Several *in vitro* studies suggests that the antiresorptive effect of raloxifene (a selective estrogen receptor modulator) might be produced by changes in several cytokines involved in the bone remodelling process. In this context, the OPG-RANKL system is considered a key component in the osteoclastogenesis regulation. In addition, the treatment with raloxifene leads to changes in hormonal profile that can be related with its extra-osseous effects. However, these effects are not adequately established in osteoporotic patients. Objectives: To determine the effects of raloxifene administration on serum concentrations of OPG, RANKL, IGF system and biochemical markers of bone turnover in women with postmenopausal osteoporosis. Subjects and methods: We selected 48 postmenopausal women (mean age 63±7 years) with densitometric criteria of osteoporosis (T-score ≤ -2.5 SD). We determined anthropometric parameters, biochemical markers of bone turnover, serum levels of IGF-I, IGFBP-3, OPG (OPG ELISA, BIO-MEDICA-GRUPPE Wien, Austria) and RANKL (sRANKL ELISA BIO-MEDICA-GRUPPE Wien, Austria), before and after three months of raloxifene-HCL (60 mg/day) treatment. Results: OPG (84 ± 35 vs. 73 ± 32 pg/ml; p = 0.001), IGF-I (131 ± 60 vs. 99 ± 39 ng/ml; p = 0.001) and biochemical markers of bone turnover (ALP: 87 ± 41 vs 67 ± 18 UI/L; p = 0,001, TRAP: 3.1 ± 0.4 vs 2.7 ± 0.6 UI/L; p = 0.002, urinary CTX: 616 ± 356 vs 499 ± 410 ugr/pmol ; p = 0.04) significantly diminished to 3 months. A high percentage of serum RANKL determinations were undetectable (basal: 68%, 3 months: 63%). RANKL was neither affected by treatment and nor related to OPG or IGF-I variations. The changes in the IGF-I/IGFBP-3 ratio were positively related with variations in OPG (r = 0.347; p= 0.018). Conclusions: The treatment with raloxifene in osteoporotic postmenopausal women leads to a decrease in serum levels of OPG that it might be attributed to the inhibitor effect on bone remodelling. The changes in IGF-I could be related to the extra-osseous effects of this drug. The determination of serum RANKL does not contribute any additional information.

The Decrease in Bone Strength induced by Ovariectomy in Adult Rats Is corrected by the New Selective Estrogen Receptor Modulator PSK3471. P. Ammann[1], P. Clément-Lacroix[2], N. Bruynick*[2], R. Baron[2], R. Rizzoli[1]. [1]Department of Rehabilitation and Geriatrics, Division of Bone Diseases, Geneva, Switzerland, [2]ProSkelia Pharmaceuticals, Romainville, France.

Prevention of bone loss after menopause with estrogens affect not only bone but also the uterus and breast. There is therefore a need for alternative therapy like selective estrogen receptor modulators (SERMs), which can prevent bone loss and decrease bone fragility, while preventing breast cancer and lacking side effects on the genital tract. PSK3471 is such a new compound and displays good safety profile on breast and uterus. We investigated the effects of this new steroidal SERM, on bone mineral density (BMD; mg/cm2) and bone strength (U St; N) at the level of the proximal tibia (PT), and midshaft femur (MF) in ovariectomized (OVX) osteoporotic rats, and compared these effects to those of Raloxifene and the bisphosphonate Pamidronate (APD). Eight weeks after OVX, 8-month old rats were allocated to 6 groups (n=8) and given orally PSK3471 at 0.03/0.1/0.3 mg/Kg, or RAL at 3.0 mg/kg BW x day, APD (0.6 mg/kg 5 days/month) or the vehicle for 16 weeks. Values are means±SEM; * indicates p<0.05 vs OVX and by ANOVA.

	PT BMD	PT U St	MF BMD t	MF U S
SHAM	259.6±4.4	220.0±11.8	261.2±4.6	155.9±7.3
OVX	229.5±3.1	164.8±8.3	247.3±2.7	155.8±2.8
OVXPSK 0.03	239.3±2.7	187.4±8.3	246.6±2.2	152.1±6.6
OVXPSK 0.1	241.5±3.7	195.2±8.3*	244.2±4.5	150.2±5.6
OVXPSK 0.3	241.5±5.2	197.9±10.7*	243.0±4.5	158.1±6.9
OVX RAL 3.0	239.0±4.4	190.3±8.3	252.0±4.1	165.7±8.0
OVX APD	255.0±5.*	197.0±4.6*	256.7±3.9	169.7±5.4

In OVX rats, moderate increment of BMD was observed in rats treated with PSK3471 and raloxifen but a full recovery in pamidronate treated rats. Interestingly at the optimal doses PSK 3471 and pamidronate resulted in similar increment of ultimate strength despite different effects on BMD. These results suggest a different mechanism of action between bisphosphonate and PSK 3471 (action on bone turnover, trabecular bone volume or level of mineralisation). Similar trends were observed at the level of the midshaft femur. In conclusion, similar to Raloxifene, PSK3471 increased moderately BMD but was very efficient in restoring bone mechanical strength in aged osteoporotic rats, while displaying good safety profile on breast and uterus. PSK3471 may therefore be an improved second generation SERM molecule, preventing bone loss while maintaining good biomechanical properties.

Insulin Receptor Substrate-1 (IRS-1) Is Essential for Bone Anabolic Function of Parathyroid Hormone (1-34). M. Yamaguchi*[1], Y. Shinoda*[1], S. Kamekura[1], N. Ogata[1], T. Kadowaki*[2], Y. Terauchi*[2], K. Nakamura[1], H. Kawaguchi[1]. [1]Orthopaedic Surgery, University of Tokyo, Tokyo, Japan, [2]Metabolic Diseases, University of Tokyo, Tokyo, Japan.

Bone anabolic function of the recombinant human parathyroid hormone (PTH 1-34), which has attracted considerable clinical attention, has been suggested to be mediated by induction of insulin-like growth factor-I (IGF-I) in osteoblasts; however, little is known about the molecular mechanism by which IGF-I leads to bone formation under the PTH stimulation. For the intracellular signaling of IGF-I, insulin receptor substrates (IRS-1 and -2) are known to be essential adaptor molecules. Our analyses of the deficient mice under physiological conditions revealed that these molecules play different roles in the anabolic action of IGF-I: IRS-1 is essential to maintain bone turnover by stimulating both anabolic and catabolic functions of osteoblasts, while IRS-2 is needed to keep the predominance of the anabolic function over the catabolic function. Hence, this study investigated the involvements of IRS-1 and IRS-2 in the bone anabolic function of recombinant human PTH (1-34). PTH treatment (100 nM) increased alkaline phosphatase activity and IGF-I mRNA level to about 2 and 4 fold, respectively, in the mouse primary osteoblast culture. Western blotting revealed that these stimulations were accompanied by phosphorylations of IGF-I receptor and IRS-1, but not IRS-2. For the *in vivo* analysis, we subcutaneously injected PTH (0.08 mg/kg BW) or the vehicle solution 5 times / week for 4 weeks to IRS-1- or IRS-2-deficient mice (IRS-1-/- or IRS-2-/-), and compared the effects with that on wild-type (WT) mice (all 8-week-old male mice of the same strain). In the WT mice, the average bone densities of the PTH-applied group were 12.1, 11.1, and 9.0% higher than the vehicle group in the femur, tibia, and vertebrae (L2-L5), respectively (n=9-10 / group, all p<0.01 between PTH vs. vehicle). On the contrary, the differences were markedly suppressed in IRS-1-/-: 4.2, 1.6, and 0.5 %, respectively (n=10 / group, all p>0.40), while they were similar to WT in IRS-2-/-: 12.4, 11.2, and 5.7% (n=8 / group, all p<0.01). Since the serum IGF-I levels were not different between PTH and vehicle-treated mice in all genotypes, IGF-I was shown to act locally as an autocrine/paracrine factor. These lines of evidence demonstrate that the bone anabolic function of PTH is mediated by the induction of IGF-I expression in osteoblasts, which acts locally to activate IGF-I receptor and IRS-I, but not IRS-2. Further studies on the downstream pathway of IRS-I in osteoblasts will elucidate the molecular mechanism of PTH anabolic function.

Vulnerability of the Post-OVX Skeleton: Is Additional Bone Loss Caused by Alcohol? F. H. Wezeman, D. Juknelis*, J. J. Callaci*. Orthopaedic Surgery, Loyola University Medical School, Maywood, IL, USA.

Peak bone mass in women occurs by the third decade followed by a plateau before its precipitous decline following menopause. The postmenopausal osteoporotic skeleton is at higher risk for fracture. As BMD declines with age and decreased ovarian function, additional factors may accelerate skeletal mass reduction. Disuse decreases BMD beyond levels associated with ovariectomy (OVX) alone indicating that the post-ovariectomized skeleton can still lose additional bone mass. We tested the hypothesis that binge alcohol administration in OVX rats increases osteopenia but that the loss can be compensated by PTH. Female Sprague Dawley rats (400 gms, n=6/group) were experimentally divided as: control non-OVX, binge alcohol-treated, PTH-treated, and PTH + alcohol-treated. Other rats were surgically bilaterally ovariectomized, briefly recovered, and divided into the same groups (n=6). Weight-matched non-OVX and OVX animals were maintained on standard rat chow ad libitum. A binge alcohol administration model used intraperitoneal injection of 20% (vol/vol) alcohol/saline. A one time/day injection of 3g/kg/day was made for 3 consecutive days followed by 4 non-alcohol days; binge cycles continued for 2 and 4 weeks. Rats received PTH (1-34), (80 ug/kg, s.c.) 5 times per week for 2 or 4 weeks. On the morning after completion of the 2nd and 4th binge cycle animals were sacrificed and the lumbar spine removed. Each 3rd lumbar vertebra was cleaned and imaged using a Scanco Medical Micro-CT 40 scanner at 16x16x16 microns/voxel. The cancellous compartment was contoured and morphometrically analyzed for BV/TV, TbN, TbTh, TbS, and trabecular connectivity density. BMD was determined using pQCT, biomechanical properties were quantified using an Instron materials testing machine, and serum osteocalcin and CTX were measured. Treatment of non-OVX rats with alcohol decreased BV/TV at 2 and 4 weeks (11.1% and 13.1%, respectively). BV/TV in OVX rats treated with alcohol decreased by 14.5% and 10.4% at 2 and 4 weeks, respectively. Intermittent PTH raised BV/TV in all groups. Two weeks of PTH compensated for alcohol-induced bone loss in non-OVX rats (BV/TV, 102.5% of control non-OVX) while 4 weeks of PTH was required in OVX + alcohol rats (BV/TV, 107.4% of control non-OVX). Statistical analysis using GLM showed no interaction between OVX, alcohol and time, while both OVX and alcohol main effects were significant ($p<.05$). Indices of remodeling (CTX, osteocalcin), microanatomical, and biomechanical parameters affected by OVX were also altered by alcohol and PTH. These findings suggest that binge alcohol administration in OVX rats results in aggressive bone loss and that intermittent PTH attenuates this bone loss.

Identification of Responders to Teriparatide Therapy by Procollagen Type I N-Propeptide (PINP) Using the Least Significant Change Approach. R. Eastell[1], P. Chen*[2], J. H. Krege*[2]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Lilly Research Laboratories, Indianapolis, IN, USA.

The response to a bone-forming therapy is best monitored using a biochemical marker of bone formation. We describe the use of procollagen type I N-terminal propeptide (PINP), which has the best signal-to-noise ratio, to monitor response to teriparatide, a bone-forming agent, using the least significant change approach expressed in absolute units. The long-term coefficient of variation of PINP in phase III clinical trials of women with osteoporosis was 16-17% (equivalent to 6.5 µg/L). Thus, the least significant change at p=0.05, for a one-tailed test was 2.36 (1.44*1.64)*6.5=15 µg/L. We also applied the method of Garnero et al. (Bone 1999) to identify 18-month spine bone mineral density (BMD) change of >3%, and a PINP increase of 15 µg/L, with a sensitivity of 70% and a specificity of 85%. “Response” was an increase of ³15 µg/L. We examined results from women with osteoporosis who were treated with teriparatide 20 µg/day once-daily in the Fracture Prevention Trial (Neer et al., NEJM 2001) and the teriparatide-alendronate comparator trial (McClung et al. JBMR abstract 2003). In the Prevention Trial 70% of 254 women, and in the comparator trial, 84% of 86 women, had an increase of ³15 µg/L by 3 months. In the Prevention Trial, 85% of patients with PINP <15 µg/L at 3 months had an increase of ³3% in spine BMD at 18 months. Thus, these response figures may be underestimates and a strategy to better investigate responders is needed. In the comparator study, the 14 nonresponders were further examined. The mean changes in procollagen I C-terminal propeptide, bone specific alkaline phosphatase, and N-telopeptide were -27 (µg/l), -2 (µg/l), and -7 (nmolBCE/mmol Cr), respectively, so the measurement of a second marker did not provide additional information. In the comparator study, PINP change was <15 µg/L at 3 months in 14 subjects (compliance was good in 9 of the 14) and by 6 months, 3 became responders and 2 were no longer responders. Thus, a second PINP measurement at 6 months is unlikely to be a helpful strategy. However, in this same population, a spine BMD measurement at 6 months identified responders in 6 out of 13 subjects. A strategy to identify responders to teriparatide is to measure PINP at 3 months, and if the change is more than 15 µg/L, consider the patient a responder; this is likely to be found in more than 75% of patients. In the rest, consider a spine BMD measurement at 6 months. This teriparatide PINP responder algorithm should not be used in patients receiving concomitant bisphosphonate therapy (Black et al. NEJM 2003).

Anabolic Effects of PTH on Cortical and Cancellous Bone when Given in Combination with Glucocorticoid. T. T. Andreassen[1], C. Ejersted*[2], G. Ortoft*[1], H. Oxlund[1]. [1]Department of Connective Tissue Biology, University of Aarhus, Aarhus C, Denmark, [2]Department of Endocrinology, University Hospital of Odense, Odense C, Denmark.

