1], S. N. Popoff[1]. [1]Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, [2]Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

The mammalian osteopetroses represent a pathogenetically diverse group of skeletal disorders characterized by excess bone mass resulting from reduced osteoclastic bone resorption. Connective tissue growth factor (CTGF) is a secreted, extracellular matrix-associated signaling protein that regulates diverse cellular functions. We have previously shown that CTGF expression was highly (8- to 10-fold) over-expressed in bone in the rat mutation, *osteopetrosis* (*op*), when compared to normal rat bone. In addition, much of the CTGF in bone is produced and secreted by osteoblasts. In this study, we examined CTGF expression in bones in the *incisors-absent* (*ia*) and *toothless* (*tl*) osteopetrotic mutations. All osteopetrotic mutants share the skeletal characteristics of osteopetrosis including; lack of bone marrow spaces and unerupted teeth. They nevertheless have dramatically different phenotypes when considering osteoclasts. In *ia* rats, osteoclasts are two to three times more abundant than normal, they are small and non-functional; they slowly normalize over the first postnatal month. In *tl* rats, there is a profound lack of osteoclasts but an abundant pool of mononuclear osteoclast precursors. In *tl* rats, osteoclast function can be restored only in response to CSF-1 treatment. Here, we examined CTGF expression at different ages (1, 2 and 4 weeks) in bones from *ia* and *tl* mutant and normal rats. CTGF expression was up-regulated in *ia* mutants at 1 and 2 weeks of age, while the expression level was normalized by 4 weeks of age. However, in *tl* rats, CTGF expression was up-regulated at all ages examined (1, 2 and 4 weeks). CTGF expression levels were normalized only when mutants treated with CSF-1 when compared to untreated or CSF-1-treated normal littermates. Down-regulation of CTGF expression was also associated with an increase in TRAP positive osteoclasts and MMP-9 expression in *tl* rats. These data suggest that restoration of osteoclast resorptive function is positively correlated with normalization of CTGF expression in osteopetrotic bone. Future studies will examine the role of CTGF as an extracellular matrix protein that promotes osteoclast-mediated bone resorption.

Ascorbic Acid Supplementation, Urinary Oxalate and Risk of Kidney Stone Disease. L. Massey[1], S. Kynast-Gales*[1], M. Liebman*[2]. [1]Human Nutrition, Washington State University, Spokane, WA, USA, [2]Family and Consumer Sciences, University of Wyoming, Laramie, WY, USA.

Endogenous conversion of ascorbic acid (AA) to oxalate contributes to urinary oxalate so AA supplementation may potentiate calcium oxalate stone risk. This study determined the effect of a divided dose of 2 g AA/d on oxalate absorption and excretion, and Tiselius risk index (TRI) for calcium oxalate precipitability.

Twenty-nine stone formers (SF) and 19 age and gender matched non-stone formers (NS) participated in a randomized crossover controlled diet study, 6 days consuming 1 g AA with each breakfast and dinner (treatment A), vs. 6 days without AA (treatment N). The study periods included two free-living adaptation days on self-selected low oxalate diet, followed by three free-living days on a controlled low oxalate diet provided by the investigators, and concluded with 25 hours in a metabolic unit during which participants were given 131 mg C^{13} labeled oxalate with a controlled low oxalate diet.
Mean oxalate absorption for all 48 subjects was not different A vs. N (13.2% vs. 12.2%), but was greater for SF on A vs. N (14.9% vs. 12.4%, p = 0.02), and SF vs. NS on A (14.9% vs. 10.6%, p = 0.002). Mean 24 h total oxalate excretion (n = 48) was increased on A vs. N (0.61 $\pm$ 0.16 vs. 0.54 $\pm$ 0.11 mmol/d, p = 0.002), and during metabolic unit collections from 2 to 4 h and 6 to 8 h after oxalate load (0.10 $\pm$ 0.04 vs. 0.08 $\pm$ 0.03 mmol/d, p = 0.02; 0.06 $\pm$ 0.04 vs. 0.04 $\pm$ 0.02 mmol/d , p < 0.001, respectively). Urine volume, calcium and magnesium were not different over 24 h A vs. N, while 24 h citrate (60.4+22.5 vs. 56.3+20.1 mmol/d) approached significance (p = 0.06).
Though 24 h mean (n=48) TRI increased on A vs. N (0.64 $\pm$ 0.4 vs. 0.56 $\pm$ 0.3), significance was not reached (p = 0.08). TRI was greater for SF vs. NS on both A and N (0.76 $\pm$ 0.41 vs. 0.45 $\pm$ 0.32, p = 0.02, and 0.66 $\pm$ 0.31 vs. 0.42 $\pm$ 0.32, p = 0.008, respectively). Mean TRI was greater during metabolic unit collections A vs. N from 6 to 8 and 8 to 11 h after oxalate load (0.68 $\pm$ 0.63 vs. 0.49 $\pm$ 0.33, p 0.01 and 0.61$\pm$ 0.37 vs. 0.49 $\pm$ 0.37, p = 0.01, respectively). 19 of 48 participants were identified as responders, defined as increased 24 h oxalate excretion $\geq$ 10% on A vs. N. Eleven responders were SF and 8 NS. Responders (n=19) had increased 24 h TRI on A vs. N (0.76 $\pm$ 0.46, vs. 0.52 $\pm$ 0.29, p=.008).
Consumption of 1 gm AA twice a day results in a distinct bimodal response in this population, with 40% of individuals experiencing increases in 24 h urinary oxalate of $\geq$ 10% and 38% of individuals having increases in TRI of $\geq$ 20%. . As individual urinary oxalate response to AA supplementation is not predictable, supplementation should be considered cautiously by both SF and NS.

Importance of the Bone in Severe Absorptive Hypercalciuria. H. J. Heller, J. E. Zerwekh*, C. Y. C. Pak. Internal Medicine, Center for Mineral Metabolism and Clinical Research, UT Southwestern Medical Center at Dallas, Dallas, TX, USA.

Absorptive hypercalciuria (AH), a stone-forming condition in which calcium is excessively absorbed from the intestine, is paradoxically associated with low bone mass. We hypothesized that in patients with severe AH, bone formation is impaired and the relative excess bone resorption contributes to hypercalciuria. Nine stone-formers (age 28 to 53; no other causes of bone loss) underwent bone biopsy at the iliac crest after tetracycline labeling. They were placed on a stone-prevention diet for 3 weeks followed by baseline inpatient evaluation on a constant metabolic diet. On the same diet, alendronate (**A:** 10 mg/d X 2 weeks) was used to probe the contribution of excess bone resorption to urinary calcium.

Cancellous Bone Parameters	AH (6 men, 3 women)	AH (Z-score)	Normal Men (n=43)	Normal Women (n=42)
BV/TV, %	14.8±4.7	-1.0	20.3±7.3	24.5±7.2
Tb. Th, mcm	95±16	-5.2	147±7	140±23
OV/TV, %	0.82±1.03 (0.51±0.31)*	-0.7 (-1.1)*	1.47±0.85	1.93±1.33
Ob.S/BS, %	2.0±2.2 (1.4±0.8)*	-0.6 (-0.9)*	3.4±2.1	4.2±3.0
BFR/BS, $mcm^3/mcm^2/yr$	0.009±0.013 (0.005±0.004)*	-0.1 (-0.8)*	0.009±0.007	0.013±0.007
ES/BS, %	3.1±1.3	-1.0	6.4±3.3	6.5±3.0
Oc.S/BS, %	0.4±0.2	-1.5	1.1±0.4	0.6±0.7

*(not including single outlier with high bone formation)

Bone volume, by histomorphometry, was markedly decreased (equal to that of postmenopausal women with osteoporosis) and out of proportion to the osteopenia demonstrated by bone mineral densitometry. Relative to the historical controls, we found low bone turnover in AH patients and there was no evidence of osteomalacia. Baseline serum CTX correlated with change in urinary calcium after **A** (r=0.75) suggesting that bone resorption was an important source of urinary calcium. The mean fall in urinary calcium with **A** was 53 mg/d; however, results were dichotomous. Urinary Ca fell in responders by 112 mg/day (n=4), but there was a nonsignificant increase (5 mg/day, n=4) in nonresponders. In the nonresponders, the source of urinary calcium changed with increased input from the intestine (intestinal calcium absorption increased by dual stable isotope method) and decreased contribution from the bone (markers of bone resorption decreased). There was no change in markers of bone formation. We conclude that 1) severe AH is associated with impaired bone quality associated with low bone turnover and 2) treatment with **A** may lower urinary calcium and, by increasing intestinal calcium absorption while decreasing bone resorption, may improve calcium balance.

Balloon Kyphoplasty Is Effective in Deformity Correction of Osteoporotic Vertebral Compression Fractures. G. Voggenreiter*. Department of Trauma Surgery, University Hospital Mannheim, Ruprecht-Karls University of Heidelberg, Mannheim, Germany.

Introduction: Kyphoplasty (KP) is a minimally invasive treatment for osteoporotic vertebral compression fractures (VCFs) designed to address the fracture (Fx)-related pain and spinal deformity. Fx mobility has not been taken into account but it has to be considered when performing vertebral augmentation and when reporting and interpreting the significance of vertebral height restoration. The aim of this study was to determine the spontaneous reduction of deformity in prone position, the subsequent correction by the inflatable bone tamp (ITB), and the overall correction after deposition of the cement in VCFs.

Materials and Methods: 25 osteoporotic VCFs were treated in 20 patients (pt) by KP. Fractures (Fx) were classified according to Faciszewski et al. (JBJS 17:185, 2002). Radiographs were analyzed at six different time points. (1) Preoperative (preop) standing AP. During the KP procedure 4 consecutive radiographs were obtained (2) after placing the patient in prone, (3) after inflation of the ITB, (4) after deflation of the ITB, and (5) after deposition of the cement. (6) Standing AP radiographs were taken after the procedure (postop). All Fx were analyzed for improvement in sagittal alignment [Cobb angle; Kyphosis angle (Ka); anterior (Ha), medial (Hm), posterior vert. height (Hm)], complications and reduction of pain (VAS). Statistical analysis was performed by paired T-test and regression analysis.

Results: The morphology was wedge in 18 and crush in 7 Fx. Fx were acute in 17 and chronic in 3 pt. The mean duration of symptoms was 8.2 (range 1 to 24) weeks. Violation of the posterior vertebral cortex was present in 21 (84%) of VCFs with a mean narrowing of the medullary canal of 20 (range 0 to50)%. Placement of the pt in prone position displayed a significant spontaneous reduction in deformity with significant further reduction after inflation of the ITB (Table). After deflation and removal of the ITB and placement of cement no change occurred. Postop all parameters improved significantly compared to preop. Cement leaks occurred in 6 of 25 Fx. All pt subjectively reported immediate relief of their pain. The VAS-score significantly improved from 8.2 ± 2.0 preop to 2.1 ± 1.0.

Conclusion: The restoration of height in kyphoplasty is attributed to dynamic fracture mobility as well as to the expansion of the ITB.

Spinal deformity and vertebral body height during the kyphoplasty procedure

	preoperative	prone	Inflation of ITB	postoperative
Cobb angle	15.8 ± 7.9	9.6 ± 7.5	6.3 ± 7.4	10.3 ± 8.4
Ka	12.1 ± 5.5	8.0 ± 6.0	3.7 ± 5.0	4.8 ± 5.0
Ha	0.55 ± 0.22	0.67 ± 0.17	0.83 ± 0.15	0.79 ± 0.16
Hm	0.55 ± 0.18	0.65 ± 0.17	0.77 ± 0.15	0.76 ± 0.15
Hp	0.78 ± 0.13	0.85 ± 0.11	0.86 ± 0.10	0.86 ± 0.09

An Effective Treatment for Localized Transient Osteoporosis: Intravenous Ibandronate Injection. J. D. Ringe. University of Cologne, Leverkusen, Germany.

Localized transient osteoporosis (LTO; bone marrow edema) is a rare condition characterized by acute onset of disabling bone pain, which typically occurs at a single skeletal site, without prior trauma. Although its etiology is unknown, LTO has been linked to pregnancy and prolonged periods of exercise. Current treatment options are limited in number and provide inadequate efficacy. Ibandronate (Boniva®) is a potent, nitrogen-containing bisphosphonate that produces significant increases in bone mineral density (BMD),[1,2] significant decreases in bone turnover and, most importantly, significant reductions in vertebral fracture risk[2] when given as an intermittent intravenous (i.v.) injection. Patients were enrolled into a 6-month, open label, observational study to investigate the effect of i.v. ibandronate on LTO. BMD at the lumbar spine and hip was measured at baseline and thereafter, at 1, 2, 3 and 6 months. Pain was assessed at the same time intervals using a visual analogue scale (VAS; 1-10). Initial treatment consisted of a 4mg i.v. ibandronate administration. An optional 2mg i.v. ibandronate injection was administered after 3 months. All participants received daily calcium (1g) and vitamin D (800IU) supplementation. Five men and seven women who had a pain duration of 2-15 weeks and mean age of 45 years (range: 29-61) participated in the study. The most frequently affected skeletal site was the hip (7/12 patients). At study onset, patients were classified as having normal BMD (n=4), osteopenia (n=5) or osteoporosis (n=3). The mean lumbar spine BMD T-score at baseline was -1.64 (range: -2.83 to +0.10). Following 6 months of treatment, the mean VAS pain score decreased from 9.3 (at baseline) to 0.5. The robust effect on pain after the initial administration of ibandronate was rapid in most patients, as indicated by individual VAS pain scores. Relative to baseline, mean lumbar spine BMD increased by 4% (range: -0.8 to +7.7% in the overall population) after 6 months of treatment. In participants with LTO in the hip region, the mean difference in BMD between affected and unaffected areas decreased from 10.1% to just 2.6% within 6 months. Improvements in mobility and QoL were also observed. In summary, i.v. ibandronate was shown to be highly effective in reducing pain, restoring BMD and improving mobility and QoL in patients with LTO.

Skeletal Fluorosis and Instant Tea. M. P. Whyte[1], K. Essmyer*[2], F. H. Gannon[3], W. R. Reinus*[4]. [1]Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA, [2]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA, [3]Orthopedic Section, Armed Forces Institute of Pathology, Washington, DC, USA, [4]Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, MO, USA.

Skeletal fluorosis occurs in various regions of Asia where inferior quality "brick" tea is especially rich in fluoride. A middle-aged American woman with axial bone pain and osteosclerosis developed these features of skeletal fluorosis while reportedly drinking 1-2 gallons of double-strength instant tea each day throughout her adult life. Dual energy x-ray absorptiometry revealed bone density Z-scores of + 9.9 and + 1.7 in her lumber spine and hip, respectively. Urine fluoride levels were distinctly elevated, but corrected after she stopped consuming this beverage. Bone density, however, was unchanged 5 years later. No explanation for high bone mass other than fluorosis was disclosed. Ion-specific electrode studies of brand name instant teas, made regular strength in distilled water, showed substantial fluoride levels (up to 6.5 parts per million).

Bone densitometry is now commonly used to screen for low bone mass. We find that chronic ingestion of instant tea could account for skeletal fluorosis if prepared extra-strength or consumed in excess (e.g., hot climates) -- especially if made with fluoride-containing or contaminated water. Skeletal fluorosis from instant tea should be considered when dense, achy skeletons are encountered. Increasingly, antioxidant flavonoids and other components in tea are said to benefit health. We suggest that further understanding of the fluoride levels in different commercial preparations of instant tea is warranted.

Effects of Thyroid Status on TNF-alpha and Vascular Endothelial Growth Factor (VEGF) Production by Peripheral Blood Mononuclear Cells (PBMCs): Potential Involvement in Bone Remodelling. S. Subesinghe*[1], E. Meade*[1], S. E. M. Clarke*[2], H. K. Mohan*[2], Y. T. Mak*[1], G. Hampson[1]. [1]Chemical Pathology, St Thomas' Hospital, London, United Kingdom, [2]Nuclear Medicine, Guy's Hospital, London, United Kingdom.

Thyroid hormone (T_3) plays an important role in skeletal remodelling. T_3 promotes bone resorption by stimulating the production of pro-resorbing cytokines by osteoblasts, although the exact mechanisms are still unclear. Cytokine production by mononuclear cells has been implicated in bone turnover. The aim of the study was to assess whether changes in thyroid status are associated with changes in cytokine production by PBMCs. We studied 11 subjects aged (mean [SEM] years) 53.1 [5.2] with newly diagnosed hypothyroidism (Group 1), 6 patients aged 46.5 [5.1] with Graves' disease undergoing radio-iodine ablation (Group 2) and a control group of 11 euthyroid subjects. Thyroid function tests were measured at baseline and at 6, and 12 weeks following thyroxine replacement in Group1, at baseline and at 6 weeks in Group 2 and the control group. Serum CTX and VEGF was also measured. PBMCs were isolated at the same time points and cultured for 4 days. TNF-alpha and VEGF were assayed in the conditioned medium by ELISA to assess the constitutive production of these cytokines. Euthyroid status was restored in Groups 1 and 2 following treatment (Group 1 baseline Free T_4 9 [0.9] pmol/L, Free T_3 3.1 [0.3] pmol/L, TSH 71.8 [14.5] m U/L, 6 weeks : Free T_4 14.9 [0.9], Free T_3 4.2[0.1], TSH 18.4 [6.5], 12 weeks : Free T_4 13.6 [1.2], Free T_3 4.0 [0.2], TSH 20 [8.1]. Group 2 baseline : Free T_4 20.7 [4.3], Free T_3 7.7 [1.6], TSH 0.9 [0.3], 6 weeks : Free T_4 12.8 [1.9], Free T_3 4.1 [0.45], TSH 5.8 [3.5]). Serum CTX increased following thyroxine replacement in Group1 (baseline : 0.2175 [0.027] ng/ml, 6 weeks : 0.3342 [0.036] p = 0.01, 12 weeks : 0.3737 [0.017] p = 0.02) and decreased in Group 2 following treatment (baseline : 0.5902 [0.018], 6 weeks : 0.4473 [0.147] p = 0.07). Serum VEGF increased significantly at 12 weeks in Group 1 only (baseline : 394 [56.2] ng/L, 6 weeks : 429 [59], 12 weeks : 487 [77] p = 0.01). TNF-alpha and VEGF in the cell culture supernatant increased at 6 weeks in Group 1 (TNF-alpha/protein ratio baseline : 0.38 [0.05], 6 weeks : 1.01 [0.22] p = 0.04, 12 weeks : 0.35 [0.06], VEGF baseline : 14.8 [3.2], 6 weeks : 21.7 [3.5] p = 0.06, 12 weeks : 20.2 [9.2]). A reduction in TNF-alpha was seen in Group 2 (baseline : 8.4 [4.05], 6 weeks : 0.6 [0.12] p = 0.001). VEGF production increased in Group 2 (baseline : 6.5 [2.75], 6 weeks : 11.6 [2.32] p = 0.04). No significant change in TNF-alpha or VEGF production was observed in the control group. These data suggest that PBMCs may play a role, at least partly, in mediating the effects of thyroid hormone on bone remodelling.

Prevalence and Evaluation of Metabolic Bone Disease in Inflammatory Bowel Disease. B. Sinnott, A. Licata. Department of Endocrinology, Cleveland Clinic Foundation, Chicago, IL, USA.

The purpose of our study was to determine the prevalence and the degree of bone loss in IBD (Inflammatory Bowel Disease) patients, by evaluating bone mineral density and indices of bone and mineral metabolism in CD (Crohns Disease) and UC (Ulcerative Colitis) patients.

This was a retrospective study of data from patients seen at the metabolic bone clinic database at the Cleveland Clinic Foundation from 1995-2001. Our study consisted of 30 patients with CD and 18 patients with UC. Dual energy x-ray absorptometry was performed to determine Bone Mineral Density (BMD) at the lumbar spine and femoral neck. Serum calcium, phosphorus, parathyroid hormone (PTH), Vit D 25OH, Vitamin D1,25OH and urinary N-telopeptide cross linked collagen type 1 (NTX) levels were studied.

Based on WHO T score definitions of bone loss, in the IBD group as a whole, 46.8% had

osteopenia and 25.5% had osteoporosis at the lumbar spine; at the femoral neck, 54.4% had osteopenia and 30.4% had osteoporosis. CD patients had evidence of a higher prevalence of bone loss (combined osteopenia and osteoporosis values) at the hip and spine compared to UC patients. The prevalence of bone loss was greater at the femoral neck compared to the lumbar spine in both the CD and the UC groups. Secondary hyperparathyroidism, defined as a PTH level >55 pg/mL, was seen in one third of IBD patients. Fifty percent of our CD patients had secondary hyperparathyroidism, in contrast to 7% UC patients. IBD patients with secondary hyperparathyroidism had a more pronounced reduction in BMD at the femoral neck compared to patients with normal PTH levels. There was evidence of a negative correlation between PTH levels and femoral neck T scores (p = 0.06) and a positive correlation between PTH and lumbar spine Z scores, in the IBD group as a whole.

	UC	CD	
BONE MARKERS	Mean (SD)	Mean (SD)	P value
CALCIUM (mg/L)	9.5(0.8)	9.0(0.6)	0.042
NTX (nmol/mmol Cr)	30.7(12.4)	42.6(24.3)	0.057
PO4	3.7(0.9)	3.7(0.7)	0.88
PTH (pg/mL)	35.1(15.5)	57.7(27.1)	0.001
Vit D 25 OH (ng/mL)	30.0(18.7)	24.0(14.3)	0.36
Vit D 1,25 OH (pg/mL)	29.6(17.0)	52.4(20.4)	0.074

Metabolic bone disease is common in IBD. There is a higher prevalence of bone loss in CD patients compared to UC patients, with evidence of a higher prevalence of bone loss at the femoral neck compared to the lumbar spine in both groups. The mechanism of bone loss appears to be different in each disease entity. In contrast to UC, bone loss in CD appears to be mediated via Vitamin D deficiency and secondary hyperparathyroidism.

Disclosures: ***B. Sinnott****, None.*

High Skin Blood Flow of the Feet in Patients with Severe Peripheral Neuropathy Is Associated with Elevated Foot BMD. K. A. Witzke[1], A. I. Vinik*[2]. [1]Health, Physical Education, Exercise Science, Norfolk State University, Norfolk, VA, USA, [2]Strelitz Diabetes Institutes, Eastern Virginia Medical School, Norfolk, VA, USA.

Peripheral neuropathy (PN) is a complication in type 2 diabetes which causes a variety of sensory, motor, and autonomic deficits. Charcot neuroarthropathy is a severe manifestation of PN which leads midfoot collapse and deformity, and is thought to indicate low bone mass. Patients with impending Charcot present with painless inflammation of the foot which resolves with progression of the condition. Using a laser doppler system (Perimed Periflux 5000) to quantify skin blood flow, we have observed elevated skin blood flow in patients with impending Charcot, which we believe may be indicative of an attempt to heal microtrauma and microfractures. Using a novel DXA technique to measure foot BMD (Lunar DPX-IQ), we sought to examine the relationship between foot BMD and skin blood flow in patients with severe PN. A retrospective analysis of 52 foot bone scans (28 female feet, 24 male feet) and 38 skin blood flow curves from 30 different patients (age 66.5 y Â±10.5y) was conducted. Each foot was classified into one of three groups based on skin blood flow data (BF) or the physician's notes if BF was not available: established Charcot neuroarthropahy (C), no Charcot (N), and transitional (T), characterized by BF > 15,000 BF units and/or presence of a "hot foot". A Standard Least Squares linear regression model revealed a significant gender ($p<0.0001$) and group effect ($p<0.017$) on foot BMD ($r2 = 0.38$, $p< 0.0001$). Specifically, the transitional (T) group displayed significantly HIGHER foot BMD and BF than the other two groups, which were not significantly different from one another. It appears that the presence of severe peripheral neuropathy accompanied by high skin BF is not only indicative of impending Charcot neuroarthropathy, but also a transient increase in bone density. Although foot inflammation has previously thought to accompany an increase in osteoclastic resorption, it may actually indicate increased bone formation in an attempt to heal microtrauma. Prospective studies should clarify the role of blood flow in bone dynamics of Charcot development and the events which immediately follow.

BMD and Skin Blood Flow for C, N, T

		Foot BMD (g/cm2)	Skin Blood Flow (BF units)
Charcot (C) (n=8)	Male	.688+/-.050	5120+/-0
	Female	.560+/-.045	17798+/-0
Non-Charcot (N) (n=19)	Male	.692+/-.076	12343+/-348
	Female	.610+/-.053	10986+/-8624
Transitional (T) (n=25)	Male	.825+/-.078*	27706+/-951**
	Female	.646+/-.092*	23763+/-5215**

Osteopontin Mediated Regression of Ectopic Calcification. R. M. Rajachar*, E. Tung*, C. M. Giachelli*. Bioengineering, University of Washington, Seattle, WA, USA.

Ectopic calcification is the leading cause of failure in bioprosthetic heart valves. The purpose of this study was to quantitatively determine the details of an ectopic mineral regression mechanism in vascular tissues by attempting to create an *in vivo* calcification regression rescue model. Osteopontin (OPN) is thought to regulate mineralization by inhibiting apatite crystal growth and promoting osteoclast function. OPN is not found in normal arteries, but is abundant at sites of vascular calcification. In our lab we have been able to show that OPN acts as an inducible inhibitor of vascular calcification. We have also developed a subcutaneous mouse implantation model, in which we have been able to show significant increases in calcification of gluteraldehyde-fixed implants in OPN deficient mice (OPN-/-). More interestingly, OPN+/- mice showed early calcification of implants with subsequent regression that correlated with the accumulation of OPN. In these studies we have been able to show OPN mediated inhibition and regression of ectopic calcification, details of the mechanism however still need to be determined. Building on these previous experiments, we tested several candidate materials to use as an *in vivo* implantation substrate to measure resorption pitting, a physical marker of mineral resorption. We induced *in vitro* osteoclast formation and resorption with bone marrow derived macrophages stimulated with M-CSF and RankL, and were able to detect resorption pitting on polished bovine cortical bone, dentin and OPN-coated hydroxyapatite (HA) substrates using scanning electron microscopy (SEM). Of the three materials we achieved maximum osteoclast formation on polished bovine cortical bone, but more importantly we also detected osteoclast formation on OPN-coated HA discs. Using the pure mineral HA discs in our model, we may be able to quantitatively measure mineral regression by local verification of resorption pitting with SEM. We are currently testing OPN-coated HA discs as a substrate for our *in vivo* calcification regression rescue model.

Frequency of Sequestosome 1 (SQSTM1) Mutations in Hereditary and Sporadic Paget's Disease of Bone in the United States. E. C. Rhodes*[1], T. L. Johnson-Pais[2], J. Wisdom*[1], E. Lin*[3], H. G. Bone[4], F. R. Singer[3], R. J. Leach[1]. [1]Department of Cellular and Structural Biology, University of Texas Health Science Center, San Antonio, TX, USA, [2]Department of Pediatrics, University of Texas Health Science Center, San Antonio, TX, USA, [3]John Wayne Cancer Institute, St. John's Health Center, Santa Monica, CA, USA, [4]Michigan Bone and Mineral Clinic, Detroit, MI, USA.

Paget's disease of bone (PDB) is a metabolic bone disease characterized by excessive bone resorption and formation due to overactive osteoclasts. This disease is distinguished by focal areas of increased and disorganized bone turnover, resulting in bone pain and fractures. One to 3 million Americans have PDB, making it the second most common metabolic bone disease. Classic familial PDB is characterized by late onset, autosomal dominant segregation, genetic heterogeneity and incomplete penetrance. Seven genetic loci (PDB1-PDB7) have been reported for late onset PDB. However, PDB3 is the only locus where a gene, SQSTM1, has been identified. S*equestosome 1* (SQSTM1/p62) plays a key role in osteoclast differentiation through its involvement in the RANK signal transduction pathway and has been implicated in both sporadic and hereditary PDB. A total of 6 mutations have been reported in SQSTM1 and all affect the ubiquitin binding domain. Previous studies suggest that the SQSTM1 mutation, P392L, is responsible for 46% of familial and 16% sporadic PDB in French-Canadians and 19% of familial and 9% of sporadic PDB in patients of British origin.

The purpose of this study was to determine the mutation frequency of SQSTM1 amongst PDB patients in the United States. Blood samples were obtained from a total of 60 PDB patients, 33 sporadic, 21 hereditary and 5 familial. We have defined hereditary PDB patients as having a documented family history and familial patients as having a suspected but not documented family history. DNA was extracted from blood samples and PCR and sequencing was performed on exons 7 and 8 of SQSTM1. Mutations were found in 8/21 (38%) of hereditary patients, 0/5 (0%) of familial patients and 0/33 (0%) of sporadic patients. P392L mutations were found in four hereditary PDB patients representing both Caucasians and African Americans.

These preliminary findings suggest a role for SQSTM1 in hereditary PDB. Interestingly, our study finds no evidence that SQSTM1 is implicated in sporadic PDB in the United States. We are in the process of analyzing more blood samples from PDB patients the United States. The information we obtain will help determine the role of SQSTM1mutations in PDB in the United States population.

Pagets Disease in the Black Community in South East London. C. Moniz[1], R. Chandra*[1], B. Bowden*[2], T. Mangion*[1]. [1]Clinical Biochemistry, Kings College Hospital, London, United Kingdom, [2]Medical School, Guys Kings Thomas, London, United Kingdom.

Paget's cases described are predominantly in caucasians and epidemiological studies suggest a decrease in prevalence. Changing migratory patterns of communities and alternative diagnostic tests warrants a review. Using biochemical testing of requests from patients over age 50 yrs, seen in primary care for non-bone diseases, who had an isolated raised total alkaline phosphatase (ALP), in the presence of a normal liver function profile (AST, GGT) were further investigated for a possible metabolic bone disease. Those with a reported diagnosis of carcinoma, diabetes, osteomalacia or recent fracture, known causes of raised ALP, were excluded. Following consent by the general practitioner and patient to further investigate, a repeat blood test, bone scintigraphy and where appropriate X rays were performed prior to a clinical consultation. Over a period of 24 months, 152 cases were identified with an isolated raised ALP with a cut-off of >200 IU/L (ref range upto 120 IU/L). 88 had a explainable diagnosis and 64 cases were further investigated of which 52 (34%) had Paget's disease of bone confirmed by scintigraphy and appropriate X-Rays of affected sites. Of the remaining 12, two had unrecognised osteomalacia, 1 had primary hyperparathyroidism, 1 had unrecognised diabetes and 8 were unexplained. Of the Paget's cases 28 were female, mean age (yrs) was 76 (60-89) and 24 were male, mean age 79.8 yrs (range 67-89). The mean ALP female to male ratio was 265:291 IU/L and symptoms were in 91: 96% of cases. The commonest site affected in females were pelvis>skull>limbs> spine, whereas in males the pattern was different: pelvis> spine>limbs> skull. Ten of the 52 cases (19%) were Black, either of West Indian or West African origin, in a local community where the black to white ratio is 1:4 and the prevalence of the disease appears to be high in this ethnic minority group. Most of these patients had repeated blood tests in the past, but none had Paget's as a primary diagnosis and the findings were serendipitious. Pagets may not be decreasing in the community and reported low rates of diagnosis could be due to low thresholds for identification. Appropriate laboratory testing and recognition of findings has helped to diagnose a disease, which hitherto has gone unrecognised.

Severe Hypocalcemia in a Patient with Paget's Disease of Bone (PD) Treated with Bisphosphonate. H. E. Whitson*[1], B. Lobaugh[2], K. W. Lyles[2]. [1]Medicine, VA Medical Center, Durham, NC, USA, [2]Duke University Medical Center, Durham, NC, USA.

A 53yo African-American woman with polyostotic PD diagnosed twelve years earlier reported pain in her skull, right arm, and left hip. She had never received any treatment for her PD. Physical exam showed obesity, BMI of 46, enlarged skull with a warm, prominent area near the hairline, limited range of motion of her spine. PD was confirmed with bone scan and radiographs, and audiometry confirmed hearing loss. Laboratory studies: alkaline phosphatase 1899 U/L [30-135], calcium 9.3 mg/dL [8.7-10.2], PTH 14 pg/mL [12-72], creatinine 0.8 mg/dL [0.7-1.4], and 25(OH) vitamin D 13ng/mL [8-38]. She received vitamin D (100,000 IU daily) and serum 25(OH) vitamin D level rose to 19ng/mL. She was enrolled in a blinded, randomized, placebo-controlled trial of PD in which she was allocated to receive oral risedronate 30mg daily for two months.Ten days after enrollment, she developed altered mental status, slurred speech, and myoclonus. Serum calcium was 5.4 mg/dL with an ionized calcium of 0.63 mmol/L [1.12-1.32]. She was hospitalized in an ICU and received IV calcium and supportive care. She was discharged eight days later in good condition with normal serum calcium levels.

We hypothesize that hypocalcemia resulted from PTH suppression caused by longstanding PD associated with elevated bone remodeling. PTH suppression is suggested by the low PTH level (14 pg/mL) in the setting of a low 25(OH) vitamin D level (13 ng/mL), which should cause a higher PTH level. We believe that Risedronate blocked bone resorption, but osteoblast activity continued without sufficient parathyroid reserve to maintain normal serum calcium. The patient fully recovered, but she continued to suffer from symptomatic PD. She received s.c. calcitonin 50 units 5 days per week for 6 weeks (30 doses) then risedronate 5mg every other day for a month (16 doses), then 30mg every other day for two weeks (5 doses), then 30mg daily for 2 months (55 doses). Throughout this course, serum calcium levels were normal and most recent laboratory findings reveal calcium 9.3 mg/dL, ionized calcium 1.22 mmol/L, PTH 65 pg/mL, and alkaline phosphatase 599 U/L. She reports that her current pain level is 0/10 on most days and never higher than 3.5/10. Reports suggest that bisphosphonates may cause hypocalcemia in patients with PD and hypoparathyroidism, as well as in patients with vitamin D deficiency (*JBMR* Stuckey B 2001, *NEJM* Rosen C 2003). This case suggests that patients in states of high bone turnover from PD may be at risk due to suppressed parathyroid function resulting in relative hypoparathyroidism.