Glucocorticoid(GC)-induced osteoporosis is the most common secondary cause of osteoporosis. We therefore have investigated the effects of parathyroid hormone (PTH) treatment when given in combination with GC with reference to bone BMC, BMD, and mechanical strength. Because GC treatment hampers linear growth, twenty-seven-month-old female Wistar rats with ceased linear growth were used. The animals were divided into the following groups: baseline; vehicle-injected (Veh); PTH-treated; GC-treated; PTH+GC-treated. Doses: PTH (1-34) 25 µg/kg b.w. daily, GC (methylprednisolone) 2.5 mg/kg b.w. daily. Treatment period was 8 weeks. The animals were labeled with fluorochromes twice during the experiment. BMC and BMD were measured in whole vertebra (L5) and femur. The vertebral body (L4) and the femoral diaphysis were tested mechanically and analyzed using static and dynamic histomorphometry (mean values with SEM are given; * = significantly different from Veh, # = significantly different from PTH).
Vertebra BMC (mg) and BMD (mg/mm^3): Veh (125±3; 1.03±0.04), PTH (163±6*; 1.31±0.03*), GC (121±4#; 1.05±2#), PTH+GC (148±5*#; 1.22±0.03*#). Femur BMC (mg) and BMD (mg/mm^3): Veh (489±13; 0.86±0.02), PTH (582±19*; 1.00±0.02*), GC (479±4#; 0.84±0.02#), PTH+GC (531±11*#; 0.93±0.01*#). Vertebral body mechanical strength (Ultimate load (newton)): Veh (190±22), PTH (368±19*), GC (213±12#), PTH+GC (327±21*). Femur diaphysial mechanical strength (Ultimate load (newton)): Veh (176±4), PTH (194±8), GC (173±7), PTH+GC (185±6). Only PTH and PTH+GC induced bone formation at the endocortical femoral diaphysis (MAR (µm/day)): PTH (1.1±0.10), PTH+GC (0.5±0.03#).
Conclusion: Combined treatment with PTH+GC enhances femoral and vertebral BMC and BMD, but not to the same extent as treating with PTH alone. Treatments with PTH+GC and PTH alone both increase mechanical strength of the vertebral body. Treatments with PTH+GC and PTH alone both induce bone formation at the endocortical femoral diaphysis; however, this response is not sufficient to increase the diaphysial mechanical strength significantly.

Serum Protein Profiling for Discovery of Early Biomarkers to Distinguish PTH Responders from Non Responders. A. K. Prahalad*[1], R. J. Hickey*[1], J. Huang*[2], S. Murthy*[1], T. Winata*[1], L. E. Dobrolecki*[1], J. M. Hock[1]. [1]Indiana University School of Medicine, Indianapolis, IN, USA, [2]Computer Science, Indiana University, Indianapolis, IN, USA.

Parathyroid hormone [hPTH(1-34)] (PTH) is an anabolic agent which stimulates bone formation and reduces risk of osteoporotic fractures. We speculate that distinctive serum protein profiles will define patients most likely to benefit from PTH therapy. Our goal was to determine if SELDI (surface enhanced laser desorption/ionization) proteinchip® array technology reliably detects changes in serum protein expression profiles in mice showing skeletal responses to PTH. To create a PTH-responder profile, 5-week old C57/BL6 male mice were given once daily sc injection of PTH (40 µg/kg bw) or vehicle control for 3 or 11 days. At 6 h after the last dose, sera were sampled for protein analysis by SELDI time-of-flight mass spectrometry. Serum protein profiling was done on a SAX2 proteinchip array surface to capture anionic proteins. Mass spectral data were corrected by baseline subtraction; peaks with high signal-to-noise ratios were selected and grouped into bins with various intervals along m/z (mass-to-charge) axis from treated and control mice. Two-sample t-test was utilized to identify candidate biomarkers in PTH spectral patterns that differed from control spectral patterns. Significant changes were observed in two proteins with molecular masses 14.8 and 15.4 kD, and their peptides 7.4 and 7.7 kD respectively, in PTH-treated mice at both 3 and 11 days. The magnitude of change was greater in serum from mice treated with PTH for 11 days. Peak intensities of albumin, an abundant serum protein, did not change with PTH treatment relative to controls, indicating that we can use albumin as a surrogate internal standard. After 3 days of PTH treatment, Kit^W/Kit^{W-v} C57/BL6 mice, whose bones fail to respond to PTH, showed a spectral pattern similar to vehicle-treated controls, and with none of the markers seen in PTH-responsive wildtype littermates. Validation of PTH responder proteins was carried out on proteinchips (WCX2, IMAC-Cu, SAX2) that captures cationic, metal binding and anionic proteins. As expected, serum albumin, pI 4.9 bound more strongly to SAX2 surface than to IMAC-Cu, and only weakly to WCX2. In contrast, PTH responder proteins and their peptides (14.8, 15.4, 7.4, 7.8 kD) bound more strongly to WCX2 than to either IMAC-Cu and SAX2. Based on comparative binding capacity of these proteins to different proteinchips, we suggest PTH responder proteins are weakly basic, with pI above 7.4. Our data demonstrate the feasibility of using serum protein biomarkers to detect a patient’s responsiveness to PTH shortly after starting anabolic therapy for osteoporosis.

Osteoblast Specific Ablation of Connexin43 (Cx43) Attenuates the Anabolic Response to Intermittent PTH (1-34) in Aged Mice. D. Chung, J. Screen, J. P. Stains, C. Liu*, R. Civitelli. Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA.

Interference with Cx43 mediated gap junctional communication alters osteoblast gene expression and inhibits PTH induced cAMP accumulation and osteoblasts differentiation, whereas PTH up-regulates Cx43. Here, we have tested the anabolic response to PTH in a model of selective Cx43 deficiency in bone forming cell using a Cre/loxP approach. Under the control of a 2.3 kb fragment of the Colα1 promoter, Cre mediated recombination of a $Cx43^{flox}$ allele replaces the entire Cx43 reading frame with the LacZ reporter cassette. A total of 101 mature, 5- to 8-month-old C57BL mice (52 males and 49 females) of three genotypes, $Cx43^{+/flox}$ (wild type equivalent), $Cx43^{-/flox}$ (heterozygous equivalent) and ColIα1Cre;$Cx43^{-/flox}$ (knockout equivalent) were injected subcutaneously (5 days a week for 4 weeks) with either vehicle (saline; n=12) or PTH (1-34) (teriparatide, Eli-Lilly) at doses of 10 (n=19), 20 (n=18), 40 (n=18), and 80 μg/kg (n=23). Whole body bone mineral content (BMC) was measured at baseline and at 2-week intervals by DEXA (PIXImus, Lunar-GE). With the exception of at the lowest dose PTH induced significant percent increments (*p<0.05, ANOVA) in BMC at 4 weeks in the $Cx43^{+/flox}$ group (8.1±2.4, 10.1±2.2*, 13.2±3.2*, and 11.4±3.9*, respectively), and in $Cx43^{-/flox}$ mice (9.2±4.9, 7.1±3.3, 9.8±3.9*, and 13.4±3.7*, respectively). However, in the conditionally deleted Colα1(I)2.3-Cre;$Cx43^{-/flox}$ mice, only the intermediate doses of PTH resulted in statistically significant BMC increments (6.9±3.2, 9.4±2.8*, 9.9±3.0*, and 8.6±4.5, respectively). Although the BMC response to PTH was dose-related in the $Cx43^{+/flox}$ and $Cx43^{-/flox}$ groups, no significant differences among doses were detected in the Colα1(I)2.3-Cre;$Cx43^{-/flox}$ group, and the effect of PTH was overall diminished in these mice relative to the other groups. Since after 4 weeks untreated animals also experienced significant BMC increases (4.8±2.1%), and since we found the BMC changes in treated mice to be inversely related to age, we extended the study to older mice (7.5-8-month-old; n=11). In this aged group, 4 weeks of 40 μg/kg PTH induced significant changes only in $Cx43^{+/flox}$ (10.6±3.5%*; n=5) and $Cx43^{-/flox}$ (9.5%*; n=2), but not in Colα1(I)2.3-Cre;$Cx43^{-/flox}$ mice (2.5±1.4%; n=4). Therefore, the anabolic response to intermittent PTH administration is attenuated in conditions of Cx43 deficiency, an effect that becomes more severe with age. These results demonstrate that osteoblast Cx43 is necessary for development of a full bone anabolic response to PTH.

Effects of Anabolic Peptide BCSP-7 (Bone and Cartilage Stimulating Peptide) Treatment in Ovariectomized Rats. D. R. Sindrey[1], J. A. Swafford*[2], M. W. Lundy*[2], E. Plawinski*[1], C. A. Blanton*[2], F. H. Ebetino[2], A. Houghton*[2], J. Auluck*[1], Y. O. Taiwo*[2]. [1]Millenium Biologix Inc., Mississauga, ON, Canada, [2]Procter & Gamble Pharmaceuticals, Manson, OH, USA.

Originally isolated from an extract of the epiphyseal of calf bone, synthetic BCSP (Bone and Cartilage Stimulating Peptides) are capable of stimulating localized increases in BMD in rat tibia by 7-12% in 7 days with one injection. A 5mer sub fragment of this peptide has shown improved local activity and may be suitable for development as a bone anabolic systemic pharmaceutical. A small molecule synthetic peptide could prove to be a promising pharmaceutical for the treatment of osteoporosis. This study was conducted to determine if the systemic administration of BCSP-7 could significantly increase bone volume compared to bisphosphonates in osteopenic rats compared to vehicle treated OVX controls. Briefly, female Sprague-Dawley rats were ovariectomized (OVX, or sham surgery) at 6 months of age, allowed to loose bone for 60 days, then treated for 57 consecutive days by subcutaneous injection with vehicle, BCSP-7 0.01, 0.03, 0.1, 0.3, 1.0, & 10 mg/kg. Positive control groups were treated with sodium Alendronate, another bisphosphonate NE-58018 or human PTH(1-34). In vivo densitometry (DXA) was used to assess changes to skeletal sites over the dosing period as well as ex-vivo micro CT measurements of vertebral and femoral bone volume. In-life bone mineral density of the vertebrae, tibia and whole body was increased with NE-58018 during the course of treatment. NE-58018 also significantly increased ex-vivo vertebral bone volume and distal femur BMD. Alendronate significantly increased in-life bone mineral density of the vertebrae, tibia and whole body compared to final OVX toward the end of treatment with significant increases also seen in ex-vivo vertebral bone volume. Alendronate did not significantly change femoral BMD compared to OVX control. In-life DXA measurements indicated that BCSP-7 (0.03 and 0.1 mg/kg) significantly increased vertebral BMD from day 14 to the end of the treatment period compared to final OVX. Although the changes seen with BCSP-7 were significantly lower than PTH(1-34), BCSP-7 demonstrated equivalent results to Alendronate. BCSP-7 did not significantly change ex-vivo vertebral bone volume or femoral BMD measurements. These results indicate that systemic administration of the 5mer peptide BCSP-7 increases bone mass equivalent to Alendronate at lower doses and in the early phase of bone resorption in an OVX model. Further studies are required to study the mode of action, pharmacokinetics and dosing paradigms to optimize the systemic bone anabolic activity to the levels achieved with local administration.

Effect of Mushroom *pleurotus eryngii* Extracts on Bone Metabolism. S. Kim[1], H. Kim*[2], B. Lee*[3], S. Chang*[3], H. Hwang*[3], D. Jung*[3], D. Baek*[4], S. Ko[5]. [1]OCT Inc., Dept. of Dental Pharmacology, Dankook University, Chonan-si, Republic of Korea, [2]OCT Inc., Dept.of Pharmacology, Dankook University, Chonan-si, Republic of Korea, [3]OCT Inc., Chonan-si, Republic of Korea, [4]Dept.of Oral Microbiology and Immunology, Dankook University, Chonan-si, Republic of Korea, [5]Dept.of Oral Biochemistry, Dankook University, Chonan-si, Republic of Korea.

The present study was performed to investigate whether *Pleurotus eryngii* extracts (PEX) play roles in the bone metabolism. We examined cellular activities of osteoblasts by measurement of cell proliferation rate, alkaline phosphatase (ALP) activity, and osteoprotegerin (OPG) secretion. Expression levels of osteopontin (OPN), ALP and collagen (COL), Runx2 were also measured. Osteoclast activity was assayed by measuring TRAP activity, and the area of resorption pits after culture of osteoclast precursor cells on the calcium-phosphate coated culture dish (OAAS™, OCT Inc.). Bone Mineral Density (BMD) measurements and histological observations were also carried out.

Results: PEX treatment showed a significant increase ALP activity of osteoblasts. PEX increased the COL, ALP and OPN mRNA expression from rat calvarial primary cells. Also PEX increased the expression of the Rnux2 gene, which was detected by p6xOSE2-Luc-transient transfected C2C12 cells. Secretion of OPG, which was detected from MG63 cell supernatant by western blot analysis, showed marked increases after treatment of PEX. In addition, PEX treatment decreased the number of TRAP (+) MNCs and the resorption areas. *In vivo* studies using ovariectomy-induced osteoporotic rats revealed that PEX alleviated the decrease in the trabecular BMD, and increased the thickness of cortical bone and trabecules of tibia.Taken together, PEX stimulates the activities of osteoblasts, while inhibiting the generation and resorptive activities of osteoclasts. It also shows preventive effects on osteoporotic bone loss induced by an ovariectomy. It is believed that the PEX seems to contain active components that have a potential to overcome osteoporosis.

Differences in Bone Response to hGH According to Sex and Age at the Manifestation of GH-Deficiency in Adults with Hypopituitarism. M. F. Farias[1], M. E. L. Duarte[2], E. M. C. Silva*[1], D. V. Soares*[1], F. L. Conceição*[1], L. D. C. Spina*[1], R. R. O. Brasil*[1], M. Vaisman*[1]. [1]Endocrinology, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, [2]Pathology, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

Growth hormone deficiency has a negative impact on bone mineral density, limiting the attainment of peak bone mass during youth and favoring bone loss in adult life. We studied the effect of two-years hGH replacement on bone markers and bone density in twenty-eight patients with hypopituitarism, 20-62 yrs.old. GH-deficiency was confirmed by a peak GH<3 ng/mL on ITT. All sixteen female and seven male patients developed GH-deficiency during adult life, while other five males manifested the deficiency during childhood (men AD and men IN, respectively). Gonadal steroids, L-T4 and prednisone were administered as needed. The mean dose of hGH was 0.83+/-0.2 mg/day. Serum insulin growth factor-1 (IGF-1), bone-specific alkaline phosphatase (BSAP) and urinary N-telopeptide of type 1 collagen (NTX) were measured at 0, 3,6,9,12,18 and 24mo. BMD was evaluated at lumbar spine (LS) and femoral neck (FN) by DEX, Lunar Corp., at baseline, 12 and 24months. Serum IGF-1 remained above baseline values during the whole period. BSAP and NTX increased significantly during the first year (p=0.014 and p=0.000 respectively), decreasing progressively during the second year. Before treatment, the absolute values of BMD did not differ between sexes, but the expected bone density (Z score) was lower in men, mostly in the IN group, which also had the lowest values of IGF-1 before treatment . During GH-replacement, only male patients had a significant increase in BMD either at lumbar spine (p=0.01) and femoral neck (p=0.02).The differences between sexes were significant at the LS at 12 mo (p=0.006) and 24mo (p=0.002). The % variation in LS BMD at 24mo tended to be higher in men IN (7.57+/-4.7%) than men AD (4.0+/-6.3%) and women (-0.15+/-3.8%). We concluded that the negative impact of GH-deficiency on bone is greater in patients who manifest hypopituitarism before the attainment of peak of bone mass, and also greater in men than in women. On the other hand, men have a better bone response to hGH than females. Further studies are needed to explain these differences and to identify antecipately which patient will not gain bone with hGH-replacement.

Additive Effects of EP4 Agonist and Risedronate on Bone Strength due to Maintaining Individual Actions on Microarchitecture. M. Ito[1], K. Nakayama*[2], Y. Shinagawa*[2], A. Konaka*[2], K. Sakata*[2], T. Maruyama*[2]. [1]Radiology, Nagasaki University, Nagasaki, Japan, [2]Discovery Res. Lab., ONO pharmaceutical Co., Ltd., Osaka, Japan.

Bone anabolic effect of EP4 agonist (ONO-4819·CD (48CD)) has been reported to inhibit the reduction of vertebral strength by gaining bone mass in ovariectomized (OVX) rats. The purpose of this study was to investigate the outcome in combination with 48CD (as bone-formative agent) and risedronate (RIS) (as anti-resorptive agent). Thirty three-week-old female SD rats were divided into 4 groups: baseline (n=10), sham (n=10), OVX (n=10), OVX with treatment (n=90). The treatments in detail were 1) monotherapy with 48CD (1,3,10mcg/kg, twice a day), 2) that with RIS (1,5mcg/kg, twice a week), 3) four combination therapies with these agents(48CD 3mcg/kg+RIS 1,5mcg/kg, 48CD 10mcg/kg+RIS 1,5mcg/kg) for 11 weeks (n=10 in all groups). Bone mineral density (BMD) values were measured in L5 and tibiae using pQCT. Trabecular microacrchitecture on cancellous bone in L6 and proximal tibiae, and cortical bone in tibiae were measured using microCT, and after these measurements, biomechanical test was performed on L6. 48CD increased the level of serum osteocalcin and urinary deoxypyridinoline, while RIS reduced them dose-dependently. Furthermore, the combination therapy maintained their does-dependent actions on bone metabolism. 48CD increased BMD both in spine and tibia, and RIS in tibia, dose-dependently. 48CD increased Tb.Th and changed rod-like structure into plate-like structure, whereas RIS showed a strong effect on connectivity density. Such independent effects on bone microarchitecture were maintained when the both agents were administered simultaneously. Combined 48CD and RIS had independent and additive effects on the strength (239.1N in OVX, 419.5N in 48CD (10mcg/kg), 288.7N in RIS (5), 445.4N in 48CD (10)+RIS (5)) as well as BMD, where the interactions of the two treatments were not significant (P>0.10) using a two-way ANOVA model. The additive effects were shown in cortical area and thickness. Although 48CD and RIS significantly independently increased the cortical density measured using microCT in comparison wth the OVX, the additive effect was not shown. Taken together, combination of 48CD and RIS could produce an additive effect on bone strength, which was considered due to maintaining individual actions on trabecular microarchitecture, as well as due to additive effects on cortical area.

Glucose-dependent Insulinotropic Peptide Potentiates Parathyroid Hormone-Induced Increases In Bone Strength. F. Puentes*[1], D. Xie[2], K. H. Ding[1], M. Hamrick[3], A. L. Mulloy[1], C. M. Isales[1]. [1]Medicine, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA, [2]Institute of Molecular Medicine and Genetics, Medical College of Georgia, Augusta, GA, USA, [3]Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA, USA.

Parathyroid hormone (PTH) is known to stimulate bone formation when injected in a daily fashion. Similarly, we have demonstrated that Glucose-dependent insulinotropic peptide (GIP), an incretin hormone released from the small intestine in response to nutrient ingestion, also increases bone mass in vivo (see abstract by D. Xie et al). PTH acts predominantly to stimulate bone formation while GIP increases bone formation and inhibits bone breakdown. In view of recent data demonstrating a lack of synergism between daily PTH injections and the bisphosphonate alendronate on bone density, we decided to examine possible synergistic interactions between daily low-dose (25 µM) injections of PTH with or without daily GIP injections (10 nM). For these experiments we utilized three-month old female C57/Bl6 mice. Age and weight matched mice (ten animals/group) received daily subcutaneous injections of either: saline control, PTH (25µM) with or without GIP (10nM) for one month.

At the end of the four-week experimental period there was no statistically significant difference between the weights, fat or lean mass of the animals in the four different groups.

Bone density measurements by PIXImus demonstrated a significant increase in bone density in the animals receiving PTH (Control: 0.0477 vs. PTH: 0.0511 g/cm2, p<0.003). However, there was no significant change in bone density in animals receiving either GIP alone (Control: 0.0484 vs. PTH: 0.0486 g/cm2, p=NS) or any additive effect on bone mass in those animals receiving both GIP+PTH (PTH alone: 0.0510 vs. GIP+PTH: 0.0510 g/cm2, p=NS).

Despite a lack of a synergistic effect of GIP and PTH on bone density, biomechanical measurements involving three point bending revealed that GIP and PTH injections together did in fact further increase bone strength (Force at failure: Control: 16.7 N; GIP: 18.0 N; PTH: 19.6 N; GIP+PTH: 20.6 N; Control vs. PTH; p<0.0001 Control vs. GIP+PTH; Stress: Control: 7.4MPa; GIP: 7.9 MPa; PTH: 8.3 MPa; GIP+PTH: 9.2 MPa, p<0.05 PTH vs. GIP+PTH; p<0.05 GIP vs. GIP+PTH, p<0.001 Control vs. GIP+PTH).

These data are consistent with the conclusion that: 1. PTH even at lower concentrations than commonly reported has an anabolic effect on bone mass and strength. 2. GIP injection can potentiate PTH's effect on increasing bone strength.

Strontium Ranelate Increases Bone Quality in Rats: Improvement of the Microarchitecture and Preservation of the Intrinsic Bone Tissue Quality. P. Ammann*, S. Barrauld*, R. Dayer*, R. Rizzoli*. Division of Bone Diseases, Department of Internal Medicine, University Hospital, Geneva, Switzerland.

Recent clinical studies have demonstrated that strontium ranelate reduces the risk of vertebral and non-vertebral fracture in women with postmenopausal osteoporosis. We previously reported that strontium ranelate treatment increased maximal load (N) without affecting stiffness in adult female rats. We investigated the specific role of various determinants of strength in bone specimens of rats fed *ad libitum* a diet containing strontium ranelate at a daily dose of 0 (control) or 900 mg/kg/day (n=5/group), for 26 months. Microarchitecture was investigated using 3D-microCT analysis. Trabecular bone volume (BV/TV, %), trabecular number (Tb.N, /mm3), trabecular thickness (Tb.Th, mm), trabecular spacing (Tb.Sp, mm) and cortical thickness (Cort.Th, /mm) were determined.

	BV/TV	Tb.N	Tb.Th	Tb.Sp	Cort.Th
Control	48.4±3.2	4.10±0.19	0.122±0.006	0.212±0.014	3.52±0.02
Treated	70.2±1.5**	4.44±0.09*	0.173±0.006**	0.154±0.005**	4.25±0.02*

From the load deflection curve, obtained by axial compression of vertebral body, total and plastic energy (N*mm) were measured. Intrinsic bone tissue quality (Elastic Modulus, GPa, Hardness, GPa and Dissipated Energy, mN*nm) was evaluated by nanoindentation test performed on the vertebral body at the level of the trabecular nodes of dry bone tissue. Maximal load was 271.3±9.7 and 327.4±17.2* in controls and treated rats respectively. Energy was 101.8±7.9 and 157.3±15.0*, and plastic energy 30.0±3.3 and 70.7±10.0**. The elastic modulus was 17.8±1.04 and 17.7±0.71, hardness 0.818±0.061 and 0.855±0.054, dissipated energy 4294±128 and 4268±96 (means ± SEM, * : p<0.05, ** : p<0.01 vs control by Student-t test).

The increased energy to failure achieved with 900 mg/kg/d strontium ranelate treatment, was mainly due to an increment of plastic energy suggesting that bone formed under strontium ranelate treatment is able to withstand greater deformation before fracture while possessing similar elastic properties than non treated animal bone. The present results of 3D-microCT analysis and nanoindentation tests show that strontium ranelate treatment improves the trabecular and cortical microarchitecture respectively, without affecting the intrinsic quality of the formed bone material. These improvements in microarchitecture and the preserved quality of the bone tissue help to explain the antifracture efficacy of strontium ranelate in osteoporotic patients.

Comparative Uptake, Metabolism and Utilization of Menaquinone-4 and Phylloquinone in Human Cultured Cell Lines. Y. Suhara*, A. Murakami*, T. Okano. Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan.

It is generally accepted that availability of vitamin K in vivo depends on the homologues and their biological activities would be different from organ to organ. To evaluate this hypothesis, we examined the uptake, metabolism and utilization of menaquinone-4 (MK-4) and phylloquinone (PK) using their ^{18}O-labeled compounds in several kinds of human cultured cell lines (Hep G2, MG-63, and HUVEC). Lipid extracts were prepared from the cells and media collected at the time interval (1, 3, 6, 9, 12, 24h after incubation). The detection of the vitamin K analogues (^{18}O-, ^{16}O-quinone and epoxide forms) was carried out with LC-APCI-MS/MS method that we had previously reported. In this method, the ^{18}O of vitamin K was exchanged by atmospheric $^{16}O_2$ during the formation of vitamin K epoxide with carboxylative catalytic reaction. As the results, significant difference was observed between MK-4 and PK in the amounts uptaken into the cells. The ^{18}O-labeled MK-4 was extremely and rapidly absorbed into the cells and metabolized to the epoxide form via a hydroquinone form when compared to the ^{18}O-labeled PK. Rapid cellular uptake of the ^{18}O-labeled MK-4 continued by the end of culture (24 h) even after its conversion into the analogues was saturated. The differential uptake of MK-4 and PK was not affected by the treatment with Warfarin although the metabolism of both compounds was extremely inhibited. These findings suggest that a specific transporter(s) in the membrane and another metabolic pathway except for vitamin K cycle would exist in the cells and unknown metabolites might be produced. We conclude that these results should provide useful information to clarify some aspects of vitamin K action in the target cells and to develop new vitamin K drugs.

Bone-protective Effects of Antidiabetic Thiazolidinediones in rat Adjuvant Polyarthritis: In Vivo DEXA Analysis. M. M. Muresan*[1], M. Koufany*[2], T. Maire*[1], D. Chappard*[3], P. Netter*[2], J. Y. Jouzeau*[2], G. Weryha[1]. [1]Endocrinology, CHU Brabois Adultes, Vandoeuvre, France, [2]Inserm, Faculte de Medecine, Vandoeuvre, France, [3]Inserm emi 335, Faculte de Medecine, Angers, France.

Adjuvant-arthritis in rats is characterized by synovial hyperplasia, inflammatory infiltration, cartilage destruction and generalized demineralization resulting both from reduced bone formation and increased bone resorption. We investigated the ability of 2 marketed TZDs to affect the severity of polyarthritis and corresponding bone changes in Wistar male rats (n=27). Polyarthritis was induced on day 0 by intradermal injection of 1 mg heat-inactivated Mycobacterium tuberculosis into the basis of the tail. Animals were randomly assigned to four groups: controls, arthritic untreated (ACF), arthritic treated with 10 mg/kg/day rosiglitazone (Rosi 10) or 30 mg/kg/day pioglitazone (Pio 30), from day of sensitization until necropsy (day 21) once/day by gastric gavage as suspension in 0.5 % carboxymethylcellulose. Arthritis severity was evaluated by a clinical score ranging from 0 (no sign) to 4 (severe) for each paw, yielding a maximum score of 16 per animal. DEXA analysis was performed in vivo the day before arthritis induction (D-1) and the day before necropsy (D20) using a Hologic fan beam QDR-4500A densitometer. Rats were anesthetized with isoflurane, positioned and scanned five times consecutively. Bone mineral density BMD, g/cm2 and bone mineral content BMC, g were determined on the whole body (total BMD & BMD) and on 3 regions of interest (ROI): lumbar spine (L2-L4), left femur and right femur. DEXA scan showed good precision and reproducibility for both whole body and ROIs. Arthritis severity was reduced by TZDs with Pio30 being more effective than Rosi 10 and loss in body weight gain corrected in a similar way. ACF rats had a less gain in total and ROIs BMD & BMC when compared to controls. TZDs prevented bone loss whatever the DEXA parameter used, with Pio30 being the most effective drug. TZD have controversial effects on normal bone since they could inhibit osteoblastogenesis by promoting stem cells differentiation into adipocytes while leaving resorption unaffected. However, they have antiproliferative, anti-inflammatory and immunomodulatory potencies which could have therapeutical relevance in the setting of inflammation-induced bone changes. The present work demonstrates that PPARg agonists prevent bone loss in experimental polyarthritis thereby suggesting that their anti-inflammatory properties account for the reduction of bone resorption. DEXA analysis in vivo is very reliable in terms of precision and reproducibility and suitable for longitudinal studies of rat skeleton in experimental models.

Disclosures: ***M.M. Muresan****, None.*

Outcome of Hip Fracture in the Elderly Aged 90 Years and Over. Y. Ishida. Department of Orthopaedic Surgery, Yamaguchi University School of Medicine, Yamaguchi, Japan.