Mutations of *p62/Sequestosome1* Gene (*SQSTM1*) in an Italian Series of Patients Affected by Paget's Disease of Bone (PDB). A. Falchetti*[1], F. Marini*[1], F. Del Monte*[1], D. Strigoli*[1], A. Gozzini*[1], A. Tanini[1], L. Masi[1], M. Di Stefano*[2], G. Isaia*[2], G. B. Rini*[3], M. L. De Feo*[4], S. Maddali*[5], M. Matucci Cerinic*[1], M. Benucci*[6], G. Marin*[6], A. Matucci*[6], V. Ferioli*[7], F. M. Ulivieri*[7], S. Giannini[8], L. Sartori[8], V. Braga*[9], S. Adami[9], L. Di Matteo*[10], M. L. Brandi[1]. [1]Internal Medicine, University of Florence, Florence, Italy, [2]Internal Medicine, University of Turin, Turin, Italy, [3]Internal Medicine, University of Palermo, Palermo, Italy, [4]Azienda Ospedaliera Careggi, Florence, Florence, Italy, [5]Critical Care, University of Florence, Florence, Italy, [6]Rheumatology Unit, Asl 10, Florence, Florence, Italy, [7]Servizio Di Radiologia, Ospedale Maggiore Di Milano Ircss, Milan, Italy, [8]Medical and Surgical Sciences, Clinica Medica 1, University of Padua, Padua, Italy, [9]Rheumatology Unit, Valeggio S/M, University of Verona, Verona, Italy, [10]Division of Rheumatology, University of Pescara, Pescara, Italy.

PDB is a genetically heterogeneous disorder and mutations in p62/*SQSTM1* gene on chromosome 5q35-qter account for most of the sporadic and familial forms of PDB reported in literature. Exons 7 and 8, encoding the ubiquitin protein-binding domain, represent a mutational hot spot area. A study on French Canadian PDB patients identified the P392L mutation at exon 8 and the same mutation has been also reported, together with two different mutations, in 18 PDB families of British descendent: exon 8 P392L in 13 families (19.1%), exon 8 T insertion at position 396 in 4 families (5.8%) and a splice donor site mutation in intron 7 in 1 family (1.5%). Moreover, P392L mutation has been reported in 8.9% of the sporadic PDB cases. Recently, 3 novel mutations have been also reported in 4/5 PDB families from the United States:1210delT, 1215delC at exon 8 and a C to T transversion (P387L) at exon 7. We previously reported mutations of exon 7 and exon 8 of *SQSTM1* gene in 62 sporadic Italian PDB patients: P392L was found in only 1/62 PDB patients. Moreover, in 2 different patients we found two novel mutations, A>G and G>A transitions, at exon 8 both consisting of amino acid changes, respectively M404V and G425R substitutions. DNA analysis from 100 healthy control subjects failed to detect such mutations. Then, we extended the mutational analysis to other 132 PDB patients, reaching a total of 194 PDB subjects. We detected the following mutations: P386L at exon 7, P392L, S396A, M404V and G425R. Our findings, compared to those on predominantly British descent PDB patients, suggest an involvement of *p62/SQSTM1* gene of 7.2% vs. 8.9% in the pathogenesis of sporadic and familial Italian PBD cases, confirming the important role that *p62/SQSTM1* gene may play in conferring a genetic susceptibility to develop PDB.

Disclosures: ***A. Falchetti****, None.*

M519

Mutations of *p62/Sequestosome1* Gene (*p62/SQSTM1*) in 4 Italian Families Affected by Paget's Disease of Bone (PDB). A. Falchetti*[1], M. Di Stefano*[2], F. Marini*[1], F. Del Monte*[1], L. Masi[1], R. Imbriaco*[1], A. Tanini[1], N. Fossi*[1], S. Carbonell Sala*[1], L. Guazzini*[1], G. Leoncini*[1], G. Isaia[2], M. L. Brandi[1]. [1]Internal medicine, University of Florence, Florence, Italy, [2]Internal medicine, University of Turin, Turin, Italy.

We performed mutational analysis of *p62/SQSTM1* gene in 194 PDB Italian cases. Consequently, it has been possible to identify 4 Italian families affected by PDB (F1, F2, F3 and F4). Specifically, we analyzed 21 members from F1, originating from Central Italy, and we found 11 M404V mutant carriers, 5 of which with the clinical diagnosis of PDB; 10 members from F2, originating from Lucania (Southern Italy) and we found 6 G425R mutant carriers, 2 of which with the clinical diagnosis of PDB; 7 members from F3, originating from Northern Italy, where we found 6 insT;E396X mutant carriers, 3 of which with the clinical diagnosis of PDB; and 5 members from F4, originating from Lucania (Southern Italy), where we found 3 G425R mutant carriers, 1 of which with the clinical diagnosis of PDB. Interestingly, F2 and F4 families, exhibiting the same G425R mutation, originate from Lucania (Southern Italy), nearby Potenza, the capital town of this small region (total surface equals to 3,3% on the national territory, 9.992 squared Km), strongly suggesting the existence of a founder effect. Actually, only for the M404V mutation (F1) has been possible to hypothesize a genotype/phenotype correlation. Twelve subjects were potentially affected and all the 5 clinically ascertained PDB cases carried out the M404V mutation and exhibited the polyostotic form of PDB, but one patient with a X-rays assessed monostotic localization. Six unaffected subjects showed to bear the M404V mutation, representing asymptomatic gene carriers. The presence of these mutations at exons 7 and 8 of the *p62/SQSTM1* gene in sporadic and familial Italian PDB patients confirms the evidence of a clustered mutation area at this level in this disorder, supporting the role of the UBA domain in the biological properties of p62/SQSTM1 protein. Biochemical and clinical evaluation of the asymptomatic mutant carriers from the four families have been performing. *p62/SQSTM1* gene analysis is at the moment extended to other sporadic Italian cases and to first-degree relatives of patients in order to detect new genetic carriers in potentially familial forms of PDB and to study the co-segregation of such DNA variants with the PDB phenotype. All together these studies could open new possibilities in the prevention and therapy of PDB and of other metabolic bone disorders.

Absence of Evidence of Paget's Disease of Bone in Subjects who Harbor Sequestosome 1 Mutations. F. R. Singer[1], E. Lin*[1], D. S. B. Hoon*[2], T. L. Johnson-Pais*[3], R. J. Leach*[3]. [1]Skeletal Biology, John Wayne Cancer Institute, Santa Monica, CA, USA, [2]Molecular Oncology, John Wayne Cancer Institute, Santa Monica, CA, USA, [3]Department of Cellular and Structural Biology, University of Texas Health Science Center, San Antonio, TX, USA.

Familial Paget's disease of bone has been found to be associated with six unique mutations in the sequestosome1 (SQSTM1) gene in some families with Paget's disease. We have found this to be the case in 5 families of heterogeneous ethnic background. The mutations include P389L, P392L, 1210delT and 1215delC. However, we have observed that some of the family members who have the family-specific mutations do not have discernable Paget's disease. In each of the five families at least one individual was demonstrated to have a SQSTM1 mutation, no physical evidence of Paget's disease and no elevation of serum alkaline phosphatase activity (18 subjects). Nine of the subjects had a technetium-99m MDP bone scan and in no case was there evidence of abnormal uptake indicative of Paget's disease. The patients were up to 63 years of age with many ranging in age from 30 to 50 years. These observations suggest that SQSTM1 mutations in members of families with Paget's disease are not sufficient to cause Paget's disease, but that the mutations confer susceptibility to the disease. It is likely that environmental factors such as viral infections or additional somatic events may be important in the pathogenesis of the disease.

Alendronate in the Treatment of Low Bone Mass in Steroid-treated Boys with Duchenne Muscular Dystrophy. G. A. Hawker[1], R. Ridout[2], V. A. Harris*[3], C. C. Chase*[4], L. F. Fielding*[4], W. D. Biggar*[5]. [1]Osteoporosis Clinical Research Program, Women's College Campus of Sunnybrook & Women's College Health Sciences Centre, Toronto, ON, Canada, [2]Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [3]Bloorview Mac Millan Children's Centre, Toronto, ON, Canada, [4]Osteoporosis Clinical Research Program, Women's College Campus of Sunnybrook and Women's College Health Sciences Centre, Toronto, ON, Canada, [5]Paediatrics, Bloorview Mac Millan Children's Centre and The Hospital for Sick Children, Toronto, ON, Canada.

The objective of this study was to examine alendronate's side effect profile and affect on bone mineral density (BMD) in deflazacort-treated boys with Duchenne Muscular Dystrophy (DMD) and low BMD.

The study design was a before-after trial. Participants were recruited from the Neuromuscular Clinic at Bloorview MacMillan Children's Centre in Toronto, Canada between 1999 and 2000. The study included all consenting boys with DMD who had z-scores < -1.00 (spine and/or total body) and in whom BMD testing was feasible. Boys received 0.08 mg/kg/day alendronate orally with daily calcium 750 mg and vitamin D 1,000 I.U. BMD, height, weight, physical activity, Tanner stage, and adverse effects were followed for two years.The main outcome measure was BMD z-scores at the lumbar spine (L1 - L4) and total body.

Of the 42 eligible boys assessed, 23 had low BMD; for 16/23, future BMD testing was feasible. Mean age was 10.8 years (6.9 - 15.6 years). Mean baseline z-scores at the total body and spine were -0.80 and -1.94, respectively. At two years, mean z-scores were unchanged. Furthermore, alendronate response varied by baseline age. In multivariable analysis, improvement in total body and spine z-scores was associated with younger age at baseline (p=0.01 for both). Based on these results we concluded, in deflazacort-treated boys, alendronate had a positive effect on BMD z-scores; the effect was greatest when given early in the course of disease.

Functional Analysis of OPG Mutations That Cause Idiopathic Hyperphosphatsia; Relationship Between Genotype and Phenotype. C. A. Middleton-Hardie, H. R. Cundy*, I. R. Reid, J. Cornish, T. F. Cundy, D. Naot. Medicine, University of Auckland, Auckland, New Zealand.

Familial Idiopathic Hyperphosphatasia (FIH) is a rare, congenital bone disease characterised by increased bone turnover. There is considerable phenotypic variation: from presentation in infancy with severe progressive deformity, through to presentation in late childhood with minimal deformity. The link between mutations in OPG and FIH has recently been established by genetic studies. Eight of the ten mutations reported are restricted to single families. The aim of our study was to investigate any relationship between the mutant genotypes, OPG production and function and the corresponding patient's disease severity. The patients were grouped into mild, intermediate and severe phenotype according to clinical, biochemical and radiographic data**.**

We have produced constructs corresponding to 4 identified mutations in the cysteine-rich domain of OPG: OPGΔD182 has a deletion of an aspartate residue, OPGC65R and OPGC87Y have missense mutations resulting in substitution of cysteine residues, and OPGF117L has a missense mutation causing the substitution of a phenylalanine residue. When expressed in HEK293 cells, the constructs have similar levels of transcription, but different levels of OPG protein are secreted into the medium. While OPGF117L has comparable expression to wtOPG, OPGC65R and OPGC87Y have much lower yields, with OPGΔD182 having an intermediate yield. We are using confocal microscopy to follow the expression of wtOPG and the OPG mutants to ascertain if an increased level of intracellular degradation is responsible for the reduced yield of OPGΔD182, OPGC65R and OPGC87Y. For functional analysis of the mutant proteins we are utilising the surface plasmon resonance technology of BIAcore, to investigating the RANKL-binding ability of all the OPGmutants. Also, as we have previously shown OPGΔD182 has reduced activity in the murine bone marrow osteoclastogenesis assay, we are investigating the ability of the OPG mutants to inhibit osteoclast formation.

Our investigations show that missense mutations in cysteine residues, predicted to cause major disruption to the structure of OPG, significantly lower the levels of OPG secretion from the cell. These mutations were associated with a severe FIH phenotype.

M523

Uncoupling of Bone Formation and Resorption Following a Thermal Injury. J. Shea, S. Miller. Radiobiology, University of Utah, Salt Lake City, UT, USA.

Severe burns result in long-term growth retardation in children and osteopenia among children and adults. The development of osteopenia is accompanied by profound disturbances in calcium metabolism including: hypocalcemia, hyper and hypoparathyroidism, and low vitamin D levels. The first goal of the current study was to determine if there were alterations to bone formation, bone resorption, and serum parathyroid hormone (PTH) levels 3, 5, and 7 days post burn. The second goal was to examine the progression of the skeletal changes in the burn group during the same time frame.

Adults male Balb/c mice at 3 months of age were divided into time control, sham-burned, and burned groups with 8 animals per group. The time controls were included on days 3 and 7. A 20% total body surface area burn was applied following a previously published protocol. Calcein, was given to all groups a day before the thermal injury and tetracycline was given one day prior to necropsy. The left proximal tibia was embedded in methylmethacrylate and utilized for dynamic histomorphometric analysis. The serum was also taken for subsequent PTH analysis (Immutopics Inc., San Clemente, Ca). Statistics were done using an ANOVA followed by a Tukey HSD post hoc test for days 3 and 7 and a t-test for day 5.

There were no differences between the time control, sham-burned, and burned groups on day 3 at the proximal tibia in measures of percent double label (p=0.49), mineral apposition rate (p=0.74), bone formation rate (p=0.59), or percent eroded surface (p=0.42). On both days 5 and 7 the burn group had reduced measures of percent double label (p=0.0005, p<0.0001 respectively) and bone formation rate (p=0.002, p=0004) and increased percent eroded surface (p=0.01, p=0.003) compared with the time control and sham-burned groups. PTH was significantly elevated in the burn groups on days 3, 5, and 7 compared with the time controls and sham-burned groups (p<0.0001, p=0.04, p=0.0002). Comparisons of the burn groups revealed that Day 5 and 7 were less than day 3 for measures of percent double label (p=0.0005) and bone formation rates (p<0.0001) and higher for percent eroded surface (p=0.01). PTH levels were not different in the burn groups on days 3,5, or 7 (p=0.73).

The current study suggests that the uncoupling of bone formation and resorption occur in less than a week in the cancellous bone of the proximal tibia in a thermal injury mouse model. These skeletal changes were preceded by an increase in PTH. The increase in PTH along with the uncoupling of bone remodeling might be a response to disturbances in calcium regulation, perhaps due in part to the reported disregulation of the calcium receptor.

Disclosures: ***J. Shea****, None.*

Serum Osteoprotegerin (OPG) and Receptor Activator of Nuclear Factor κB Ligand (RANKL) in Healthy United States Children and in Children with Cystic Fibrosis. H. E. Price*, C. B. Langman, A. Arwady*, S. McColley*, K. Lyons*. Department of Pediatrics, Feinberg Medical School, Northwestern University, Chicago, IL, USA.

The morphogenesis and remodeling of bone requires the synthesis and ossification of bone matrix by osteoblasts and its coordinated resorption by osteoclasts. Osteoprotegerin (OPG), as an inhibitor of the differentiation and activation of osteoclasts is balanced by RANKL, which promotes active osteoclast resorption and embryogenesis. Abnormalities in the balance of RANKL/OPG system may lead to disturbances of bone that underlie osteoporosis, Paget's disease, bone loss in metastatic cancers, and rheumatoid arthritis. The purpose of this study was to measure serum OPG and RANKL in healthy US children to establish a normal range, and then compare the established normal range to children with cystic fibrosis (CF), a disease in which bone density is reduced. OPG and RANKL were measured in the serum of 80 healthy children (37 males, 43 females). The age range was 1-17 years (X=10.3 y), and self-reported Tanner stages ranged from 1 to 5. Seven children were African-American, three were Asian; the remainder were Caucasian. Levels of OPG and RANKL were determined using an enzyme immunoassay (ALPCO Diagnostics, Windham, NH). The assays were performed in duplicate and results are reported in pg/mL. To determine a normal reference range in children, the mean and standard deviation of measured OPG and RANKL values were calculated ($X \pm \sigma$ = 69.1 ± 20.3 and 7.5 ± 8.4 pg/mL, respectively). The normal range was assigned as the mean ± 2SD, resulting in normal ranges for OPG and RANKL = 25.8-109.7 and 0-24 pg/mL, respectively. There were no differences in healthy children of either OPG or RANKL based on ethnicity or pubertal status within a narrow age range. However, there was an inverse relationship between measured OPG and chronological age. Serum OPG and RANKL were measured in 20 children with CF (8 males, 12 females), age range 6-14 years (X=8.6 y), all Tanner stage 1, and whose mean DXA lumbar BMD Z-score was -0.22. There were increases in RANKL (X=17.5 pg/mL, p<0.01), and decreases in OPG (X=56.3 pg/mL, p<0.01) when compared to healthy children. As a result, the RANKL/OPG ratio was elevated. In conclusion, we established a normal value set for OPG and RANKL in the blood of US children, and have applied it to understand better the mechanisms of bone disease in children with CF. These data support our hypothesis that inappropriate osteoclast activation occurs in children with cystic fibrosis, leading, in part, to diminished bone mass. We will evaluate the blood OPG/RANKL ratio in the therapeutic response to recombinant human growth hormone and/or anti-resorptive therapies in the care of the bone disease in such children.

Skeletal Assessment In Duchenne Muscular Dystrophy Using New DXA Pediatric Tools. J. D. Landoll*[1], H. S. Barden*[2], W. King*[3], J. T. Kissel*[3], K. G. Faulkner*[2], V. Matkovic[1]. [1]Bone and Mineral Metabolism Laboratory, The Ohio State University, Columbus, OH, USA, [2]GE Healthcare, Madison, WI, USA, [3]Department of Neurology, The Ohio State University, Columbus, OH, USA.

Dual-energy x-ray absorptiometry (DXA) provides rapid, low dose assessment of total body bone in children, but the areal measurement of bone mineral density (BMD, g/cm^2) is influenced by body size. Recently, GE Healthcare introduced software with pediatric body-size ratios (height for age, bone area for height, and bone mineral content (BMC) for bone area) for assessing bone status in children with developmental disabilities.

We assessed bone status using DXA (Lunar Prodigy) in 22 male children age 6 to 17 y (mean 11.5 y) with Duchenne Muscular Dystrophy (DMD). Children were evaluated for BMD, height for age, BMC for bone area, and bone area for height Height-for-age Z-scores were calculated using USA Center for Disease Control data. BMC-for-area and area-for-height Z-scores were calculated from normal male children in the Lunar pediatric database with SEEs that varied with age.

Subjects with DMD had a substantial deficit in BMD (Z= -1.3), but were normal for BMC for bone area (Z= 0.04). The BMD deficit appeared to result from short stature (height-for-age Z = -1.2) and small (narrow) bone area for height (Z= -2.8). Both BMD and height-for-age Z-scores decreased with subject age, mirroring the progressive nature of this disease.

The head region contribution to total body BMC in normal subjects decreased from 45% at age 5 to 15% at age 19 years. Z-scores for total body BMC for area with and without the head were 0.0 and -1.6, respectively (p<0.001). Z-scores for BMD for age with and without the head were -1.3 and -2.2, respectively (p<0.001). Head BMC for area and BMD for age were positive, Z = 0.5 and 0.3, respectively.

Adjustments for body size provide a more complete representation of bone status than BMD alone in children with developmental abnormalities. Exclusion of the head region may enhance the ability of the BMC-for-area ratio to detect deficits at total body and regional sites. Total body BMD and BMC-for-area Z-scores including the head were significantly higher than Z-scores excluding the head. DMD boys had negative Z-scores for total body and regional BMD, as well as for BMC-for-area Z-scores for arms, legs and, trunk, but not the head.

Total body and regional Z-scores for boys with DMD

	BMC for Area	BMD for Age	Bone Area for Height	Height for Age
Total Body with Head	0.0	-1.3	-2.8	-1.2
Total Body without Head	-1.6*	-2.2*		
Arms	-0.4	-1.7		
Legs	-0.6	-2.6		
Trunk	-2.1	-1.8		

* With and without head difference significant at p<0.001

Vitamin D Insufficiency Is Common Among Pediatric Subjects Participating in an Osteoporosis Treatment Trial: A Glaser Pediatric Research Network Study. E. von Scheven*[1], C. M. Gordon*[2], K. Gallagher*[3], M. Wertz*[1], L. Bachrach[4]. [1]Pediatrics, UCSF, San Francisco, CA, USA, [2]Pediatrics, Harvard, Boston, MA, USA, [3]Pediatrics, UCLA, Los Angeles, CA, USA, [4]Pediatrics, Stanford, Stanford, CA, USA.

Background: We screened subjects with inflammatory disorders for a double-blind placebo-controlled trial of alendronate at four US University Hospitals. Eligibility included baseline vitamin D (25OHD) levels > 20 ng/mL.

Objective: To determine the prevalence of 25OHD deficiency and hyperparathyroidism in pediatric patients at risk for osteoporosis secondary to inflammatory disease and glucocorticoid therapy.

Methods. Sixty-one patients (69 % female, 34% Caucasian, 25% Hispanic, 21% Asian, 8% African-American and 12 % mixed), age 13.7 ±3.5 yrs, with inflammatory disease (30% lupus, 28% dermatomyositis, 13% Crohn's, 11% vasculitis, 7% systemic JRA, 2% mixed connective tissue disease) were consented and screened. Inflammatory disease duration was 0.7 - 12 yrs (mean 4.3). Medications included biologic agents (41%), cyclophosphamide (18%), Cellcept (13%), Imuran (7%), and Azacol, Azulphidine, 6MP, Thalidamide, and MTX or Arava (each 5%). Forty-eight (77%) of subjects were taking systemic steroids (mean prednisone dose 0.22 mg/kg/d [SD 0.24]) at screening. Only 25 % of subjects were taking vitamin D supplements (mean dose for those taking was 445 IU/d ±122). Vitamin D level (competitive protein binding radioassay) and intact PTH concentration (immunochemiluminometry) were determined at a commercial laboratory.

Results. Serum 25OHD levels ranged from 0-38 ng/mL (mean 20.7) and were <20 ng/mL in 46% of subjects. PTH concentration ranged from 0-70 pg/mL (mean 33.0). Increased 25OHD levels were associated with younger age (beta -1.0, p= 0.001), vitamin D supplements (beta 0.01, p=0.009) and lower PTH (beta -0.49, p=0.03). 25OHD levels did not correlate with underlying diagnosis, ethnicity, disease duration, or current prednisone dose. Twelve subjects diagnosed with vitamin D insufficiency were supplemented with varying vitamin D regimens (2,000 IU po QD (6 subjects), 50,000 IU po Q week (4 patients) and 100,000 IU IM per dose (5 patients)). This resulted in 7 of 12 subjects achieving a 25OHD level >20 ng/mL after 1-14 months.

Conclusion. Vitamin D deficiency was observed in nearly half of these subjects receiving glucocorticoids for childhood inflammatory diseases. Furthermore, 25OHD levels were inversely associated with PTH concentrations, suggesting compensatory hyperparathyroidism. These data suggest a need to monitor for vitamin D deficiency in this clinical setting and to establish the optimal regimen for vitamin D supplementation.

Predicting Low Bone Mineral Density in Childhood Inflammatory Diseases: Experience from a Glaser Pediatric Research Network Alendronate Trial. E. von Scheven*[1], C. M. Gordon*[2], K. Gallagher*[3], M. Wertz*[1], L. Bachrach[4]. [1]Pediatrics, UCSF, San Francisco, CA, USA, [2]Pediatrics, Harvard, Boston, MA, USA, [3]Pediatrics, UCLA, Los Angeles, CA, USA, [4]Pediatrics, Stanford, Stanford, CA, USA.

Background Subjects with inflammatory disorders were screened for low bone mineral density (BMD) in a controlled trial of alendronate at 4 University Hospitals. Steroid exposure inclusion criteria were employed to enhance recruitment of low BMD subjects.

Objective To determine frequency and correlates of low BMD in pediatric subjects receiving glucocorticoids for inflammatory diseases screened for an osteoporosis treatment trial.

Methods Sixty-one patients (69 % female, 34% Caucasian, 25% Hispanic, 21% Asian, 8% African-American and 12 % mixed), mean age 13.7 ±3.5 yrs, with inflammatory disorders (30% lupus, 28% dermatomyositis, 13% Crohn's disease, 11% vasculitis, 7% Systemic JRA, 2% mixed connective tissue disease) were consented and screened. The underlying inflammatory disease duration ranged from 0.7 - 12 yrs (mean 4.3). Medications included biologic agents (41%), cyclophosphamide (18%), cellcept (13%), imuran (7%), and azacol, azulphidine, 6MP, thalidamide, and MTX or arava (each 5%). 77% of subjects took systemic steroids (mean dose 0.22 mg/kg/d [SD 0.24]). Age-adjusted lumbar spine BMD Z-scores (BMD Z-score) were determined by DXA (Hologic 4500, Hologic Research Upgrade software).

Results 33% of screened subjects were eligible for randomization. BMD Z-scores ranged from -3.2 to 2.2 SD (mean -1.3) and only 41% met the diminished BMD inclusion criteria (BMD Z-Score <-1.5 SD). 46% of subjects failed to meet the vitamin D (25OHD) inclusion criteria of > 20 ng/mL. A multivariate linear regression model for predicting low BMD Z-score included diagnosis, age at diagnosis, disease duration, gender, ethnicity, prior year average prednisone dose (mg/m^2/d), family history of osteoporosis, 25OHD level, and intact PTH concentration. It revealed a protective effect for African American's (beta 1.9, p=0.003) and increased risk for prednisone exposure (beta -0.025, p=0.046). However, this model explained only a small portion of the Z-score variance (adj R^2= 13).

Conclusion Less than half the patients treated with Glucocorticoids for inflammatory disorders were eligible for this trial due to unexpected vitamin D insufficiency and BMD Z-scores above -1.5. The weak association between BMD Z-score and risk factors suggests unmeasured factors, a highly multifactorial process, or unanticipated resilience of the pediatric skeleton. Furthermore, these data suggest that osteoporosis risk assessment is difficult in young patients and prophylactic bisphosphonate therapy should be approached cautiously.

A Longitudinal Study of Tibial Speed of Sound and Lower Limb Length in Preterm Infants: Relationship with Biochemical Markers of Bone Turnover. J. May*[1], J. Dutton*[2], J. Morris*[3], W. D. Fraser[2], A. J. B. Emmerson*[1], M. Z. Mughal[4]. [1]Neonatal Medicine, St Mary's Hospital for Women & Children, Manchester, United Kingdom, [2]Clinical Biochemistry, Royal Liverpool Hospital, Liverpool, United Kingdom, [3]Medical Statistics, University of Manchester, Manchester, United Kingdom, [4]Paediatric Medicine, St Mary's Hospital for Women & Children, Manchester, United Kingdom.

In healthy singleton infants between 31 to 42 weeks gestation, we showed that the tibial speed of sound (SOS; m/s) measured at median age of 2.1 days after birth increased with gestational age (*Yiallourides et al. Biol Neonate. 2004;85(4):225-228.*). The tibial SOS is known to be influenced by cortical thickness and bone mineral density (*Prevrhal et al. Osteoporos Int 2001;12 (1):28-34*).

In this longitudinal study we measured the tibial SOS using the Sunlight Omnisense quantitative ultrasound device (Sunlight Medical Ltd., Israel) and the knee-heel limb length (mm) using an electronic neonatal knemometer (FORCE Institutes, Denmark), in the same limb, in 58 preterm infants. The median (range) gestation and birth weight of infants was 26.4 weeks (23 to 34.4 weeks) and 928 grams (506 to 1499 grams), respectively. The measurements were performed weekly; median period of 4 weeks (2 to 14 weeks). As shown in figure 1, there was a significant decrease (within-subject correlation, r = -0.15; p=0.011) in tibial SOS with postnatal age. In contrast, as shown in figure 2, the lower limb length increased significantly (r = +0.96; p<0.001) with postnatal age.

In a subgroup of 24 infants, changes in serum concentration of bone specific alkaline phosphatase (BSALP; a marker of bone formation) and urinary excretion of urinary deoxypyridinoline (DPD; a non-reducible cross link of collagen that is a marker of bone resorption) were measured on the same day and around the same time as tibial SOS and lower limb length measurements. The serum concentration of BSALP (r = +0.44; p=0.001) and urinary DPD/creatinine (r = +0.24; p=0.033) increased with postnatal age.

The observed increase in lower limb length during the early neonatal period is consistent with a rapid tibial growth, whereas the decrease in tibial SOS during this period might either be due to a lag in tibial cortical mineralization or cortical thinning. Preliminary results also suggest that bone turnover increases progressively during the early neonatal period.

Bone Histomorphometry in Children with Suspected Secondary and Idiopathic Juvenile Osteoporosis. E. Sochett[1], O. Mäkitie*[2], A. Doria*[3], M. G. Mendes*[4], K. Pritzker*[5]. [1]Pediatric Endocrinology, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [2]Pediatric Endocrinology, The Hospital for Children and Adolescents, Helsinki University Hospital, Helsinki, Finland, [3]Radiology, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [4]Pathology, Mount Sinai Hospital,, University of Toronto, Toronto, ON, Canada, [5]Pathology and Laboratory Medicine, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada.

The Bone health clinic at the Hospital for Sick Children, Toronto is evaluating an increasing number of patients with severe chronic illnesses for osteoporosis. In many this appears likely given the chronic nature of the illness and the prolonged use of medications, such as high dose glucocorticoids. In addition an increasing number of patients with symptomatic Idiopathic juvenile osteoporosis (IJO) are being referred for bisphosphonate therapy. Areal bone mineral density (aBMD), the most commonly used investigative tool in adults, is limited in children because of the confounding effects of short stature and delayed puberty, common characteristics of chronically ill children. Ancillary tests such as bone turnover markers and spinal X-rays often suggest but are not diagnostic of osteoporosis.

To address these developments, we now undertake transcortical iliac crest biopsies before bisphosphonate therapy, in those with a high probability of osteoporosis and report here bone histomorphometry, aBMD, and spinal X-ray results in 7 patients.

Mean age was 14.2 years (range 10.0-16.6 yrs). Underlying medical conditions included rheumatological diseases (3), cerebral palsy (1) and leukemia (1); two patients had IJO. Mean aBMD z-score was -3.1 (range -1.6 - -4.8). Moderate to severe spinal compression fractures were documented in 6/7 patients. Serum calcium, phosphate, 25-OH-Vit D and PTH were normal in all subjects. Table 1 details the key static structural, formation and resorption bone morphometric findings.

Iliac crest bone histomorphometric parameters confirm the clinical assessment of osteoporosis in approximately 40% of this group and suggest an adynamic form of the disease. Overall resorption appears to be consistently suppressed with variable decrease in formation. Further studies will be required to fully characterize the various forms of osteoporosis in childhood.

Bone histomorphometric findings in 7 children with osteoporosis. N, normal; L, low; I, increased

Patient	Trabecular Bone Volume (%)	Osteoid Volume (%)	Mean Mineralized Trabecular width (ug)	Eroded Trabecular Surface (%)

The Novel Bone Alkaline Phosphatase Isoform B1x and Bio-Intact (1-84) Parathyroid Hormone in Children with Renal Failure. P. Magnusson[1], S. Hansson*[2], L. Larsson[1], D. Swolin-Eide[2]. [1]Division of Clinical Chemistry, Faculty of Health Sciences, Linköping, Sweden, [2]Department of Pediatrics, Queen Silvia Children's Hospital, Göteborg, Sweden.

Children with renal failure are at high risk developing metabolic bone disease with long-term consequences as growth retardation and low peak bone mass. This study focused on novel markers of bone and mineral metabolism in pediatric patients since these markers are of potential value for diagnosis and monitoring of renal osteodystrophy. The study group was comprised of 31 patients, 3 - 20 years of age, with different kidney diseases of which 18 patients had acquired and 13 congenital disease. We measured parathyroid hormone (PTH), bio-intact (whole 1-84) PTH, and osteoprotegerin (OPG), and bone formation by serum type I procollagen intact amino-terminal propeptide (PINP), osteocalcin, total alkaline phosphatase (ALP), and four bone ALP (BALP) isoforms B/I, B1x, B1, and B2. Bone resorption was assessed using serum CrossLaps (CTX), derived from the carboxy-terminal telopeptide of type I collagen, and tartrate-resistant acid phosphatase isoform 5b (TRACP5b). There was a significant correlation between PTH and bio-intact PTH, r = 0.83, with 19 (61%) and 20 (65%) patients above the reference interval, respectively. However, we observed, on average, 50% higher levels of PTH vs. bio-intact PTH demonstrating non-(1-84) PTH fragments detected by the PTH assay. Increased activities were found in five, three, and four patients for total ALP, B1, and B2, respectively. However, 17 (55%) patients had increased B/I levels of which 13 had a glomerular filtration rate (GFR) <70 ml/min/1.73 m^2. The BALP isoform B1x was identified in two (6%) patients. B1x has previously only been detected in (60%) adults with chronic renal failure on dialysis but not in healthy individuals or in other bone diseases. The two children with B1x had OPG levels in the higher range independently of age, GFR, and bio-intact PTH. One boy, 9 years, with identified B1x was monitored during one year of growth hormone (GH) treatment. B1x was identified prior to and after 9 days of GH therapy, however, not after 1, 3, 6, and 12 months. In conclusion, our study demonstrate that: 1) The BALP isoform B1x is expressed in children with renal failure (and not only in adults) and should be further evaluated as a marker of adynamic renal bone disease; 2) There are selective differences between the BALP isoforms in children with renal failure; 3) The BALP isoforms, PINP and TRACP5b are useful markers of bone turnover in renal bone disease since their clearance is independent of renal function; and 4) Children with renal failure have increased levels of circulating non-(1-84) PTH fragments.

Assessing Fracture Risk in Patients with Renal Failure. S. A. Jamal[1], P. MacFarlane*[1], D. Pearce*[2], S. V. Jassal*[3]. [1]Medicine, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada, [2]Diagnostic Imaging, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada, [3]Medicine, The University Health Network, University of Toronto, Toronto, ON, Canada.