This longitudinal study was conducted to investigate survival prognoses and functional results in the elderly aged 90 years and over with hip fracture. Seventy-four patients aged 90 years and over with hip fracture admitted to Tsushimi hospital between 1996 and 1999 were analyzed and followed until death or for at least 4 years. The age of the patients ranged between 90 and 99 years (65 women and 9 men, mean age 92.8 years) and all patients were surgically managed. All patients had severe osteoporosis (mean BMD at distal 1/3 radius, 0.33±0.01 mg/cm^2; T-score, 48.0±0.8%). Seventy-one of 74 patients (95.9%) presented at least one prevalent vertebral fracture on admission and the mean number of prevalent vertebral fractures was 2.48±0.19 per person. Overall, mortality was 27.0% during the first year. The significant predictors of survival prognoses were the pre-operative American Society of Anesthesiologists (ASA) score (relative risk of survival rate, RR= 2.82, 95% CI 1.57-5.08), pre-fracture walking ability (RR= 1.56, 95% CI 1.03-2.34), type of fracture (RR= 2.08, 95% CI 1.05-4.12), type of surgery (RR= 1.98, 95% CI 1.01-3.91), and the number of prevalent vertebral fractures on admission (RR= 1.38, 95% CI 1.11-1.72). Dementia was the significant predictor of the recovery of walking ability (on admission, odds ratio, OR=28.6, 95% CI 3.73-200.0; after surgery, OR=22.7, 95% CI 3.03-166.7): the recovery rate of walking was lower in patients with severe dementia. The number of prevalent vertebral fractures on admission was also the significant predictor of the recovery of walking ability (OR=1.64, 95% CI 1.04-2.59). Results of this study suggest that the type of surgery is the factor that can be chosen after injury among factors related to survival prognosis. In addition, the prevalent vertebral fracture is the significant predictor of both functional and survival prognosis, indicating the importance of treatment of osteoporosis for preventing vertebral fractures as well hip fractures.

Does Vertebral Height Restoration Achieved at Vertebroplasty Matter? F. E. McKiernan, T. Faciszewski, R. Jensen*. Center for Bone Diseases, Marshfield Clinic, Marshfield, WI, USA.

Many vertebral compression fracture (VCF) sequelae are thought to result from loss of normal vertebral height and sagittal alignment. Percutaneous vertebroplasty (PV) can result in vertebral height restoration (VHR) and sagittal realignment but the assumption that this results in improved clinical outcomes is untested. The objective of this study was to determine whether VHR achieved at PV resulted in additional improvements in pain or functional outcome compared to no VHR.

This is an IRB approved, prospective study of consecutive patients undergoing PV. All subjects completed the OQLQ, a validated, 30-item, 5-domain (symptoms (Sx), physical function (Pf), activities of daily living (ADL), leisure (Le), emotional function (Ef)), 7-point response option instrument that measures health related quality of life (HRQOL) in osteoporotic women with back pain due to VCF. 2 wks, 2 mos and 6 mos postoperatively subjects completed the mini-OQLQ, a validated extraction of OQLQ. Pain was rated using a standard visual analogue scale (VAS) pre-op, 1 d post-op and each evaluation point thereafter. X-rays were manually digitized using centralized PACS system software and evaluated for the presence of dynamic mobility (DM) and VHR. DM is change in anterior vertebral height (ΔHa) between preoperative standing and supine X-rays that exceeds our in vivo precision error for Ha by 2 SD (thus, DM ≥ +/- 0.8 mm). VHR was ΔHa between pre- and post-operative standing lateral X-rays centered on the treated VCF after correction for magnification error.

46 subjects (32F/14M) underwent 49 PVs to treat 66 painful VCFs. Mean age was 74.3 ±10.9 years. 50% of treated VCFs were at T11-L1. Mean fracture age was 2.5 ± 2.1 mos. 59% had sustained previous fragility fracture. 26% were current steroid users. 1d after PV pain rating fell from 7.7 to 2.8 ± 1.8 ($p<0.001$) and remained improved through mo 6 ($p<0.001$). 2 wks post-PV all 5 OQLQ domains improved substantially (Sx, ADL and Le ($p\leq0.001$), Pf ($p=0.003$) and Ef ($p<0.02$)) and remained improved through mo 6 ($p\leq0.001$, except Ef; $p=0.007$). Average DM for all treated VCFs = +3.7 mm. Average DM in mobile VCFs = +5.5 mm (-2.9 to 19.9 mm). Average postoperative VHR in mobile VCFs = +2.9 mm (-2.1 to +9.6mm). Correlation between DM and postoperative VHR was excellent ($r=0.9$, $p<0.001$). Multivariate analysis showed that VHR achieved at PV did not correlate with superior postoperative pain relief or consistent additional improvement in any OQLQ domain compared with failure to achieve VHR.

The rationale and desire to restore vertebral height and sagittal alignment during PV are compelling but these initial data do not demonstrate additional benefit to pain relief or QOL over 6 months when incomplete VHR is achieved.

The Cost-effectiveness of Bone Protection in Patients Using Oral Glucocorticoids. T. P. van Staa[1], P. Geusens[2], H. Leufkens*[3], H. Pols[4], C. Cooper[5]. [1]Procter&Gamble Pharmaceuticals, Egham, United Kingdom, [2]Limburg University Center, Diepenbeek, Belgium, [3]Utrecht University, Utrecht, Netherlands, [4]Erasmus University Medical Center, Rotterdam, Netherlands, [5]University of Southampton, Southampton, United Kingdom.

There are few data on the cost-effectiveness of bone protection in patients using oral glucocorticoids (GC). An individual patient-based pharmaco-economic model was developed using data from a large cohort of oral GC users aged 40+ (N=190,000) in the UK General Practice Research Database.

Mortality and hip, vertebral, and other osteoporotic fracture risks for each individual were estimated by age, sex, daily and cumulative GC dose, indication and other clinical risk factors (using Cox regression). The vertebral risks were standardised to those of the EPOS study (1/3 of the vertebral fractures were considered to be clinically symptomatic). UK costs on medication (the middle cost of a bisphosphonate) and direct costs of fracture were obtained from a UK national report (NICE) and discounted annually by 6% (£1=US$1.75). The fracture reduction by bisphosphonates was taken as 50%. The excess mortality in the 1 year after a fracture was based on a comparison of fracture cases to controls matched by age, sex, and GC indication and adjusted for GC dose and clinical risk factors. Using the individual mortality and fracture risks, the outcomes were simulated over a 5-year period, comparing presence and absence of bone protection. Bootstrapping techniques were used to calculate 95% confidence intervals (CI).

It was found that mortality and fracture risks were related to GC dose, indication and clinical risk factors. With use of 5 mg GC daily, the cost to avoid one fracture with a bisphosphonate was $49,023 (95% CI $46,765-51,066) in women aged 45 [men $80,841 (76,377-84,771)] and $6410 (5861-6877) in women aged 85 [men $17,163 (16,088-17,889)]. With 15 mg GC, these figures were $28,348 (27,328-29,131) and $5840 (5394-6259) in women and $46,120 (43,979-47,775) and $13,766 (13,109-14,558) in men, respectively. The cost-effectiveness improved in patients at high risk of fracture. With 5 mg GC daily, the cost to avoid one fracture was $54,800 in women aged 45 at low risk of fracture (15 mg GC: $32,313) and $28,102 at high risk (with 15 mg GC: $15,231). For men, these figures were $94,819 and 43,173 for 5 mg GC and $53,766 and $24,908 for 15 mg GC, respectively.

These data support the cost-effectiveness of bisphosphonates in oral GC users, improving with higher GC dose and targeting of high risk patients.

Health Utilities Index 3 Scores in Osteoporosis Compared to other Chronic Medical Conditions: A Population-Based Study from the Canadian Multicentre Osteoporosis Study (CaMos). A. M. Sawka[1], L. Thabane*[2], A. Papaioannou[3], A. Gafni*[2], G. Ioannidis[4], E. Papadimitropoulos[5], W. Hopman[6], A. Cranney[7], D. A. Hanley[8], L. Pickard[4], J. D. Adachi[4], C. Investigators*[9]. [1]Endocrinology, McMaster University, Hamilton, ON, Canada, [2]Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada, [3]Medicine, McMaster University, Hamilton, ON, Canada, [4]Rheumatology, McMaster University, Hamilton, ON, Canada, [5]Eli Lilly, Toronto, ON, Canada, [6]Queens University, Kingston, ON, Canada, [7]Rheumatology, University of Ottawa, Ottawa, ON, Canada, [8]Endocrinology, University of Calgary, Calgary, AB, Canada, [9]Canadian Multicentre Osteoporosis Study, Hamilton, ON, Canada.

The Health Utilities Index 3 (HUI3) is a generic health status classification system. Data from the Canadian National Population Health Survey (NPHS) of 1996/97 have been used to compare relative decrements in HUI3 measurements between chronic conditions. HUI3 results were not reported for osteoporosis in the NPHS. We aimed to determine the relative decrement in HUI3 score attributed to osteoporosis compared to other chronic medical conditions using CaMos data. CaMos is a national cohort study in which regional participants were randomly recruited. We studied participants aged 65 years and older who completed a Health Utilities Index 3 (HUI3) questionnaire. An age- and gender-adjusted linear regression analysis was performed predicting mean decrement in HUI3 score for the following self-reported medical conditions: arthritis (osteoarthritis or rheumatoid arthritis), chronic obstructive pulmonary disease (COPD), diabetes mellitus (DM), heart disease (heart attack), and hypertension. Of the 4550 participants age ≥65 years recruited in CaMos, 1226 men and 3269 women completed a baseline HUI3 questionnaire, and 3712 participants provided information on presence of chronic medical conditions. The mean changes in HUI3 adjusted for age and gender (with 95% confidence intervals) were as follows: arthritis -0.10 (-0.11, -0.08), COPD -0.07 (-0.09, -0.05), DM -0.06 (-0.08, -0.03), heart disease -0.06 (-0.08, -0.03), hypertension -0.02 (-0.03, -0.01), and osteoporosis -0.09 (-0.11, -0.06), respectively. The mean changes in HUI3 for chronic conditions adjusted for age and gender for patients ≥65 years in the NPHS were similar to those seen in CaMos: arthritis -0.08, COPD -0.09, DM -0.06, heart disease -0.06, and high blood pressure 0.0. In conclusion, the decrement in HUI3 score seen in patients with self-reported osteoporosis was similar to that observed with other self-reported chronic medical conditions such as arthritis, COPD, diabetes mellitus, or heart disease.

Quality of Life Measures in Canadian Aboriginal Women: The First Nations Bone Health Study. C. J. Metge*[1], W. D. Leslie[2], H. A. Weiler*[3], C. K. Yuen[2], M. Doupe*[2], E. A. Salamon[4], P. Wood Steiman*[5], J. D. O'Neil*[2], C. R. Greenberg*[2], L. M. Lix*[2], L. L. Roos*[2], A. Tenenhouse[6]. [1]Faculty of Pharmacy, University of Manitoba, Winnipeg, MB, Canada, [2]Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada, [3]Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada, [4]Department of Medicine, University of Manitoba, Winnipeg, MB, Canada, [5]Assembly of Manitoba Chiefs, Winnipeg, MB, Canada, [6]Department of Medicine, McGill University, Montreal, PQ, Canada.

Canadian Aboriginal women are at increased fracture risk compared with the general population (JBMR 18:S151,2003) but little is known about the burden of osteoporosis in this population. The First Nations Bone Health Study (FNBHS) is assessing indicators of bone health in Aboriginal and non-Aboriginal adult women and has relied on the Canadian Multicentre Osteoporosis Study (Ca*Mos*) for many of its measures and for Canadian normative data. Included in the baseline measurements was a health status measure, the Rand Health Science Program SF-36. The physical dimensions of this measure have been reported by Ca*Mos* to be sensitive to osteoporotic fractures (Osteoporos Int 2001;12:903). There have been no previous reports of use of the SF-36 measure in Canadian Aboriginal women. The FNBHS recruited a random age-stratified (25-39, 40-59 and 60-75) sample of Aboriginal women (n=267) and age-matched White women (n=184). The SF-36 survey was administered by trained interviewers as part of a detailed baseline survey. Aboriginal women had lower scores than White women on both the SF-36 physical health summary (PCS) and mental health summary (MCS) quality of life (QOL) components [PCS: 44.1±12.2 vs. 48.1±10.8, P=0.0004; MCS: 46.8±12.7 vs. 51.0±10.5, P=0.0050]. Fracture cases had lower PCS scores than non-fracture cases while MCS was similar [PCS: 44.4±12.3 vs. 47.2±11.1, P=0.0119; MCS: 47.5±12.7 vs. 48.6±11.3, P>0.2]. A 2-way ANOVA tested the independent effects of self-reported fracture and Aboriginal ethnicity on QOL. For PCS, there were significant main effects of fracture [F(1,440)=5.38, P=0.0208] and ethnicity [F(1,440)=12.11, P=0.0005] but no significant interaction [F(1,440)=0.64, P=0.4224]. For MCS, there was a main effect of ethnicity [F(1,440)=8.48, P=0.0038] but no significant fracture effect or interaction. In summary, the FNBHS provides the first comprehensive assessment of health status using the SF-36 in Canadian Aboriginal women. Our findings justify further work to validate the use of the SF-36 physical dimensions as a specific indicator of fracture-related QOL in Aboriginal women.

Combination Therapy with Alfacalcidol and Risedronate at Their Subtherapeutic Doses Can Additively Improve Bone Dynamics in Ovariectomized Rat Model of Osteoporosis. A. Shiraishi*[1], M. Ito[2], N. Hayakawa*[1], N. Kubota[1], N. Imai*[1]. [1]Product Research Dept., Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, [2]University of Nagasaki, Nagasaki, Japan.

Both alfacalcidol (ALF) and risedronate (RIS) have been reported to prevent estrogen deficiency-induced bone loss by an anti-resorptive effect. The aim of this study was to clarify the additive effect of simultaneous administration with ALF and RIS on the bone dynamics in ovariectomized (OVX) rats. Female wistar rats were OVX- or sham-operated at 40 weeks of age. Twelve weeks post-surgery, rats were randomized into 7 groups (n=7-8): 1) sham+vehicle, 2) OVX+vehicle, 3) OVX+ALF 0.025 μg/kg/day, 4) OVX+ALF 0.05 μg, 5) OVX+RIS 0.3 mg, 6) OVX+RIS 3.0 mg, 7) OVX+ALF 0.025 μg+RIS 0.3 mg. Each drug was administered orally 5 times a week for 12 weeks. The combined administration with ALF and RIS increased the mechanical strength in lumbar vertebra and femoral midshaft ($p<0.01$, $p<0.001$ vs. OVX group, respectively). The vertebral strength in ALF+RIS group (423N) was higher than the 371 and 296N in the ALF 0.025- and RIS 0.3-treated groups (n.s., $p<0.01$, respectively). To evaluate whether the site-specific improvement by combination therapy influenced the spinal strength, micro-CT and pQCT analyses were performed. As analyzed by pQCT, of particular interest, the additive effect of ALF and RIS on bone density was produced in cortical and sub-cortical regions more than trabecular region, whereas the BV/TV, Tb.Sp. and BS/BV in the ALF+RIS group were significantly higher than those in the OVX group. This indicated that the combined therapy affected not only trabecular bone but also cortical site, resulting in marked increment of spinal strength. Combined ALF and RIS had independent and additive effects on the strength as well as BMD in both spine and femur, where the interactions of the two treatments were not significant ($P>0.10$) using a two-way ANOVA model. Additionally, the combination therapy reduced urinary deoxypyridinoline excretion more than either drug alone (76.2% reduction vs. 42.2% for ALF, 14.5% for RIS, from OVX group). In conclusion, ALF and RIS can additively improve bone dynamics through the beneficial effect on both cortical and trabecular regions, and exert the additive anti-resorptive activity in rats, although the histomorphometrical analysis has been proceeding to clarify the exact mechanisms. Taken together, it is suggested that the combination of ALF and RIS therapy has a therapeutic advantage over each monotherapy for the treatment of osteoporosis.

Identification of Fast Bone Losers and Treatment with Alfacalcidol. M. A. Dambacher[1], M. Neff*[2], M. Ito*[3], E. Schacht*[1], R. Kissling*[1]. [1]Rheumatology and Rehabilitation, University Clinic Balgrist, Zürich, Switzerland, [2]Center for Osteoporosis, University Clinic Balgrist, Zürich, Switzerland, [3]Department of Radiology, School of Medicine, Nagasaki, Japan.

For the individualisation of prophylaxis and treatment of osteoporosis we use the high resolution peripheral quantitative computed tomography (hrpQCT system). We could show that postmenopausal patients with high bone turnover evaluated by biochemical parameters are identical to fast bone losers as determined by the hrpQCT system. As a consequence, we prefer agents that inhibit bone resorption in fast bone loser patients and agents that stimulate bone formation in slow bone loser patients.

For evaluation of the rate of bone loss, we use a high resolution pQCT system (DENSISCAN 1000), reproducibility of 0.2-0.4% in mixed population of normal individuals and patients with osteopenia or osteoporosis. This system enables us to assess trabecular and cortical bone density separately in the radius and differentiate between fast and slow bone losers within 6 to 9 months (threshold: >3 % loss of trabecular bone density in the radius per year).

In this study we examined fast bone losers with osteoporosis and osteopenia (N = 33) and could show with this high precise system that Alfacalcidol can halt fast bone loss (see graph).

In an animal study (Ito) with OVX rats, the results can be summarized: max. load, trabecular volume, trabecular thickness, trabecular number are increased, inter-trabecular space decreased with Alfacalcidol. The loss of bone mass and quality in these ovarectomized animals could be stopped with Alfacalcidol.

We can conclude that Alfacalcidol has an excellent effect especially on the trabecular bone in fast losers and that we can adapt the treatment for different forms of osteoporosis and bone turnover by the highly sensitive hrpQCT system. The result is not only a reduction of the number of nonrespondens but also a better compliance of the patients. Because our treatment was based on precise objective measurements, treatment modifications - especially in those patients who change from a slow to a fast bone-loser-state - can easily be justified.

A New Active Vitamin D, ED-71, Increases Bone Mass in Osteoporotic Subjects under Vitamin D Supply. T. Matsumoto[1], M. Shiraki[2], T. Nakamura[2], T. Hashimoto*[2], H. Itakura*[2], K. Suzuki*[2], T. Miki[2], N. Hamada*[2], T. Sugimoto[2], Y. Kuroki*[2], Y. Fujii[2], H. Hagino[2], S. Takata[2], S. Ikeda*[2], T. Nakano*[2], S. Okamoto[2], T. Hirota[2], Y. Tanigawara[2], M. Fukunaga[2], Y. Hayashi[2]. [1]University of Tokushima, Tokushima, Japan, [2]The ED-71 Clinical Study Group, Tokyo, Japan.

ED-71 [1α,25-dihydroxy-2ß-(3-hydroxypropoxy)vitamin D_3] is an analog of 1α,25-dihydroxyvitamin D_3 [1α,25$(OH)_2D_3$] with potent effects on bone. An earlier clinical study in osteoporotic subjects demonstrated that treatment with 0.25 to 1.0 µg/day ED-71 for 6 months increased lumbar bone mineral density (L-BMD) in a dose-dependent manner without causing sustained hypercalcemia or hypercalciuria. However, because many patients showed serum 25(OH)D levels below 20 ng/mL, there was a possibility that the effect of ED-71 on bone mass may be observed due to a nutritional vitamin D insufficiency of these patients.

The present study was undertaken to clarify whether the effect of ED-71 on bone is different from that of native vitamin D, and whether ED-71 can effectively increase bone mass in osteoporotic subjects under vitamin D supply with normal serum 25(OH)D.

Osteoporotic subjects with 49 to 87 years of age (mean 67.2 years, 218 subjects) were enrolled in the study. They were stratified by serum 25(OH)D levels, and for subjects with serum 25(OH)D below 20 ng/mL, 400 IU/day vitamin D_3, and for subjects with serum 25(OH)D over 20 ng/mL, 200 IU/day vitamin D_3 was supplemented throughout the study. In each stratum, the subjects were randomly assigned to placebo, 0.5, 0.75 or 1.0 µg/day ED-71, and treated for 12 months. L-BMD was measured as a primary end point, along with total hip BMD (H-BMD) and bone markers.

In 162 subjects (74%), serum 25(OH)D levels were below 20 ng/mL at the entry. Serum 25(OH)D became over 20 ng/mL in 93% of subjects by vitamin D_3 supplement at 3 months. After 12 months, L-BMD decreased slightly in placebo group (-0.72%), whereas ED-71 treatment increased L-BMD in a dose-dependent manner (2.16, 2.64 and 3.19, in 0.5, 0.75 and 1.0 µg/day groups, respectively. $p<0.01$ vs placebo in all three groups). H-BMD also increased significantly by 0.75 and 1.0 µg ED-71 treatment (0.6 and 0.9%, respectively). ED-71 was well tolerated at all doses examined, and only 2 patients developed transient hypercalcemia over 11 mg/dL.

These results demonstrate that ED-71 treatment can effectively increase bone mass in patients with sufficient vitamin D supply without causing sustained hypercalcemia. It is suggested that ED-71 may serve as a tissue-selective vitamin D agonist with stronger effects on bone.

Hearing Impairment in Familial X-Linked Hypophosphatemic Rickets. G. Fishman*[1], D. Miller-Hansen*[2], C. Jacobsen*[2], V. K. Singhal*[1], U. S. Alon*[3]. [1]Plastic and Craniofacial Surgery, Children's Mercy Hospital, Kansas City, MO, USA, [2]Hearing and Speech Department, Children's Mercy Hospital, Kansas City, MO, USA, [3]Pediatric Nephrology, Bone and Mineral Disorders Clinic, Children's Mercy Hospital, Kansas City, MO, USA.

Objective: The aim of the study was to assess hearing in patients with familial X-linked hypophosphatemic rickets (XLH) in order to better understand the association between the disease and hearing status, thus providing information regarding patients management. **Material and Methods:** Hearing evaluations including audiometry, tympanometry and stapedial reflex thresholds recording were prospectively performed in 16 children with XLH (aged: 1-18 years, mean: 8.5, median: 9.0, 6 males, 10 females) and all their 10 afflicted parents (aged 22-55 years, 3 male, 7 female). Further investigations were conducted when indicated. Related literature was searched and reviewed. **Results:** None of the individuals had a history of receiving treatment with ototoxic drugs, noise exposure, previous ear surgery or chronic ear disease. Fifteen of 16 children demonstrated normal hearing. One with bilateral profound hearing loss was found to have a congenital inner ear malformation (Mondini malformation). Among the adults, 2 males and 1 female (30%) ages 34-52 demonstrated sensorineural hearing loss, which was attributed to the disease process since other etiologies were ruled out. All three had severe XLH-related orthopedic manifestations. Analysis of three previously published articles studying a total of 66 XLH patients revealed hearing impairment in 1/14 children (7.1%) and 26/52 adults (50.0%) (Chi-square, $p<0.01$). **Conclusions:** We conclude that hearing impairment in XLH is likely part of the natural history of the disease, developing during adulthood. Therefore, whereas close follow-up and hearing monitoring is recommended in adults, serial audiograms in children with XLH are not justified. Furthermore, in a child with XLH and hearing impairment other etiologies should be explored.

Cementum and Dentin in Childhood Hypohosphatasia Teeth. T. VandenBos*[1], G. Handoko*[1], A. Niehof*[1], M. Whyte[2], W. Beertsen[1]. [1]Periodontology, ACTA, Amsterdam, Netherlands, [2]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA.

Hypophosphatasia (HPP) is characterized biochemically by reduced activity of the tissue-nonspecific isoenzyme of alkaline phosphatase (TNSALP). Consequently, skeletal mineralization can be impaired causing rickets in affected children. Additionally, HPP almost invariably leads to premature loss of deciduous teeth due to defective formation of cementum. It was the objective to determine whether acellular and cellular cementum and various compartments of dentin are equally affected in HPP.

31 teeth from 7 children with the odonto- (n=2) or childhood (n=5) forms of HPP were compared with matched teeth from 21 healthy children. In addition to light and electron microscopy, mineral content was determined biochemically and by quantitative microradiography.

In all but 3 of the HPP teeth, acellular cementum layers were absent. Cellular cementum were present in 7 of 22 HPP teeth (9 not assessed due to root resorption). In the various dentin compartments (crown, root, circumpulpal, mantle), significant variations in mineral content were detected in both controls and HPP -highest density coronally, and lowest apically. However, no statistically significant differences were found between HPP and controls in any dentin compartment. To determine whether the dissimilar effects concerning cementum and dentin in HPP were related to pyrophosphate (PP_i) metabolism, we quantitated the PP_i concentrations and the expression and activity of TNSALP and other enzymes related to PP_i metabolism (e.g., PC-1 and ANK) in the periodontal ligament (PDL) and pulp of healthy teeth. Compared to the PDL, expression of TNSALP and PC-1 (per GAPDH) in pulp was about 50% and 10%, respectively. Also, the activity of PC-1 was significantly lower in pulp, as was the concentration of PP_i. ANK expression, however, was similar in the two tissues.

In HPP teeth, formation of cementum is severely diminished whereas the mineralization of dentin is unaffected. Differences in gene expression and activity of enzymes involved in PP_i metabolism are in keeping with the dissimilar impact on cementum and dentin of childhood and odonto-HPP.

Osteoporosis Pseudoglioma Syndrome: 4 Siblings With a Compound Heterozygote LPR5 Mutation. E. A. Streeten[1], E. Puffenberger*[2], H. Morton*[2], D. McBride*[1]. [1]Endocrinology, Diabetes and Nutrition, University of Maryland School of Medicine, Baltimore,, MD, USA, [2]The Clinic for Special Children, Strasburg, PA, USA.

Osteoporosis-pseudoglioma syndrome (OPPG) is a rare autosomal recessive disorder of severe juvenile osteoporosis and congenital blindness, due to mutations in the LRP5 gene. Approximately 35 cases of OPPG are known worldwide. One year ago at this meeting, we reported 3 siblings with OPPG (Family 1), members of a conservative Mennonite church in PA, with an exon 6 (Trp-425-X) LRP5 mutation. We now report 4 additional siblings with OPPG (Family 2) who are cousins to Family 1. The 4 siblings in Family 2 are boys aged 15 and 5 and girls aged 10 and 4 years. All have been blind from birth, similar to Family 1, but have a more mild bone phenytype. The spine Z scores of the affected children in Family 2 are -3.5, -2.8, -1,7 and -2.3, compared to -6.1, -5.0 and -3.4 in Family 1. All OPPG children in both families appear intellectually normal. Unlike Family 1, only 1 affected (10 yo girl) in Family 2 had typical OPPG facies and joint hyperextensibility.

In Family 2, only one affected child (10 yo girl) has had a fragility fracture (wrist). The parents have osteopenia with spine T scores of -1.5 (mother) and -1.6 (father); both had normal hip T scores. There are 4 unaffected siblings. To study the LRP5 gene in Family 2, genomic DNA for PCR was obtained from the oldest (15 yo) boy's leukocytes in order to confirm the LRP5 exon 6 mutation found in Family 1. Sequence analysis demonstrated he was heterozygous for the exon 6 LRP5 mutation found in Family 1 (W-425-X) and a second exon 6 mutation (T-409-A). This compound heterozygote mutation appears to be sufficient to cause congenital blindness and osteoporosis but the bone phenotype is more mild than was seen in Family 1. DNA analyses of the 3 other OPPG children and the parents in Family 2 are in progress.

In summary, we report 4 siblings with OPPG and a novel compound heterozygote LRP5 mutation with a more mild bone phenotype than their cousins who are homozygous for one of the same mutations

Analysis of Variation in Expression of ADO2: Searching for the Modifier Genes. K. Chu*[1], D. L. Koller[2], R. Snyder*[1], D. Lai*[2], T. Fishburn*[1], T. Foroud[2], M. J. Econs[1]. [1]Medicine, Medical School of IUPUI, Indianapolis, IN, USA, [2]Medical and Molecular Genetics, Medical School of IUPUI, Indianapolis, IN, USA.

Autosomal Dominant Osteopetrosis type II (ADO2) is an osteosclerotic disorder due to heterozygous mutations in the ClCN7 gene. Analysis of ADO2 in our pedigrees indicates that the penetrance is 66%, with a highly variable phenotype even between family members with the same mutation. To identify genes that modify disease severity, we performed a 10cM genome-wide scan using 400 microsatellite markers in 8 ADO2 families. Parametric linkage analysis was conducted with the MLINK program, using both dominant and recessive models. Using the recessive model, evidence of linkage was detected with marker D9S283 (LOD=2.03) and with D2S347 (LOD=1.52). Additional microsatellite markers were then genotyped on chromosomes 9 and 2 to better delineate the position of the putative modifier locus. Based on the key recombinants in the families, a candidate 4.6 cM region was identified on chromosome 9q22. Of note, candidate genes in this region include cathepsin L, which is secreted by osteoclasts and processed to an active enzyme by acid, surface activation, or proteolysis. We are currently analyzing cathepsin L as well as other genes on chromosomes 9q22 and 2q14 to identify genes that modify phenotypic expression.