Men and women with dialysis dependent renal failure have a high prevalence of fractures. To assess if bone mineral density (BMD) measurements and/or tests of muscle strength were associated with fractures we studied 37 men and 15 women, 50 years and older, who had been on hemodialysis for at least one year. We excluded patients with prior renal transplants and women taking hormone replacement therapy. We inquired about risk factors for fractures and low trauma fractures since starting dialysis. A chart review gave the most recent laboratory tests. Subjects underwent BMD testing at the lumbar spine and total hip with a Lunar DPX-L densitometer. Tests of muscle strength included: timed up and go (TUG), six minute walk, functional reach, and grip strength. We obtained radiographs of the thoracic and lumbar spine and identified prevalent fractures by morphometry. We used logistic regression to examine the relationships between fracture (prevalent vertebral, self-reported low trauma and/or both) and BMD, and fracture and muscle strength tests. Results are adjusted for age and weight and reported as Odds Ratios (OR) per standard deviation increase in the dependent variable. The mean age of subjects in our study was 65.9 ± 8.9 years, the mean weight was 72.8 ± 15.2 kg, and most (35 of 52 subjects) were Caucasian. The average duration of dialysis was 3.9 ± 2.5 years. The most common cause of renal failure was diabetes (17 subjects). The mean levels of calcium, phosphate, and alkaline phosphatase were normal. The mean level of PTH was 42.1 ± 41.8 pmol/L. There were no differences by gender or between subjects with and without fractures. Of the 52 subjects, 12 had prevalent vertebral fractures, 20 reported a low trauma fracture since starting dialysis, and 27 subjects had either a vertebral fracture or low trauma fracture. Just under half of the subjects (24) reported having at least one fall in the past year. Mean lumbar spine BMD was 1.1 ± 0.2 g/cm^2 and total hip BMD was 0.8 ± 0.2 g/cm^2. Mean grip strength was 21.5 ± 9.3 kg, mean TUG was 19.7 ± 25.9 seconds, mean functional reach was 17.3 ± 10.9 cm, and mean six minute walk 108.8 ± 58.1 meters. There was no association between fractures, falls in the past year, hip BMD, spine BMD, or grip strength. Fractures were associated with the six minute walk (OR = 0.1; p = 0.001), functional reach (OR = 0.3; p =0.005), and TUG (OR = 6.9; p = 0.004). Adjusting for spine or hip BMD did not change our results. Simple, inexpensive tests of muscle strength may identify subjects with renal failure at increased risk for fractures.

Nutritional Assessment in Renal Osteodystrophy Patients Submitted to Parthyroidectomy. B. S. E. Peters*[1], V. Jorgetti[2], R. M. A. Moyses*[2], L. A. Martini[1]. [1]Nutrition, Sao Paulo University, Sao Paulo, Brazil, [2]Medicine, Sao Paulo University, Sao Paulo, Brazil.

Its recognized that undernutrtion is frequent in patients with renal osteodysthrophy with elevated parathyroid hormone (iPTH). The elevated iPTH induce nutritional abnormalities in these patients, such as loss of appetite, abnormal food taste, protein catabolism and weight loss. These complications could be relived by parathyroidectomy (PTX). This study was undertaken in order to evaluate the nutritional status of Chronic Renal Failure patients (CRF) with Renal Osteodystrophy six months after parathyroidectomy. The study was carried out in a renal osteodystrophy outpatient clinic from the São Paulo University. Fifteen patients, mean age 42 ± 11 years old, participated in the study. All of them completed a 3 days dietary records (energy, protein calcium and phosphorus), anthropometric measurements (body mass index - BMI, skinfold thickeness, midarm muscle circunference and body fat), and biochemical indices (serum calcium and phosphorus, total protein and albumin, alkaline phosphatase, and iPTH), before and six months after the PTX. The results are presents as mean ± SD. The iPTH was negatively correlated with weight and fat mass (r= -0.53 and r= -0.55 respectively; p<0.05) before the PTX. The mean energy, carbohydrate, protein, lipid and phosphorus intake, increased after the surgery with no statistical significance. Only the calcium intake significantly increased after PTX (397 ± 189 mg to 676 ± 401 mg, p<0.05). There are no significant differences in body composition, six months after the PTX. However, the biochemical indices of nutritional status, serum total protein (g/dl) and albumin (g/dl) increased significantly (6.9 ± 0.9 to 7.6 ± 0.6 g/dl and 3.8 ± 0.4 to 4.2 ± 0.6 g/dl p<0.05, respectively). As expected, the serum total calcium (mg/dl), phosphurus (mg/dl), alkaline phosphatase (U/l), iPTH (pg/ml) significantly decreased after PTX (9.5 ± 1.2 to 8.4 ± 1.2 mg/dl; 6.5 ± 1.8 to 4.5 ± 1.4 mg/dl; 689.9 ± 789.0 to 155.4 ± 108.6 U/l; 1516.14 ± 841.7 to 449.8 ± 753.7 pg/ml, p<0.05 respectively). In conclusion, the present study confirm the evidence that high iPTH levels have deleterious effects on the nutritional status of CRF patients, and based on biochemical indices of nutritional status, the PTX could have beneficial effects on nutritional status.

Long Term Bone Health In Male Renal Transplant Patients. A. H. Khan*[1], N. Bhargava*[1], R. Chandra*[1], P. Kon*[2], C. Moniz[1]. [1]Clinical Biochemistry, Kings College Hospital, London, United Kingdom, [2]Renal Unit, Kings College Hospital, London, United Kingdom.

Metabolic bone disease is a recognised complication following renal transplantation, but whether this persists several years after transplantation was investigated. We studied consecutively 43 male patients with renal transplantation, on average 13 yrs post transplantation (range 2- 38 yrs). A fracture risk assessment including risk questionnaires, second void urine samples for bone turnover markers and morning serum samples and BMD of the lumbar spine and femoral neck was undertaken. The mean age of patients was 49 years (range 25-75). All were on steroids with a mean daily cumulative dose of 6.8 mg, although individuals' doses varied from year to year. At the lumbar spine, osteopenia and osteoporosis seen in 9 (21%) and 7 (16%) cases with a mean T score BMD of -1.57 and -3.18 respectively. At the femoral neck, osteopenia was present in 13 cases (30%) with a mean T score -1.65 and osteoporosis in 7 cases (16%) with mean T score of -2.96, 12 cases 28% reported low trauma fracture. Mean BMDs with pre-existing fractures were T score spine -1.67 and femur -1.96. Gonadal status was within normal limits (mean testosterone 14.2 nmol/L; reference range 10-30). Serum adjusted calcium homeostasis was within normal limits, with secondary hyperparathyroidism (mean PTH 135 pmol/L (14-1670), and vitamin D, mean 19.9 ug/L (range 7-38). Mean Urine deoxypyridinoline (DPD) was 6.2 nmol/mmol creatinine (range 2.2-13.8; reference range 7.8-9.4). 79% of cases had low DPD (mean 4.8 nmol/mmol creatinine) and only three cases had DPD above the reference range. This study shows that fractures occur at a higher BMD and long-term fracture risk persist in male post renal transplant patients. Our data also demonstrates low DPD despite hyperparathyroidism indicating low bone turnover persists which might restrict the use of antiresorptive agents in the treatment and prevention of osteoporosis

Bone Quality and Fractures or Osteonecrosis in Renal Transplant Recipients. S. M. Ott, S. Kuehner*, D. J. Sherrard. University of Washington, Seattle, WA, USA.

Recipients of solid organ transplants suffer a high incidence of skeletal complications. These are not consistently predicted by bone density measurements, which suggests that other aspects of bone quality contribute to bone strength. One such factor could be the mineralization density (MinDen) of the bone, which reflects how tightly mineral crystals are packed into the bone matrix. We examined bone biopsies from a prospective study of 34 hemodialysis patients who underwent living-related kidney transplantation from 1985-89. Mean age was 33 ± 12 yrs, duration of dialysis 16 mo, and none had previous glucocorticoid use. Tetracylcine-labeled bone biopsies, bone density, and magnetic resonance imaging were done at transplant and repeated after 20 ± 4 mo in 21 patients. Bone density was measured using single and dual photon absorptiometry. MinDen was measured using backscattered electron imaging. Images were analyzed with the NIH Image program, and results expressed in grey-scale values.

After transplantation 5 patients had experienced fractures, 9 had osteonecrosis and 7 no bone symptoms. In the entire group, bone density did not change significantly (-2.0 ± 5%/yr at radius and -1.0 ±7.9%/yr at spine). Baseline bone density was slightly but not significantly lower in the fracture group, with no difference in change of bone density among the three groups. Those with fractures had higher aluminum surface (AlS), higher MinDen, lower mineralizing surface (MS/TA), less decrease in PTH and less decrease in fibrosis (Fib) compared to those without fractures. Osteoid area, bone area, and eroded surfaces were not different. The MinDen showed significant inverse correlation with the mineralizing surface (r = -.55) and with area of fibrosis (r = -.46). The total prednisone dose was similar among groups, but the dose in the first month was higher in the osteonecrosis group.

These data show that changes in bone quality affect the risk of fractures in the transplant patients. Those who had fractures had lower bone formation. The MinDen was probably increased because low bone turnover allowed longer time for mineral crystals to accumulate in the bone matrix. The bone formation rates increased after transplantation (possibly because aluminum was removed), with decrease in MinDen. In the patients with osteonecrosis, bone formation rates did not increase, possibly a result of the glucocorticoids.

Data at transplant and after 20 months; * p<.05 baseline values; # p<.05 change after Tx

	Fracture (5)	No Fracture (7)	Osteonecrosis (9)

Pamidronate Shows a Novel, Renal-Insufficiency-Specific Deposition of Mineral on the Endosteal Bone Surface. J. Jokihaara*[1], P. Koobi*[2], P. Jolma*[3], M. Feng*[2], I. Porsti*[4], T. L. N. Jarvinen[1]. [1]Department of Orthopaedics and Traumatology, University of Tampere, Tampere, Finland, [2]Department of Pharmacology, University of Tampere, Tampere, Finland, [3]Department of Neurology, University of Tampere, Tampere, Finland, [4]Department of Medicine, University of Tampere, Tampere, Finland.

To characterize the structural effects of Pamidronate (PAMI), an intravenously administered bisphosphonate, on healthy and diseased bone, 30 twelve-wk-old rats were subjected to either SHAM-surgery or 5/6 nephrectomy (NTX). After a 4-wk disease-progression period, the rats were further randomized into placebo or PAMI groups for 8 wks. At the end of the intervention, the cross-sectional characteristics of the femoral midshaft and distal femur were analysed using pQCT scanner.

In the femoral midshaft, a cortical bone region, the only NTX-effect was a significant reduction in total and cortical bone mineral density (**A-B**), whereas PAMI had a clearly more pronounced effect on the tBMD (p=0.001). This general PAMI-effect also appeared specific to the NTX (+11%, p=0.002), as there was no effect in the SHAM rats (+3%, NS) (**A-B**). A general PAMI-effect was also observed on the cortical wall thickness (p=0.01) (**C**). However, a more detailed assessment showed that identically to the situation with the tBMD, the PAMI-effect was highly specific to the NTX'd rats. PAMI-treatment also resulted in significant reduction of bone size (tCSA) irrespective of the renal function (p=0.02, **D**), an apparent consequence of the PAMI-induced deposition of mineral and the resulting increase in bone stiffness. A significant interaction was also observed between PAMI-treatment and NTX: In the SHAM rats, the PAMI-treatment had no effect on the cortical (not shown) or total BMC (**E**) or cortical CSA (**F**), but resulted in a significant increase in all of these parameters in the NTX rats. Finally, in the distal femur, a mainly trabecular region, NTX had no effect at all, while the PAMI-treatment resulted in increased total BMC (+27%, p=0.000) and BMD (+30%, p=0.000) (not shown).In conclusion, the NTX-induced deleterious effects on bone appear to concern mainly the cortical bone, while pamidronate has a clear preference on the trabecular bone. However, an intriguing interaction was found between NTX and PAMI in the femoral midshaft, as a clear PAMI-induced endocortical deposition of mineral was observed.

CKD Induces an Adynamic Bone Disorder and Vascular Calcification Amenable to Skeletal Anabolism in the Metabolic Syndrome. R. J. Lund[1], M. R. Davies*[2], S. Mathew*[3], G. Saab*[2], K. A. Hruska[3]. [1]Internal Medicine, Washington University, St. Louis, MO, USA, [2]Internal Medicine, Washington University, St. louis, MO, USA, [3]Pediatrics, Washington University, St. louis, MO, USA.

In low density lipoprotein receptor null (LDLR-/-) mice, a model of the metabolic syndrome, we have shown that vascular calcification (VC) is worsened by chronic kidney disease (CKD) and ameliorated by Bone Morphogenetic Protein -7 (BMP-7), an efficacious agent in treating renal osteodystrophy (ROD). Here, LDLR-/- animals without CKD had significant reductions in bone formation rates, associated with increased VC and hyperphosphataemia. Superimposing CKD resulted in the adynamic bone disorder (ABD), while VC worsened and hyperphosphataemia persisted. This supports a pathological link between abnormal bone mineralization and VC. BMP-7 treatment corrected the ABD, ameliorated CKD-induced VC and corrected hyperphosphataemia, compatible with BMP-7-driven stimulation of skeletal phosphate deposition reducing plasma phosphate and thereby removing a major stimulus to VC.

To examine the mechanisms underlying osteogenic insufficiency induced by high fat feeding, we analysed the proliferation and differentiation of pluripotent bone marrow stromal cells (BMSC) that include osteoblast lineage precursors. LDLR-/- BMSC proliferated more than wild type cells, but LDLR-/- cells from high-fat fed animals proliferated less than wild type, a finding reversed and further stimulated by BMP-7 treatment. Since LDLR-/- adaptatively upregulates the Lrp family of proteins, we examined the function of Lrp5, a high bone mass gene, in LDLR-/- BMSC. Lrp5 was induced by LDLR-/-, but its function was diverted from Wnt signalling to lipid metabolism by high fat feeding. Thus, a putative mechanism of high fat feeding induced deficiency in bone formation was discovered. BMP-7 markedly induced Lrp5 restoring skeletal precursor proliferation and differentiation in vitro and bone formation in vivo.

Thus in the metabolic syndrome with CKD, a reduction in bone forming potential of osteogenic cells leads to the ABD producing hyperphosphatemia and VC, processes ameliorated by the skeletal anabolic agent BMP7, in part through deposition of phosphate and increased bone formation.

Curcuminoid-Enriched Turmeric Extract Prevents Arthritis in Lewis Rats. J. L. Funk, G. Chen*, G. McCaffrey*, G. Stafford*, J. A. Beischel*, J. Wilson*, R. C. Lantz*, A. M. Solyom*, S. D. Jolad*, B. N. Timmermann*. Arizona Center for Phytomedicine Research, University of Arizona, Tucson, AZ, USA.

Turmeric, the ground dried rhizome of the herb *Curcuma longa* L. (Zingiberaceae) that contributes flavor and lively yellow color to curries and mustard, has also been used for centuries in Ayurvedic medicine for the treatment of inflammation. Turmeric has been found to be a rich source of phenolic compounds (besides essential oil, the second major component of turmeric) commonly referred to as curcuminoids. Botanical dietary supplements, including turmeric extracts, are increasingly being used by the public in the United States for the treatment of chronic diseases, such as rheumatoid arthritis. However, scientific data regarding the clinical efficacy of these chemically complex botanical extracts are lacking. Studies were therefore undertaken to test the effect of an essential oil-free, curcuminoid-enriched extract of turmeric (curcuminoid extract) on joint inflammation and destruction in streptococcal cell wall (SCW)-induced arthritis, an animal model of rheumatoid arthritis (RA). Female Lewis rats were treated with: (1) vehicle alone; (2) curcuminoid extract (45 mg curcuminoids/kg/d ip); (3) SCW (25 mg/kg ip); (4) SCW + curcuminoid extract. Extracts were administered via intraperitoneal injection 5-7 days/week beginning 4 days prior to SCW injection. SCW-treated animals rapidly developed an acute phase of joint swelling, as assessed clinically by daily arthritic index, and subsequent nadir in disease activity, followed by a persistent chronic phase of joint swelling that is associated with joint destruction. Treatment with the curcuminoid extract profoundly inhibited joint swelling, a statistically significant effect that was seen as early as day 3 and persisted throughout the subsequent course of acute and chronic arthritis. Indeed, arthritis incidence was reduced to 20% by curcuminoid extract treatment (vs. 100% in SCW alone). Bone destruction was also significantly inhibited, as determined by measurement of osteoclast number in the distal tibia and BMD (Piximus, GE Lunar) of the distal femur. Curcuminoid extract also prevented the increase in circulating leukocytes that occurs during SCW-induced inflammation. In addition, ex vivo treatment of LPS-stimulated bone marrow or spleen cells with curcuminoid extract inhibited TNF-α secretion. The marked inhibitory effect of this turmeric extract on inflammatory cells and inflammatory mediator production in association with a profound inhibition of joint inflammation and destruction in SCW-induced arthritis suggests that essential oil-free extracts of turmeric may be efficacious in the treatment of RA.

The Effect of of Multiple Sclerosis on Bone Metabolism. A. Cranney[1], L. Ruhland*[2], W. Hopman*[2], V. McBride*[2], T. Anastassiades[2], D. Brunet*[2]. [1]Medicine, University of Ottawa, Ottawa, ON, Canada, [2]Medicine, Queen's University, Kingston, ON, Canada.

Previous studies have noted that Multiple Sclerosis (MS) subjects have a higher prevalence of osteopenia, vitamin D deficiency and more frequent fractures. The purpose of this study was to determine the proportion of MS subjects with low bone mass, vitamin D deficiency, and identify potential predictors of low BMD in an MS population. In a cross-sectional study we identified 100 subjects who attended a tertiary care MS clinic. The study population involved men and women > age 25 years with a neurologist-confirmed diagnosis of MS. Bone density, serum calcium, TSH, vitamin D, PTH and biochemical markers were measured. BMD (DXA Hologic) results were compared to a healthy age and sex-matched population. A questionnaire with details on duration, type of MS, medications, osteoporosis risks and dietary calcium intake was administered. The degree of walking disability was evaluated with the Kurtzke EDSS (1-10) with higher scores indicating greater disability. The Katz Comorbidity Index and an Osteoporosis Knowledge Questionnaire (OPQ) were completed. Mean age of the sample was 47.2 yrs (range 27-70), mean weight 76.1 kg (SD 17.8) and height 168.5 cm (SD 8.0). 65% were female and 38% were postmenopausal. 69% had relapsing remitting (RR) MS, 14% had primary progressive (PP) and 17% secondary progressive (SP). The mean EDSS was 3.3 (SD 1.9) and mean duration of MS was 11.4 (SD 8.8 years). 54% of subjects were on disability and 84% had a comorbidity score of zero. 25% reported having a prior BMD, 8% had been told they had osteoporosis and 9% had received osteoporosis counseling. 38% were taking ≥400 IU vitamin D and 22% had received IV glucocorticoids. 26% of the sample reported having a prior fracture after age 25 and 67% reported falling during the previous year. Mean femoral neck BMD (FN) was 0.77 g/cm^2 for females and 0.76 g/cm^2 for males. Mean total hip BMD was 0.89 and 0.92 g/cm^2 and mean lumbar spine BMD was 1.01 and 1.00 g/cm^2 for females and males, respectively. Twenty-three percent of subjects had a Z score ≤ -1.0 at the lumbar spine, 31% had Z score ≤ -1.0 at the FN and 25% at the total hip. Total hip BMD was 0.92g/cm^2 for (RR), 0.87 g/cm^2 for (PP) and 0.83 g/cm^2 for Secondary Progressive MS subjects. Total hip BMD was lower in those with an EDSS ≥ 5.5, ($p<0.05$). Mean vitamin D level was 92.0 nmol/l (46.8) and mean PTH 4.08 pmol/l (2.0). The mean score on the OPQ (max of 20) was 9.58 (4.64). There was a significant negative correlation between duration and type of MS with hip BMD. The prevalence of low BMD is not as high as noted in other hospital-based studies of MS subjects, which may reflect the lower level of disability seen in our population.

A Novel Macromolecular System to Image and Therapeutically Target Inflammatory Diseases In or Near Bone. B. Anderson*[1], D. Wang*[2], S. C. Miller[1], M. Sima*[2], P. Kopeckova*[2], J. Kopecek*[2]. [1]Radiobiology, University of Utah, Salt Lake City, UT, USA, [2]Pharmaceutics and Pharmaceutical Chemistry, University of Utah, Salt Lake City, UT, USA.

Inflammatory diseases can cause substantial localized and regional bone loss and skeletal dysfunction. A macromolecular delivery system has been developed that may improve the ability to image inflammatory foci in and near bone. In addition, this same technology may be used to enhance the delivery and retention of therapeutic agents to these sites. For these studies, the rat adjuvant-induced arthritis (AIA) model was used to induce inflammation-mediated skeletal disease. The macromolecular delivery system is synthesized based on N-(2-hydroxypropyl)methacrylamide (HPMA) copolymers. The localization and retention of the polymers to inflammatory sites was first demonstrated by magnetic resonance imaging (MRI) using a gadolinium (Gd) polymer complex. The injected polymer-Gd complex had preferential uptake and a prolonged retention in the inflammatory regions in skeletal and associated soft tissues as demonstrated by MRI and confirmed by histopathology. To demonstrate the utility for using this system in therapeutics, AIA rats with established inflammation were treated with 4 continuous daily injections of dexamethasone (Dex) or one injection of a polymer-Dex conjugate with an equivalent dose of Dex. The inflammation in the Dex-treated animals was transiently reduced, but returned within several days after the 4 doses of Dex treatment. The inflammation in the animals treated with polymer-Dex was suppressed for a longer period. Local bone mass and density measured by pDXA was significantly greater with the polymer-Dex treatment compared with Dex treatment alone. Histomorphometry of the tarsal bones showed that the osteoclast and resorption parameters were substantially reduced in the animals treated with polymer-Dex compared with Dex alone. These results demonstrate the utility of a novel macromolecular imaging and therapeutic delivery system that may prove advantageous in the diagnosis and treatment of inflammatory diseases that affect skeletal tissues and joints.

Assessment of 3D Cortical and Trabecular Bone Microstructure and Erosion on Micro CT Images of a Murine Model of Arthritis. Y. Jiang[1], J. J. Zhao[1], R. Mangadu*[2], S. Medicherla*[2], A. A. Protter*[2], H. K. Genant[1]. [1]Osteoporosis and Arthritis Research Group, University of California San Francisco, San Francisco, CA, USA, [2]Scios Inc., Fremont, CA, USA.

The study of inflammatory arthritis lacks reliable 3D imaging indices of disease activity and treatment response to direct the development of specific therapies. Due to the wide availability of various genetically altered mice in genomics research, drug discovery and development, a murine model may be useful for studying inflammatory arthritis. We evaluated 3D bone microstructure and erosion in such a model. Male DBA-1 Lac/J mice were immunized with collagen in complete Freund's adjuvant, boosted with collagen II in incomplete Freund's adjuvant on day 21. The paws were collected on days 33 (n=6) and 53 (n=14). Naïve paws were also harvested (n=3). They were scanned using a Scanco µCT with isotropic resolution of 16 µm. 3D cortical and trabecular structure were directly measured in the distal radius and the scaphoid, the distal tibia and the talus. The specimens were re-scanned and -measured 2-month later. 3D images were displayed from different angles to demonstrate integrity of bone surfaces. Bone erosion was independently scored by 2 experienced readers using a method adapted from a radiologic grading method used in epidemiological studies and clinical drug trial for rheumatoid arthritis. The readers were blinded to ID and scored twice with an interval of 2-month, according to an 8 point scale with 0.5 increments, from 0 as normal to 3.5 as severe worse. In the frontal paw, 8 joints were examined: metacarpo-phalangeal of digits I to V, combination of all carpometacarpal and intercarpal joints, distal radius, and distal ulna. Maximum score is 28. In the rear paw, 14-joint were examined: bases of metatarsals I to V, cuneiforms I to III, cuboid, navicular, calcaneus, talus, distal fibula, and distal tibia, with maximum score of 49. The root mean square coefficient of variation was 1.8% for bone volume fraction, 2.9% for thickness, 2.1% for separation. Intraclass correlation coefficients were 0.98 and 0.99 (intra-reader), and 0.98 (inter-reader). The images demonstrated mild changes on day 33 to moderately advanced disease on day 53. The erosion score was over 2-fold greater on day 53 than on day 33 (p=0.01). Thus, assessment of 3D cortical and trabecular microstructure and bone erosion in a murine model of inflammatory arthritis provides highly reproducible results. The 3D bone microarchitecture imaging system and the animal model may find application testing anti-inflammatory arthritis agents and anti-osteoporotic agents and investigating pathophysiology of inflammatory arthritis and arthritis-induced osteoporosis.

Factors Associated with Knee Osteoarthritis among Japanese Women. T. Hashikawa*[1], K. Aoyagi[2], S. Yoshida*[3], P. D. Ross[4]. [1]Orthopaedics, St.Francis Hospital, Nagasaki, Japan, [2]Public Health, Nagasaki University, Nagasaki, Japan, [3]Orthopaedics, Suga Orthopaedic Hospital, Isahaya, Japan, [4]Merck Research Laboratories, Rahway, NJ, USA.

Several studies have been conducted to determine the risk factors for knee osteoarthritis (OA) in western counties, but there are no population-based reports in Japan.
We studied 582 community-dwelling Japanese women ages 40 to 89 years (mean age = 64.2, SD = 9.6 years). Radiographs were obtained of bilateral knees (antero-posterior weight bearing), and were graded according to the criteria described by Kellgren-Lawrence (K/L). Definite OA was defined as K/L grade 2 or higher, present in at least one joint. Height (m) and weight (kg) were measured, and body mass index (BMI) was calculated as weight (kg) /height (m^2). Occupation and history of knee injury were obtained from questionnaire. Daily intake of vitamin C and carotene were estimated by a self-administered semiquantitative food frequency questionnaire.
In univariate analyses, women with knee OA were significantly older and weighed more than those without. Women engaging in farming had higher prevalence of knee OA. Women with history of knee injury had significantly higher prevalence of knee OA than those without. There was no significant difference in daily intake of vitamin C and carotene between women with and without knee OA. Multivariate logistic regression analysis showed that older age (per 5 years increase, odds ratio [OR]; 1.8, 95% confidence interval [CI]; 1.6-2.1), greater BMI (per 5-unit increase, OR; 2.2, 95% CI; 1.7-3.0) and history of knee injury (yes/no, OR; 3.1, 95% CI; 1.7-5.6) were significantly associated with knee OA. Daily intakes of vitamin C and carotene were not associated.
Our findings suggest that aging, obesity and previous knee injury are important risk factors for development of knee OA among Japanese women, which is consistent with previous reports among Caucasian populations.

Systemic Bone Loss Induced by Local Inflammation Is Associated with Greatly Increased Mast Cell Number in Bone Marrow. G. L. Evans*[1], N. H. Bell[2], R. T. Turner[1]. [1]Orthopedic Research, Mayo Clinic, Rochester, MN, USA, [2]Dept. of Medicine, Medical University of South Carolina, Charleston, SC, USA.

Prostaglandins can produce either pro- or anti-inflammatory actions depending upon their route of administration. We previously reported that subcutaneous implantation of prostaglandin E_2 (PGE_2) results in local inflammation and systemic bone loss in normal and ovariectomized (OVX) rats. Others reported that circulating 17ß-estradiol (E_2) inhibits inflammation, whereas PGE_2 induces local mast cell differentiation. Mast cells accumulate in the marrow cavity following OVX and treatment with estrogen suppresses the release of the osteolytic cytokines TNFα and IL-6 by mast cells. The purpose of this study was to determine the effects of local PGE_2 and circulating E_2 on cancellous bone mass and bone marrow mast cell number in growing OVX rats. Drugs and carrier were delivered by use of 7.5 mg PGE_2 pellets, 0.5 mg E_2 pellets and placebo pellets after s.c. implantation onto the back of 7-w-old OVX rats. Histological analysis of the proximal tibial metaphysis was performed 3 w later. The results are shown in the Table (values are mean ± SE; N=5-7).

Measurement	Control	PGE_2	E_2	E_2 + PGE_2	PGE_2 P Value	E_2
BV/TV (%)	14.4 ± 6.5	6.9 ± 2.1	42.1 ± 5.6	26.0 ± 13.3	0.026	0.0001
Mast cells (#/mm^2)	12.0 ± 4.6	143 ± 21	12.6 ± 1.7	38 ± 10	0.0001	0.0001

PGE_2 produced local inflammation at the site of implantation without increasing circulating PGE_2 values. E_2 increased uterine weight indicating that serum E_2 values were increased. PGE_2 decreased, whereas E_2 increased cancellous bone volume. There was a 13-fold increase in mast cell number in bone marrow following PGE_2 treatment compared to only a 3-fold increase when E_2 was administered concomitantly. These findings demonstrate a strong association between local inflammation-induced systemic bone loss and accumulation of mast cells in bone marrow. The results provide evidence that mast cells mediate inflammation-induced bone loss.

Decreased Bone Strength in HLA-B27 Associated Ankylosing Spondylitis. M. P. Akhter[1], A. D. Lund*[1], M. Wing*[2], L. K. L. Jung*[2]. [1]Medicine, Creighton University, Omaha, NE, USA, [2]Pediatrics, Creighton University, Omaha, NE, USA.

Ankylosing spondylitis is an inflammatory disorder which involves the spine, peripheral joints and entheses. Patients with this disorder often develop osteopenia /osteoporosis. The exact etiology of the osteopenia/osteoporosis is not clear. Possible causes include corticosteroid use and the underlying inflammatory disease. This project investigated the nature of osteopenia/osteoporosis in this disorder using the histocompatibility leukocyte antigen (HLA)-B27 transgenic rat model of ankylosing spondylitis. HLA-B27 transgenic rats and their littermates were purchased from Charles River Laboratories at 6 - 8 weeks of age. The animals were housed individually and sacrificed at the peak of their disease (8-month-old). The spine and femurs were removed and stored at -20ºC in saline until analysis. The bone structure and strength were determined using a micro computed tomography device (µCT20, Scanco Medical) and mechanical testing (Instron 5543). Vertebral bodies were scanned (17 micron resolution with an integration time of 50 milliseconds) to determine trabecular structural properties in terms of bone volume (BV/TV), trabecular thickness, and spacing. After scanning, the mid-shaft femur was subjected to a 3-point bending test (along anterior-posterior direction), the femoral neck was tested in bending, and vertebral bodies (L4) were tested in compression. All tests were performed at a rate of 3mm/minute. Structural strength parameters (ultimate/yield load, stiffness) were obtained from the load-displacement diagram. The apparent material strength (ultimate/yield stress, modulus) was calculated. Genotype-related differences in all the measured variables were tested using one-way ANOVA at a significance level of $P<0.05$. B27-trangenic rats had poor biomechanical strength and structural properties at every site (Table). All the measured parameters (Table) were significantly lower ($P<0.05$) in the B27 transgenic rats as compared to control littermates. Micro-CT data suggest that the transgenic animals had lower BV/TV and trabecular thickness in their vertebral bodies. The poor trabecular structure in B27 rats is consistent with the poor biomechanical strength properties in the vertebral bodies. In conclusion, the HLA-B27 genotype contributes to the bone fragility in ankylosing spondylitis.

Table. Biomechanical Properties (Mean ± SD)	Control littermate [n=5]	Transgenic (B27) [n=8]
FS Ultimate Load (N)	141±27	110 ± 21 [a]

Combination Therapy With Ibandronate and Calcitriol Is Effective in Patients Following Liver Transplantation: A Three Year Prospective Controlled Study. A. Fahrleitner-Pammer[1], G. Prenner*[2], D. Kniepeiss*[2], K. Tschelissnigg*[2], G. Leb*[1], C. J. Piswanger-Sölkner*[1], B. M. Obermayer-Pietsch*[1], H. Dobnig[1]. [1]MedUnivKlinik, Endocrinology, Graz, Austria, [2]ChirUnivKlinik, Transplantation, Graz, Austria.

Due to improved long term survival rate, transplantation bone disease is of growing importance as a potential serious late complication following liver transplantation (LTX).
Aim of the present study was to evaluate the influence of 2mg ibandronate iv. every 3 mos in combination with oral calcitriol in 15 LTX patients (f/m 5/10) with osteoporosis (OPO). Results were compared to respective baseline evaluations as well as contrasted to 8 LTX recipients (f/m 2/6) with normal bone mineral density (BMD) and bone metabolism receiving 1200mg Calcium and 800 IU cholecalciferol as controls. Median age of the patients was 55±2 years and average time since TX was 27±4 mos. All patients were on immunosuppressive therapy and none of them had received any specific osteoporosis treatment prior to study entry. The study was conducted over 3 years; scheduled BMD measurement at the hip, spinal x-ray and laboratory analysis for bone metabolism were performed every year. Baseline Z-score values were -1.64±0.26 at the neck and -1.67±0.27 at the trochanteric region in the treatment group as compared to +0.17±0.29 and -0.09±0.43 in the control group. Furthermore bone markers (iPTH, TRAP 5b, sCTX, bALP and Osteocalcin) were significantly higher (p<0.05) among OPO patients than in controls.
After 3 years BMD of the ibandronate/calcitriol treated group had significantly increased by 17±3% at the neck (p<0.0001) and 14±3% at the trochanter (p=0.0002). Although most of the increase (+11% and +7% respectively, p<0.05) was evident in the first year of treatment, during the second and third year BMD continued to increase significantly. Control patients revealed a total bone loss of -4.8±3% at the neck and -3±1% at the trochanteric region compared to baseline (p<0.05). In the OPO patients` group bone markers decreased significantly (p<0.001) and stayed low throughout therapy.
Study results clearly indicate that a combination therapy with ibandronate and calcitriol is an effective and well tolerated treatment option in patients following LTX.