Since the linkage search strategy pursued above would be invalid in the chromosome 16pter region due to confounding of the disease mutation and putative modifier effects, we have also considered the hypothesis that genetic variation at other sites within the ClCN7 gene might influence disease expression. DNA sequence data has shown that at position 418 of the ClCN7 protein sequence there is a missence polymorphism resulting in an amino acid change from valine to methionine (V418M). To test the hypothesis that this polymorphism affects disease severity we genotyped this polymorphism in our ADO2 families. We found that, on the chromosome with the WT-ClCN7 allele, 94.54% (52/55) of affected and 75% (24/32) of carriers had the M allele while 5.45% (3/55) of the affected and 25% (8/32) of carriers had the V allele (p=0.016). Further analysis indicated that most of the evidence of association came from the 4 families with the G215R mutation. In these families, 100% (16/16) of affected and 42.86% (3/7) of carriers had the V allele on the non-disease carrying chromosome, while none of the affected and 57.14% (4/7) of the carriers had the M allele.

In conclusion, regions of chromosome 9 and 2 may harbor genes that affect disease severity. Additionally, we find statistical support for the hypothesis that the V418M polymorphism, on the non-mutant ClCN7 gene allele, influences the tendency to become an asymptomatic carrier.

Tumoral Calcinosis: Resolution With Nasal Calcitonin Therapy / Dietary Mineral Reduction. D. Wenkert[1], W. H. McAlister*[2], M. P. Whyte[1]. [1]Shriners Hospitals for Children, St. Louis, MO, USA, [2]Washington University School of Medicine, St. Louis, MO, USA.

Tumoral calcinosis features painless mineral deposits involving periarticular bursae on the extensor surfaces of major joints. Hyperphosphatemia and increased TmP/GFR (phosphate transport maximum/glomerular filtration rate) occur in some patients. Treatment by phosphate (Pi)-binding with aluminum hydroxide (together with dietary Ca and Pi deprivation) as well as surgical excision has had some success. We document complete resolution of tumoral calcinosis after treatment with salmon calcitonin given by nasal spray together with dietary mineral reduction.

Our patient, a 15-7/12 year old Mexican-American girl, presented with a 3-4 year history of periarticular calcifications. She was healthy until age 12 or 13 years when she noticed pain and a mass overlying her right hip. Xrays revealed calcific deposits surrounding both hips. Serum calcium, Pi, 25-hydroxyvitamin D, aldolase, AST, ALT, CK, and alkaline phosphatase activity were normal. At age 14 years, xrays showed persisting calcific masses surrounding her hips. Bone scan revealed uptake on the right. Her masses continued to grow. She complained of discomfort and decreased range of motion of her right hip, although physical activities continued. Family history and review of systems were unremarkable for signs of autoimmune disease or calcinosis. Physical exam disclosed mild dermatographism, lividoreticularis (without Raynaud's phenomenon), 3-4 small café-au-lait spots, vitiligo, and stretch marks overlying her hips, but no facial or shawl rash, Gottron's papules, telangiectasias, or periungual changes. The palpable mass overlying her lateral right hip was somewhat mobile. Hip flexion there was decreased as compared to the left. Laboratory evaluation was remarkable only for an elevated sedimentation rate (40). Renal tubular reabsorption of phosphate was 95%. Nasal calcitonin therapy was begun (200u q day). During this time, our patient electively decreased her calcium intake by 50% and her phosphate intake by 25%. Within the first few months of therapy, her parents reported disappearance of the lump under her jeans. Complete radiographic resolution had occurred when first re-radiographed after 10 months of therapy. Nasal calcitonin was then stopped. Eight months later, physical examination revealed no re-emergence of the mass, and a return of her right hip range of motion. Xrays showed no recurrence. A single dose of calcitonin given at that time decreased her TRP from 97% to 94%.

Dietary mineral restriction with nasal calcitonin therapy to enhance mineral excretion should be evaluated in additional cases of tumoral calcinosis.

Cinacalcet HCl Attenuates Hypercalcemia Observed in Mice with Either a Rice H-500 Leydig Cell or C26-DCT Tumor. M. Colloton*, E. Shatzen*, B. Wiemann*, C. Starnes*, D. Martin. Departments of Metabolic Disorders and Oncology, Amgen, Thousand Oaks, CA, USA.

Excessive secretion of PTHrP from certain tumor cells produces hypercalcemia by stimulating bone resorption and increasing renal tubular reabsorption of calcium. Hypercalcemia is associated with substantial morbidity and mortality. The calcium-sensing receptor (CaR) plays a key role in systemic calcium homeostasis by regulating parathyroid hormone (PTH) secretion in response to changes in extracellular calcium. The calcimimetic cinacalcet HCl binds to and allosterically modulates the CaR to increase its sensitivity to extracellular calcium. We investigated the ability of cinacalcet HCl to attenuate hypercalcemia in mice bearing either a Rice H-500 Leydig cell (Leydig tumor) or C26-DCT tumor and determined the effects of cinacalcet HCl on serum PTHrP levels in mice bearing a Leydig tumor.

Rice H-500 Leydig cells or C26-DCT cells were implanted subcutaneously into the proximal dorsal midflank of female CB17/SCID or male CDF-1 mice, respectively. Implanted mice in each group were divided into 8 subgroups and treated with cinacalcet HCl (3 or/and 30 mg/kg p.o.), its less active enantiomer S-AMG 073 (30 mg/kg p.o.), or vehicle, starting from day one after inoculation until sacrifice on day 10 (Leydig tumor), as a single dose on day ten (Leydig tumor), or as a single dose on day 17 (C26-DCT tumor). Animals were sacrificed 4 hrs after final drug treatment, and blood was removed for determination of calcium, phosphorus and PTHrP levels.

Vehicle-treated mice bearing either tumor had significantly higher baseline serum ionized calcium and/or total calcium levels than control mice without tumors. Cinacalcet HCl given daily or as a single dose significantly reduced serum ionized calcium and total calcium in both tumor models when compared to vehicle-treated animals (Table illustrates single dose studies). Furthermore, cinacalcet HCl normalized serum phosphorus levels but had no effect on elevated serum PTHrP levels. The less active enantiomer S-AMG 073 had no effect on serum calcium or phosphorus levels or on PTHrP levels in either tumor model.

Biochemistry in Mice (4 hours after a single treatment dose)

		C26-DCT Tumor			Rice H-500 Leydig Tumor	
Group	Tumor	Ca^{2+} (mmol/L)	Calcium (mg/dL)	Phosphorus (mg/dL)	Ca^{2+} (mmol/L)	PTHrP (pg/ml)
Control	No	1.4 ± 0.01	10.3 ± 0.5	10.1 ± 4.5	1.2 ± 0.2	0.1 ± 0.04
Vehicle	Yes	1.8 ± 0.03[a]	13.1 ± 0.3[a]	6.7 ± 0.5	1.7 ± 0.07[a]	6.6 ± 0.9[a]
Cinacalcet 30mg/kg	Yes	1.3 ± 0.05[*]	10.2 ± 0.9[*]	10.6 ± 1.1[**]	1.2 ± 0.08[**]	9.9 ± 3.4[a]
Cinacalcet 3 mg/kg	Yes				1.4 ± 0.07*	6.1 ± 1.1[a]
S-AMG073 30mg/kg	Yes	1.7 ± 0.05[a]	13.2 ± 0.4[a]	8.3 ± 0.6	1.53 ± 0.05[a]	6.1 ± 1.0[a]

Control vs Tumor [a]$p < 0.05$

Vehicle vs Drug Treatment [**]$p < 0.01$; [*]$p < 0.05$

These data support the potential use of cinacalcet HCl to reduce serum calcium in conditions of humoral hypercalcemia of malignancy.

Bone Tissue Effects of Combined Dioxin and Sucrose Exposure Are Gender Related in Rats. P. M. Lind[1], H. M. Miettinen*[2], J. Örberg*[3], I. Pettersson*[3], M. Viluksela*[2]. [1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Environmental Health, National Public Health Institute, Kuopio, Finland, [3]Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden.

Our previous experimental studies have demonstrated that high affinity aryl hydrocarbon receptor ligands such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and the dioxin-like PCB congener, 3,3',4,4',5-pentachlorobiphenyl (PCB126), impair bone tissue composition and function. The effects of PCB126 on bone tissue in rats are related to endogenous estrogen status and estrogen supplementation modulates PCB126 induced effects on bone tissue. The aim of the present study was to investigate possible gender differences in effects on rat bone tissue caused by co-exposure to TCDD and sugar. Pregnant dams were exposed to a single oral dose of 1 ug/kg b.w. at gestation day (GD15). Control rats received the vehicle (corn oil). After weaning the rats were given either sucrose-rich diet (15% sucrose) and tap water containing 7 % sucrose or normal rat powder feed and tap water. Pups were killed at the age of 77 days. Peripheral quantitative computed tomography (pQCT) analyses were performed on the excised tibia. Trabecular volumetric BM D (trab BMD) was determined by metaphyseal scans of the proximal tibiae. Cortical parameters, including total and cortical volumetric bone mineral density (total and cortical BMD), total and cortical cross-sectional area (tot and cort CSA), medullary area, cortical thickness and polar moment, were determined by mid-diaphyseal scans.

In male rats the effect of TCDD alone was seen only as a reduced cortical BMD at the diaphysis whereas in the female rats a significant reduction of bone growth manifested as reduced total BMD, total and cortical CSA, and also reduced medullary area and polar moment. Adding sucrose to the diet ameliorated the toxic effects of TCDD. This sucrose-effect might be related to an increased stimulation of the bone tissue as a result of a higher body weight in the female rats. In conclusion, our results suggest that TCDD affected bone tissue in a gender dependent manner; the female rats being more sensitive.

Recommendations for Management of Heterotopic Ossification Based on 12-Year Experience. K. Banovac, A. Sherman*, I. Estores*. Rehabilitation Medicine, Univ. of Miami, Miami, FL, USA.

Heterotopic ossification (HO) is one of the most common and irreversible complications after spinal cord injury (SCI). The purpose of this study was to develop an algorithm for management of HO after SCI based on our 12-year experience. This is a retrospective analysis of our results published over a period of 12 years. All studies were performed at the rehabilitation center of a university teaching hospital and were approved by the institutional review board. A total of 344 SCI patients with HO were included in the studies we reviewed. Prevention of HO was conducted by using selective and nonselective COX-2 inhibitors during the first 2 months after SCI. Diagnosis of HO was based on clinical findings and was confirmed by three-phase bone scintigraphy. The extent of muscle involvement by HO was followed by determination of serum creatine phosphokinase (CPK). Treatment of HO was initiated with intravenous and continued with oral etidronate for a period of 3 or 6 months. Serum C-reactive protein (CRP) was used to monitor inflammatory activity of HO. Our results showed an incidence of HO in approximately 50% of patients by using bone scintigraphy as a diagnostic test. Prophylactic administration of indomethacin and rofecoxib reduced the incidence of HO 2.7 and 2.5-fold respectively. Early treatment of HO with etidronate resulted in a 5-fold decrease of radiographic findings of HO. The elevation of CPK correlated with severity of HO in majority of patients. CRP declined during the first 3 to 4 weeks of etidronate therapy. In conclusion, our data suggest that the incidence of HO and subsequent progression to advanced HO can be significantly decreased by using the following algorithm: (1) Preventive use of NSAIDs early after SCI, (2) Use of bone scintigraphy for early diagnosis of HO prior to positive radiographic findings, (3) More aggressive treatment with etidronate when patients have elevated CPK levels, and (4) Use of NSAIDs with etidronate in the acute stage of HO until normalization of serum CRP.

Bone Mineral Density Changes After One Year of Antiepileptic Drug Treatment in Women with Epilepsy. A. M. Pack[1], E. Shane[2], L. Holloway*[3], E. Flaster*[1], M. Morrell*[1]. [1]Neurology, Columbia University, New York, NY, USA, [2]Medicine, Columbia University, New York, NY, USA, [3]VA Palo Alto Health Care System, Stanford University, Palo Alto, CA, USA.

Rationale: Antiepileptic drugs (AEDs), particularly those that induce the hepatic cytochrome P450 system, have been associated with abnormal vitamin D metabolism and osteoporosis. Recent studies have reported that low bone mineral density (BMD) in adults on AEDs is common and associated with multidrug regimens, generalized seizures, longer disease duration, and increased bone turnover markers. We therefore examined the effects of individual AEDs on healthy premenopausal women with epilepsy (WWE), hypothesizing that those receiving enzyme inducing AEDs, particularly phenytoin (PHT) and carbamazepine (CBZ), would have more bone loss than those receiving valproate (VPA), an enzyme inhibitor, or lamotrigine (LTG) which has no effect on the cytochrome P450 system.

Methods: Community-dwelling WWE aged 18-40 receiving AED monotherapy for at least 6 months were recruited. BMD was measured at the lumbar spine (LS), total hip (TH) and femoral neck (FN) hip by dual energy X-ray densitometry at baseline and one year, if they remained on the originally prescribed AED. Serum calcium, 25-(OH) vitamin D (25-OHD), parathyroid hormone (PTH), bone specific alkaline phosphatase (BAP, marker of bone formation) and urine N-telopeptide of type I collagen (NTX, marker of bone resorption) were measured at baseline and examined with respect to percent change in BMD.

Results: Of 71 women, 11 were on PHT, 26 on CBZ, 14 on VPA and 18 on LTG. Average age was 32 +/- 5.9 years and BMI was 26.5 +/- 6.3 kg/m^2 with no significant between-groups differences. Baseline Z scores were normal at all sites and did not differ among AED groups (range: -0.42 - 0.34). BMD was stable at the LS and TH in all groups after 1 year of treatment. In women on PHT, FN BMD declined by -2.75% +/- 2.76, p=0.05 compared to the other groups (CBZ, +0.49% +/- 4.03; VPA, +1.09% +/- 3.73; LTG, -0.005% +/- 0.02). In the group overall, bone loss correlated with serum calcium levels, but not other markers of bone function.

Conclusion: In general, BMD is stable in premenopausal WWE on AED monotherapy. We observed significant bone loss at the FN in those taking PHT. The bone loss was associated with lower serum calcium levels but not with serum 25-OHD or PTH levels, nor with markers of bone turnover. Although the mechanism of the bone loss is uncertain, our results suggest that premenopausal women receiving PHT are at significant risk for considerable bone loss and warrant BMD monitoring.