Bone Density After Renal Transplantation in Relation to Immunosuppressive Therapy: a Follow-Up Study. C. Ejersted*[1], J. D. Jensen*[2], B. Jespersen*[3], C. Bistrup*[3], J. Carstens*[4], T. Torfing*[5], L. Lund-Olesen*[6], L. Mosekilde[7], K. Brixen[1]. [1]Dep. of Endocrinology, University Hospital of Odense, Odense, Denmark, [2]Dep. of Nephrology, University Hospital of Aarhus, Aarhus, Denmark, [3]Dep. of Nephrology, University Hospital of Odense, Odense, Denmark, [4]Dep. of Nephrology, University Hospital of Aarhus, Aarhus, Denmark, [5]Dep. of Radiology, University Hospital of Odense, Odense, Denmark, [6]Dep. of Radiology, University Hospital of Aarhus, Aarhus, Denmark, [7]Dep. of Endocrinology, University Hospital of Aarhus, Aarhus, Denmark.

After renal transplantation (RTx) a decline in bone mass has been described and is thought to be due to the use of immunosuppressive agents especially glucocorticoids.
In this study, bone mineral density (BMD) of lumbar spine and femoral neck where measured by dual energy x-ray absorptiometry (DEXA) at 0, 3, 6, and 12 months after RTx. Patients were included from 2 cities in Denmark having the same criteria for RTx but using different immunosuppressive therapy: in Odense a combination of cyclosporine and mycophenolate (group I, n=37) and in Aarhus a combination of prednisolone, azathioprine and cyclosporine (group II, n=29). The purpose of the study was to evaluate differences in BMD between the 2 groups.
In both groups, vertebral BMD in percent of baseline value (mean±SEM) decreased at 3, 6, and 12 months: group I:, 100±0, 96.7±0.6 *, 95.1±1.5*, 97.5±1.2*, group II: 100±0, 98.6±1.5, 94.9±1.9*, 94.8±1.8* whereas femoral neck BMD only decreased in group II (mean±SEM at 0, 3, 6, 12 months: group I:100±0, 98.9±0.6*, 98.5±0.8, 98.5±1.4, group II: 100±0, 97.9±0.5*, 96.7±0.6*, 97.1±0.7*). No BMD differences were found between the groups.
Excluding patients given anti-rejection therapy with high dose prednisolone (group I: n=9/37, group II: n =4/29) vertebral BMD decreased more in group II than group I 1 year after RTx (mean±SEM at 0, 3, 6, 12 months: group I: 100±0, 97.2±0.6 *, 97.3±1.0*, 99.4±1, group II: 100±0, 98.4±1.6, 94.9±1.9*, 94.4±2.0*#). No differences between the groups were found concerning femoral neck BMD but femoral neck BMD decreased only in group II (mean±SEM at 0, 3, 6, 12 months: group I: 100±0, 98.9±0.7, 98.7±1.0, 99.5±1.7, group II: 100±0, 98.1±0.6*, 97.0±0.7*, 97.8±0.7*).
In conclusion, BMD decreased within the first year after RTx and BMD tended to be lower in the prednisolone treated group II. However, this was only significant for vertebral BMD. (*:p<0.05 compared to baseline value, #p<0.05 group I compared to group II)

Bone Turnover Markers, Bone Mineral Density and Vitamin D-Calcium-phosphate Homeostasis before and after Liver Transplantation. E. Karczmarewicz*. ZBiMD, IPCZD, Warsaw, Poland.

Introduction: Bone disorders, frequently with fractures, are common in children with end stage liver diseases, especially associated with cholestasis. Abnormal hepatocyte function, disturbed vitamin D-Ca-P homeostasis, malnutrition and immunosupressive treatment are potential factors of bone pathology before and after transplantation.
Aim of the study: The aim of the study was to investigate bone turnover, bone mineral density, vitamin D-Ca-P homeostasis in children qualified for liver transplantation (Ltx) and during 6,9,12 and 24 months after transplantation.
Material and methods: 24 children aged 1,3 to5 years before performed living related liver transplantation were enrolled into the study. Serum levels of bone formation marker (osteocalcin - OC), bone resorption marker (CTX), densitometric bone mineral density (TB BMD -total body BMD) and BMI (body mass index) were analyzed. All patients were supplemented with 25OHD (1-2 µg/kg body weight). After transplantation immunosupressive treatment was introduced with tacrolimus (to keep the serum level 8-19 ng/dl) and prednison (0,1 mg/kg body weight). Vitamin D-Ca-P homeostasis was monitored with serum levels of 25(OH)D, Ca and P.
Results: Six months after transplantation. Marker of bone formation has increased two-fold: bone formation (OC: 60±39/141±58 ng/ml; p=0,000075) as well as bone resorption (CTX: 0,68±0,37/1,22±0,55 ng/ml, p=0,000187) reflecting pronounced stimulation of bone growth process. In the same time a twofold increase in serum PTH (20±15/39±14,0 pg/ml; p=0,000549) and 1,25$(OH)_2$D (36±14/63±20 pg/ml: p=0,000123) were observed. Increased serum levels of OC, CTX, PTH and 1,25$(OH)_2$D after 6 months continued up to 2 years of observation after transplantation. The velocity of bone growth after transplantation measured as densitometric total body bone mineral density changes per year (TB BMD/ year) was twofold increased in comparison to control group. BMD before and after transplantation was positively correlated with nutritional status (BMI). Stable levels of serum 25(OH)D, Ca and P during whole period of observation documented balanced vitamin D-Ca-P homeostasis.
Conclusions: Successful transplantation in cholestatic children with balanced vitamin D-Ca - P homeostatis triggered pronounced bone growth manifested by increased bone turnover and velocity of TB BMD changes. The role and mechanism of concomitant increase in 1,25$(OH)_2$D and PTH need further investigations.

Calcitriol and Alendronate Do Not Affect Immunological Status in Cardiac Transplant Recipients. S. Xydas*[1], R. Rosen*[1], V. K. Topkara*[1], V. Addesso[2], E. M. Burke*[1], D. M. Mancini*[2], Y. Naka*[1], S. Itescu*[1], S. Maybaum*[2], M. C. Oz*[1], E. Shane[2]. [1]Surgery, Columbia University College of Physicians & Surgeons, New York, NY, USA, [2]Medicine, Columbia University College of Physicians & Surgeons, New York, NY, USA.

Calcitriol (CAL) and Alendronate (ALN) have been shown to have immunomodulatory effects in *in vitro* and *in vivo* experimental models. A recent study reported lower immunosuppression doses in cardiac transplant (CTX) recipients receiving CAL for osteoporosis prevention. We therefore examined the effects of CAL and ALN on immunological status, exposure to immunosuppressive drugs, and rates of rejection and transplant coronary artery disease (TCAD) after CTX.
We followed 211 patients who participated in a trial comparing CAL and ALN for prevention of bone loss during the first year after CTX. Patients randomized to CAL (n=71, 0.5 mcg/d) or ALN (n=70, 10 mg/d) were compared to a concurrently transplanted reference group (n=70, REF). Immunological data were analyzed retrospectively by intention-to-treat. Panel reactive antibody (PRA) and lymphocyte growth assays (LGA) were performed at the time of endomyocardial biopsies and if rejection was suspected. The presence of anti-HLA antibodies was defined as >10% panel reactivity. Outcome variables included: PRAs, LGAs, medication regimen dosages, rejection history, and TCAD incidence.
The mean age was 53.3 ± 11.2 years. Patients were predominantly male (n=175, 83%) and evenly split between ischemic (n=115, 55%) and non-ischemic (n=97, 46%) cardiomyopathy. Actuarial survival was 96% and 89% at 1 and 5 years, respectively. The mean number of rejection events was 0.86 ± 0.96 per year of followup. There were no pre-study differences between the CAL, ALN, and REF groups in age, gender, race, heart failure etiology, cross-match status, HLA class A, B, and DR matches, or PRA levels. After CTX, there were no differences among the groups in the proportion of patients with post-transplant anti-HLA IgG class I (CAL: 29%, ALN: 32%, REF 26%; p = 0.73) or class II (CAL: 34%, ALN: 38%, REF 40%; p = 0.80) antibodies or growth on LGA (CAL: 55%, ALN: 58%, REF 49%, p = 0.58). The groups did not differ in daily immunosuppressive doses at 2, 6, 9, or 12 months for prednisone, cyclosporine, FK506, azathioprine, or mycophenolate mofetil. There were no differences in the rejection rate (CAL: 1.1 ± 1.4, ALN: 1.0 ± 1.0, REF 1.0 ± 1.1 events per patient year; p = 0.61) or time-free from TCAD over a follow-up of 4.6 ± 1.7 years.
Our results revealed no clinically signficant changes in the immunological status of CTX patients treated with CAL or ALN. Patients receiving calcitriol or alendronate for the prevention of bone loss after CTX are unlikely to sustain immunological benefits from these therapies.

Bone Status in 52 Patients after Kidney Transplantation with and without Bisphosphonates Treatment. P. Guggenbuhl[1], S. Dupeux*[1], J. D. Albert*[1], G. Chalès*[1], P. Le Pogamp*[2], S. Werner-Leyval*[1], V. Joyeux*[2]. [1]Rheumatology, University Hospital, Rennes, France, [2]Nephrology, University Hospital, Rennes, France.

Bone loss and osteopenia are frequent complications after kidney transplantation. Many factors can explain this osteopenia, particularly the pre-existing bone renal disease and the immunosuppressive treatments. Nevertheless, treatment of osteopenia after kidney transplantation is not well established. Bisphosphonates'use after transplantation has to be validated. We retrospectively studied 52 unselected patients with kidney transplantation regularly followed in a nephrology department. There were 18 females and 34 males with a mean age of 50.4±14.5 years; all patients received immunosuppressive treatment (most of them ciclosporin) and low doses of corticoseroids. At the time of the first BMD measurement with DEXA, the median delay from transplantation was 9 months, with a mean of 68±90.5 months (0-331). A second measurement was available in 32 patients at 19±9.6 months (3-43) from the first BMD. Among them, twelve had been treated with bisphosphonates (BP): 11 with pamidronate (30 mg/3 months) and 1 with alendronate (10 mg/day) during 19.7±5.2 months (11-28). At baseline, the lumbar spine BMD was 0.775±0.167 g/cm² and the femoral neck BMD was 0.655±0.09 g/cm² ; 51/52 patients had an osteopenia (T score<-1 SD) and 34/52 an osteoporosis (T score<-2.5 SD) according to WHO criteria. Before treatment, BP patients group differed from untreated patients group only by a significantly lower T score at lumbar spine (+ 3.6 vs -1.7%*) and at femoral neck (-2.8 vs -2.11 SD*) and a higher serum creatinine level (154.17 vs 124.05 µmol/l*). The BMD annualized mean variation between the two BMD measurement, showed a significant increase at lumbar spine in the BP group (+ 3.6 vs -1.7%*) but not at femoral neck (+1.1 vs +1.4%). There was a non significant decrease of annualized variation of bone alkaline phosphatase (-9.8 vs +0.15%) and osteocalcin (-3 vs +35%) in the BP group. **Conclusion**: Osteopenia and osteoporosis are frequent after kidney transplantation. Bisphosphonates significantly increase lumbar spine BMD in patients with low BMD.
*statistically significant difference

Urinary Calcium Excretion after Renal Transplant Is Inversely Associated with Bone Mineral Density. P. S. Coates[1], W. H. Lim*[2], G. R. Russ*[2], P. T. H. Coates*[2]. [1]Burnside Diabetes Centre, Rose Park, Australia, [2]Renal Unit, The Queen Elizabeth Hospital, Woodville, Australia.

Kidney transplantation is the preferred treatment for end stage renal disease. However, patients are at significantly increased risk for osteoporosis and fracture. To investigate calcium metabolism and bone turnover after renal transplant and the effects on the skeleton, we studied all stable renal transplant patients at our outpatient clinic over 3 months. Data are shown as mean ± SD (reference range). Calcium metabolism, bone turnover and bone mineral density were assessed in 31 male and 28 female patients, 10 ± 8 years post transplant, serum creatinine 133 ± 37 umol/l (50-120). All patients were treated with calcineurin inhibitors and 55 patients were also taking prednisone 10 mg daily. No patients took either thiazides or calcium supplements. Total serum calcium was 2.37 ± 0.18 mmol/l (2.10-2.55), albumin 39 ± 3.8 g/l (34-48). Intact parathyroid hormone was elevated at 11.4 ± 8.5 pmol/l (0.8-5.5*),P*<0.01*;* 25 hydroxy vitamin D 68 ± 28 nmol/l (desirable 60-160); 1,25 dihydroxyvitamin D 103 ± 41 pmol/l (50-160). Urinary calcium excretion was significantly reduced compared to the reference range at 2.8 ± 2.2 mmol/24 hours (2.5-7.5), *P*<0.01; urine creatinine 12.9 ± 4.7 mmol/24 hours (6.0-16.0). Urine deoxypyridinoline: creatinine (DPD/Cr) was 24 ± 18 nmol/mmol (<23); pyridinoline: creatinine (PYD/Cr) was 66 ± 40 nmol/mmol (<77). L1-L4 BMD (Lunar) was 1.211 ± 0.210 g/cm2 (male), 1.059 ± 0.146 g/cm2 (female). Total hip BMD was 1.004 ± 0.215 g/cm2 (male), 0.861 ± 0.109 g/cm2 (female). In a multiple stepwise regression model, independent determinants of BMD were age, bone resorption (PYD/Cr), 24 hour urine calcium and log PTH. We hypothesize that low urine calcium after renal transplant, due to a combination of dietary insufficiency and persistent secondary hyperparathyroidism contributes to loss of bone mass at clinically relevant sites. Longitudinal studies are needed to confirm this.

Osteoprotegerin Levels in Cirrhotic Patients Referred for Orthotopic Liver Transplantation. A. Monegal[1], N. Guañabens[1], M. Navasa*[2], L. Alvarez[3], D. Ozalla*[4], P. Peris[1], J. Rodes*[2]. [1]Rheumatology, Hospital Clinic, Barcelona, Spain, [2]Liver Unit, Hospital Clinic, Barcelona, Spain, [3]Biochemistry, Hospital Clinic, Barcelona, Spain, [4]IDIBAPS, Barcelona, Spain.

Aim: The purpose of the study was to analyse osteoprotegerin (OPG) levels and it's relationship to bone disease in cirrhotic patients referred for orthotopic liver transplantation.

Patients and Methods: A prospective study was carried out in 22 cirrhotic patients (13 m/9 f) (age: 54±12 years) referred for orthotopic liver transplantation. Biochemical parameters of bone mineral metabolism, standard liver function tests, urinary N-terminal cross-linking telopeptide of type I collagen (uNtx), serum levels of procollagen type I N propeptide (sPINP), serum parathyroid hormone (PTH), 25-hydroxyvitamin D levels (25OHD) and serum OPG were measured in all patients. OPG results were compared to those obtained in 29 healthy controls of similar age and sex. Bone mineral density (BMD) of the lumbar spine and proximal femur was measured by DXA and spinal X-rays were performed to detect vertebral fractures.

Results: OPG levels were higher in cirrhotic patients than in controls (6.4±2 vs 2.7±0.7; p=0.000). Ten patients had osteoporosis (45%) and only two patients (9%) had normal BMD. Moreover, 45% of cirrhotic patients showed skeletal fractures. No differences were found in OPG levels between patients with and without osteoporosis by densitometric criteria. In addition, patients with or without fractures showed similar OPG values. Negative correlations were found between OPG levels and femoral neck (R -0.46; p= 0.03) and total hip BMD (R -0.48; p= 0.025). By contrast, OPG values were not related to markers of bone turnover.

Conclusion: OPG values are elevated in patients before liver transplantation, particularly in those with reduced femoral BMD.

Post-transplantation Hypogonadism: A Reflection of Sex Steroids Deficiency due to Previous Congestive Heart Failure or an Immunosuppressive Side Effect? J. Stief*, R. Gaertner, P. Ueberfuhr*, K. Theisen*, H. Stempfle. Cardiology, Med. Poliklinik Innenstadt, LMU, Munich, Germany.

Background: Hypogonadism might play an important role in the multifactorial pathogenesis of the immunosuppressant-induced bone loss. We recently demonstrated that cardiac transplants with hypogonadism reveal a significant decrease in bone mineral density compared to normogonadal patients. It remains unclear, however, if the post-transplantation hypogonadism reflects only a sex steroid deficiency due to previous congestive heart failure (CHF) or a side-effect of the immunosuppressive therapy.

Methods: The following longitudinal study examined the role of hypogonadism in the evolution of bone loss in 20 male patients before and after heart transplantation (HTx). Immunosuppressive therapy included calcineurin phosphatase inhibitors, antiproliferative agents and corticosteroids. Total serum testosterone (T ng/dl), sex hormone binding globulin, serum free testosterone, as well as gonadotropins: luteinizing hormone (LH U/l) and follicle stimulating hormone (FSH U/l) were measured in fasting patients before and six months after HTx.

Results: The mean testosterone level decreased significantly after transplantation (433ng/dl vs. 314ng/dl; p = 0,024). 6 of the 20 (30%) patients with CHF showed an hypogonadism with a mean testosterone level of 239±35 ng/dl and inadequately low gonadotropins (LH 5U/l±5,7, FSH 6,4U/l±7) indicating a hypogonadotropic hypogonadism. Six month after HTx, all six patients remained hypogonadal. Additionally three transplant patients developed a new hypogonadism within the study period (T 202ng/dl±74, LH 7,8U/l±1,8, FSH 8,9U/l±2,7). Therefore 45% (9 of 20) of patients after HTx demonstrated a sex hormone deficiency followed by a decrease in bone mineral density.

Conclusions: Hypogonadism is frequently seen in patients with CHF. After HTx, however, a significant decrease in gonadal hormones is observed probably due to the immunosuppressive therapy. Furthermore hypogonadal patients showed no recovery of gonadal function within six months. To prevent rapid bone loss, truly hypogonadal patients might profit from testosterone replacement after HTx. The role of replacement therapy in patients with CHF remains still unclear.

Bone-Protective Therapy after Kidney and Kidney Pancreas Transplantation. G. J. Elder, C. Moy*. Department of Renal Medicine, Westmead Hospital, Sydney, Australia.

After transplantation, immunosuppressives and residual changes of osteodystrophy influence bone strength. Kidney pancreas transplant recipients may be at particular risk. Eighty-three kidney and 49 kidney pancreas recipients were assessed before and 2 weeks, 3 and 12 months after transplantation. One-year data is available on 38 kidney and 19 kidney pancreas recipients. BMD was assessed by dual-energy X-ray absorptiometry at baseline and 12 months. Patients with diabetes spent fewer months on dialysis (21±17 vs. 38±37, p=0.005), had lower body mass index (BMI) (24.7±2.8 vs. 26.5±4.9 kg/m^2, p<0.05) and levels of 25-hydroxyvitamin D (49±24 vs. 70±30 nmol/l, p=0.0003). Patients without type 1 diabetes had normal Z scores at the lumbar spine (0.1±1.5) femoral neck (-0.2±1.3) and wrist (0.5±2). Patients with type 1 diabetes had lower BMD at the lumbar spine (p<0.05), femoral neck (p<0.0001) and wrist (p<0.02) but BMD was normal except at the femoral neck (Z score -1.4±0.9). Prevalent vertebral fracture was present in 31% but did not differ for patients with or without diabetes. After transplantation, patients commenced standard therapy (calcium plus ergocalciferol or calcitriol as required). Patients with osteoporosis and/or prevalent fracture added bisphosphonates. Treatment did not differ with transplant type. Baseline iPTH of 6.9±6.7 fold the assay upper range, reduced to 2.4±2.9 fold at 2 weeks and 1.4±1 fold at 1 year. Deoxypyridinoline/creatinine ratios fell from 2 weeks to 1 year (p=0.005) but levels remained at or above the upper range. Serum osteocalcin in the mid-normal range was lower in kidney pancreas recipients (p<0.05 at 2 weeks). BMD did not change significantly within either group (paired t-test) but between groups, lumbar spine BMD for kidney recipients increased by 5±2% (mean±SEM) vs. -1±2% for kidney pancreas recipients (p<0.05). Patients treated with bisphosphonate or standard therapy did not differ in outcome. In conclusion, with targeted therapy, BMD loss was not detected in the first year after kidney or kidney pancreas transplant. Bone turnover markers suggest hyperparathyroidism and elevated bone resorption are present in both groups. Kidney pancreas recipients have additional risk factors, including lower baseline BMD and 25-hydroxyvitamin D levels.

The Type I PTH/PTHrP Receptor Associates with Karyopherins in Cultured Osteoblast-like Cells. B. W. Pickard*, L. J. Fraher, A. B. Hodsman, P. H. Watson. Medicine, Lawson Health Research Institute, University of Western Ontario, London, ON, Canada.

Parathyroid hormone regulates bone turnover via its interaction with the type 1 PTH receptor (PTH1R) present on osteoblasts. Our studies have demonstrated that PTH1R is not only found on the cell membrane, but also in the nucleus, thus providing a new avenue for the exploration of the mechanisms behind the action of PTH. Proteins destined for the nucleus contain intrinsic nuclear localization signals (NLS). Such a signal is present in the PTH receptor carboxy-terminus region (rat/mouse:471-487) which is highly conserved across all known PTH1R sequences. Receptors are targeted to the nucleus through the interaction of their NLS with proteins of the karyopherin (Kap) family of transport regulatory molecules. To determine the identity of individual members of the Kap family in the regulation of nuclear transport of PTH1R, rat osteosarcoma (ROS 17/2.8), mouse non transformed osteoblast cell line (MC-3T3-E1), and human osteosarcoma (SaOS-2) were cultured under standard conditions for use in assays. Cells were grown on cover slips and probed with antibodies to the C-terminal domains of PTH1R, Kap apha2 and Kap beta1 by immunofluorescence. Immunoprecipitation and western blots were used to investigate the interaction between the karyopherins and PTH1R. PTH1R, Kap alpha2/beta1 were immunoprecipitated with antibodies to the C-terminal domains with protein G Sepharose 4 Fast Flow beads. Immunoprecipitations were then separated by SDS-PAGE and probed with antibodies to the N-terminal domain of PTH1R and Kap beta1 and antibodies to the C-terminal domain of Kap alpha2. Blots were also probed with biotinylated hPTH(1-84) (ligand blots) to confirm the presence of PTH1R in immunoprecipitates. Immunoprecipitation and western blots have identified karyopherin alpha2 and beta1 as proteins that associate with PTH1R. Biotinylated PTH 1-84 recognized a 66.3 KD band on blots of samples immunoprecipitated with each of the 3 antibodies, thus confirming the Western blot results. Immunofluorescence has confirmed the presence of PTH1R and Kap alpha2/beta1 in three osteoblast like cell lines as well as demonstrated the spatial overlap of these proteins. Studies on the co-localization of these proteins in rat liver tissue add additonal support these results. These studies have demonstrated that PTH1R associates with Kap alpha2 and beta1 suggesting a role for the karyopherins in the regulation of PTH1R transport to the nucleus. Future studies on the function of PTH1R in the nucleus will identify candidate genes potentially involved in the anabolic response of bone to PTH or novel genes involved in the PTH regulation of bone metabolism.

Mechanism of Concanavalin A on PTH Receptor Down-regulation on Cell Membrane. Q. Sun[1], R. W. Katz[2], X. Fan*[1], J. P. Bilezikian[1]. [1]Division of Endocrinology, College of Physicians and Surgeons, Columbia University, New York, NY, USA, [2]Oral Medicine, College of Dentistry, New York University, New York, NY, USA.

Stimulation of PTH receptors in intact cells causes, first, rapid functional uncoupling from its G-protein complex, and, second, a somewhat slower sequestration of receptors to internal compartments. We have previously reported that pretreatment of EW-29 cells with hPTH(1-34) down-regulates the PTH receptor. The present study addresses the hypothesis that concanavalin A, which has been used in some cell lines to block receptor sequestration, will impair PTH-receptor down-regulation. Exposure of EW-29 cells to 10-7M hPTH(1-34) caused a time-dependent receptor internalization. Maximal internalization of labeled PTH was reached by 3 hours. After 3 hours exposure to 10-7 M hPTH(1-34), PTH-dependent adenylyl cyclase (ACA) and phospholipase C (PLC) activities were suppressed by 25% and 84%, respectively, and membrane PTH receptor labeling was 31% of untreated control cells. Pretreatment with concanavalin A and hPTH(1-34) resulted in complete recovery of ACA and only 40% suppression of PLC compared to untreated control cultures. Surprisingly, concanavalin A pretreatment with hPTH increased PTH receptor internalization by 20%, increased the amount of surface receptor two-fold, but did not alter receptor recycling rate to the surface. This study indicates that concanavalin A recovery of homologous down-regulation of PTH-dependent ACA and PLC activity is independent of receptor internalization. The mechanism by which PTH receptor function is protected by concanavalin A in this model may provide information on how to extend the activity of PTH analogues through modulation of receptor down-regulation.

The Sodium/Proton Exchanger Regulatory Factor Type I (NHERF1/EBP50) Regulates PTH(7-34) but not PTHrP(7-34)-induced Type I PTH Receptor (PTH1R) Internalization. W. B. Sneddon. Dept of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

Internalization of the Parathyroid Hormone Type I Receptor (PTH1R) is regulated in a cell- and ligand-specific manner. We have previously demonstrated that the presence or absence of the sodium/proton exchanger regulatory factor type 1 (NHERF1) is pivotal in determining the range of peptides that are capable of internalizing the PTH1R. For example, PTH(7-34), which binds to, but does not activate the PTH1R, internalizes the PTH1R in kidney distal tubule (DT) cells, where NHERF1 is not expressed. Introduction of NHERF1 into distal tubule cells blocks PTH(7-34)-induced PTH1R internalization. Similarly, PTH(7-84), a secreted C terminal fragment, internalizes the PTH1R in a NHERF1-dependent manner. Very little is known, however, about PTH1R internalization in response to PTH-related protein (PTHrP) fragments. We, therefore, examined a series of synthetic PTHrP fragments for their ability to induce PTH1R internalization. PTH1R internalization was examined using real time confocal fluorescence microscopy of mouse DT cells stably expressing an EGFP-tagged PTH1R. PTHrP(1-36), which binds and activates the PTH1R, internalized the PTH1R 50% after 15 min. PTHrP(7-34), a PTH1R antagonist, internalized the PTH1R 80% after 15 min. This is similar to the level of PTH1R endocytosis observed in response to PTH(7-34). In contrast to PTH(7-34), however, PTHrP(7-34)-stimulated PTH1R internalization was not inhibited by overexpression of NHERF1. This effect of a synthetic PTHrP fragment, while not physiological, is informative in terms of how PTH1R levels can be exogenously regulated. Under pathophysiological circumstances such as renal failure, PTH(7-84) levels are elevated and may contribute to PTH resistance by selectively downregulating the PTH1R in specific tissues such as renal distal tubules, where NHERF1 is absent. If a less selective downregulation of the PTH1R is desirable, synthetic peptides could be designed to remove the NHERF1-dependence of this process and promote PTH1R internalization in a broader range of cells and tissues.

A role for Src Family Kinases in PTH Activation of ERK1/2 Mitogen Activated Protein Kinases. H. A. Tawfeek*, A. B. Abou-Samra. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

Our previous results suggested that PTH/PTHrP receptor phosphorylation and internalization are not required for PTH activation of ERK1/2 mitogen-activated protein (MAP) kinases. The goal of the current study was to investigate the role of Src family non-receptor tyrosine kinases in PTH activation of ERK1/2 MAP kinases and to examine whether these signaling pathways are involved in PTH regulation of P90RSK ribosomal kinase, CREB/ATF-1 and c-fos. PTH increased phosphorylation of Hck Src kinase in LLCPK-1 stably expressing PTH/PTHrP receptor. To study the role of Src family kinases, we used a combination of pharmacological and biochemical inhibitors. PP2, a specific Src family kinase inhibitor, caused a remarkable decrease in PTH activation of ERK1/2. Furthermore, stable over-expression of a c-terminal Src family kinase (CSK), a physiological down-regulator of Src kinases activity, in LLCPK-1 cells attenuated ERK1/2 activation in response to PTH treatment. PTH increased phosphorylation of P90RSK and CREB/ATF-1 and induced transcription of c-fos. U0126, a specific inhibitor of ERK1/2 pathway, and PP2 Src family kinase inhibitor did not significantly affect PTH activation of CREB/ATF-1. Both U0126 and PP2, however, significantly reduced PTH phosphorylation of P90RSK. Additionally, U0126 decreased PTH stimulation of c-fos expression. Taken together, these data suggest that Src family kinase(s) are involved in PTH activation of ERK1/2 MAP kinases and P90RSK but not in PTH activation of CREB/ATF-1 and that ERK1/2 MAP kinases play a role in PTH-stimulation of c-fos expression.

Defining the Entry Point of Parathyroid Hormone (1-34) into the PTH1 Receptor. A. Wittelsberger[1], M. Corich*[1], B. Lee*[1], B. E. Thomas*[1], A. Ahmad*[1], M. Chorev[2], D. F. Mierke[3], M. Rosenblatt[1]. [1]Department of Physiology, Tufts University School of Medicine, Boston, MA, USA, [2]Laboratory for Translational Research, Harvard Medical School, Cambridge, MA, USA, [3]Department of Chemistry and Molecular Pharmacology, Brown University, Providence, RI, USA.

Parathyroid hormone (PTH) 1-34 contains two a-helical domains associated with specific functions: the N-terminal helix is required for activation of its G protein-coupled receptor, and the C-terminal helix is responsible for receptor binding. We recently focused on the role of the mid-domain of PTH. The region from residue 14-15 to residue 19-21 was found to be unstructured in solution by NMR studies. Whereas distinct contact sites between N-terminal and C-terminal residues of PTH and the receptor had been identified by photoaffinity crosslinking studies and could be used for molecular modeling of the ligand-receptor complex, little information was available on interactions of the hormone mid-region. In particular, it was not known at what site of the helix bundle the mid-region of PTH traversed to connect the N-terminal activation domain in contact with the top of transmembrane helix (TM) VI and the C-terminal binding domain interacting with the N-terminal extracellular domain (N-ECD) of the receptor. Recently, we introduced the photoreactive p-benzoylphenylalanine singly at positions 11, 15, 18, and 21 in a series of PTH-(1-34) analogs. By digestive mapping of the crosslinked conjugates, we then identified receptor regions [165-189], [183-189], [189-240], and [165-189] as respective contact sites. Molecular dynamics simulations, using the crosslinking regions of the mid-region in addition to previously identified contact sites as distant restraints, showed a refined model of the PTH ligand-receptor complex in which the ligand traverses between the top of TM's I and II. This finding prompted us to propose an intermediate step in the ligand-receptor interaction: after binding of the N-terminal ligand domain to the N-ECD of the receptor, extensive contacts in the mid-region anchor the hormone in the correct orientation for the N-terminal domain to reach, in the third step, the binding groove within the helix bundle, leading to receptor activation. Our current work investigates several routes to test the important role we propose for the mid-region of the hormone. Primarily, using point mutations within the [165-189] region of the receptor for introduction of additional cleavage sites and/or probing for important side-chain contacts, we are aiming at a higher resolution model of the entry point of PTH-(1-34) into the receptor's 7 transmembrane helical bundle.

PTH1R Endocytosis and G_q Signaling Independently Contribute to the Activation of the Mitogen-activated Protein Kinases ERK1 and ERK2. C. A. Syme*, A. Bisello. Department of Medicine/Division of Endocrinology and Metabolism, University of Pittsburgh, Pittsburgh, PA, USA.

Agonist-mediated activation of the type 1 parathyroid hormone receptor (PTH1R) results in several signaling events, and receptor endocytosis. It is well documented that arrestins contribute to desensitization of both G_s- and G_q-mediated signaling and mediate PTH1R internalization. However, whether PTH1R trafficking directly contributes to PTH1R signaling remains unclear. To begin addressing this, we investigated the role of PTH1R trafficking in cAMP signaling and ERK1/2 activation in HEK-293 cells. Dominant-negative forms of dynamin (K44A) and β-arrestin2 (319-418) abrogated PTH1R internalization but had no effect on cAMP signaling: neither acute cAMP production by PTH, nor desensitization and resensitization of cAMP signaling were affected. Identical observations were made in either the absence or presence of cyclohexamide. Therefore, PTH1R trafficking is not necessary for regulation of cAMP signaling. ERK1/2 activation by PTH(1-34) peaked at 5 min (average 4.8-fold ± 1.3, n=15). A PTHrP-based analog (Bpa[1]-PTHrP-(1-36)) that selectively activates the G_s/cAMP/PKA without inducing PTH1R endocytosis, failed to activate ERK1/2, indicating that G_q-signaling and/or PTH1R internalization are required for ERK1/2 activation. Inhibition of PTH1R endocytosis by K44A-dynamin dampened ERK1/2 activation in response to PTH(1-34) by 45%. For wild-type PTH1R, ERK1/2 activation occurred only in response to the full agonist PTH(1-34) but not to PTH(7-34). In contrast, a mutant PTH1R (M593A-PTH1R) which does not require activation for endocytosis was able to induce ERK1/2 phosphorylation in response to both PTH(1-34) and PTH(7-34). Collectively, these data indicate that PTH1R trafficking and G_q (but not G_s) signaling independently contribute to ERK1/2 activation. Together with previous reports, these findings underlie the complexity of the molecular mechanisms leading to PTH-stimulated ERK1/2 activity, which may involve G_q-mediated ERK1/2 activation, transactivation of EGF receptors and PTH1R trafficking.

Specific Activation of Type I or C-Terminal PTH Receptors Regulate Gap-Junctional Communication Among Bone-Derived Cells Expressing or Lacking PTH1R. P. C. Schiller*[1], G. D'Ippolito*[1], P. Divieti[2], F. R. Bringhurst[2], G. A. Howard[1]. [1]Medicine, University of Miami/VAMC, Miami, FL, USA, [2]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

We and others have reported that gap-junctional communication (GJC) plays a critical role in bone physiology. A potential part of the mechanism of that role is the fact that parathyroid hormone (PTH) can increase cell-to-cell GJC among bone cells via activation of the type 1 PTH/PTHrP receptor (PTH1R). In other studies we have shown that long fragments of PTH, lacking the N-terminal portion of the hormone, are able to bind to a receptor distinct from the PTH1R and specific for the C-terminal region of PTH, the CPTH receptor (CPTHR). To assess if CPTHR activation is involved in cell-to-cell communication, we studied GJC in bone cells lacking PTH1Rs but expressing CPTHRs. Quantification of GJC was determined in PTH1R-null osteoblastic (F1-14) and osteocytic (OC14) cell lines as well as in MC3T3-E1 mouse and ROS 17/2.8 rat osteoblastic cells expressing functional PTH1Rs. Specifically, fluorescent dye transferred from loaded PTH1R-null F1-14 and OC14 cells, as well as from MC3T3-E1 and ROS 17/2.8 cells to F1-14 and OC14 cells. Similarly, F1-14 and OC14 cells transferred pre-loaded dye to MC3T3-E1 and ROS 17/2.8 cells, demonstrating that PTH1R expression is not required for GJC. We then investigated whether PTH fragments, with different C termini, could modulate the extent of GJC among PTH1R-null bone cells and PTH1R-expressing osteoblastic cells. We quantitatively assayed GJC in the presence and absence of PTH(1-34), PTH(53-84) or PTH(1-84). Interestingly, PTH(1-84) and PTH(53-84) significantly increased GJC among PTH1R-null cells, while PTH(1-34) had no effect in these cells. PTH(1-84) also increased GJC between ROS 17/2.8 and OC14 or F1-14 cells. In those experiments PTH(1-34) also had a stimulatory effect similar to that of PTH(1-84). Finally, PTH(53-84) increased GJC between MC3T3-E1 cells and OC14 or F1-14 cells. Our results demonstrate that PTH1R-null cells not only form functional GJ channels among themselves but also with cells expressing PTH1Rs. In addition, activation of CPTHR not only increases GJC between PTH1R-null cells but also with PTH1R-expressing osteoblasts. Our data strongly suggest that CPTHRs may play a critical role in regulating cell-to-cell communication and maintaining bone homeostasis independent of the PTH1R.

Parathyroid Hormone Activates a Galpha12/Galpha13-RhoA-Phospholipase D Signaling Pathway in Osteoblastic Cells. A. T. K. Singh[1], A. Gilchrist*[2], T. Voyno-Yasenetskaya*[3], P. H. Stern[1]. [1]Molecular Pharmacology and Biological Chemistry, Northwestern University, Chicago, IL, USA, [2]Molecular Pharmacology and Biological Chemistry, Cue BIOtech, Chicago, IL, USA, [3]Pharmacology, University of Illinois, Chicago, IL, USA.

Parathyroid hormone (PTH) interaction with its receptor in osteoblasts activates signaling through heterotrimeric G proteins. We have shown that PTH activates phospholipase D (PLD) in both UMR-106 osteoblastic cells and primary osteoblasts, however the G protein mediating this response, and the intermediate signaling events between G protein activation and PLD are not yet established. To determine the involvement of specific Gα subunits, UMR-106 cells were transfected with minigenes coding for expression of small peptides antagonistic to specific G protein alpha subunits, prior to 30 minute treatment with 10 nM bPTH 1-34. PLD was measured by transphosphatidylation. Minigenes coding for antagonists to Gα12 and Gα13 prevented the effect of PTH, whereas those coding for Gαs and Gαq were ineffective. The lack of effect of Gαs supports previous findings that PTH stimulation of PLD does not require PKA. We previously found that PTH activates RhoA, and that RhoA is essential for PTH stimulation of PLD in UMR-106 cells. The role of RhoA in Gα12 and Gα13-stimulated PLD activation was evaluated. Transfection with dominant negative RhoA prevented PLD activation by constitutively active Gα12 and Gα13. PTH-stimulated PLD is inhibited by the statin, mevastatin, and the aminobisphosphonate, alendronate. Since RhoA is activated by isoprenylation, the effects of these agents on PLD could be due to their inhibition of the formation of isoprenyl groups in the cholesterol biosynthesis pathway. To investigate this, intermediates in cholesterol biosynthesis were tested. Mevalonate, the product of HMGCoA reductase, prevented the inhibitory effect of the statin, but not of the bisphosphonate on PTH-stimulated PLD activity. Squalene, which acts at a step beyond the generation of isoprenyl groups, failed to prevent the effects of either inhibitor. However, the geranylgeranyl group donor, geranylgeranylpyrophosphate, which would bypass the steps at which both statins and bisphosphonates inhibit the pathway, prevented the inhibitory effects of both compounds on PLD. The current findings demonstrate that Gα12 and Gα12-containing heterotrimeric G proteins, and subsequent RhoA activation, mediate the effects of PTH on PLD in osteoblastic cells. The results further suggest that effects of statins and aminobisphosphonates on isoprenylation mediate their inhibitory effects on PTH-stimulated PLD activity, which could lead to their modulation of differentiated functions of osteoblasts.

Pelvic Sexual Dimorphism Is Generated through Opposite Functions of Sex Hormone Receptors in Mice. S. Tanaka*[1], T. Matsumoto*[1], T. Yamada[2], K. Yoshimura*[1], H. Shiina*[1], J. Miyamoto*[1], Y. Yamamoto*[1], T. Sato*[1], A. Krust*[3], P. Chambon*[3], S. Kato[1]. [1]IMCB, Univ. of Tokyo, Tokyo, Japan, [2]Dept. of Orthopedic Surgery, Faculty of Medicine, Univ. of Tokyo, Tokyo, Japan, [3]IGBMC, ULP, Strasbourg, France.

Sexual dimorphism in bone patterning, mineral density and size is well known in mammals. Particularly, the sexual dimorphism of humans is evident in pelvic patterning. The pelvic cavity in female is larger than that in male. Although a number of morphometric analyses have been performed, the molecular basis for the generation of such sexual dimorphism remains largely unknown. To address this issue, we established the analysis model of pelvis in growing mice for genetic identification of factors, that generate sexual dimorphism. In the present study, we found that opposite functions of sex hormone receptors define the sexual dimorphism of the pelvis.

Pelvic patterning was examined in 9-week-old wild-type (WT) mice. In female mice, the pubis was about 50% longer than that in male mice, and accordingly the cavity area of pelvis was also about 50% larger. The analyses of 2 to 9-week-old WT mice revealed that the sex difference of these parameters could be detected at the age of 4 weeks, and became marked before sexual maturation, thus implicating sex hormone actions.

To investigate this possibility, we analyzed androgen receptor knockout (ARKO) and estrogen receptor α/β knockout (ERα/βKO) mice. The pelvic cavity in either male ARKO mice or female ERαKO mice was clearly altered, and both of them exhibited an almost identical intermediate volume.

Gonadectomy of mice at the age of 2 weeks grew up in both adult male and female WT mice with an intermediate type pelvis. Treatment with 5α-dihydrotestosterone (DHT) reduced the intermediate type pelvis into the narrow male type pelvis in both male and female gonadectomized WT mice. Conversely, treatment with 17β-estradiol (E2) enlarged the intermediate type pelvis into female wider type pelvis in both male and female gonadectomized WT mice. However, such hormonal actions were not seen in mice deficient in the cognate receptor.

To further investigate the molecular basis of the hormonal actions in the pelvis, we performed morphological and histological analyses of the pelvis of growing mice. We identified growing chondrocyte layers at the distal end of the pubis, that is presumed to support bone growth. A BrdU incorporation experiment showed that the rate of proliferation of the proliferating chondrocyte layer in female pubis was higher than that in male, while such a sex difference was not seen in receptor KO mice.

From these studies, we conclude that the sexual dimorphism of the pelvic pattering is generated through opposite functions of sex hormone receptors, but not genetic sex.

Bone and Muscle Protection and Prostate-Sparing Effects of the Selective Androgen Receptor Modulator (SARM) 7α-Methyl-19-Nortestosterone: Evidence from the Aged Orchidectomized Male Rat Model. K. Venken*[1], S. Boonen[1], E. Van Herck*[1], L. Vandenput*[1], N. Kumar*[2], R. Sitruk-Ware*[2], K. Sundaram*[2], R. Bouillon[1], D. Vanderschueren[1]. [1]K.U. Leuven, Leuven, Belgium, [2]Center for Biomedical Research, Population Council, New York, NY, USA.

The synthetic androgen 7α-methyl-19-nortestosterone (MENT™) is a selective androgen receptor modulator (SARM) which is not converted to a dihydroderivative by 5α-reductase in the prostate. This study reports its bone protective potential as assessed in the aged orchidectomized male rat model. Male, 13-month old Wistar rats were either sham-operated (sham) or orchidectomized (orch). Groups of orchidectomized rats were treated with different doses of MENT (4, 12 or 36 µg/day) subcutaneously for 16 weeks via mini-osmotic pumps. Analysis of the effects of androgen deficiency versus MENT replacement was performed using quantitative computed tomography (pQCT), dual energy X-ray absorptiometry (DEXA), and biochemical markers of bone turnover. At the end of the study period, prostate weight in orchidectomized rats treated with low- (4 µg/day) or mid-dose (12 µg/day) MENT

remained significantly lower compared to the sham-operated animals (-47% and -25%, respectively, $p < 0.05$). High-dose MENT (36 µg/day), on the other hand, induced prostate hypertrophy (+21%, $p < 0.05$). Low-, mid-, and high-dose MENT were found to be effective in suppressing the acceleration of bone remodelling following orchidectomy, as assessed by osteocalcin (-25%, -44% and -53% respectively, $p < 0.05$) and deoxypyridinoline (-45%, -66% and -79% respectively, $p < 0.05$) and in preventing orchidectomy-induced bone loss at the spine, femur, and total-body, as evaluated by DEXA and, at the femur, as evaluated by pQCT (+ 76%, + 75% and +67% respectively, $p < 0.05$). Compared to sham-operated animals, the low- and mid-dose MENT groups showed no decline in lean body mass and no muscle atrophy (as measured by m. quadriceps weight) at 16 weeks, whereas high-dose MENT was associated with a significant decline in lean body mass (-8.5%, $p < 0.05$) and quadriceps weight (-10.6%, $p <0.05$). MENT behaves as a SARM in orchidectomized aged rats as low- and mid-doses have full bone and muscle protective effects while not inducing prostate hypertrophy. Our findings support the need for human studies to explore the potential of MENT as an option for androgen replacement in aging men.

Estrogen Stimulates Periosteal Expansion in Male Mice, Even in the Context of Depressed Systemic Levels of Insulin-Like Growth Factor-I. K. Venken*[1], S. Boonen[1], M. Lindberg*[2], N. Andersson*[2], S. Movérare*[2], J. Svensson*[2], R. Bouillon[1], C. Ohlsson[2], D. Vanderschueren[1]. [1]K.U. Leuven, Leuven, Belgium, [2]Gothenburg University, Gothenburg, Sweden.

Based on animal research in ovariectomized animal models, estrogen is generally considered to inhibit, not stimulate skeletal growth. This concept, however, was not supported by recent observations of ongoing radial skeletal growth during estrogen treatment in a young man with aromatase deficiency (R. Bouillon et al., unpublished data). The current study in male orchidectomized mice was designed to address the question as to whether estrogen is able to stimulate periosteal bone formation and, if so, to what extent this stimulatory action involves interaction with systemic insulin-like growth factor-I (IGF-I). To this end, periosteal bone formation was assessed by dynamic histomorphometry following estradiol (E_2) replacement (0.05 µg/day via subcutaneous silastic implants) in 3-month-old orchidectomized (orch) male mice with Cre-loxP-induced liver-specific IGF-I gene inactivation (LI-IGF-I KO) and corresponding WT mice. Mice were treated for 5 weeks. Results are expressed as % gain or loss compared to orch and analysed via two-factor ANOVA. As shown in the figure, periosteal bone formation (Ps.BFR/B.Pm.) increased significantly, not only in E_2-treated orch WT (+114%) but also in E_2-treated orch Li-IGF-I KO mice (+46%). In the latter, periosteal bone apposition was induced despite severely reduced serum IGF-I levels (-79%). E_2 activated both osteoblast number (+93% and +37%, respectively) and activity (+18% and +8%, respectively) at the periosteal site in WT and Li-IGF-I KO. Periosteal bone apposition resulted in significant thickening of the femoral cortical area, both in WT (+22%) and Li-IGF-I KO (+23%). Moreover, E_2 upregulated cortical (+5% and +9% in WT and Li-IGF-I KO, respectively) and trabecular (+38% and +40%, respectively) bone mineral density, as measured by pQCT. In addition, polar moment of inertia, a non-invasive marker of bone strength, was higher in E_2-treated animals (21% and 38%, respectively).We conclude that estrogen is able to stimulate periosteal expansion in male orchidectomized mice, even in the context of depressed systemic IGF-I levels.

Effect of OVX and E2 Treatment on Bone in Aged ERKO Mice. Z. Peng, H. Väänänen*, P. Härkönen*. Department of Anatomy, Institute of BioMedicine, Turku, Finland.

In order to understand the role of estrogen receptors in bone metabolism we studied effects of ovariectomy (OVX) and estradiol (E2) treatment on bone in aged estrogen receptor alfa knockout (ERKO) mice. Over one year old ERKO and wild type mice were ovariectomized and half of them were implanted with subcutaneous E2 pellets for four weeks. Bone analysis included pQCT, bone histomorphometry and mechanical testing. Results from OVX and E2 treatment groups were compared to age matched control groups of wild type (WT) and ERKO animals. pQCT measurements showed that E2 treatment significantly increased trabecular bone density at proximal tibia and distal femur of both WT-OVX and ERKO-OVX animals. In histomorphometry both OVX-WT and OVX-ERKO groups showed increased area of bone marrow cavity, which was prevented by E2 treatment in both groups. Dynamic histomorphometry revealed highly elevated mineral apposition rate (MAR) and bone formation rate (BFR) at periosteum of the femoral shaft in both OVX groups. This increase was more efficiently inhibited by E2 in WT than in ERKO mice. OVX did not have a clear effect on endocortical MAR or BFR but E2 treatment markedly elevated MAR. E2 stimulation of BFR was, however, more enhanced in the WT than in the ERKO group. TBV was higher in ERKO than WT mice. It was decreased by OVX and strongly increased by E2 treatment in both groups. However, the maximal load of the bending strength was decreased in WT-OVX-E2 group compared to WT-OVX or WT group. This difference was not seen in ERKO groups. Histological appearance of E2-increased trabecular bone was roughly similar in WT and ERKO mice indicating a typical high turnover situation with an increased number of active osteoblasts and osteoclasts. These results suggest that aged female ERKO mice are almost as sensitive as WT mice to E2 treatment and arouse interesting questions concerning possible age dependent functions of different estrogen receptors.

SRC-2 Associates Preferentially with ERα. F. J. Secreto[1], D. G. Monroe[1], S. K. Dutta*[1], B. L. Riggs[2], S. Khosla[2], T. C. Spelsberg[1]. [1]Biochemistry, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Nuclear co-activators (NCo-A) and co-repressors (NCo-R) play a critical role in mediating the ability of nuclear receptors to effect gene expression in a tissue specific manner. Although some NCo-A/NCo-R proteins are required for estrogen receptor (ER) mediated gene transcription in many tissue types (ex. SRC-1), others are not as ubiquitous in their tissue distribution. AIB-I (SRC-3) is a carcinoma specific NCo-A, virtually undetectable in human osteoblasts. Further, the various SERMS and pure ER antagonists profoundly effect the recruitment of co-activator proteins. Since estrogen (E2) regulates many key processes involved in bone homeostasis, we wanted to extend our studies of NCo-A/NCo-R beyond SRC-1, which our lab and others have found to be an essential component of ER mediated gene expression in osteoblasts. We choose to examine SRC-2 (NCo-A), a co-activator that has not been thoroughly investigated in osteoblasts to date. Although SRC-2 has been studied at the protein level in other tissues, we have had limited success with commercial antibodies recognizing the protein. Therefore, we developed polyclonal antibodies to SRC-2 using a specific peptide epitope. Using nuclear extract isolated from human fetal osteoblast cells (hFOb), U2OS cells, and COS-7 cells, immunoblots showed that SRC-2 was present, and the signal was successfully reduced using antibodies pre-incubated with an excess of the corresponding immunoreactive peptide. Nuclear extract pull-down assays using GST-ERα C-terminal domain (AF-2) fusion proteins pre-incubated with either E2, 4'OH-Tamoxifen (4HT), or ICI, showed that SRC-2 binding to the AF-2 domain of the ERα increased with E2 treatment. SRC-2 binding was nearly absent in ICI and 4HT treated samples, comparable to control levels. Interestingly, minimal binding of SRC-2 was seen in pull-down assays using similarly treated GST-ERβ fusion proteins, regardless of the source of nuclear extract on the bound ligand. This isoform specificity may explain the preferential enhancement of gene expression we observed in osteoblasts co-transfected with SRC-2 and ERα compared to similarly treated cells co-expressing SRC-2 and ERβ. Future experiments, including the use of Si-RNA targeted to both SRC-1 and SRC-2, will be used to elucidate E2-dependent gene expression differences that exist between cells expressing ERα and ERβ .

Growth Plate Chondrocytes Respond to Estrogen with Sex Specific Increases in IP3 and Intracellular Ca^{++} Signaling via a Capacitative Entry Mechanism. Z. Schwartz[1], J. Ekstein*[2], E. Nasatzky*[2], A. Ornoy*[2], B. D. Boyan[1]. [1]Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, USA, [2]Periodontics, Hebrew University, Jerusalem, Israel.

17-Beta-estradiol (E_2) regulates growth plate chondrocyte differentiation through two interacting pathways: via classic nuclear receptors ERα and ERβ, and through membrane associated signaling. E_2's effects are gender-specific and cell-maturation-dependent. This study examined the role of intracellular calcium concentration (ICCC) in determining cell response and the mechanisms involved. Resting zone (RC) and growth zone (GC) chondrocytes were isolated from costochondral cartilage of male and female rats. ICCC was measured using a fluorescent probe, Flou-4. Chondrocytes were treated with E_2 or 17-alpha-estradiol in the presence of high and low extracellular Ca^{++}. Changes in fluorescence were recorded every 5 sec for 500 sec. To examine the source of Ca^{++} responsible, Ca^{++} pumps on the endoplasmic reticulum were inhibited with 3 uM thapsigargin and Ca^{++} channels on the cell membrane were inhibited with 1 uM verapamil. External Ca^{++} was removed using EGTA. We monitored the levels of two products of phospholipase C (PLC) action: diacylglycerol (DAG) and inositol 1,4,5-trisphosphate (IP3). DAG is a regulator of protein kinase C (PKC), which is activated by E_2 in a sex-specific manner and IP3 is known to control ICCC in other systems. E_2 increased ICCC only in the cells from female rats. The effect was stereospecific; it was found in RC and GC chondrocytes but it had a greater magnitude in RC cells. The increase was rapid and peaked at approximately 140 seconds; the entire event was over within 300 seconds. Low Ca^{++} media did not abolish the E_2-dependent ICCC elevation, nor did verapamil. However, thapsigargin reduced the effect of E_2 on ICCC. E_2 caused increased IP3 and DAG only in female cells. IP3 was generated within 10 seconds and the greatest increases were in RC cells. These results indicate that E_2 increases ICCC via membrane-associated mechanisms mediated by PLC-dependent production of IP3. The effect on ICCC is rapid and sex-specific and cell maturation-dependent. The source for this Ca^{++} was almost exclusively from the endoplasmic reticulum. The results indicate that the entity responsible for sex-specific responses to E_2 is upstream from PLC activation.

Adhesion and Apoptosis Are Regulated by 17β-estradiol in Differentiating and Mature Murine Osteoclasts. D. Saintier*, V. Khanine*, M. de Vernejoul, M. E. Cohen-Solal. 606, INSERM, Paris, France.

Estrogen deficiency induces enhanced bone resorption which might be responsible for osteoporosis. The mechanism of action of estradiol in the inhibition of osteoclastic bone resorption is still unknown. We have previously shown that in vitro estradiol exerts a direct inhibitory effect on osteoclast activity in human osteoclast progenitors that was associated with decreased β3 integrin expression. Therefore, this study was designed to evaluate the effect of estradiol on both adhesion and apoptosis in differentiating or mature murine osteoclasts. We used RAW 264.7 cells which were differentiated for 3 days (D3, differentiating osteoclasts) or 5 days (D5, mature osteoclasts) in phenol red free αMEM supplemented with 10% FCS and RANKL (30 ng/ml) in the presence (E+) or absence (C) of 10^{-8}M 17β estradiol. At D5, estradiol reduced the number of TRAP+ multinuclear cells by 50 % compared to controls (3.1±0.9 vs 6.1±0.4/mm^2, p<0.01), as well as TRAP+ mononuclear cells (237.6±20.7 for E+ vs 306.4±12.6 /mm^2, p<0.01). Moreover, estradiol decreases TRAP+ multinuclear/mononuclear cells ratio, indicating that estradiol decreased the fusion of osteoclast precursors.The effect of estradiol on cell adhesion in vitronectin pre-coated plates was tested by crystal violet method. Exposure for 2 hours with estradiol decreased adhesion time of mature osteoclasts by 35% compared to controls (1.01±0.35 vs 1.33±0.83 AU respectively).

Apoptosis was then investigated through the caspase 3 and 8 activities at D3 and D5 after 24 and 48h exposure of estradiol using fluorescence spectrometry method. Caspase 3 and 8 activities were not changed by 24 hour-treatment with estradiol. However 48 hour-exposure with estradiol promoted caspase 3 activity by 34 % in differentiating cells and by 59% in mature osteoclasts compared to controls. Caspase 8 activity was enhanced by estradiol as well. These effects were reversed by estrogen receptor antagonist ICI 182-780.

Moreover differentiating and mature osteoclasts were cultured with estradiol for 48 hours in the presence of caspase 8 inhibitor for the measurement of caspase 3 activity. Caspase 8 inhibitor induced a lower caspase 3 activity in both cultures. However estradiol had no effect on caspase 3 in mature osteoclasts cultured with caspase 8 inhibitor. These data suggest that estradiol might act upstream caspase 8 pathway.In conclusion, 17β estradiol decreased osteoclast resorption through decreased fusion of precursors and adhesion of osteoclasts. Apoptosis was promoted in differentiating and mature osteoclasts after 48 hours indicating the involvement of several pathways in direct inhibition of bone resorption by estradiol.

Correlations between *in Vi*vo Activities of Estrogens and Their Differential Effects on ERα-Controlled Repression of MMP-1 Promoter Activity. A. Schmidt[1], A. Scafonas*[1], P. J. Masarachia*[1], G. J. Sedor*[1], E. T. Birzin*[1], S. Kim*[2], H. Y. Chen*[2], Q. Tan*[1], H. A. Wilkinson*[1], X. S. Hou*[3], F. DiNinno*[2], S. P. Rohrer*[1], J. M. Schaeffer*[4], M. L. Hammond*[2], G. A. Rodan[1], D. A. Towler[5], D. B. Kimmel[1]. [1]Molecular Endocrinology, Merck Research Laboratories, West Point, PA, USA, [2]Medicinal Chemistry, Merck Research Laboratories, Rahway, PA, USA, [3]Biometrics Research, Merck Research Laboratories, West Point, PA, USA, [4]External Scientific Affairs, Merck Research Laboratories, Rahway, PA, USA, [5]Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

Estrogen receptors (ER), ERα and ERβ, are ligand-dependent transcription factors that bind to specific DNA sequences and regulate gene expression. Genetic studies in mice and man suggest that ERα controls bone, uterus, and breast effects of estrogen. To date, the mode of action of estrogen and SERMs (selective estrogen receptor modulators) on bone is not fully understood. Furthermore, no *in vitro* assays that show agonist actions of estrogenic agents can predict their agonist activities *in vivo*. We report the development of a transrepression assay in which ERα controls the activity of an AP-1 transcription factor binding site in the MMP-1 promoter. In this assay, ICI-182780, raloxifene, 4-hydroxytamoxifen, estradiol, and SERAMs 4-D and 5 (selective estrogen receptor alpha modulators) exhibit differential agonistic activities by repressing the MMP-1 promoter by 20 to 80%. MMP-1 transrepression efficacy and potency not only correlates positively with uterotrophic activity (R^2=0.98), but also predicts their osteoprotective potential in the ovariectomized rat (R^2=0.98). Using structure-function analysis of ERα, we determined that raloxifene repression is predominantly controlled by the amino terminal region, while that of estradiol is controlled by both the amino- and carboxy-terminal regions of ERα. Introducing the AF-2 mutation L540Q to the ER does not influence the ability of raloxifene to repress MMP-1. However, L540Q increases the repression of MMP-1 by ICI-182870 to the level of raloxifene and decreases that of estradiol to the level of raloxifene. These results suggest that estradiol and selective and non-selective osteoprotective SERMs display agonistic activity in transcription, controlled by ERα via protein-protein interaction that correlates with their actions in vivo in bone and uterus. AP-1 transrepression via ER-alpha is a multi-step process that may be responsible for the differential actions of various ER ligands.

Expression Levels of ERα in Different Compartments of Proximal Tibia and the Effect of Ovariectomy. G. Zaman*[1], R. F. L. Suswillo*[1], A. Pitsillides[1], T. Arnett[2], L. E. Lanyon[1]. [1]Basic Sciences, The Royal Veterinary College, London, United Kingdom, [2]Anatomy & Developmental Biology, University College London, London, United Kingdom.

A number of *in vitro* and *in vivo* studies have highlighted the role of Estrogen Receptor alpha (ERα) in bone's adaptive response to loading. A number of recent reports have described the distribution of ERα in human bone. Braidman et al. [1] (using 6F11 monoclonal antibody to the recombinant human full-length sequence of ERα, Novocastra Laboratories, Newcastle-upon-Tyne, UK) have reported that only about 14% of the osteocytes express ERα in human and rat bones. Using the same antibody Hoyland et al. [2] reported that the proportion of osteocytes with immunodetectable ERα decreases from 25% in hormone replete women to 12% in women with ovarian steroid deficiency. Conversely, Ankrom et al. [3] (using ERα-EIA, Abbott Laboratories Chicago, IL, USA) have reported that older women have higher levels of ERα than younger women. Somewhat conflicting patterns of ER expression reported may possibly be due to methodological variations, such as different antibodies used and the methods employed for antigen retrieval. We have used two antibodies (HC-20 and MC-20, purchased from Santa Cruz, CA, USA) both directed specifically against the carboxy terminus of ERα having no cross reactivity with ERβ. Immunocytochemistry was performed on sections from fixed and decalcified rat tibiae mounted on poly-lysine coated slides. Deparaffinated and re-hydrated sections were immunostained for ERα using an indirect immunoperoxidase method as described previously [4]. Semi-quantification analysis of ERα protein expression per cell was performed using a Vickers M85 microdensitometer. Using this methodology ERα was expressed in over 90% of the osteocytes. ERα expression levels per cell were higher in osteoblasts than in osteocytes. Expression levels of ERα per cell varied in different compartments of the proximal tibia with the strongest immunostaining seen in osteocytes within the mid-shaft. The epiphysis and primary spongiosa had equal ERα expression but the levels were lower than mid-shaft osteocytes. The secondary spongiosa expressed by far the lowest levels of ERα. Ovariectomy significantly reduced the ERα expression levels per cell in the midshaft osteocytes suggesting that ERα number is regulated by circulating estrogen levels. The variation of ERα expression levels in different compartments of the bone may reflect the potential for loading related osteogenic response.

Bone-Sparing and Cholesterol Lowering Effects of Non-Uterotropic, Selective Estrogen Receptor Alpha Modulators (SERM-αs). A. A. Reszka[1], S. Adamski*[1], J. E. Fisher[1], E. T. Birzin*[2], L. Lipfert*[1], S. Kim*[3], H. Y. Chen*[3], Q. Tan*[3], F. DiNinno*[3], S. P. Rohrer*[2], J. M. Schaeffer*[2], M. L. Hammond*[3], G. A. Rodan[1], L. P. Freedman*[1], D. B. Kimmel[1]. [1]Molecular Endocrinology and Bone Biology, Merck Research Laboratories, West Point, PA, USA, [2]Molecular Endocrinology and Bone Biology, Merck Research Laboratories, Rahway, NJ, USA, [3]Medicinal Chemistry, Merck Research Laboratories, Rahway, NJ, USA.

Two isoforms of the estrogen receptor (ER), ERα and ERβ bind equally well to the natural ligand, 17β-estradiol. In the present study, we tested the hypothesis that transcriptional activation of ERα *in vivo* was sufficient to protect against ovariectomy (OVX)-induced bone loss and to suppress serum cholesterol without substantially increasing uterine wet weight in the rat. We selected eight SERM-αs from the chromane and dihydrobenzoxathiin platforms to test for *in vivo* effects on bone and lipids and in comparison to 17α-Ethinyl Estradiol (EE) and/or raloxifene. SERM-αs were competitive inhibitors for the binding of 17β-estradiol to ERα with IC50s of 0.21-1.8 nM. Selectivity for ERα vs. ERβ was between 10 and 48-fold (5.6-fold for raloxifene). In the immature rat, SERM-α-induced uterotropism was equal to or less than that of raloxifene and far below that of EE. In six-month old, newly-OVX rats, urinary deoxypyridinoline/creatinine rose ≥two-fold at two weeks. Treatment with the SERM-αs suppressed this by 59-86% (replete to sham), while raloxifene and EE suppressed by 83% and 100%, respectively. To directly assess effects on bone mass, we measured the ratio of bone mineral density of the distal femoral metaphysis and central femur (DFM/C ratio). The OVX control lost 11-12% of DFM/C vs. sham six weeks post-OVX. All SERM-αs maintained DFM/C at 56-100% replete to sham. DFM/C was 64% replete with raloxifene and 86-100% with EE. In three day OVX-rat assays, all SERM-αs significantly reduced total serum cholesterol by 27-45% vs. baseline, comparable to the 37% suppression by raloxifene (all at 1.5 mg/kg/d, p.o.). After six weeks of treatment of the OVX rat, cholesterol suppression was 29-62% vs. 49% with raloxifene. EE (0.6 mg/kg/day, p.o.) induced 85-90% suppression of serum cholesterol over three days, but only 48-56% by six weeks. Together, these data suggest that ERα-selective ligands can elicit similar desirable effects to those of EE and raloxifene on endpoints related to bone and lipids. Similar to the less ERα-selective SERM, raloxifene, the SERM-αs maintain bone mass and reduce serum total cholesterol without inducing substantial uterotropism. This suggests that SERM-αs can achieve the same desirable effects of non-receptor specific SERMs on bone and lipids while avoiding ERβ antagonism.

Sex Specific Responses of Growth Plate Chondrocytes to Testosterone Require Metabolism to Dihydrotestosterone by Steroid 5-Alpha Reductase Type 1. P. Raz*[1], E. Nasatzky*[1], B. D. Boyan[2], Z. Schwartz[1]. [1]Periodontics, Hebrew University Hadassah, Jerusalem, Israel, [2]Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, USA.

Growth plate chondrocytes exhibit sex-specific responses to testosterone. Only cells from male rats exhibit testosterone-dependent changes in proliferation and differentation, although testosterone receptors are present in both male and female cells, indicating that mechanisms other than those mediated by nuclear receptors may be involved. In male cells testosterone is preferentially metabolized to dihydrotestosterone (DHT), suggesting that DHT may play a role. Here we tested the hypothesis that the sex-specific response to testosterone requires further metabolism of the hormone to DHT. Rat costochondral resting zone (RC) and growth zone (GC) cartilage cells from male and female Sabra strain rats were treated with 10^{-11} to 10^{-7} M testosterone or DHT for 24 h. Measurement of [^{3}H]-thymidine incorporation in quiescent, preconfluent cultures and alkaline phosphatase specific activity in cell layer lysates of confluent cultures showed that testosterone and DHT has comparable effects in GC cells. Both parameters were increased in cells from male rats. Testosterone decreased DNA synthesis in male RC cells but DHT had no effect. Moreover, neither testosterone nor DHT affected alkaline phosphatase specific activity of male RC cells. Female GC and RC chondrocytes had no response to testosteroneT or DHT. Inhibition of steroid 5α-reductase activity with finesteride (1, 5 or 10 μg/ml) reduced the response of male GC cells to testosterone in a dose-dependent manner, indicating that metabolism to DHT was required. RT-PCR showed that both male and female cells expressed mRNAs for steroid 5α-reductase type 1 but lacked mRNAs for the type 2 form of the enzyme. These observations indicate that the sex-specific response of rat growth plate chondrocytes to testosterone is maturation-state dependent and requires the further metabolism to DHT. Failure of female chondrocytes to respond to the hormone may reflect differences in testosterone metabolism, since these cells possess the ability to aromatize testostoerone to estradiol. (Supported by GTEC)

Identification and Characterization of Androgen Response Elements on the Rat IGF-1 Promoter. B. C. Yaden*, H. Bullock*, K. Chen*, T. Moore*, G. Krishnan*. Eli Lilly, Indianapolis, IN, USA.