Primary Aldosteronism and the Secondary Hyperparathyroidism of the Vitamin D Deficiency. D. N. Nguyen*[1], L. T. Nguyen*[2], K. V. Luong[2]. [1]Metropolitan State Hospital & Vietnamese American Medical Research Foundation, Norwalk, CA, USA, [2]Vietnamese American Medical Research Foundation, Westminster, CA, USA.

Objective: The purported originality of this case report is that the biochemical stigmata of hyperaldosteronism disappeared after vitamin D deficiency treatment.

Methods: We describe the clinical presentation, laboratory findings and clinical course in a vitamin D-deficient patient with primary aldosteronism and discuss underlying factors potentially contributing to the condition.

Result: A 62-year-old Caucasian male with history of type 1 diabetes mellitus presented with hypertension and persistent hypokalemia. Laboratory examination revealed hypokalemia, metabolic alkalosis, low level of renin activity, and an elevation of plasma aldosterone level. He also had low levels of serum ionized calcium, 25-hydroxyvitamin D, and an elevated level of intact PTH. The ultrasound of the adrenal revealed a normal size of the adrenal gland. Of interested, his serum levels of PTH and aldosterone were decreased with 1,25 hydroxyvitamin D_3 (1,25OHD) treatment in one month. Serum potassium level was normalized without potassium supplement or aldosterone antagonism treatment.

Discussion: 1,25OHD has been known to suppress PTH secretion. PTH-binding sites have been autoradiographically localized in the rat adrenal cortex. It was demonstrated that PTH and PTH-related peptide concentration dependently enhanced basal aldosterone and cortisol secretion from dispersed human adrenocortical cells.

Conclusion: The presence of the primary aldosteronism in the secondary hyperparathyroidism of the vitamin D deficiency suggested that hyperparathyroidism might have a role in the inducing primary aldosteronism. However, a coindental presence of two diseases cannot be excluded.

Intraperitoneal Administration of Recombinant Receptor-Associated Protein Impairs Megalin Function and Increases Renal Phosphate Excretion. M. Yamagata*[1], K. Ozono[2], Y. Hashimoto*[1], H. Kondou*[1], T. Michigami[1]. [1]Department of Environmental Medicine, Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Osaka, Japan, [2]Department of Pediatrics, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.

Megalin is a multifunctional endocytic receptor expressed in apical membrane of renal proximal tubules, and plays critical roles in vitamin D metabolism through renal reabsorption of vitamin D binding protein (DBP) complexed with 25-hydroxyvitamin D. In the present study, to examine the acute effects of impairment of megalin function in kidney, we utilized a recombinant protein for soluble form of 39-kD receptor-associated protein (RAP), which binds to megalin and inhibits the binding of all other ligands. His-tagged soluble form of recombinant murine RAP [a.a.38-356] lacking the N-terminal signal peptide and the C-terminal ER retention signal was prepared by expression in E.coli (designated His-sRAP). After confirming the direct interaction between the purified His-sRAP and megalin by a ligand blot analysis, male ICR mice were given a single intraperitoneal administration of His-sRAP (3.5 mg/dose). Immunostaining using an antibody against His-tag demonstrated the subapical localization of His-sRAP in the proximal tubular cells after the administration, suggesting that His-sRAP interacted with megalin expressed in the brush border membrane and was taken up via megalin-dependent endocytosis. Using the same specimen, we performed immunohistochemical examination for type II Na/Pi co-transporter. Interestingly, it was observed that type II Na/Pi co-transporter was also internalized after the injection of His-sRAP. When the three administrations of His-sRAP were given to mice with 4-hour intervals, urinary excretion of low-molecular-weight proteins including vitamin D binding protein (DBP) was increased, confirming the impairment of megalin function. Consistent with the increased urinary loss of DBP, serum concentration of 25-hydroxyvitamin D was decreased after the administration. As to the urinary excreation of phosphate, it was increased by the treatment with His-sRAP, suggesting the involvement of megalin function in renal phosphate reabsorption. The plasma level of intact PTH was not altered by the administration of His-sRAP. Taken together, megalin might be involved in renal phosphate excretion via type II Na/Pi co-transporter independently of plastma PTH levels. These findings suggest the possibility that there might be a physiological or pathological ligand of megalin which exerts the similar effects to those of His-sRAP.

Time-evolution and Reversibility of Strontium-Induced Osteomalacia (OM) in Chronic Renal Failure (CRF) Rats. L. Oste*[1], P. C. D'Haese*[1], A. R. Bervoets*[1], G. J. Behets*[1], G. Dams*[1], S. C. Verberckmoes[1], V. O. Van Hoof[2], M. E. De Broe*[1]. [1]Nephrology - Hypertension, University of Antwerp, Wilrijk, Belgium, [2]Biochemistry, University Hospital Antwerp, Edegem, Belgium.

In dialysis patients we showed an association between increased bone Sr levels and OM. Evidence for a causal role of the element in the development of the disease was presented in CRF rats. Sr-ranelate has been put forward as a therapeutic agent in the treatment of osteoporosis. Since the target population for Sr-treatment consists mainly in post-menopausal osteoporotic women, who may have a reduced renal function, the risk for OM should be considered.

We studied the time evolution and reversibility of the Sr-induced mineralization defect by oral loading of CRF rats with Sr (2g/l in the drinking water) during 2, 6 and 12 weeks, followed by a withdrawal period of 2, 4 or 8 weeks.

Histological examination revealed clear signs of OM already after 2 weeks of Sr treatment. Animals that received Sr during 6 and 12 weeks had significantly higher osteoid perimeter (68±12 vs 22±19% p=0.008 and 69±20 vs 36±17% p=0.044), osteoid area (31±15 vs 3±3% p=0.006 and 31±17 vs 7±7% p=0.008) and osteoid thickness (17.5±8.9 vs 4.2±1.1µm p=0.006 and 18.2±5.8 vs 5.9±2.4µm p=0.006) compared to controls. After 12 weeks of Sr administration, the mineralization was significantly affected, as evidenced by lower double-labelled surface (0±0 vs 10±10% p=0.008), lower mineral apposition rate (0.0±0.0 vs 1.9±1.1µm/day p=0.008), higher osteoid maturation time (>12 vs 4.1±4.4 days p=0.008), lower bone formation rate (0±0 vs 1054±1233µm²/mm²/day p=0.008) and higher mineralization lag time (>1000 vs 137±432 days p=0.008). After 6 and 12 weeks of loading the osteoblast perimeter was significantly lower in the Sr treated animals (3±5 vs 26±15% p=0.038 and 10±9 vs 14±15% p=0.05. A significant rise in serum total alkaline phosphatase (ALP) activity in the Sr-treated animals compared to controls was apparent after 2, 6 and 12 weeks of loading (81±7 vs 44±10U/l p=0.006; 92±16 vs 28±13U/l p=0.006 and 75±8 vs 42±8U/l p=0.006). Measurement of the ALP isoenzymes indicated that Sr loading not only stimulates the bone-ALP, but the intestinal and liver ALP iso-enzymes as well. In animals treated with Sr, at all time points a decrease of serum iPTH was found, suggesting a calcimimetic effect of Sr on PTH secretion.

After cessation of Sr treatment, the effects of Sr on ALP and PTH were reversed and the histological and histodynamical parameters evolved to control levels during the wash-out period of 2, 4 or 8 weeks.

In conclusion, in this study evidence is provided for a fast development of a Sr-induced mineralization defect in CRF rats, that is rapidly reversed after withdrawal of the compound.

Canine Distemper Virus Dose-Dependently Increases Human Osteoclast Formation and Function. A. P. Mee*. Medicine, University of Manchester, Manchester, United Kingdom.

Paget's disease is characterised by a dramatic increase in size and number of osteoclasts, leading to uncontrolled bone resorption. Previously we have shown that canine distemper virus (CDV) RNA is present in Pagetic bone samples. However, the effects of CDV on human osteoclast formation in vitro have not been previously studied.

Replicate cultures (n=3) of purified human osteoclast precursors (Poietics Osteoclast Precursors, Cambrex, UK) were infected with increasing doses of CDV (50, 500 and 5,000 pfu/ml) and cultured on dentine slices for 14 days. Control cells were incubated in the absence of virus. Osteoclasts were stained for tartrate-resistant acid phosphatase and the dentine slices were examined for evidence of resorption. Ten high-power microscopy fields were analysed for each sample.

CDV dose-dependently increased osteoclast number and size ($p<0.0001$, ANOVA), and there was a corresponding increase in resorption on the dentine slices ($p<0.0001$, ANOVA). The maximum effect was seen with 500 pfu/ml CDV (20.3±4.4 osteoclasts/high power field cf. 9.8±1.3 osteoclasts in control culture; 14.3±5.5 cf. 5.5±0.7 nuclei/osteoclast; 54.0±5.2 cf. 25.0±4.6 percent of dentine slices covered by resorption pits).

These results provide the first conclusive evidence that CDV can infect human osteoclast precursors. The resulting increase in size and number of osteoclasts, and increased resorption, provide further evidence for the possible role of Paramyxoviruses in the pathogenesis of Paget's disease.

Characteristics and Familial Aggregation of Paget's Disease of Bone in Italy. R. Nuti, D. Merlotti, B. Galli*, G. Martini, A. Calabrò*, V. De Paola*, E. Ceccarelli*, S. Salvadori*, A. Avanzati*, L. Gennari. Dept. of Internal Medicine Endocrine Metabolic Sciences and Biochemistry, University of Siena, Siena, Italy.

The aetiology of Paget's disease of bone (PDB) remains unknown. Current evidence suggests that interactions among genetic or exogenous factors, appear to be necessary for disease expression. Major epidemiological studies were performed in United Kingdom as well as in other populations of British descent. To date there are no reliable data on PDB characteristics among the Italian population, and its frequency in different areas of the country remains unknown. In attempt to evaluate clinical characteristics, the proportion of familial cases and the influence of environmental features on the occurrence of the disease we studied 147 consecutive PDB patients. For all subjects a detailed medical history was obtained, and constitutional features were recorded. Characteristics of PDB patients were compared to those obtained from 323 consecutive non PDB outpatient subjects. Among PDB cases, there was a slight male predominance, with a male to female ratio of 1.5:1. Of the 147 PDB patients, 22 (15%) had at least one other family member affected, 19 (13%) referred one family member with suspected features of PDB and 106 (72%) were classified as sporadic PDB. No significant differences between familial and sporadic cases were observed concerning skeletal extent, male to female ratio, age of onset, somatic features like hair and eyes color. A trend approaching statistical significance was observed for age of diagnosis that was lower in familial than in sporadic cases (59.0±12.3 vs. 53.6±14.6; p=0.06 ANOVA). Even though we observed a reduced clinical severity of PDB with respect to other populations (mean number of affected sites 2.2±1.6), we did not found any evidence of a decreased severity of the disease through years. We also found an association of PDB with animal-related factors (OR 2.22, $p<0.0005$) and a significant prevalence of PDB in rural vs urban districts (OR 2.42, $p<0.0005$). Osteoarthritis (40%), fractures (14%), hearing loss (14%), and valvular calcifications (15%) were the most observed complications. Interestingly, the geographical distribution of PDB showed a concentration of cases in rural areas of Campania and Tuscany. PDB characteristics differed significantly in PDB subjects from these high prevalence areas. In particular, age of diagnosis was significantly lower (48.15±13.1 yrs vs. 60.6±11.6; p=0.0005 ANOVA) and the number of involved sites was higher (3.15±2.3 vs. 2.07±1.4; p=0.019, ANOVA) in PDB subjects from the high prevalence areas than in the other PDB cases. These areas may indicate local clustering of PDB cases in Italy, similar to what observed in other countries.

Different Responses Of Bone Turnover Markers To Bisphosphonate Therapy In Pagetic Patients With Skull Involvement. L. Alvarez[1], P. Peris[2], N. Guañabens[2], S. Vidal-Sicart*[3], H. Solberg*[4], P. Cloos*[4], A. Monegal*[2], J. Bedini*[1], F. Pons*[3], A. Ballesta*[1]. [1]Biochemistry, Hospital Clinic, Barcelona, Spain, [2]Rheumatology, Hospital Clinic, Barcelona, Spain, [3]Nuclear Medicine, Hospital Clinic, Barcelona, Spain, [4]Nordic Bioscience, Herlev, Denmark.

Aims: The aims of this study were to evaluate response to therapy in disease activity in pagetic patients with and without skull involvement and to compare the usefulness of new bone markers in the evaluation of these patients.

Patients and Methods: 37 patients with Paget's disease (9 with skull involvement) treated with tiludronate (400 mg/d x 3 months) and 26 healthy controls were included in the study. Serum total alkaline phosphatase (TAP), bone alkaline phosphatase (BAP), PINP and urinary α-α CTX, β-β CTX and NTX were measured at baseline and at 1 and 6 months after discontinuation of therapy. Quantitative bone scintingraphy was performed at baseline and at 6 months, and an index of disease activity (SAI) was obtained. Patients were classified into three groups: patients with skull involvement (Sk group), patients without skull involvement and patients without skull involvement but with similar disease activity to those of the Sk group (based on SAI).

Results: All groups of patients showed higher baseline values in all markers compared to controls. At baseline patients with skull involvement showed significantly higher values in all markers when compared to the rest of the pagetic patients. In addition, there were no significant differences between the group of patients with similar SAI and those with skull involvement except for NTX, which was higher in the latter group. The α-α CTX was the marker with the highest values in this group of patients (46 times higher than normal values in Sk group vs 20 times higher in the rest of patients). Six months after discontinuation of therapy the percentage of patients with markers within the normal range in patients without skull involvement were: 71% for TAP, 71% for BAP, 63% for PINP, 54% for NTX, 48% for α-α CTX and 52% for β-β CTX; in patients with similar SAI to Sk group the values were 60% for TAP, 60% for BAP, 50% for PINP, 33% for NTX, 31% for α-α CTX and 38% for β-β CTX, whereas in patients with skull involvement they were: 33% for TAP, 22% for BAP, 0% for PINP, 13% for NTX, 17% for α-α CTX and 17% for β-β CTX.

Conclusion: Pagetic patients with skull involvement showed a marked increase in bone turnover and a lower response to bisphosphonate therapy. Moreover, α-α CTX is the marker with the highest increased values in these patients. The results suggest that these patients probably need to be treated with higher doses or more potent bisphosphonates.

Paget's Disease Of Bone In A Younger Cohort: A More Subtle Disease. M. Seton. Allergy, Immunology & Rheumatology, Mass General Hospital, Boston, MA, USA.