Insulin-like growth factors are critical for normal growth and development of the organism. IGF1, has been shown to positively regulate cell proliferation, DNA replication, RAS protein signal transduction, muscle development, skeletal development, cell motility, and signal transduction. Androgen receptor (AR) belongs to the nuclear receptor family of DNA-binding transcriptional activator proteins. Binding of the natural steroid hormone ligands testosterone or dihydrotestosterone (DHT) to AR causes the protein to translocate from the cytoplasm to the nucleus where it binds to the promoters of androgen target genes and has been shown to have anabolic effects in various tissues such as muscle and bone. IGF1 has also been shown to induce myotube formation in myoblastic cell lines. The myoblast lines L6 and C2C12 were treated with R1881 (methyl trienolone) and IGF1 expression was measured. No significant changes were identified, but when a newly developed cell line LA-20 (rat striated levator ani muscle cells) was treated with R1881, IGF1 protein and mRNA levels increased. To further elucidate the mechanism of AR-mediated changes in IGF1, the rat IGF1 5' prime upstream region (+1 being the first nucleotide in the start codon, -4915/-37) was cloned into a luciferase reporter. The IGF1 promoter/upstream region has no defined TATA, CAAT homologies or a region that is GC rich, however it contains an imperfect Inr sequence at the -185 position. In addition several proximal response elements (AP1, CRE, GATA1 etc…) were found in this region. Transient transfections were performed using this construct in LA-20 cells. After treatment with R1881 for 48 hr, reporter expression was increased to 4.5 fold when compared to vehicle control. Deletion constructs were designed (-1716/-155 and -478/-145) to identify the potential ARE within this region. However, the truncated 333bp promoter continued to show maximal androgen-responsiveness in the reporter assay. From the data obtained in the deletion experiments three atypical androgen response elements were found at the 5' end of the proximal promoter construct. Detailed characterization of the androgen response element using ChIP assays suggests that it androgen-bound AR mediates its action on IGF-1 gene expression by targeting this element.

1-alpha, 25-dihydroxycholecalciferol Reduces ApoA1 Expression. K. R. Wehmeier*, M. J. Haas*, A. E. Beers*, A. D. Mooradian*. Division of Endocrinology, Diabetes and Metabolism, Department of Internal Medicine, Saint Louis University School of Medicine, St. Louis, MO, USA.

Daily Vitamin D intake over 30 mcg has been correlated with higher myocardial infarction events. In addition, supplemental cholecalciferol in women taking estrogens blunts the elevation of HDL-cholesterol. Members of the steroid receptor superfamily are known to alter the transcription of the major apoprotein of HDL cholesterol, ApoAI. To assess the effect of a ligand to the vitamin D receptor (VDR) on ApoAI, we investigated the effect of 1-alpha, 25-dihydroxycholecalciferol (1,25 OH2D3) on ApoAI protein, mRNA, and transcriptional activity in the human hepatoma cell line HepG2. ApoAI secretion was suppressed in a dose-dependent manner in HepG2 cells treated with 1,25 OH2D3. ApoAI protein levels were 166+/-10.0, 155.5+/-10.5, 130.5+/-8.5 and 89+/-7.0, arbitrary units (AU) in cells treated with 0, 10, 50, and 250 nM 1,25 OH2D3, achieving statistical significance in the 250 nM range (P<0.02). In order to determine if the effect of 1,25 OH2D3 occurs at the transcriptional level, HepG2 cells were transfected with a chloramphenicol acetyltransferase (CAT) reporter gene plasmid containing the full-length apoAI promoter, and after 24 h, treated with 1,25 OH2D3. CAT activity was suppressed by the VDR ligand 19.2+/-1.0% acetylation in control cells vs. 12.0+/-0.9% (P<0.005) and 6.3+/-1.1% acetylation (P<0.001) in cells treated with 50 and 250 nM 1,25 OH2D3, respectively. Therefore, the VDR activation by 1,25 OH2D3 suppressed ApoA1 expression at the transcriptional level in a dose dependent manner. These studies suggest that various ligands for the VDR may regulate apoAI gene expression. Further studies are needed to define implications of vitamin D supplementation on cardiovascular risk.

1,25(OH)$_2$ D$_3$ Is an Important Regulator in Organogenesis of Bone. K. Hasegawa*[1], Y. Seino*[2], S. Kato*[3], H. Tanaka*[1]. [1]Department of Pediatrics, Okayama university graduate school of medicine and dentistry, Okayama city, Japan, [2]Department of Pediatrics, Osaka Kosei Nennkinn Hospital, Osaka city, Japan, [3]Tokyo University, Tokyo, Japan.

Vitamin D plays an important role in bone metabolism. The role of Vitamin D to the bone is considered indirect, and there is little evidence that Vitamin D has direct effect to the bone. We have shown that 1,25(OH)$_2$D$_3$ (D3) may directly suppress the bone formation by bone transplantation experiments and organ culture system of femur of Vitamin D receptor Knock Out Mice(VDRKO). To clarify the direct effect of D3 on the membranous bone formation, we performed the organ culture calvaria which was removed from neonate of VDRKO .

There were no significant difference in the thickness of parietal bone between WT and VDRKO before the culture (20±2 VS20±1micrometer). After the culture, the thickness decreased compared with before the culture (20±2 to 12±2 micrometer) in WT. Contrary to WT, thickness of parietal bone didn't change before and after the culture in the VDRKO. Before and after the 5 days culture, there was no significant difference in the osteoclast number between VDRKO and WT. This shows that vitamin D directly suppresses the bone formation.

Next, to assess the difference of ossification during the organogenesis, we examined the whole skeletal preparation of VDRKO and WT (+/+ and +/-). Calcificated bone was stained red with alizalin red and cartilage was stained blue with alcian blue in the skeleton. Calcification of parietal bone in VDRKO began as early as at 13.5 d.p.c. while it began at 14.5 d.p.c. in WT (+/+) mouse. Skeletal findings in WT(+/-) were apparently middle between in VDRKO and in WT(+/+).

From these results, we conclude that vitamin D directly suppresses membranous bone formation of neonate. Moreover, the findings in whole skeletal preparation indicate that vitamin D is an important organogenesis regulator of bone.

Attentuation of Disuse-Induced Bone Loss by Estrogen and Vitamin D Receptor Ligands in Unloaded and Ambulatory Female Rats. R. Narayanan*[1], C. Seng*[1], N. L. Weigel[1], S. A. Bloomfield[2], C. L. Smith[1]. [1]Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX, USA, [2]Health and Kinesiology, Texas A&M University, College Station, TX, USA.

Decreased mechanical usage as experienced during spaceflight, bedrest, and hindlimb unloading (HU) induces bone loss. Two estrogen receptor (ER) ligands, estradiol (E2) and raloxifene (RAL; a selective estrogen receptor modulator), and two vitamin D receptor (VDR) ligands, 1,25-dihydroxyvitamin D3 (1,25D) and EB1089 (a less calcemic analog of 1,25D, Leo Pharmaceuticals) were tested previously for prevention of bone loss in HU male rats. In this study RAL and EB1089, alone and in combination, were assessed for their ability to prevent bone mineral density (BMD) loss during 28d HU in 6-mo-old virgin female Sprague-Dawley rats in comparison to E2 or 1,25D (n=10-12 animals/group). Estradiol (12 μg/d) and RAL (535 μg/d) were administered by time-release pellets (Innovative Research of America), while 1,25D (0.03 μg/kg BW) and EB1089 (0.3 μg/kg BW) were administered by Alzet osmotic pump; appropriate vehicle (VEH) controls were employed. Peripheral quantitative computed tomography scans (pQCT; Stratec XCT Research M) for BMD and geometry were taken *in vivo* at the proximal tibial metaphysis on d0 and after 28d of HU and hormone treatment. Administration of EB1089 alone (+1.6%) or together with RAL (-0.4%) prevented the loss of total BMD (-5.8%) observed for the VEH group, in comparison to d0 values, while E2 treatment attenuated BMD loss. Individually, neither RAL nor 1,25D were effective. Both EB1089 and EB1089+RAL prevented endocortical bone loss, blocking the increase in marrow area observed in VEH rats (+9.2%), and instead reduced marrow area by 5.1 and 3.1%, respectively. EB1089 and EB1089+RAL increased cancellous BMD over d0 values (9.8 and 3.9%, respectively), while the BMDs of VEH animals were reduced by 6.2%. Increased serum osteocalcin in EB1089 relative to VEH groups was consistent with EB1089 effects on bone. No significant changes in serum calcium were detected relative to VEH controls. In ambulatory animals, 28 d of treatment with EB1089, EB1089+RAL, E2 or 1,25D increased total BMD over baseline values by up to 7.3%, and this was reflected in increased cancellous BMD of up to 20.4%. In the case of EB1089 and EB1089+RAL, BMD alterations were accompanied by reductions in marrow area of 13.0 and 8.8%, respectively. Taken together, these results indicate that EB1089 effectively counteracts the deleterious effects of HU on bone in mature female rats. Our previous work suggested that in HU male rats, 1,25D more effectively prevented loss of BMD than EB1089, and future experiments will address the gender-based differences in response to EB1089 and 1,25D.

The Vitamin D Receptor (VDR) Coactivators, DRIP/205, SRC/1 and 3, and TAF_{II}-17 Are Differentially Involved in VDR Mediated Transactivation during Pagetic Osteoclasts (OCL) Differentiation. N. Kurihara[1], S. Onate*[2], A. Hidalgo*[2], M. Ito[1], G. D. Roodman[3]. [1]University of Pittsburgh, Pittsburgh, PA, USA, [2]Roswell Park Cancer Institute, Buffalo, NY, USA, [3]University of Pittsburgh & VA Med Ctr, Pittsburgh, PA, USA.

OCL in Paget's disease (PD) are abnormal and characterized by expression of the measles virus nucleocapsid protein (MVNP) gene, increased levels of TAF_{II}-17 and hyperresponsivity to 1,25-$(OH)_2D_3$. The basis for the hyper-responsivity to 1,25-$(OH)_2D_3$ is unclear. It is our hypothesis that MVNP induces enhanced VDR mediated gene transcription by increasing expression of VDR coactivators in pagetic OCL precursors. To test this hypothesis, we determined the expression levels of known coactivators of VDR in OCL isolated from normal individuals and from PD patients, and in MVNP transfected human OCL precursors or empty vector (EV) using PCR, Western blot analysis and immunocytochemistry. We then used the chromatin immunoprecipitation (ChIP) assay with NIH3T3 cells stably transfected with EV or MVNP to examine the recruitment of these coactivators to the VDR response element (VDRE) occurred in the 24-(OH)-ase gene promoter. Increased levels of DRIP205 were detected in early OCL precursors from PD patients or normal precursors transfected with MVNP compared to EV transfected cells. DRIP205 levels decreased as PD OCL precursors differentiated. After 14 days of culture, SRC-1 and SRC-3, and TAF_{II}-17 were increased as DRIP205 decreased in MVNP transfected and PD OCL precursors. ChIP analysis demonstrated that in MVNP transduced cells the association of un-liganded VDR with its corepressor SMRT was significantly decreased. MVNP transduced cells also had increased recruitment of DRIP205/TRAP220 and SRC-1 to the VDRE in the 24-OHase promoter, in a ligand-dependent manner. Furthermore, when CFU-GM transduced with MVNP were cultured for 14 days in the presence or absence of a DRIP205 antisense oligonucleotide (AS-DRIP205) and treated with 10^{-11}-10^{-7} M 1,25-$(OH)_2D_3$ to induce OCL formation, AS-DRIP205 inhibited OCL formation about 20% ($P < .05$) compared to mismatch sense oligonucleotide (MS) treated control cultures. AS-TAF_{II}-17 also significantly inhibited OCL formation by 40% ($P < .01$) compared to MS-ODN treated control cultures. These results indicate that DRIP205 is initially upregulated in PD OCL precursors followed by SRC1, 3, and TAF_{II}-17, and suggest that these coactivators may be involved in the enhanced VDR mediated gene expression that occurs in PD.

Molecular and Functional Characterization of the 1α,25$(OH)_2$-Vitamin D_3-Sensitive Chloride Channel in Osteoblasts. L. P. Zanello, W. Smith*, H. L. Henry, A. W. Norman. Biochemistry, University of California-Riverside, Riverside, CA, USA.

Osteoblasts are a major target for the steroid hormone 1α,25$(OH)_2$-vitamin D_3 [1,25D]. 1,25D deficiency leads to impaired osteoblastic functions and decreased bone formation. 1,25D mechanisms of action comprise genomic (modulation of gene expression via a nuclear 1,25D receptor) and non-genomic pathways. The latter include rapid intracellular calcium elevation, signal transduction activation, and ion channel potentiation. Osteoblasts express a 1,25D-sensitive anion (Cl^-) current that is significantly enhanced by nanomolar concentrations of the hormone within 1-5 min (Zanello and Norman, J.Biol.Chem. 1997). This Cl^- conductance is responsible for a local repolarization of the osteoblast, and couples to secretion (Zanello and Norman, Bone 2003, Proc.Natl.Acad.Sci. 2004). We characterized the biophysical properties of this voltage-gated Cl^- channel by means of whole-cell patch-clamp recordings on rat osteosarcoma ROS 17/2.8 cells. The specific Cl^- channel blocker 4,4'-diisothiocyanatostilbene 2,2'-disulfonic acid (DIDS, 200 μM) partially reduced (up to 50%) 1,25D-enhanced Cl^- conductance at depolarizing potentials (80 mV). This blockade developed in a voltage and time-dependent manner. The 1,25D-sensitive channel is permeable to $I^- > Cl^- > F^-$ > glutamate > gluconate. With the purpose to study the molecular identity of this Cl^- channel, we investigated at the mRNA level the expression of different types of Cl^- channels of the ClC gene family of voltage-gated Cl^- channels. For RT-PCR experiments, we used primers designed from previously cloned rat Cl^- channels whose sequences are available in data banks. We found that ROS 17/2.8 cells express transcripts of the outward rectifier, DIDS-sensitive ClC-3 gene, but not the ubiquitous swelling-activated ClC-2 or the intracellular ClC-7 channel found in osteoclasts. This agrees with our pharmacological and electrical studies. We conclude that the 1,25D-sensitive Cl^- channel in osteoblasts appears to be the ClC-3 type. We have thus identified a potential therapeutic target for the treatment of bone pathologies associated with 1,25D deficiency and characterized by decreased bone mass and insufficient mineralization.

1,25-Dihydroxyvitamin D Regulates Soluble RANKL and OPG Release from Bovine Vascular Endothelial Cells. K. J. Lamb*[1], J. L. Berry[1], C. E. Evans*[2], A. E. Canfield*[3], A. P. Mee[1]. [1]Vitamin D Research Group, University of Manchester, Manchester, United Kingdom, [2]LMAG, University of Manchester, Manchester, United Kingdom, [3]School of Biological Sciences, University of Manchester, Manchester, United Kingdom.

Recent evidence has suggested a role for the receptor activator of nuclear factor kappa beta (RANK) system in modulating vascular calcification. 1,25-dihydroxyvitamin D (1,25D) is produced in extra-renal sites, and vascular endothelial cells can both synthesise and respond to 1,25D. Therefore, the purpose of this study was to investigate the effects of 1,25D on soluble RANK Ligand (RANKL) and osteoprotegerin (OPG) production by vascular endothelial cells. Bovine aortic endothelial cells were incubated in standard medium, in the absence of fetal calf serum, with varying doses of 1,25D (10^{-7}, 10^{-9}, 10^{-11}M) for 6, 24 and 48 hours. Control cells were incubated in the absence of 1,25D. OPG and RANKL levels were assessed by ELISA. Both dose- and time-dependent effects were seen in OPG and RANKL production. At all time points examined, 1,25D stimulated OPG production, with the effect being greatest at 10^{-11}M 1,25D. The maximum effect was seen after 24hrs with 10^{-11}M 1,25D (4.1±1.2pmol/l cf. 0.95±0.05 in control medium). RANKL secretion showed a more phasic response; using 10^{-11}M 1,25D the response was greatest at 24hrs and was reduced at 6 and 48hrs, whereas at 10^{-9} and 10^{-7}M, there was an increase at 6hrs, with a decrease at 24hrs and then a dramatic increase after 48hrs. The maximum response was seen after 48hrs at 10^{-7} M 1,25D (0.92±0.14pg/ml cf. 0.04±0.08pg/ml). This study has confirmed both a dose-dependent and duration-associated secretion profile of RANKL and OPG in response to 1,25D. Interestingly, the maximum effect on OPG secretion was seen after 24hrs at a low dose of 1,25D, with a corresponding decrease in RANKL secretion, whereas the maximum effect on RANKL was seen at 48hrs with a high dose of 1,25D, with a corresponding decrease in OPG. These findings clearly demonstrate that 1,25D, produced locally, is a candidate to modulate the effects of RANK, RANKL and OPG within the vascular system, which may have profound effects on vascular calcification.

Bone Anabolic Effects of 1,25(OH)$_2$ Vitamin D3 Are Detected Only in the Presence of a Powerful Antiresorptive. A. A. Reszka, S. Pun*, G. A. Rodan, L. P. Freedman*, D. B. Kimmel. Molecular Endocrinology and Bone Biology, Merck Research Laboratories, West Point, PA, USA.

Controversy exists concerning the in vivo skeletal response to pharmacologic levels of 1,25(OH)$_2$ vitamin D3 (1,25D3). We hypothesize that feedback loops that involve the regulation of the bone remodeling system influence the outcome of experiments with 1,25D3. The purpose of this experiment was to assess the effect of 1,25D3 on the skeleton of estrogen deficient, osteopenic adult rats.

Three month-old Sprague-Dawley rats were ovariectomized (OVX) three months prior to treatment with alendronate (ALN; 10 µg/kg, s.c., 3X/wk). At that time, rats were also given 0, 0.01, 0.03, or 0.1µg/kg/d 1,25D3, p.o., or PTH (80 µg/kg. s.c., 3X/wk). Non-ALN-treated rats given 1,25D3 (0 or 0.1 µg/kg/day, p.o.) were also included. Treatment continued for eight weeks. *In vivo* dual calcein labeling was used to assess directly lumbar vertebral body cancellous bone formation rate (BFRBS, based on double label). Osteoclast surface (OcSBS), urine calcium (UCa), urinary DPD (uDPD/Cre), and lumbar vertebral bone mineral density (LVBMD) were also measured.

Tx (ug/kg/d)	UCa	uDPD/Cre	LVBMD	BFRBS	OcSBS
Veh	196±93	102±15	196±20	6.1±3.38	1.8±1.2
1,25D3 (0.1)	735±254vo	40±17v	227±22v	2.6±1.8vo	0.3±0.2vo
Veh + ALN	135±77v	37±9v	216±20v	0.1±0.1v	0.9±0.4v
1,25D3 (0.01) + ALN	511±124vo	26±6vo	225±15v	0.2±0.3v	0.4±0.2vo
1,25D3 (0.03) + ALN	666±114vo	19±7vo	220±19v	0.6±0.4vo	0.3±0.3vo
1,25D3 (0.1) + ALN	818±108vo	16±3vo	222±14v	2.4±1.6vo	0.2±0.2vo
PTH (80) + ALN	221±93	32±8v	243±25vo	1.3±0.6vo	1.0±0.6v

Mean ± S.D.; v- diff from vehicle (P<.05); o- diff from Veh + ALN (P<.05)

Despite equivalent reductions of uDPD/Cre by ALN and 1,25D3, lumbar vertebral cancellous bone formation rate was reduced by different degrees, suggesting an uncoupled response to 1,25D3. In the presence of the powerful anti-resorptive, ALN, the ability of 1,25D3 to stimulate cancellous bone formation after eight weeks treatment was clearly demonstrated. Together, these data show that 1,25D3 increases bone formation both when administered alone and in the presence of ALN. These anabolic effects of 1,25D3 occurred despite significant decreases in osteoclast activity, suggesting an independent effect of 1,25D3 on osteoblast function/activity. We hypothesize that the net decrease in cancellous bone formation rate seen with 1,25D3 monotherapy is a combination of its direct effect to stimulate bone formation and an indirect effect of antiresorptive-mediated coupling associated with cancellous bone remodeling.

Assessment of Total and 'Free' Circulatory 25-hydroxyvitamin D and 1, 25-dihydroxyvitamin D$_3$ Status in Men with Osteoporosis. Z. H. Al-Oanzi*[1], S. S. Varanasi[1], S. P. Tuck*[2], R. M. Francis[2], H. K. Datta[1]. [1]School of Clinical & Laboratory Sciences, University of Newcastle, Newcastle upon Tyne, United Kingdom, [2]School of Clinical Medical Sciences, University of Newcastle, Newcastle upon Tyne, United Kingdom.

The clinical assessment of vitamin D$_3$ status often relies upon measuring total circulatory levels. The metabolites 25OHD$_3$ and 24,25(OH)$_2$D circulate in blood at concentration about 1000 times higher than those of 1,25(OH)$_2$D$_3$, but because of the remarkably high concentration of DBP in relation to the vitamin D metabolites, many binding sites are still available for 1,25(OH)$_2$D$_3$ and the percentage of free hormone is very low. Therefore the concentration of the free rather than total forms of 1,25(OH)$_2$D$_3$ and 25OHD$_3$ are likely to provide a better assessment of the vitamin D status. The present study was carried in of male control subjects (n=114) and men with osteoporosis (n=56), with a view to determine the relationship of free 25OHD$_3$ and 1,25(OH)$_2$D[[Unsupported Character - Codename]]$_3$ concentrations with total plasma 25OHD$_3$, 1,25(OH)$_2$D$_3$, vitamin D-binding protein (DBP) and albumin levels. The total plasma DBP was determined using monospecific polyclonal goat anti-human DBP antibody. The assay used for 25OHD$_3$ and 1,25(OH)$_2$D$_3$ in human plasma was carried out using commercially available kit. 'Free' 25OHD$_3$ and 1,25(OH)$_2$D$_3$ levels were inferred from plasma 25OHD$_3$, 1,25(OH)$_2$D$_3$, DBP and albumin levels, using the following equation: [F] = [T] / (1 + Ka$_{ALB}$ [ALB] + Ka$_{DBP}$ [DBP]). [T] and [F] are the total and free vitamin levels respectively, whereas Ka$_{ALB \text{ and}}$ Ka$_{DBP}$ are the association constants for albumin and DBP. Our data shows that whilst there were no differences between men with osteoporosis and male control subjects in total plasma 25OHD$_3$ (44.7±21 nmol/L (n=56) vs. 43.3±17 nmol/L (n=114)), and 1,25(OH)$_2$D$_3$ (90±37 pmol/L (n=50) vs.103 ± 39 pmol/L (n=50)). However, calculated free plasma 25OHD3 levels were significantly lower (p<0.00001) in the osteoporotic men (6.1±3.1 pmol/L) than in the control subjects (9.1±4.4 pmol/L). Calculated free plasma 1,25(OH)$_2$D$_3$ was also significantly lower (p<0.00001) in osteoporotic men (77±37 fmol/L) than in the control subjects (142±58 fmol/L). The mean ±SD plasma level of DBP was significantly higher (p<0.001) in men with osteoporosis (224 ± 62 mg/L; n=56) than in the control subjects (143 ± 34 mg/L; n=114). Whilst there was no correlation between total plasma 25OHD$_3$ and 1,25(OH)$_2$D$_3$ levels, the calculated free plasma 25OHD$_3$ and 1,25(OH)$_2$D$_3$ showed positive correlation (r=0.614, p<0.01). These results suggest the measurement of plasma DBP and the ratio of total vitamin D metabolites to plasma DBP may provide a useful index of the biological activity of the vitamin.

ED-71, a Novel Vitamin D Analog, Promotes Bone Formation and Inhibits Bone Resorption after Bone Marrow Ablation. N. Okuda[1], S. Takeda*[2], K. Shinomiya*[3], T. Muneta*[1], S. Itoh*[4], Y. Asou[4]. [1]Section of Orthopeadic Surgery, Department of Molecular Regulation of Supportive Tissue, Graduate School Tokyo Medical and Dental University, Tokyo, Japan, [2]Chugai Pharmaceutical Co., LTD., Tokyo, Japan, [3]Section of Orthopeadic Surgery, Tokyo Medical and Dental University, Tokyo, Japan, [4]Division of Molecular Tissue Engineering, Human Genes and Science Center, Tokyo Medical and Dental University, Tokyo, Japan.

A novel vitamin D analog 1α,25-dihydroxy-2β-(3-hydroxypropoxy)vitamin D$_3$ (ED-71) had reported to have greater activity than vitamin D in preventing bone loss in ovariectomized rat, and the effect of promotion in bone formation and reduction in number of osteoclast. However, the effect of ED-71 on acute phase of bone remodeling remains to be elucidated. Bone marrow ablation causes vigorous new bone formation within the first week and then subsequent rapid bone resorption in the second week to regenerate bone marrow with normal levels of trabecular bones. It is a highly reproducible in vivo assay to evaluate bone remodeling. The purpose of this study was to evaluate the effect of ED-71 on bone remodeling in vivo by using mice bone ablation model. ICR mice were divided into ED-71 treatment and control groups, and all the femoral bone marrow were ablated by using K-wire . First, ED-71 (0.8µg/kg body weight) was injected intraperitoneally once the day after surgery to elucidate the effect of ED-71 on rapid bone formation during bone remodeling. Histological examination showed that ablated bone marrow in ED-71 treatment group were filled with more abundant matrix compared with control 3 and 5 days after surgery. As trabecular bone volume reaches at its maximal level 7 days after surgery, more abundant and thicker newly formed trabecular bones were observed in ED-71 treatment group by histological and micro CT analysis. Osteoblast surface (Ob.S/BS) was increased in ED-71 treatment group, whereas osteoclast number (Oc.N/BS) was not significantly affected by ED-71 possively because of reduced bone resorption activity at the time of ED-71 injection . Second, to elucidate the effect of ED-71 on bone resorption, ED-71 was injected once 8 days after surgery. Bone volume were 50 % more in ED-71 treatment group 14 days after surgery. Interestingly, Ob.S/BS was increased and Oc.N/BS was reduced significantly in ED-71 treatment group 2 days after administration. These results indicated that ED-71 administration at the period of trabecular bone maturation raised trabecular bone volume through both increase in osteoblast number and reduction in osteoclast number. We concluded that ED-71 promote bone formation and inhibit bone resorption in the region of rapid bone turn over after bone marrow ablation.

In vivo Actions of a Novel Vitamin D Analogue, ED-71, Mediates VDR. Y. Yamamoto*[1], K. Yoshimura*[1], T. Nakamura*[1], K. Takeyama*[1], H. Saito*[2], S. Kato[1]. [1]Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan, [2]Pharmaceutical Research Dept. II, Chugai Pharmaceutical Co., Ltd., Gotemba, Japan.

Most of vitamin D actions are believed to be exerted through VDR-mediated transcriptional control of target genes. The physiological impact of VDR in bone remodeling and formation have been well documented by generating VDR deficient mice (VDRKO) mice with features typical of vitamin D-dependent type II rickets, but only after weaning.

A variety of vitamin D analogues has been developed with characteristic actions derived from diverse biological actions of 1α,25(OH)$_2$D$_3$. ED-71 [1α,25-dihydroxy-2β-(3-hydroxypropoxy)vitamin D$_3$] is an analog of 1α,25-dihydroxyvitamin D$_3$ [1α,25(OH)$_2$D$_3$]. Clinical studies in osteoporotic patients demonstrated that the ED-71 treatment increased bone mass in a dose-dependent manner without causing sustained hypercalcemia or hypercalciuria, through serving as a tissue-selective vitamin D agonist. However, the molecular basis of the bone-selective agonistic action of ED-71 in terms of VDR activation in intact animals remains to be studied.

To address the VDR function in the ED-71 actions in vivo, we assessed the ED-71 activity in the VDR KO mice. Even excess doses of ED-71 given to the VDR KO mice caused no hypocalcemia and hypophosphatemia, confirming the indispensable function of VDR in the ED-71 actions. Currently, to more characterize the bone-selective ED-71 actions, we analyzing the ED-71 actions in osteoblast-spcific VDRKO (Ob-VDRKO) mice generated through a Cre/loxP system.

Transcriptional Effects of a Shortened Side Chain Vitamin D Analog 2-Methylene-19-Nor-(20S)-Bishomopregnacalciferol in Bone and Intestinal Cells. M. Watanuki, N. K. Shevde, L. A. Plum, H. F. DeLuca, J. W. Pike. Biochemistry, University of Wisconsin- Madison, Madison, WI, USA.

A major role of 1,25-dihydroxyvitamin D3 (1,25(OH)2D3) is to maintain calcium and phosphorus homeostasis through direct actions on gene expression in intestine, kidney and bone. 1,25(OH)2D3 also regulates growth and differentiation, providing the impetus for the development of synthetic analogs of this hormone that might be useful therapeutically in psoriasis, immune suppression, renal osteodystrophy or cancer. A significant limitation of many of these analogs, however, is their tendency to increase serum calcium levels due entirely to the homeostatic actions described above. In this report, we explore the actions of 2-methylene-19-nor-(20S)-bishomopregnacalciferol (2MbisP) on gene expression in bone and intestinal cells. Importantly, 2MBisP is unable to induce hypercalcemia at high doses in vivo relative to 1,25(OH)2D3. Interestingly, 2MBisP induced the expression of marker genes equally well in both osteoblast and intestinal cell lines, displaying a potency that was slightly less than that of 1,25(OH)2D3 and consistent with its affinity for the vitamin D receptor (VDR). Surprisingly, 2MBisP was also capable in osteoblasts of inducing the expression of RANKL and suppressing the expression of OPG, gene products involved in osteoclast-mediated bone calcium mobilization. As a consequence, 2MBisP was nearly equivalent to 1,25(OH)2D3 in inducing osteoclastogenesis in coculture assays. Equally surprising was the observation that 2MBisP was fully efficacious in inducing the expression in Caco2 cells of the calcium channel gene TRPV6 and the calcium "transporter" gene calbindin D9K. In keeping with these findings, 2MBisP also promoted the localization of VDR/RXR to the promoters of several of these genes as analyzed by chromatin immunoprecipitation assay. 2MBisP was also similar in its ability to promote VDR interaction with RXR as well as with coactivators such as SRC-1 and -2 and DRIP205, as assessed in GST pull-down and in mammalian 2-hybrid assays in both bone and intestinal cell backgrounds. These studies indicate that 2MBisP is fully able to activate the expression of genes involved in calcium homeostasis. Thus, the inability of 2MBisP to induce bone calcium mobilization or to stimulate intestinal calcium absorption in vivo may be independent of the molecular mechanisms essential to the activation of gene expression by this compound.

Molecular and Apoptotic Mechanisms of 25-hydroxyvitamin D_3 Analogs in Prostate Cancer Cells. J. Lambert*[1], S. Sarkar*[2], R. Ray*[2]. [1]Pathology, University of Colorado Health Sciences Center, Denver, CO, USA, [2]Medicine, Boston University School of Medicine, Boston, MA, USA.

Recently we described that 25-hydroxyvitamin D_3-3-bromoacetate (25-OH-D_3-3-BE), a non-toxic and vitamin D receptor (VDR)-cross-linking analog of 25-hydroxyvitamin D_3 (25-OH-D_3) strongly inhibited the proliferation of LNCaP, PC-3, DU-145 and LAPC-4 prostate cancer cells and induced apoptosis. In the present study we synthesized 25-hydroxyvitamin D_3-3-epoxide (25-OH-D_3-3-Epoxide), another VDR-cross-linking analog of 25-OH-D_3 that is stable towards esterases. We observed that 25-OH-D_3-3-Epoxide strongly inhibited the proliferation of PC-3 cells, similar to 25-OH-D_3-3-BE. In LNCaP cells both 25-OH-D_3-3-BE and 25-OH-D_3-3-Epoxide induced the expression of prostate derived factor (PDF), a protein that is implicated in the vitamin D activity in prostate cancer cells, similar to 1,25-dihydroxyvitamin D_3 (1,25$(OH)_2D_3$). In a growth-assay with ALVA-31 prostate cancer cells and a VDR-antisense ALVA-31 clone, 25-OH-D_3-3-BE and 25-OH-D_3-3-Epoxide showed growth-inhibitory effect similar to1,25$(OH)_2D_3$. Earlier we showed that 25-OH-D_3-3-BE induced apoptosis in PC-3 cells by fragmenting nuclear DNA and enhancing caspases 3,8 and 9 activities. In this study we probed the apoptotic behavior of 25-OH-D_3-3-BE and 25-OH-D_3-3-Epoxide in PC-3 cells, and observed that both the compounds activated AKT-phosphorylation. In summary results described in this communication strongly suggested that antiproliferative property of 25-OH-D_3-3-BE and 25-OH-D_3-3-Epoxide in prostate cancer cells is mediated by 1,25$(OH)_2D_3$-signaling pathway, and the apoptotic behavior involves AKT-mediated pathway.

WORKING GROUP ON MUSCULOSKELETAL REHABILITATION IN PATIENTS WITH OSTEOPOROSIS ABSTRACTS

WG1

Introduction of a New Concept to Assess Quality of Life in Patients with Osteoporosis. H. W. Minne, C. Hinz, M. Pfeifer, Institute of Clinical Osteology "Gustav Pommer" and Clinic "DER FÜRSTENHOF", Bad Pyrmont, Germany.

The morbidity of osteoporosis is caused by fractures. Vertebral fractures lead to pain and disability and a decrease in quality of life. Over the last 15 years several important parameters have been identified, which determine quality of life in patients suffering from vertebral fractures in postmenopausal osteoporosis. Besides the degree of kyphosis and deformity [1,2], especially time since last fracture [3] and sense of coherence [4] are important predictors of health-related quality of life (HRQoL).

In order to estimate quality of life, several questionnaires have been developed. Starting with generic instruments such as the Nottingham Health Profile and the Short Form 36, which provide a general estimate of health perception, we introduced more and more disease-specific questionnaires [2,3], which agree better with grade of disease and which are usually more sensitive to change in parallel with improvement or deterioration of disease. Together with clinicians and other quality of life specialists from eight European countries, we validated the so-called "QUALEFFO" in two multi-center studies [5]. This questionnaire contains 41 questions in 5 domains: pain (5), physical function (17, divided over subdomains : activities of daily living, jobs around the house, mobility), social function (7), general health perception (3), and mental function (9). Most of this 41 questions were specifically designed for this questionnaire, but a few were taken from the MEDOS and EVOS questionnaires.

QUALEFFO has been shown to discriminate between patients with osteoporotic fractures and control subjects and the contents of the questions were derived from complaints and common problems of patients with osteoporosis. Clinical experience, however, indicate that the degree of disease specificity is not high enough to reveal the whole picture of osteoporosis and to reflect the burden of the disease in its complexity and various appearances in different patients. We, therefore, undertook the task to create a new assessment tool with the aim to reflect function, handicap, impairment and disability of patients after vertebral fractures more accurate than previous questionnaires. In its first and crude version, our instrument consisting of 103 questions now entered the validation phase to test for within-subject reproducibility, internal consistency and construct validity. Preliminary results suggest a good reproducibility and a discrimination between patients and controls.

Effects of Whole Body Vibration on Bone Density and Muscle Function. S. Boonen, S. Versheuren. Leuven University Center for Metabolic Bone Diseases and Division of Geriatric Medicine, Katholieke Universiteit Leuven, Leuven, Belgium.

High-frequency mechanical strain has been shown to stimulate bone strength in different animal models. However, the effects of vibration exercise on the human skeleton have hardly been studied. Particularly in postmenopausal women – who are most at risk of developing osteoporosis – randomized controlled data on the safety and efficacy of vibration loading are lacking. The aim of this randomised controlled trial was to assess the musculoskeletal effects of high-frequency loading by means of whole-body vibration in postmenopausal women.

Seventy volunteers (age, 58-74 years) were randomly assigned to a whole-body vibration training group (WBV, *n*=25), a resistance training group (RES, *n*=22), or a control group (CON, *n*=23). The WBV-group and the RES-group trained three times weekly during 24 weeks. The WBV-group performed static and dynamic knee-extensor exercises on a vibration platform (35-40 Hz, 2.28-5.09 g), mechanically loading the bone and evoking reflexive muscle contractions. The RES-group trained knee-extensors by dynamic leg press and leg extension exercises, increasing from low (20RM) to high (8RM) resistance. The CON-group did not participate in any training. Hip bone density was measured using DXA at baseline and after the 6-month intervention. Isometric and dynamic strength were measured by means of a motor-driven dynamometer. Data were analysed by means of repeated measures ANOVA.

No vibration-related side effects were observed. Vibration training improved isometric and dynamic muscle strength (+15% and +16%, respectively, $p<0.01$), but also significantly increased BMD of the hip (+0.93%, $p<0.05$). No changes in hip BMD were observed in women participating in resistance training or age-matched controls (-0.60% and –0.62%, respectively, NS). Serum markers of bone turnover did not change in any of the groups.

These findings suggest that WBV training may be a feasible and effective way to modify well-recognized risk factors for falls and fractures in older women, and support the need for further human studies.

WG3

Assessment of the Risk of Falls.E. Preisinger. Physical Medicine and Rehabilitation, Krankenhaus Lainz, Vienna, Austria

Approximately 30% of people over 65 years of age and living in the community fall each year; the number is higher in institutions. 1 in 10 falls results in a fracture or in another serious injury. Therefore, to prevent fractures in the elderly reduction of the risk of falling is as important as the augmentation of bone quality. Although few falls have a single cause, the majority result from interactions between long-term and short-term predisposing factors and short-term precipitating factors in a person's environment. Each of the following conditions has been shown to increase the subsequent risk of falling in two or more observation studies: arthritis; depressive symptoms; orthostasis; impairment in cognition, vision, balance, gait or muscle strength; and the use of four or more prescription medications. Furthermore, the risk of falling consistently increases as the number of these risk factors increases. The risk of falling increased in a cohort of elderly persons living in the community, from 8% among those with no risk factors to 78% among those with four or more risk factors.[1] Also it is suggested that risk factors for indoor and outdoor falls are different.[2]

A risk assessment of falls should include the number of falls in the past, current diseases or chronic conditions and medications, as well as an investigation of balance and some activities of daily living (ADL), such as getting up from chair and walking. Tinnetti has been summarized the clinical approach to the prevention of falls among elderly persons living in the community in an algorithm:[1]

Ask all patients ≥75 years old about falls,→no falls→preventive exercising:

balance or gait difficulties → Two or more falls or balance or gait difficulties

no balance orbalance, strength gait difficultiestraining → One fall and no balance or gait difficulties → ↑ → →

↓

Assessment of predisposing and precipitating factors, followed by interventions suggested by the results of detailed assessment

Balance assessment tools could be divided in high tech assessment tools and clinical assessments. The basic requirements of such high tech equipments have a forceplate or platform the patient stands on which has sensors embedded in it. Data of measurements, i.e. excursions of body's center of gravity (static posturography), were calculated by a computer. In a previous study Nguyen et al. reported that body sway was an important predictor of osteoporotic fractures.[3] Clinical assessments of balance, for example, are the Romberg Test, One-Legged Stance Test, Postural Stress Test, the Berg Balance Scale, Timed Get Up and Go Test and Tenetti Index. These clinical tools can be used for screening. They are simple, but mainly not extensively tested. In a prospective cohort trial Guralnik et al. demonstrated that objective measures of lower-extremity function were highly predictive of subsequent disability in the elderly.[4] It is well known that functional deficits in the lower-extremities increase the risk of falling. Therefore, in view of the literature and in my opinion physicians should ask their elderly patients about any falls and ask about and look for any difficulties with balance or gait. Brief clinical screens followed by assessments providing more specific information about balance or gait abnormities should be included. A comprehensive assessment of risk for falls should prepare the way for further strategies to prevent osteoporotic fractures in the elderly.

WG4

Effects of Vitamin D on Musculoskeletal Health. M. Pfeifer, H. W. Minne. Institute of Clinical Osteology "Gustav Pommer" and Clinic "Der Fürstenhof", Bad Pyrmont, Germany.

We have found in a first prospective, randomized, placebo-controlled trial that short-term supplementation with vitamin D and calcium reduced body sway and the mean number of falls during a one-year period of follow-up in women 70 years of age or older who were vitamin D deficient (mean serum 25OHD level: 23 nmol/liter) with a mean calcium intake of 560 mg per day and living at a latitude of 52°N [1]. Compared with calcium monotherapy, supplementation with vitamin D and calcium in women with vitamin D insufficiency resulted in a decrease in plasma PTH of 18% ($p = 0.0435$), and a decrease in body sway of 9% ($p = 0.0435$). The mean number of falls during one year of single-blinded follow-up was 0.47 for the calcium monotherapy group and 0.24 for the vitamin D and calcium group ($p = 0.0346$) [1]. These results support the concept that hypovitaminosis D impairs neuromuscular coordination, as measured by body sway, and thus increases the risk of falling and fall-related fractures. In an other randomized, controlled trial Bischoff *et al.* demonstrated a reduction in falls after treatment with vitamin D and calcium in elderly institutionalized women [2]. The women with a mean age of 85 ± 7 years received either 1200 mg of elemental calcium or 1200 mg of elemental calcium plus 800 IU of vitamin D [2]. Mean fall incidence rate – the number of falls before treatment subtracted from the number of falls during treatment period – was 2.4 in the calcium group and 0.9 in the calcium and vitamin D group ($p = 0.04$).

This effect of cholecalciferol on fall risk was confirmed by Larsen *et al.* (2004) in 9,605 community-dwelling residents aged 65 years and over (females 5,771, males 3,834; median age 74.0 years; range 65-103 years) in the municipality of Randers in Denmark. The participants were offered a daily supplement of 1,000 mg of elemental calcium as calcium carbonate and 400 I.U. of cholecalciferol. During 3½ years of follow-up, female residents fell more rarely (RR: 0.9; $p<0.05$), whereas both males and females had a reduced risk of osteoporotic fractures (RR: 0.8; $p<0.025$), [3].

In veiled Arab women living in Denmark, Glerup *et al.* [4] found that muscle power as determined by maximal voluntary contraction (MVC) significantly correlated to serum levels of 25OHD ($r = 0.34$; $p < 0.01$) but not to $1,25(OH)_2D$ ($r = -0.14$; NS) [4]. Compared with Danish controls maximal voluntary knee extension as measured with a strain gauge dynamometer was reduced by 34% in 55 vitamin D deficient Arab women (serum 25OHD < 20 nmol/liter). Treatment with intramuscular injections of ergocalciferol 100,000 IU per month and an oral supplementation of 1200 mg calcium and 400 IU ergocalciferol per day resulted in an increase in mean MVC of 13% after 3 months and 24% after 6 months [4].

Gallagher *et al.* demonstrated in a randomized double blind placebo-controlled trial in 489 postmenopausal women that treatment with 0,25 µg calcitriol twice daily reduced the number of falls [5]. The three-year incidence rate for falls was 0.43 on placebo compared to 0.29 on calcitriol ($p<0.001$), [5]. Concerning another vitamin D metabolite, Dukas *et al.* showed in a prospective, placebo-controlled study among 191 women and 187 men 70 years of age or older that alfacalcidol ($1(OH)D_3$) reduces fall risk (OR: 0.69; 95% C.I.: 0.41-1.16), [6]. Over 36 weeks of treatment, 1 µg alfacalcidol reduced not only mean number of falls (OR: 0.46; 95% C.I.: 0.22-0.99; $p=0.045$) but also mean number of fallers (OR: 0.45; 95% C.I.: 0.21-0.97; $p=0.042$) among participants with a mean nutritional calcium intake above 512 mg per day [6] This study highlights the importance of calcium in mediating the effects of vitamin D on parameters of muscle function, because study subjects with a mean calcium intake below 512 mg per day did not show a fall reduction [6].

Proprioceptive Dynamic Program for Osteoporotic/Kyphotic (O/K) Individuals. M. Sinaki[1], R. Brey[2], C. Hughes[3], D. Larson[4] K. Kaufman[3]. [1]Physical Medicine and Rehabilitation; [2]Vestibular Laboratory; [3]Biomechanics and Motion Analysis Laboratory; [4]Biostatistics, Mayo Clinic, Rochester, MN, USA.

Falls are multifactorial; therefore, multifaceted approaches are required to prevent falls. Imbalance and posture sway are two important risk factors for falls. Controlling sedative pharmacotherapy decreases iatrogenically affected alertness and can reduce falls in the geriatric population. Axial muscle strength decreases about 50% from age 30 to 80.[1] Axial bone mass also decreases approximately 50% in women and 30% in men by age 80.

This study was designed to investigate the influence of kyphosis on postural sway, gait unsteadiness and falls in osteoporotic individuals. Age, height, weight, gait, muscle strength and balance were objectively evaluated in 13 osteoporotic/kyphotic (OK) women with thoracic kyphosis (Cobb angle between 50 to 60 degrees)[2] and 13 healthy controls of comparable age. Isometric lower extremity strength data was collected using a Quantitative Muscle Assessment (QMA) system (The Computer Source, Gainesville, GA). Isometric back extensor strength was measured using the BID-2000 back dynamometer. Gait was studied during unobstructed level walking and while stepping over obstacles of four different heights randomly assigned (2.5, 5, 10 and 15% of the subject's height). Repeated measures ANOVA was used for the statistical analysis with the significance level set at $p < 0.05$. Balance was objectively assessed using Computerized Dynamic Posturography (CDP), (Neurocom, Clackamas, Oregon). A composite score of the Sensory Organization Test (SOT) component was used for this study. Each subject also completed a Dizziness Handicap Inventory and falls efficacy test prior to inclusion in the study. Statistical analysis was done using a student t-test.

O/K subjects had lower muscle strength than the controls in the lower extremities and back extensors ($p<0.05$). Gait analysis showed a significant difference in the anterior/posterior (A/P) and medial/lateral (M/L) displacements and velocities. The OK subjects had less A/P displacement, greater M/L displacement and reduced A/P velocity when compared to the control subjects. This was true for all conditions of unobstructed and obstructed level walking. Also, there was a significant effect of obstacle height on all center of mass (COM) parameters. CDP test showed that the OK subjects had statistically significantly greater balance abnormalities compared to the control group ($p<0.001$).

Following baseline evaluations, the 13 O/K subjects began a specific 4-week home based proprioceptive dynamic program.[3] At the end of the study period, lower extremity strength was unchanged; however, balance improved significantly. Gait parameters also showed statistically significant improvement compared to baseline evaluations.

Back Exercise for Management of Osteoporosis. E. Itoi[1], M. Hongo[1], N. Miyakoshi[1], M. Sinaki[2]. [1]Department of Orthopedic Surgery, Akita University School of Medicine, Akita, Japan. [2]Department of Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, USA.

Increased thoracic kyphosis is a typical postural deformity observed in patients with osteoporosis. Disadvantages of increased thoracic kyphosis are chronic back pain, decreased vital capacity, reflux esophagitis, increased risk of fall, and deteriorated QOL. Falls may cause a new vertebral fracture, which in turn aggravates the kyphotic deformity. In order to stop this vicious circle, prevention and treatment of malposture is required. We have demonstrated that back strengthening exercise is effective not only in increasing the back extensor strength but also in reducing the risk of vertebral fractures in healthy postmenopausal women. Another potential benefit of back strengthening exercise is to increase or maintain the spinal mobility. Recently, we have demonstrated that QOL is affected by the spinal mobility and that the back extensor strength is the most significant contributor to the spinal mobility. However, the safety and effectiveness of back strengthening exercise in patients with osteoporosis have not been clarified. Last year, we reported that reducing each of the weight of the backpack, repetition times, or frequency of the exercise resulted in reduction in the amount of obtained strength of the back extensors. From the view point of reducing the risk of vertebral fractures, it seemed reasonable to reduce the amount of weight rather than reducing the repetition times or frequency. We further investigated the relationship between the reduction of the weight of the backpack and the back extensor strength in healthy young female volunteers. Even without a backpack, the subjects obtained an average 17% increase in back extensor strength in 4 months compared with 5% increase in the control group. Based on this preliminary study, we started a prospective randomized study to determine the effect of back strengthening exercise on posture, spinal mobility, and QOL of patients with osteoporosis. We will share the preliminary results of this ongoing clinical trial.

Rheumatologic Manifestations of Pediatric Forms of Hypophosphatasia. D. Wenkert[1], S. Mumm[2], J. Zerega[1], W. H. McAlister[2], M. P. Whyte[1]. [1]Shriners Hospitals for Children, St. Louis, MO, USA;[2]Washington University School of Medicine, St. Louis, MO, USA.

Hypophosphatasia (HPP), an inborn-error-of-metabolism characterized biochemically by subnormal serum levels of alkaline phosphatase (ALP), is caused by deactivating mutations in the gene which encodes the tissue-nonspecific ALP isoenzyme (TNSALP). Radiographs in "childhood" HPP typically show rickets, including "tongues" of lucency that project from physes into metaphyses in major long bones and sometimes, areas of metaphyseal osteosclerosis. Yet children with the most mild form, odontoHPP, have no skeletal radiographic abnormalities and seek medical attention for early tooth loss.

Purpose: To define the prevalence of joint and bone pain with various pediatric forms of HPP and to highlight two patients with presentations mimicking *chronic recurrent multifocal osteomyelitis* (CRMO).

Methods: We reviewed 111 HPP patient charts. Nearly all have completed molecular diagnoses. 11 had infantile HPP, 64 had childhood HPP, and 36 had odontoHPP. Patients with complex phenotypes (ie. more than one disease),a marrow transplant recipient, and patients less than 2.5 years at last evaluation were excluded.

Results: Among patients who met inclusion criteria: Significant joint and skeletal pain troubled 8 of 8 children (100%) diagnosed with infantile HPP. Of 58 patients with childhood HPP, 72% complained of pain varying from mild to incapacitating (sometimes with morning stiffness) often following physical activity. All reported lower extremity pain. 20% had upper extremity pain as well. Of 32 patients with odontoHPP, 59% complained of pain in their lower extremities and/or back. Hence, joint and or bone pain occur often in each pediatric form of HPP. These, symptoms may often be attributable to obvious rickets, but pain also troubled patients with early tooth loss as their only HPP manifestation.

Two of our HPP patients presented with an unusual syndrome of periarticular pain and bone edema mimicking CRMO: A 13-year-old boy without premature loss of deciduous teeth, had life-long a stiff-legged gait and joint pains twice considered elsewhere as possible CRMO. Additionally, he had distal tibial metaphyseal expansion worsening over 2 years that is atypical for HPP. Serum ALP was 94 (133-347 IU/L). Study of the *TNSALP* gene showed a mutation (Asp361Val) in one allelle.

At age 11 years, a girl with infantile HPP (and a history of morning stiffness and joint and bone pain) developed bilateral, incapacitating leg pain and bone edema (detected by MRI) consistent with CRMO on MRI after an epiphyseal stapling procedure to correct knock knee deformity. Serum ALP was 39 (mutational analysis revealed compound heterozygosity: Ala34Ser; Thr117His).

Conclusions: Causes of pediatric joint pain are numerous and sometimes are unexplained. Premature tooth loss (less than 5 years of age) and careful assessment for low serum levels of ALP using age-appropriate norms should be included in the differential diagnosis of puzzling pediatric joint and bone pain syndromes.

Parathyroid Carcinoma and Atypical Adenoma Associated with Germline *HRPT2* Mutation in Familial Isolated Hyperparathyroidism. T. Kelly[1*], T. Shattuck[2*], M. Reyes-Mugica[1*], B. Kinder[1*], A. Arnold[2], T. Carpenter[1] [1]Yale Univ., New Haven, CT, USA, [2]University of Connecticut, Farmington, CT, USA

Familial isolated hyperparathyroidism (FIHP) is a rare cause of parathyroid (PT) tumors without other neoplasms or endocrinopathies. Mutations in *CASR*, *MEN1* and rarely, *HRPT2*, a putative tumor suppressor, have been identified in kindreds with FIHP. *HRPT2* mutations may be enriched in FIHP families with PT carcinoma, underscoring the importance of identifying causative mutations. Unsuspected germline *HRPT2* mutations occur in sporadic PT carcinoma, and genetic testing of such patients has been advocated.

A 13-year-old boy developed hematuria, hypercalcemia (12.6 mg/dL) and elevated serum PTH (93 pg/mL). Ultrasound demonstrated nephrolithiasis with no other renal pathology. His father had died three years earlier from complications of PT carcinoma. Ultrasound identified a left superior PT mass, which was removed surgically with the ipsilateral inferior PT gland. Aggressive histological features of the tumor included fibrous trabeculae, mitoses, and microscopic capsular infiltration; the inferior gland had normal histology. PTH levels corrected intra-operatively after extirpation of the adenoma, and serum calcium normalized post-operatively. Serum prolactin and calcitonin, and urinary catecholamine excretion were normal. Two years later hematuria, hypercalcemia, and elevated PTH levels recurred. Ultrasound and MRI indicated no recurrent disease in the left neck. An enlarged right inferior PT gland was identified and removed surgically; histology was typical of a benign adenoma. Serum PTH corrected intra-operatively, and serum calcium normalized following surgery. Leukocyte DNA analysis revealed a 5 bp deletion at nucleotide 138 of *HRPT2* (leading to an early frameshift at parafibromin amino acid 46). The initial tumor manifested the expected germline *HRPT2* mutation, plus a distinct somatic mutation (4 bp deletion at nucleotide 60 causing frameshift at amino acid 20), consistent with the Knudson "two hit" concept of biallelic inactivation of a tumor suppressor gene.

Germline mutations in *HRPT2* occur in the hyperparathyroid-jaw tumor syndrome (HPT-JT), in which ossifying fibromas of the jaw and renal lesions occur. These features were not present in our patient, however as they usually appear in the 2nd or 3rd decade of life, HPT-JT remains a possible diagnosis. Genetic screening of the patient's 7 siblings (ages 11-28) is planned, however all have been normocalcemic. Thus, despite the reported rarity of *HRPT2* mutations in FIHP, a personal or family history of PT carcinoma in FIHP mandates serious consideration of a germline *HRPT2* mutation that would affect diagnosis and management.

WG9

Toward a Molecular Understanding of Bone Sarcoma Formation and Malignancy: Implication of a Poly(ADP-ribose) Polymerase-1 Pseudogene. A. Moreau[1, 2], D.S. Wang[1], J. Doyon[3], M. Isler[4], R. Turcotte[5].[1]Bone Molecular Genetics & Musculoskeletal Malformations Laboratory, Research Centre, Hôpital Sainte-Justine; [2]Department of Stomatology and Biochemistry, Université de Montréal, Montreal, Canada; [3]Department of Pathology, Hôpital Maisonneuve-Rosemont; [4]Orthopedic Division, Hôpital Maisonneuve-Rosemont & Hôpital Sainte-Justine Hospital; [5]Orthopedic Division, Montreal's General Hospital & McGill University, Montreal.

Bone cancer is the fourth most common cancer in people under 25 years of age. These skeletal cancers in children are serious and highly fatal conditions while in adolescents and adults, they can have devastating consequences for the life and the limb of the patient. Very little is known about the etiology and the molecular mechanisms involved in skeletal cancerogenesis due to the heterogeneous nature and unpredictable behavior of that disease, which results in controversy as its cause and progression. In the course of studying the role of different factors in bone sarcomas, we serendipitously discovered two transcripts of a PARP-1 pseudogene located to 13q33-qter (PARP-1p), one corresponding to the common A allele and the other to the less common B allele harboring a 193-bp deletion. Poly (ADP-ribose) polymerase 1 is a nuclear enzyme and a DNA binding protein that catalyzes the synthesis of ADP-ribose polymers from NAD+ and their attachment to a variety of nuclear proteins and enzymes. Transcription factors that are ribose modified by poly (ADP-ribose) loose their ability to bind DNA. The PARP-1 gene has been mapped to human chromosome 1q42 and two PARP-1 pseudogenes to 13q33-qter (PARP-1p) and 14. A two-allele PARP-1p polymorphism has been originally detected resulting from a 193-bp deletion of part of the PARP-1p pseudogene at chromosome 13. It has been suggested that PARP-1p polymorphism may be linked to a predisposition to certain cancers. Interestingly, the expression of both alleles were detected only in severe and malignant osteosarcomas (high grade), which contrasted with benign tumors like Giant Cell Tumors or low grade osteosarcomas (grade 2 or less) expressing only the A allele. Moreover, the B allele of PARP-1p was detected only in severe and malignant bone sarcomas and in tumorigenic cancer cell lines. Taken together these results showed for the first time that PARP-1p pseudogene is expressed in human malignant bone sarcomas and co-expression of its B allele could be used as a molecular marker for the early identification in children of skeletal tumors exhibiting a high tumorigenic and malignant potential for whose better pharmacological approaches could be designed.

WG10

Longitudinal Pediatric Reference Standards for the Assessment of Bone Mineral Content. A.D.G. Baxter-Jones[1], R.L.Mirwald[1], M. Petit[2], T. Lloyd[2], L. Bachrach[3], H.A. McKay[4]. [1]College of Kinesiology, University of Saskatchewan, SK, Canada, [2]Department of Health Evaluation Sciences, Penn State University, PA, [3] Department of Pediatrics, Stanford University School of Medicine,[4]Department of Orthopaedics, University of British Columbia, BC, Canada.

There are a number of childhood diseases that can deleteriously affect bone mineral accrual during the growing years. Further, with current bone assessment tools children can easily be misclassified with low bone mass based on small size. Thus, appropriate normative data are needed to accurately determine children at risk for low bone mass and to monitor the effects of intervention designed to enhance bone mass. The present study developed an anthropometry-based prediction model for the assessment of bone mineral content (BMC) in children and adolescents aged 8 to 19 years. Data from 4 longitudinal studies, across 3 sites were collapsed. Healthy boys and girls from four ethnic groups (Caucasian, African-American, Asian and Hispanic) were measured annually for a minimum of four consecutive years. The studies were: the Saskatchewan Pediatric Bone Mineral Accrual Study (BMAS) (239 subjects; 1341 observations), UBC Healthy Bones Trials (1021 subjects; 1964 observations); Penn State Young Women's Health Study (217 Subject; 1113 observations) and Stanford's Bone Mineral Accretion (BMA) Study (325 subjects; 758 observations). Dual-energy X-ray absorptiometry (DXA) (Hologic 4500) was used to measure total body (TB), total proximal femur (PF), femoral neck (FN) and lumbar spine (L1-L4) (LS) bone mineral content (BMC). Data were analyzed using random effects models and gender and site-specific models were created. Models were built in a stepwise procedure with predictor variables added one at a time, using the loglikelihood ratio statistic to determine if one model was a significant improvement over the previous one. The initial models were based on the BMAS data and were verified in the other two data sets. The data were then combined for the final models and variance between predicted and actual data was investigated using the Bland-Altman procedure. The coefficients that best predicted BMC were age, height, weight and their interactions. Ethnic differences were also found, for example when compared to Caucasians, African-Americans and Hispanics had significantly greater FNBMC 0.39 (± 0.06) and 0.34 (± 0.07) g respectively ($p<0.05$), once the confounders of age and size had been controlled. In contrast Asians had 0.20 (± 0.03) g less FNBMC than Caucasians ($p<0.05$). The Bland-Altman graphs of boys FNBMC indicated that the difference between actual and predicted values was less than 1.0 g in 95% of the cases and in girls less than 1.5 g, 95% of the time. Similar results were found for the other sites. In conclusion we have produced a series of longitudinal growth models that predict BMC by accounting for sex, body size and ethnicity. Our findings suggest that the prediction models provide a useful clinical tool to determine potential bone mineral deficits in pediatric populations.

WG11

Vitamin D Deficiency Among Children Living in Canada: Results of a National Disease Surveillance Program. L.M. Ward[1], C.A. White[1], S. Zlotkin[2]. [1]Department of Pediatrics, University of Ottawa, Ottawa, Ontario, Canada, [2]Departments of Pediatrics and Nutritional Sciences, University of Toronto, Toronto Ontario, Canada.

The incidence of Vitamin D deficiency rickets is rising in many countries worldwide. Our experience suggested Canada may be no exception, despite the Canadian Paediatric Society position statement that all breast-fed infants receive daily, oral vitamin D (400 IU). We sought to determine the disease incidence through the Canadian Paediatric Surveillance Program (CPSP), a national network which provides regular, written contact with 2,300 pediatricians across the country. Between July 2002 and March 2004, there were 71 confirmed cases of vitamin D deficiency rickets among children living in Canada. The mean age at diagnosis was 1.45 years (SD 0.94; range 0.10-6.34), 44% of confirmed cases were female, and half were from Ontario. The ethnicity profile was as follows: 34% Black, 14% First Nations, 13% Middle Eastern, 10% Inuit, 10% Caucasian, and 1% Asian (not indicated in the remaining 18%). The mean maternal age at delivery was 29 years (SD 6.2; range 18-39). Eighty-six percent of cases were intermediate- or dark-skinned, and 85% had been breast-fed (the feeding status was not indicated in the remaining 15% of cases). The vast majority (86%, 61/71) of cases had not received vitamin D prior to diagnosis. In the remaining 14%, vitamin D was either unreliably administered or supplementation data was not available. Only 16% of mothers received vitamin D during pregnancy, a number which fell to 6% following delivery, and the majority of mothers did not drink milk. Milk allergies and sunscreen use among children were not significant risk factors for developing the disease, as both were documented in less than 5% of cases. Significant morbidity was present at diagnosis, including skeletal deformity (48%), seizures (14%), failure to thrive (13%), fractures (10%) and delayed developmental milestones (3%). The remaining 12% of cases presented with an incidental discovery of rickets on x-rays. The mean alkaline phosphatase level at diagnosis was 1,381 U/L (range 296 to 6,067), while the 25-hydroxyvitamin D level prior to treatment was a mean of 21.0 nmol/L (SD 14.7; range 1-58). Though it is not surprising that children with the greatest number of risk factors for vitamin D deficiency were the most frequently diagnosed, it is surprising that the condition is frequently detected in a country with ready access to vitamin D and a clear recommendation for prevention from the country's national paediatric organization. These results highlight an urgent need for heightened awareness among health care providers and the general public for prevention of vitamin D deficiency among children in Canada.

ADULT BONE AND MINERAL WORKING GROUP ABSTRACTS

Prevalence of High Incidences of Secondary Causes of Osteoporosis in Men and Women. S. Wimalawansa Department of Medicine, Division of Endocrinology, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Osteoporosis is a disease with continuous loss of bone and, therefore, artificial division into type I and type II (e.g. senile) is not logical. Simple classification of primary and secondary osteoporosis is more practical and useful in their management. Osteoporosis affects ~10% of the World's population, and 3-4% of these patients have treatable secondary causes leading to, or aggravating, this most common metabolic bone disease which is neglected in many instances.

We have examined the incidence of secondary causes of bone loss in 1,000 consecutive patients referred to a tertiary osteoporosis referral clinic. 72% of these patients were female, and 90% of these women were postmenopausal.

The percentages reported with secondary osteoporosis vary with referral patterns. For example, Francis et al. have reported figures of 20% and 35%, and Mayo Clinic reported figures of 40% and 55% for females and males respectively. Current study shows 46% of females and 75% of males referred to this tertiary osteoporosis clinic had treatable secondary causes of bone loss. Since these reported data are from highly selected populations, the true incidence of secondary causes leading to osteoporosis in the community is likely to be much lower.

Table: Incidence of secondary causes of osteoporosis (numbers* and percentages) in 1,000 consecutive patients referred to a tertiary osteoporosis clinic.

Disease / Ailment	Females (n = 720)		Males (n = 280)		Mean Incidence
	Number	Percentage	Number	Percentage	%
Glucocorticoid	89	12.4	28	10.0	11.7
Other medications	45	6.3	17	6.1	6.2
Smoking/alcohol abuse	62	8.6	25	8.9	8.7
Cytotoxic drugs/ radiotherapy	37	5.1	10	3.6	4.7
GI problems	53	7.4	17	6.0	7.0
Malignancy/myeloma	29	4.0	12	4.3	4.1
Hyperthyroidism	19	2.6	6	2.1	2.5
Hyperparathyrodism	36	5.3	9	3.2	4.5
Vitamin D deficiency	65	9.0	16	5.7	8.1
Miscellaneous causes	67	9.3	19	6.8	8.6
Idiopathic hypercalciuria	60	8.0	28	10.0	8.8
Hypogonadism	Excluded	0	42	15.0	---

* Some patients had more than one identifiable/treatable secondary cause.

Environmental factors and habits, such as excessive cigarette smoking and/or alcohol abuse, poor diet and other causes leading to osteomalacia (e.g., malabsorption, gastric surgery, drug interference, etc), and various medications especially glucocorticoids lead to bone loss. Other secondary causes include hypogonadism, GnRH therapy, hyperparathyroidism, hyperthyroidism (i.e., sub-clinical or biochemical hyperthyroidism, excessive intake of thyroxin), hypopituitarism, chronic liver disease, myeloma, conditions associated with immobilization and paralysis including hemiplegia.

In addition to a good history, physical examination and biochemical markers, non-routine tests such as 24 hour urine calcium; serum intact PTH, 25 (OH) vitamin D, sex-steroid hormone levels are useful in identifying these secondary causes. It is essential to identify and treat the underlying secondary causes aggravating further bone loss prior to embarking on anti-osteoporosis therapy.

WG13

Prevalence and Seasonal Variation of Vitamin D in ESRD Patients on Hemodialysis. M. Padda[1], D. S. Rao[2], G. Zusuwa[3], M. Goggins[3], S. Bhat[3], A. Gupta[1]. [1]Division of Nephrology, University of California at Los Angeles and Charles R. Drew University Schools of Medicine and Science, Los Angeles, CA, USA, [2]Bone and Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA, [3]Division of Nephrology, Henry Ford Hospital, Detroit, MI, USA.

Seasonal and racial differences in vitamin D levels have been studied extensively in the general population but not in patients with end stage renal disease (ESRD).

We measured serum 25-hydroxyvitamin D levels in chronic hemodialysis patients at the end of the summer and again at the end of the winter, and determined the prevalence and risk factors for vitamin D deficiency.

Serum 25-hydroxyvitamin D level was measured at the end of summer (September) in 142 patients and again at the end of winter (April) in 73 of these 142 patients. The prevalence of vitamin D depletion, defined as serum 25-hydroxyvitamin D level less than 20 ng/mL, was 54% at the end of summer and further increased to 85% by the end of winter (P <0.001 summer *versus* winter).

Vitamin D depletion is present in about half of ESRD patients with marked seasonal variations. Patients with ESRD should have more frequent assessment of their vitamin D nutrition by serum 25-hydroxyvitamin D levels and vitamin D supplementation should be routinely prescribed, which may prevent many of the complications related to vitamin D deficiency and secondary hyperparathyroidism.

WG14

Osteitis Fibrosa Cystica: An Unusual Manifestation of Primary Hyperparathyroidism and Its Relationship to Vitamin D Nutrition. F. Cheema, M.G. Lagman, D.S. Rao, H.D. Nair, M.W. Lee, M.R. Ansari, G.B. Talpos. Henry Ford Hospital, Detroit, MI. USA.

Osteitis fibrosa cystica was an important diagnostic clue to the presence of hyperparathyroidism in the past. Over the last 50 years, its prevalence declined dramatically in the US, following fortification of milk with Vitamin D. We report four cases of hyperparathyroidism in whom osteitis fibrosa cystica was present, and explore its relationship to vitamin D nutrition.

A total of 565 cases of hyperparathyroidism presented to the bone and mineral clinic of Henry Ford Hospital over a period of 12 years (1989-2001). We reviewed relevant history, diagnostic evaluation, radiographic findings, parathyroid pathology, and response to treatment. The estimated prevalence of osteitis fibrosa cystica is 0.70%, 4 out of 565 patients with hyperparathyroidism seen during this time period. Two patients had primary hyperparathyroidism, one patient developed hyperparathyroidism 12 years after renal transplantation, and another patient with cystic fibrosis and severe vitamin D depletion developed autonomous hypercalcemic hyperthyroidism. On thorough chart review of the remaining 561 patients, a total of 98 patients had alkaline phosphatase > 120 IU/L. The alkaline phosphatase elevation was associated with other causes (such as fractures and elevated liver enzymes). None of these 98 patients were observed to have radiographic lytic lesions consistent with osteitis fibrosa cystica.

Among the patients with osteitis fibrosa cystica, the mean duration of hypercalcemia was 3 years (range 2-4 years), mean serum 25-hydroxyvitamin D level was 11 ± 9 ng/mL, and mean parathyroid gland weight was 6.7 g (range 2.8-10.6 g). The mean gland weight in these 4 patients was approximately 5-fold larger than in 147 patients without osteitis fibrosa cystica (1.27 ± 1.61 g) and in each case, the parathyroid gland weight was at or above the 95% CI predicted for the level of serum 25-Hydroxyvitamin D level. Parathyroidectomy resulted in resolution of bone lesions in each patient.

We conclude that osteitis fibrosa cystica is an unusual manifestation of modern day hyperparathyroidism in the US and is associated with larger parathyroid tumors. Based on the relationship between parathyroid gland weight and serum 25-hydroxyvitamin D level, we believe that vitamin D nutrition plays an important role not only in parathyroid tumor growth but also contributes to development of osteitis fibrosa cystica through increased PTH secretion. There appeared to be a significant delay in the diagnosis of osteitis fibrosa cystica primarily because of the rarity of its occurrence and an apparent lack of awareness by physicians of this specific bone disease.

WG15

Acute Renal Failure, Hypercalcaemia and Cytokine Profiles in Human T-Cell Lymphotropic Virus Type 1 Associated Adult T-Cell Leukaemia/ Lymphoma. J.H. Wang[1], J.B. Eastwood[1], F. Harris[1], W.D. Fraser [2], M. Pazianas[3]. [1] Renal Unit, St. George's Hospital, London, United Kingdom.

A 52-year-old Guyanese man presented with lethargy, severe renal failure, thirst and polyuria having recently started a thiazide for hypertension. Plasma HTLV-1 test was positive and immunophenotyping confirmed Adult T-Cell Leukaemia/Lymphoma (ATLL). His plasma creatinine was 248 umol/l (2.8mg/dl) and calcium was raised at 5.12 mmol/l (20.4mg/dl) and was resistant to therapy. Hand radiographs showed widespread bone resorption with subperiosteal erosions. 25-hydoxyvitamin D_3 and Alkaline Phosphatase levels were in the normal range but 1,25-$(OH)_2$vitamin D_3 was low and PTH levels were suppressed. PTHrP level was greatly raised. Also, IL-6 was elevated, the Receptor activator of nuclear factor kB ligand (RANKL) reported at upper limit values and Osteoprotegerin was raised. TNFa levels were suppressed. Soluble TNF Receptor-1 (sTNFR-1) levels were extremely high. Therefore, the low TNFa levels may not reflect true values in the face of markedly raised sTNFR-1 levels. Interestingly, for such severe hypercalcaemia both RANKL and TNF levels were low in the presence of high OPG & sTNFR-1 levels. However, since the assay only measures the free fraction of molecules it may be that the bound portions of RANKL & TNF were far greater. This case highlights the complexity of the pathophysiology of the humoral hypercalcemia of malignancy and physicians will need to be aware of this particular cause of calcium imbalance.

	Units	Patient Values	Reference Range
Adjusted Calcium (ACa)	mmol/l	5.1	2.2-2.6
Phosphate (PO_4)	mmol/l	1.7	0.75-1.5
Parathyroid Hormone (PTH)	pmol/l	0.3	0.5-5.5
25-OH Vitamin D_3	nmol/l	29	>50
1,25-$(OH)_2$vitamin D_3	nmol/l	38	43-144
Parathyroid Hormone Related Peptide (PTHrP)	pmol/l	6.3	< 1.8
Interleukin-6 (IL-6)	pg/ml	4.6	< 3
Receptor activator of nuclear factor B Ligand (RANKL)	pmol/l	1.3	0.7-1.2
Osteoprotegerin (OPG)	pmol/l	8.3	2.7-3.2
Tumour Necrosis Factor (TNF)	pg/ml	2.9	< 15.6
Soluble TNF Receptor-1 (sTNFR-1)	pg/ml	3787	512-1739

WG16

A Randomized Study to Evaluate Strategies to Improve Osteoporosis Detection and Treatment in Elderly Women. B. Muma[1], J. Lafata[1], B. McCarthy[2], D. Kolk[1], E. Peterson[1], D. Rao[1], T. Weiss[3], Y. Chen[3]. [1] Henry Ford Health System, Detroit, MI, USA, [2] Alina Medical Group, Minneapolis MN, USA, [3]Merck & Co., Inc., West Point, PA, USA.

Current estimates are that only 20% women age 65 and older have received a bone mineral density (BMD) test, despite recommendations from the US Preventive Services Task Force and the National Osteoporosis Foundation. Thus, a large number of women are at risk of avoidable late-stage osteoporosis. We report preliminary findings of a randomized prospective study to evaluate strategies to enhance the quality of care for osteoporosis.

We identified women aged 65-89 that received primary care from 15 ambulatory care clinics of a large medical group in southeast Michigan between 4/1/2001 and 3/31/2003. The clinics were stratified by size and BMD availability, and randomized to one of 3 study arms: (1) usual care; (2) patient mailing (BMD reminder letters + educational material); and (3) patient mailing plus physician reminder prompts for BMD testing. Women that previously received a BMD test, a diagnosis for osteoporosis, or a prescription drug claim for an osteoporosis-specific therapy (alendronate, risedronate, raloxifene, or calcitonin) were excluded. A total of 10,565 eligible women were included in the study: 3,110 women in strategy (1) clinics; 3,368 in strategy (2) clinics; and 4,087 in strategy (3) clinics. Preliminary analysis of BMD testing rates were calculated for each study arm for a six-month window starting in August 2003. Differences between groups in BMD testing rates were evaluated using generalized estimating equations. To adjust for different intervention start times, we matched the usual care group to each of the intervention groups separately by starting time. Statistically significant differences in BMD testing rates between groups were evaluated using generalized estimating equation approaches.

Preliminary analysis adjusted for intervention start date indicate differences in BMD screening rates between the usual care and patient mailed reminders (2% vs. 13%); and the usual care and the patient mailing plus PCP prompt (5% vs. 27%).

Differences between usual care and patient mailing strategies were statistically significant (p<.001). The use of a patient mailing plus physician prompts lead to significant improvements in BMD testing compared to both usual care and patient mailing alone (p<.001). Results did not change with adjustments for clinic, race, and age.

Preliminary results indicate that the use of mailed patient reminders alone or in combination with physician prompts can lead to significant increases in osteoporosis screening rates compared to usual care, with the combination intervention (patient mailing + PCP prompt) showing the greatest effect.

WG17

Bone Mineral Density (BMD) in Healthy Indian Women: Development of a Reference Database and Implications for Diagnosis of Osteoporosis in Indian Women. S. Nangia, P. Reddy, N. Ramaswamy, A. Mithal, U. Sriram, Indraprastha Apollo Hospital, New Delhi, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, and Apollo Specialty Hospital, Chennai, India.

Genetics and ethnicity are the two most important determinants of peak adult bone mass, thereby necessitating the need for a separate reference databases for different ethnic groups. We sought to establish the first BMD reference database for Asian Indian women so that appropriate comparisons can be made in evaluating individuals of Asian Indian origin for osteoporosis.

Seventy five women from Lucknow, North India and 65 women from Chennai, South India, and aged 20-29 years were recruited to develop a reference database to facilitate calculation of ethnic-specific T-scores. BMD was measured at the lumbar spine, proximal hip, and non-dominant forearm by Hologic 4500 DEXA. Height, weight, BMI, age at menarche and the estimated dietary calcium intake were determined in all subjects.

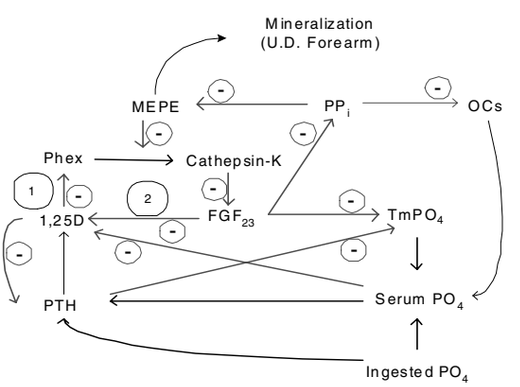
BMD in Asian Indians was significantly lower than that of the U.S. white women at all relevant measurement sites and at both centers (p<0.001 for all). The peak adult BMD for Indian women was 0.927 ± 0.097 g/cm^2 at the spine (L1-L4), 0.788 ± 0.10 g/cm^2 at the femoral neck, 0.839 ± 0.095 g/cm^2 at the total hip, and 0.555 ± 0.050 g/cm^2 at the forearm (distal 1/3 radius). Compared to the U.S. white women, peak BMD was about 11% lower at the left femoral neck and total hip; 12% lower at the lumbar spine; and 35% lower at the distal forearm. Dietary intake of calcium in this reference group was 556.3 ± 253.2 mg/day. The spine BMD was slightly higher (p=ns) and femoral neck and forearm BMDs were slightly lower (p=0.018 and p<0.001 respectively) in Chennai women compared to Lucknow women. This difference could be explained by higher BMI and lower calcium intake in Chennai women.

At all measurement sites, BMD was significantly lower in Asian Indian women from two large cities in India, as compared to U.S. white women, although the lower BMI, calcium intake, and vitamin D nutrition might explain some or most of this difference between the two racial groups. Nevertheless, until the BMD-fracture relationship is established in this ethnic group, we recommend the use of the peak adult BMD from this study to calculate T-scores for Asian Indian women.

WG18

Phosphate and 1,25 Vitamin D Interaction Expressed in the Context of PHEX, FGF_{23}, and MEPE. R.S. Fredericks. Endocrine Associates. Reno, NV, USA

Molecular genetic exploration of syndromes involving phosphate metabolism has identified key mediators influencing phosphate homeostasis. 1,25 D has a fundamental role in metabolism as a signal of environmental phosphate deficiency. We have previously demonstrated that bisphosphonate signals are capable of modulating an unusual presentation of dysmetabolic syndrome X. Through extensive use of an N of 1 research strategy we have reported on regional regulation of skeletal mineralization as influenced by evolutionary constraints, where competition for environmental phosphate and energy is the fundamental organizing principle informing the models developed. Organic pyrophosphate functions as a primary signal of the adequacy of energy and phosphate. In the course of evaluating patients with subjective complaints in energy metabolism, we have utilized bone density results as a record of individual physiology. Two cases recently evaluated appear to demonstrate findings consistent with a disruption in the signaling of 1,25 D, Phex, FGF_{23} and MEPE. The bone phenotype is restricted to the ultra distal forearm where there appears to be less of a negative influence of 1,25 D on Phex, and the models would predict a decrease in MEPE. This process appears to be inherited as an autosomal dominant trait. The 2nd case presents as a disruption in the ability of FGF_{23} to decrease serum 1,25 D. These cases are supportive of the concept that the fundamental role of 1,25 D is best understood as it influences phosphate metabolism, with the influence on calcium homeostasis being manifestations of an integrative function developing in more complex biological systems.



WG19

Fanconi's Syndrome and Osteomalacia. M.A. Cameron, O.W. Moe, K. Sakhaee. UT Southwestern Medical Center, Dallas TX

Osteomalacia (OM) is a metabolic bone disease with diverse etiologies. In adults, the commonest acquired and genetic causes are vitamin D deficiency and X-linked hypophosphatemic rickets, respectively. We present a case of OM in an adult subject with characteristics distinctive of Fanconi's syndrome.

A 36 year old African American male was evaluated for bone pain present for three years. The pain originated in his feet, progressed to his legs, and significantly impaired ambulation. He suffered spontaneous fractures of the metatarsal and ankle bones. The physical examination was remarkable for a waddling gait and tender extremities. X-rays showed pseudofractures in the hips.

Plasma	Values	Normal
Creatinine	2.2 mg/dL	0.9 - 1.1 mg/dL
Total CO_2	16 mEq/L	22 – 28 mEq/L
Anion Gap	10	10 - 12
Phosphorus	2.0 mg/dL	2.4 – 4.4 mg/dL
Glucose	106 mg/dL	70 – 105 mg/dL
1,25 $(OH)_2$ vitamin D_3	16 pg/mL	8-42 pg/mL
Alkaline Phosphatase	308 U/L	20-225 U/L
PTH	24 pg/mL	10-65 pg/mL

24 hour Urine	Values	Normal
pH	6.87	Variable
Glucose	9.2 g/24 hours	None
Protein	2.382 g/24 hours	< 0.15 g/24 hours
Aminoacids	Present	Absent
TmP/GFR	0.75 mg/dL	> 2.38 mg/dL

In conclusion, it is important to recognize that patients with congenital or acquired forms of Fanconi's syndrome are at risk for OM. Fanconi's syndrome can cause OM by multiple mechanisms: including phosphate wasting, calcitriol deficiency, and metabolic acidosis.

WG20

The Latent Mobility of Osteoporotic Vertebral Compression Fractures. F. E. McKiernan, Center for Bone Diseases, Marshfield Clinic, Marshfield, WI, USA.

Dynamic mobility (DM) is a property of some osteoporotic vertebral compression fractures (VCFs) that is being recognized with increasing frequency. DM is defined as a measurable change in vertebral body configuration between standing lateral and supine crosstable lateral radiographs (vertebroplasty series). DM can be harnessed to result in restoration of vertebral body height and reduction of sagittal kyphosis during the course of percutaneous vertebroplasty (PV). Recent experience, exemplified by this case report, reveals an important new dimension of DM.

A 74 yo woman experienced back pain 2 days after vigorous housework. 2 weeks later X-ray showed mild new T7+T8 VCFs. In spite of comprehensive medical management she worsened and was hospitalized 4 wks after pain onset. X-ray then showed moderate T7 VCF, T8 vertebra plana and a severe sagittal deformity. MR confirmed the acute nature of both VCFs. No intravertebral cleft was seen in either vertebra. She was transferred to our institution 5 wks after pain onset for possible PV. PE revealed a severe, painful thoracic kyphosis and a normal neurologic exam. Vertebroplasty series showed insufficient DM to permit safe PV at T8. PV at T7 was recommended for partial pain relief and prevention of further vertebral T7 collapse. After strict overnight confinement to the supine position the T8 vertebra plana increased to 80% of its original height and revealed a typical intravertebral cleft. Successful PV of both T7 and T8 resulted in vertebral height restoration, reduction of the sagittal deformity and pain relief.

The absence of DM in a mid T-spine VCF was not surprising since DM is more common at the thoracolumbar junction. But mature osseous union of T8, sufficient to preclude DM, seemed unlikely within 2 wks of catastrophic vertebral collapse. We postulated that DM was hindered by hemorrhage, soft tissue scarring or muscle contraction. After 12 hrs in the supine position the "latent mobility" (LM) of this VCF became apparent and led to a favorable symptomatic, functional and biomechanical outcome. We speculate that the current vertebroplasty series underestimates the prevalence and magnitude of DM since patients only assume the supine position for a brief period of time. Furthermore, vertebral height restoration achieved during PV might be further enhanced if patients were kept supine for some period of time preoperatively.

Both DM and LM raise important questions about vertebral injury response, fracture healing, vertebral morphometry and care of patients. Failure to recognize and incorporate these simple observations into clinical practice and PV outcomes research *a priori* may result in missed opportunities for pain relief, invalidated study designs and flawed study conclusions.

WG21

Cervical Spine Anomalies in Patients with Fibrodysplasia Ossificans Progressiva: Clues from the BMP Signaling Pathway. A.A. Schaffer,[1,6,7] F.S. Kaplan,[1,2,3,6] M.R. Tracy,[6,7] M.L. O'Brien,[6,7] J.P. Dormans,[2,6] E.M. Shore,[1,2,4] R.M. Harland,[8] and K. Kusumi.[5,6,7] [1]The Center For Research In FOP & Related Disorders, The University of Pennsylvania, Philadelphia, PA, USA, [2]The Departments of Orthopaedic Surgery, [3]Medicine, [4]Genetics and [5]Pediatrics, The University of Pennsylvania School of Medicine, Philadelphia, PA, USA, [6]The Divisions of Orthopaedic Surgery, and [7]Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA, USA, and [8]The Department of Molecular and Cell Biology, The University of California, Berkeley, CA, USA.

Minor developmental features of diseases can often provide seminal clues to underlying etiologies and pathophysiologic pathways. While progressive replacement of connective tissue with heterotopic bone is the most dramatic and disabling feature of fibrodysplasia ossificans progressiva (FOP), less severe phenotypic anomalies of the normotopic skeleton often receive minimal attention. After noting generalized neck stiffness and decreased range of motion of the cervical spine in nearly all children with FOP prior to the formation of heterotopic bone at that anatomic site, we reviewed available plain films in 70 FOP patients and found characteristic anomalies including large posterior elements, tall narrow vertebral bodies, and fusion of the facet joints between C_2 and C_7 while the occiput-C_2 levels were ubiquitously spared. Most notably, the characteristic anomalies of the cervical spine in patients with FOP were distinctly different from those of the Klippel-Feil syndrome and were nearly identical to those seen in mice with homozygous deletions of the gene encoding Noggin, a potent BMP antagonist. While the Noggin gene is not mutated in patients who have FOP, our findings provide strong support for the role of the BMP signaling pathway in the morphogenesis of the vertebrate cervical spine and extend a growing body of evidence implicating overactivity of the BMP4 signaling pathway in the molecular pathogenesis of FOP.

WG22

Ectopic Production of PTH by a Neuroendocrine Carcinoma of the Pancreas. N. Yu, J. VanHouten, L. Ardeshirpour, D. Rimm, R. Udelsman, J. Wysolmerski. Yale University Medical School, New Haven, CT, USA.

A 74 y/o female presented to an outside hospital and was found to have a serum calcium level of 15.3mg/dL. CT scanning revealed a 2.2cm hypodense mass in the liver and a pancreatic mass. However, a PTH level of 399 pg/mL (10-65) suggested the diagnosis of primary hyperparathyroidism. She was transferred to our hospital where her calcium was 18.0mg/dL (ionized Ca 10.5mg/dL). Repeat intact PTH level was 2,310pg/mL. A sestamibi scan revealed uptake in the lower pole of the left thyroid bed. She was taken to the operating room and a left-sided mass was resected that proved to be a thyroid nodule. Subsequently a thymic parathyroid was also resected and 4 other parathyroid glands appeared normal. Right and left internal jugular intra-operative PTH levels were similar to peripheral levels, suggesting a source of PTH outside the neck. The patient underwent CT-guided liver and pancreatic biopsies. Histology revealed high-grade neuroendocrine carcinoma, which stained for PTH. The PTHrP level also returned elevated at 11.7pg/L (<1.3). The patient's hypercalcemia could not be controlled and she died several days later.

An autopsy revealed neuroendocrine carcinoma of the pancreas with metastases to the liver, mesenteric, periaortic, and peripancreatic lymph nodes. Tumor cells from these sites stained for PTH. Expression of PTH mRNA in the tumor was documented by real-time RT-PCR analysis of RNA prepared from the pancreatic primary and the liver metastasis. Uninvolved pancreas and liver tissue from the patient was negative. Interestingly, the tumor tissue was negative for GCMB expression. Primary cell lines have been established from malignant ascites, the liver metastasis and the pancreatic primary. The tumor cell lines are all positive for PTH and PTHrP mRNA and conditioned media from the cells contained 15-80 pM PTH (1-84) and 5-25 pM PTHrP (1-86).

In summary we report a patient with "parathyroid crisis" that was caused by the rare ectopic production of PTH and PTHrP by a poorly differentiated neuroendocrine tumor of the pancreas. This case is instructive in several ways. First, it demonstrates the utility of the intra-operative PTH assay in suggesting the possibility of ectopic PTH production. Second, it demonstrates that GCMB expression is not absolutely necessary for PTH gene expression. Third, the tumor tissue and cell lines harvested from the patient will be valuable for the study of the molecular mechanisms underlying ectopic hormone production by tumors as well as the study of PTH gene expression.

WG23

Hypocalcemia as the Presenting Manifestation of Metastatic Prostate Cancer. E. Gonzalez-Feldman, Y. Hmadeh. D.S. Rao. Department of Internal Medicine and Bone & Mineral Metabolism, Henry Ford Hospital, Detroit, MI, USA

Hypercalcemia is a well known complication of several types of cancer, but symptomatic hypocalcemia is less frequently reported. We report two such unusual cases.

Case 1: A 70 y old African American man without any previous medical problems was admitted to the medicine service with a 3 month history of persistent hiccups and 20 pound weight loss. He was severely anemic and complained of right hip pain. His serum calcium was 5.6 mg/dl but Chevostek and Trousseau signs were absent. In spite of normalizing serum 25-hydroxyvitamin D levels (which was 9 ng/ml) with vitamin D and continuous calcium supplementation, his serum calcium level remained low. Only after pharmacologic doses of Calcitriol (5 ug/d for several weeks) his serum calcium normalized.

Case 2: A 79 y old African American man was admitted to the emergency service after having a generalized seizure. His serum calcium was low (4.3 mg/dl) despite normal serum 25-OHD (28 ng/ml) and 1,25-dihydroxyvitamin D (30 pg/ml) levels. Continuous iv and oral calcium supplements were given over two weeks, but serum calcium remained persistently low. Only after starting pharmacologic doses of Calcitriol (4 ug/d) his calcium normalized.

Relevant laboratory are shown in the Table

	calcium mg/dl	iCa mmol/L	PTH pg/ml	creatinine mg/dl
Case 1	5.6	0.7	268	2.2
Case 2	4.3	0.56	175	4.3

DISCUSSION: True hypocalcemia is an uncommon manifestation of prostate cancer. Apparent hypocalcemia is more prevalent is most often due to low serum albumin. A prevalence of 16 % has been noted in a series of 143 patients with bone metastasis from different kinds of cancers, all asymptomatic, but ionized calcium was not measured. In another report, the prevalence of hypocalcemia was 23% in patients with bone metastasis, but only one patient had low ionized calcium. Various theories have been proposed to explain hypocalcemia including "hungry bone" syndrome with quantum of uptake of calcium with rapid growth of osteoblastic metastasis.

In spite of baseline high levels of 1,25-DHCC and correction of 25-OHD, our patients continued to have hypocalcemia. We believe that our patients were resistant to vitamin D from an unknown cause, perhaps from an antivitamin D factor produced by the neoplastic cells.

WG24

Unusual Femoral Shaft Fractures Following Long Term Bisphosophonate Therapy. S. Levy[1], C. Odvina[2], S.Palnitkar[1], D.S. Rao[1]. [1]Bone & Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, and [2]University of Texas, Southwestern Medical School, Dallas, TX.

There has been a growing concern about long term effects of bisphosphonate therapy. We previously reported 6 patients with unusual fractures while on long term bisphosphonates. Now we present 4 additional cases.

A 68 y white man had metatarsal stress fractures at the age 60 y. A BMD of the spine at the time was T score -0.27 and femoral neck T score -1.32. Alendronate 10mg/d was begun and changed later to once weekly. In Jan 2003 he stepped off a step in his garage and sustained fracture of the left femoral shaft. He underwent open reduction and internal fixation (ORIF). Recovery was uneventful. He was well until January 2004, while walking down a corridor he felt a snap and fell sustaining fracture of the right femoral shaft again requiring ORIF. Most recent BMD: spine T score +1.3 and femoral neck T score -1.1.

A 52 y white woman with a history of ovarian cancer had surgery and chemotherapy in 1994. She was prescribed alendronate 10 mg/d in 1995 primarily to prevent postmenopausal bone loss, and was changed to 70 mg once a week. In August, 2003 while vacationing on a cruise she turned around, felt a snap and fell suffering a left femoral shaft fracture requiring ORIF. The patient discontinued alendronate in October, 2003. A BMD in 1991 was normal, as was one in 1998.

A 67 y white woman with osteopenia in 1998 was started on alendronate therapy. She had been on estrogen, calcium and vitamin D. Breast cancer was diagnosed in 2002, estrogen was stopped and Arimidex was started in 2003. In May 2003, she developed spontaneous fractures of both femoral shafts requiring intramedullary rods. BMD in 2001: spine T-score +1.38 and femoral neck T-score +0.23, and a repeat BMD of the spine T-score in 2003 was +1.7.

A 74 y white woman with a history myasthenia gravis and steroid osteoporosis was started on alendronate in 1995. Her BMD prior to treatment was T score -4.5 in the lumbar spine and T score -2.4 in the femoral neck. In 2003 she heard a snap and then she fell sustaining a right femoral fracture requiring ORIF. Her BMD in 2002: spine T score -2.8 and femoral neck T score -2.4.

A transiliac bone biopsy following tetracycline labeling in 3 of the 4 patients showed severely suppressed bone turnover.

Femoral shaft fractures are rare even in patients with osteoporosis. Therefore, the occurrence of femoral shaft fractures in our four patients on long term bisphosphonate therapy raises the possibility that such treatment may be associated with spontaneous unusual fractures.

WG25

Bisphosphonate-Induced Hypocalcemia. N.M. Maalouf, P.J. Kim, H.J. Heller, K. Sakhaee. Center for Mineral Metabolism, U.T. Southwestern Medical Center, Dallas, TX, U.S.A.

Bisphosphonates (BPs) are pyrophosphate analogs that are potent inhibitors of osteoclast-mediated bone resorption. Although BPs are widely used in the treatment of osteoporosis and of hypercalcemia of malignancy, it is important to carefully consider the limitations and risks of these drugs. We hereby present two patients who developed severe symptomatic hypocalcemia following BP administration.

Patient #1 is a 56 year-old man who presented with facial tingling. He had received a single dose of intravenous pamidronate and one round of chemotherapy with vincristine, adriamycin, and dexamethasone for multiple myeloma and was discharged a week prior to his admission. His laboratory information is presented in the table below, and was consistent with severe hypocalcemia, vitamin D insufficiency and secondary hyperparathyroidism.

Patient #2 is a 75 year-old woman who had a history of Crohn's disease, requiring glucocorticoid use and 4 bowel resection surgeries. She also was taking phenytoin for a seizure disorder. Due to the finding of a low bone mineral density, she was started on alendronate 10 mg daily three months prior to her admission with severe paresthesias and weakness. At presentation, she had a positive Trousseau's sign and profound hypocalcemia and vitamin D deficiency (see table).

Patient #	1	2	Normal Range
Presenting serum calcium, corrected for albumin (mg/dl)	6.5	5.6	8.4-10.2
Ionized serum calcium (mg/dl)	3.2	2.1	4.7-5.1

Bone resorption constitutes a major protection against hypocalcemia of various etiologies. Since BPs are very potent inhibitors of osteoclastic bone resorption, this defense mechanism is blunted in BP-treated patients. Cases of BP-induced hypocalcemia have previously been described, mostly in patients with undiagnosed hypoparathyroidism. In the two patients described, hypoparathyroidism was not the cause of the hypocalcemia.

Rather, a decreased intestinal absorption of calcium due to underlying vitamin D deficiency likely contributed to the severe symptomatic hypocalcemia.

In addition to their indications for the treatment of osteoporosis, BPs are increasingly used in the therapy of patients with various malignancies. This factor, along with the high prevalence of occult vitamin D deficiency among medical patients, will likely lead to an increase in the incidence of symptomatic hypocalcemia in BP-treated patients. Thus, patients at risk for vitamin D deficiency should have an evaluation of their vitamin D reserve prior initiation of treatment with BPs.

PHYSICAL ACTIVITY WORKING GROUP

WG26

Vitamin D and Physical Function in the Older Population. H. A. Bischoff-Ferrari. Brigham and Women's Hospital, Boston, MA, USA.

The protective effect of vitamin D on fractures has been primarily attributed to the established moderate benefit of vitamin D on calcium homeostasis and bone mineral density[1]. However, an alternative or complementary explanation might be that vitamin D affects factors directly related to muscle strength and function, thus reducing fracture risk through fall prevention. Muscle weakness is a prominent feature of the clinical syndrome of vitamin D deficiency. A physiologic explanation for the beneficial effect of vitamin D on muscle strength is that 1,25-dihydroxyvitamin D (1,25(OH)2D), the active vitamin D metabolite, binds to a highly specific nuclear receptor in muscle tissue leading to improved muscle function and reduced risk of falling[2]. In older persons there is some support in the literature for higher 25-OHD levels being preferable to lower levels in regard to musculoskeletal function. The positive associations between vitamin D and musculoskeletal function observed in cross-sectional studies are supported by two recent randomized controlled trials (RCTs)[3, 4], where vitamin D supplementation improved musculoskeletal function and body sway in older women. However, most of this literature has been collected in populations at risk for vitamin D deficiency, such as institutionalized elderly persons or ambulatory elderly residing in Europe, where food is not fortified with vitamin D. Still, in a large US survey, we found that in both active and inactive ambulatory individuals age 60 and older, 25-OHD levels above 40nmol/l and as high as 90 nmol/l, the upper end of the reference range, are associated with better musculoskeletal function in the lower extremities. This association was consistent across two lower extremity function tests, the timed 8-foot walk and the timed repeated sit-to-stand test. Given the high prevalence of low 25-OHD levels and inactivity in this national survey and the positive association between 25-OHD and lower extremity function, vitamin D supplementation may offer a way to improve lower extremity function in both active and inactive subjects 60 years and older. This recommendation is supported by a recent meta-analysis of RCTs on the risk of falling, where, vitamin D reduced a persons' risk of falling by more than 20%[5].

WG27

Mechanical Loading Responses in Genetically Engineered Mice. C. Turner. Department of Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

Mechanical loading provides an anabolic stimulus for bone. More importantly the mechanosensing apparatus in bone directs osteogenesis to where it is most needed for improving bone strength. The biological processes involved in bone mechanotransduction are poorly understood and further investigation of the molecular mechanisms involved might uncover drug targets for osteoporosis. One characteristic of the mechanosensing apparatus that has only recently been studied is the important role of desensitization. Experimental protocols that insert "rest" periods to reduce the effects of desensitization can double anabolic responses to mechanical loading. Several pathways are emerging from current research, including membrane ion channels, ATP signaling, and second messengers such as prostaglandins and nitric oxide. Some key molecular targets include the L-type calcium channel (alpha 1C isoform), a gadolinium-sensitive stretch-activated channel, P2Y2 and P2X7 purinergic receptors, EP2 and EP4 prostanoid receptors, and the parathyroid hormone receptor.

WG28

What Types of Exercise Work in Fall Prevention (The FaMe Study). D. Skelton. University of Manchester, Manchester, United Kingdom.

Nearly half of nursing home admissions in the UK are due postural instability (1) and older people themselves fear hip fracture and subsequent nursing home admission (2). Frequent fallers have poor outcomes. In one trial, 27% of people who fell 3 or more times in a year were admitted to hospital, transferred to nursing homes or died at one year follow-up (3). Although there is evidence that exercise alone can help prevent falls, there is still concern over safety and effective types and intensities of exercise for those who already have a history of falls (4).

To investigate the effectiveness of a 9 month group Exercise intervention (FaME), compared with a control intervention to reduce falls and injuries, frequent fallers were recruited. 100 community dwelling, independent women aged 65 years and over with a history of three or more falls in the previous year were enrolled into the study and randomly allocated (blind) into Exercisers (n=60) or Controls (n=40). 43 Exercisers and 27 Controls completed full diary returns, for the entire duration of the trial (30 months) with a (mean age 72.6 (SD 5.5 years)). 5 Exercisers dropped out of the intervention and 7 were lost to follow up (ill, health, death). The frequent fallers completed fortnightly fall diaries for 36 weeks as a prospective Baseline fall history, 36 weeks during their Intervention and 36 weeks in the Follow- up period. Those not allocated to group exercise (Controls) performed home-based seated flexibility training. Exercisers attended weekly one hour tailored dynamic balance and strength exercise classes (taken by qualified, advanced exercise instructors) and performed home exercise twice-weekly for nine months.

Poisson regression models suggest that Exercisers had half the risk (RR 0.53, 95% CI 0.38 to 0.73) of a fall compared to the Controls during the Follow-up period. Although women with a history of frequent falls increased their risk of falls during this exercise Intervention (relative risk 1.19, 95% CI 0.86 to 1.66) they were less likely to sustain injurious falls (relative risk 0.51, 95% CI 0.21 to 1.23) than those who did not exercise and were much less likely to sustain an injurious fall during the Follow-up period (relative risk 0.39, 95% CI 0.16 to 0.93). A nine-month specific, progressive group exercise programme (FaME) is effective at reducing further falls and injuries in community dwelling women with a history of falls. Group balance exercise should be a referral option for any evidence-based interdisciplinary falls prevention programme. The challenge is to effectively deliver these classes within the "health" setting, ensuring balance specificity, tailoring, adequate duration and intensity, sufficient progression, education and telephone support.

Osteoclastic differentiation and bone resorption, SU324
Runx2 expression regulation and runx2 P1 promoter activation, 1213
SFRP-1 as antagonist of, F260, SA260
Taqman gene expression analysis of, 986
Women. SEE ALSO *Osteoporosis, postmenopausal; Perimenopause; Postmenopausal women; Premenopause; Sex differences*
Aging, cortical bone cross-sectional structure and mineralization, SA015
Asthmatic, inhaled steroids and, SA122
BMD and systemic lupus erythematosus, SA516
$25(OH)_2D$ variations by age and race, M361
Isokinetic muscular strength training and tibial bending stiffness, SU229
Poly adenosine repeat in VDR and bone loss in elderly, SU170
Rowing effects on BMD, SU235
Sex hormones and proximal femur diameter, 1151
Young-elderly differences in femoral neck, SA018
WP9QY, SU343
Wrist fractures, SU356, M124
WT145 (vitamin D receptor) cells, SA554

X

XL-α proteins, SU561

Y

$Y^{747/759}$ (β_3-integrin mutant), F304**,** SA304
Yaktrax walker, SA420
YD-1901, SU299
Young's cortical bone modulus, SU077

Z

Zebrafish, SU547, M029
Zinc, SU244, M375
ZIP1, SU244
Zoledronate, M416
Zoledronic acid
Bone loss in spinal cord injury model of microgravity, M425
Bone volume and strength increases with OP-1, SU444
Calcitriol in malignancies with bone involvement, M071
Differential BMD thresholds for once-yearly dose trials, SU433
Duration of action after single dose, SU432
Endochondral ossification in rat fracture model, SU443
Neridronate combination effects on bone remodeling, SU442
Osteoclasts in C57bl mice with calcium deprivation, M421
Risedronate for Paget's disease *versus,* F482, SA482