Purpose: This study was designed to examine the skeletal distribution of Paget's disease of bone (PD) in persons enrolled in the New England Registry for Paget's Disease of Bone (NERPD) born after 1940. Studies in the prevalence of Paget's disease of bone (PD) have suggested that the number of bones involved has diminished as an inverse correlate with date of birth. This pattern is different in individuals with a positive family history of PD in whom there is a tendency towards polyostotic disease. Methods: The NERPD is a database designed to examine the distribution and determinants of disease frequency. Diagnosis is confirmed by bone scan and x-ray report; the highest alkaline phosphatase (AP) is noted. Of the 295 persons now entered into the database, all persons were selected with birth dates from 1940 forward, N= 35 (12%). This was an arbitrary cut off, chosen to include enough histories for an observational study. Results: Birth dates ranged from 1940 - 1961. Three of the 35 persons did not have PD after medical record review. Of the remaining 32 persons, 29 (91 %) had PD confirmed by radiographic studies. They are the subjects of this review. Of these persons, 17 were men, 12 women. One man was born in Haiti, and was the only person of color; 28 persons were born in the USA, as were most of their parents. Only 3 noted both grandparents from this country. The birth lands otherwise included Italy, Central Europe and Russia, followed in frequency by Ireland, Canada, Scotland, and Greece. One pair of grandparents was identified as American Indian. Of the 29 persons with PD born after 1940, 23 (79%) had monostotic disease, 7 involving the thoracolumbar spine, 8 the pelvis, 4 the skull, 2 the humerus, 1 a hip, 1 a tibia. Four persons (14%) had 2 sites involved; in all cases the pelvis was one of these. The two persons in the Registry with a positive family history of PD, had polyostotic disease, a female with 5 pagetic bones, and a male with 4. Nearly half of the persons in this cohort had a normal serum AP. Conclusions: The study corroborates what other scientists are reporting, that there may be a trend towards less extensive skeletal involvement in younger persons with PD. The individual histories suggest that cultural diversity will continue to appear in persons with PD. The environmental determinants of disease - whether those of the microenvironment of aging bone or the macroenvironment of our world- remain poorly understood. Epidemiological methods for determining disease frequency of PD may need to change. Screening with plain radiographs of the abdomen would have missed a full 25% of persons with PD. Elevations in AP may not prevail in persons with monostotic disease. In the clinical care of patients with PD, new guidelines on early diagnosis and effective treatment are needed.

Fibroblast Growth Factor 23, Parathyroid Hormone, and 1α,25 Dihydroxyvitamin D in Surgically Treated Primary Hyperparathyroidism. P. Tebben[1], B. L. Clarke[1], R. J. Singh*[2], R. Kumar[3]. [1]Endocrinology, Mayo Clinic, Rochester, MN, USA, [2]Laboratory Medicine, Mayo Clinic, Rochester, MN, USA, [3]Nephrology Research, Mayo Clinic, Rochester, MN, USA.

Hypophosphatemia and suppressed renal phosphate reabsorption are observed in primary hyperparathyroidism. As fibroblast growth factor 23 (FGF23) has been implicated in the hypophosphatemia of several hypophosphatemic syndromes, we measured serum FGF23 to determine whether it contributes to the hypophosphatemia of primary hyperparathyroidism. In thirteen patients with primary hyperparathyroidism we measured serum inorganic phosphorus (Pi), calcium (Ca), 1α,25-dihydroxyvitamin D_3 ($1\alpha,25(OH)_2D_3$), parathyroid hormone (PTH), FGF23 (Immutopics, San Clemente, CA), creatinine, and bone specific alkaline phosphatase (BSAP) prior to, one day after, and at least 6 weeks after surgical cure of their disease. Normal serum FGF23 concentrations were derived from 80 healthy controls. Prior to surgery, patients had elevated serum Ca and PTH concentrations (Table 1). Serum Pi concentrations were in the low normal range. FGF23 concentrations were not elevated in patients with primary hyperparathyroidism compared to normal controls ($p>0.05$). Within 24 hours of surgery, serum Ca, PTH, $1\alpha,25(OH)_2D$, and BSAP concentrations were lower ($p<0.001$) and Pi concentrations were higher ($p<0.001$) than in the pre-operative state. FGF23 concentrations were similar prior to, one day after and six weeks following surgery. FGF23 concentrations did not correlate with serum Pi, Ca, PTH, $1\alpha,25(OH)_2D$, or BSAP concentrations in the pre- or post-operative state.

Parathyroid hormone is the major regulator of Pi, Ca and vitamin D metabolism in patients with primary hyperparathyroidism. FGF23 does not appear to play a role in Pi homeostasis in this group of patients with surgically treated primary hyperparathyroidism.

Table 1. Concentrations of serum analytes in patients with primary hyperparathyroidism before and after surgical excision of parathyroid adenomas or hyperplastic parathyroid glands.

	Pre Surgery	1 Day Post Surgery	6 Weeks Post Surgery
PTH (pmol/L)	10.9 ± 2.2	0.9 ± 0.2*	5.2 ± 0.7***

Increased Body Weight in Primary Hyperparathyroidism: Implications for Disease Associations. M. J. Bolland*, A. B. Grey, G. G. Gamble*, I. R. Reid. Department of Medicine, Auckland University, Auckland, New Zealand.

Although primary hyperparathyroidism (PHPT) is frequently asymptomatic, it has been associated with an increased prevalence of hypertension, insulin resistance, dyslipidemia, cardiovascular mortality, and cancer. Previously, we reported that patients with PHPT are heavier than age-matched controls, but further studies addressing this important question have not been undertaken. Increased body weight potentially could explain the association between PHPT and these complications, and impact upon the effects of PHPT on bone density. We have carried out a meta-analysis of all available data to determine whether patients with PHPT are heavier than age- and sex-comparable eucalcemic controls.

MEDLINE was searched for English-language studies published between 1975 and 2003. 17 studies met pre-determined eligibility criteria. Data regarding weight, body mass index (BMI), serum calcium and PTH were extracted from each study. Data were pooled and meta-analyzed using weighted and standard mean difference analyses.

Subjects with PHPT were on average 3.34kg (95% CI 1.97 to 4.71, $P < 0.00001$) heavier than controls in 13 studies reporting body weight. In 4 studies reporting BMI, subjects with PHPT had an increased BMI of 1.13kg/m^2 (-0.29 to 2.55, $P = 0.12$) compared to the controls. Standard mean difference analysis showed that patients with PHPT have an increased weight or BMI of 0.3 standard deviations (0.19 to 0.40, $P < 0.00001$) compared to the controls.

A weight difference of this magnitude is likely to be of clinical significance. Data from published prospective studies indicate that an increased BMI of 1.1kg/m^2 would predict an increase in the risk of diabetes by 155%, hypertension by 15%, ischemic heart disease by 6%, overall mortality by 6-10%, and an increased risk of a variety of cancers. These predictions are consistent with published data on the prevalence of these diseases in PHPT.

We hypothesize that increased body weight predisposes to the development of PHPT. Body weight is positively associated with PTH and inversely correlated with 25(OH)-Vitamin D in eucalcemic populations. Thus, increased body weight may promote vitamin D deficiency, resulting in secondary hyperparathyroidism that in the long term increases the risk of the development of parathyroid adenomata.

Since no evidence exists that parathyroidectomy reduces body weight, our findings suggest that surgical intervention in an attempt to reduce the risk of cardiovascular or neoplastic disease is not justified.

Effect of Bone Growth in Juvenile Dogs Administered Cinacalcet for 28-Days. S. F. Greene*[1], A. Coluci*[1], B. B. Smith*[1], R. C. Mandella*[2], J. Bussiere*[1], M. E. Cosenza,*[1], H. E. Davis*[1]. [1]Toxicology, Amgen, Inc., Thousand Oaks, CA, USA, [2]Toxicology, Huntingdon Life Sciences Inc, East Millstone, NJ, USA.

Cinacalcet is a potent calcimimetic agent that lowers serum parathyroid hormone (PTH), ionized calcium, and calcium x phosphorus product in nonclinical and clinical studies and is used in the treatment of secondary hyperparathyroidism. Potential effects of cinacalcet on growing bone were evaluated in juvenile dogs treated with cinacalcet. At the start of the study, dogs were 10 weeks old (post weaning), or the human equivalent of 2 to 12 years (prepuberty). The dogs were administered 0, 0.5, 1.5, or 5.0 mg/kg/day cinacalcet for 28 consecutive days (n = 7/sex/group), with reversibility of effects evaluated in 3 animals/sex/group in a 28-day treatment-free recovery period. Analyses for bone biomarkers in serum (bone-specific alkaline phosphatase, C-telopeptide, and osteocalcin) were done pretest and at the end of the dosing and recovery periods. Urine deoxypyridinoline and creatinine were measured at the termination of dosing and recovery periods. The right femur was collected from all animals at the terminal and recovery sacrifice for bone density measurements using peripheral quantitative computerized tomograph (pQCT). Bone density measurements were made at 2 sites in the femur, the diaphysis and the metaphysis. Cortical, subcortical, trabecular, and total area, content and density were measured at the metaphyseal site. Total content and density as well as cortical area, content, density and thickness were measured at the diaphyseal site. Histopathologic evaluations of hematoxylin and eosin-stained left femur also were done.

Cinacalcet was well tolerated at oral doses up to 5.0 mg/kg/day. As expected, serum ionized calcium and PTH levels were reduced in a dose-dependent manner. Serum parameters for bone formation (alkaline phosphatase and osteocalcin) or bone resorption (C-telopeptide) were not altered at dosing termination or after the treatment-free recovery period. No effects on urine parameters for bone resorption (deoxypyridinoline) or creatinine concentrations were observed. No effects of cinacalcet on bone densitometry measurements in the mid-shaft (diaphysis) or metaphysis of the femur were observed at any dose. No microscopic changes related to cinacalcet administration were observed in the bone.

Cinacalcet did not alter serum or urinary bone biomarkers, bone densitometry measurements, or histopathologic evaluations in juvenile dogs. Oral administration of cinacalcet to juvenile dogs for 28 days was well tolerated with no effect on bone or the growth plate.

Effect of Mild Asymptomatic Primary Hyperparathyroidism (PHPT) on Bone Geometry and Strength. T. S. H. Khairalla*[1], V. Reddy*[2], E. Phillips*[2], G. B. Talpos*[3], G. W. Divine*[4], G. Jacobson*[4], D. Rao[2]. [1]Internal medicine, Henry Ford Hospital, Detroit, MI, USA, [2]Bone and Mineral Metabolism, Henry Ford Hospital, Detroit, MI, USA, [3]Surgery, Henry Ford Hospital, Detroit, MI, USA, [4]Biostatistics and Research Epidemiology, Henry Ford Hospital, Detroit, MI, USA.

Moderate to severe PHPT is associated with decreased bone mineral density (BMD) and cortical thinning. However, whether the decrease in BMD leads to decreased bone strength and increased fracture risk is not known. Furthermore, the effects of mild PHPT on bone strength have not been previously reported. In this study we assessed the effect of mild PHPT on bone strength using indices of second metacarpal bone dimensions to calculate physical strength of the bone and compared the results to historical controls.

Forearm BMD was measured by DEXA. Metacarpal cortical thickness (MCT) was measured on the second metacarpal in 65 postmenopausal women with mild PHPT. Bone strength was assessed by cross sectional moment of inertia (CSMI), section modulus (SM), and bending breaking resistance index (BBRI). The results were compared to 60 healthy women.

The mean BMD was 0.638 ± 0.093 g/cm^2 and correlated significantly with MCT ($p<0.001$). As in patients with more severe PHPT, MCT was lower in mild PHPT compared to normals (4.2 ± 0.78 versus 5.53 ± 0.634; $p<0.001$). Both periosteal and endosteal diameters increased in PHPT patients compared to normals (8.5 ± 0.61 versus 7.86 ± 0.676; $p<0.001$ and 4.3 ± 1.05 versus 2.33 ± 0.865; $p<0.001$ respectively). Consequently, bone strength as assessed by CSMI (246 ± 66.3 versus 193 ± 68; $p=0.004$), SM (56.9 ± 11.3 versus 48.1 ± 12.4; $p=0.007$), and BBRI (579 ± 115 versus 490 ± 126; $p=0.007$), was greater in PHPT.

BMD and MCT are decreased in PHPT, but the changes in bone geometry appear to compensate for any adverse effects of decreased BMD and MCT on bone strength. Our results are consistent with the decreased prevalence of vertebral fracture in mild PHPT and for the anabolic role of PTH in osteoporosis.

Correction of Extracellular Calcium Reduces Parathyroid Gland Size in a Model of Secondary Hyperparathyroidism Using Mice with a Nonfunctioning Vitamin D Receptor. K. Weber*, U. Zeitz*, C. Bergow*, R. G. Erben. Institute of Animal Physiology, University of Munich, Munich, Germany.

Cell proliferation and parathyroid hormone (PTH) secretion in the parathyroid gland is known to be regulated by the vitamin D hormone via the vitamin D receptor (VDR) and by extracellular calcium via the calcium-sensing receptor. In this study, we sought to separate the effects of extracellular calcium from the effects of vitamin D on parathyroid gland function and size using mice with a nonfunctioning VDR. Beginning from 16 days of age, wild-type and homozygous VDR mutant mice were kept on a rescue diet containing 2% calcium (Ca), 1.25% phosphorus (P), and 20% lactose until they were 4 - 5 months of age. Subsequently, all mice were switched to a challenge diet containing 0.5% Ca, 0.4% P, and 0% lactose. After 2 months on the challenge diet, groups of VDR mutant mice were either fed the challenge diet, a normal diet with 0.9% Ca, 0.7% P, and 0% lactose, or the rescue diet for another 3 months. All diets had the same energy, fat, protein, and carbohydrate content. At baseline, blood ionized calcium, PTH serum levels, PTH mRNA levels, parathyroid gland size, biochemical markers of bone turnover, femoral bone mineral density (BMD) and bone histology were normal or only slightly altered in VDR mutants. The 2-month challenge diet phase induced severe secondary hyperparathyroidism (sHPT) with PTH serum levels of 1444 ± 779 pg/ml (mean ± SD), a 2.3-fold increase in parathyroid gland area, increased expression of the PTH mRNA, profoundly reduced femoral BMD, and a dramatic increase in bone turnover in VDR mutant animals, but only mild increases in serum PTH and unchanged femoral BMD in wild-type mice. Interestingly, the increase in parathyroid gland area in VDR mutants was mainly caused by enlargement of existing chief cells, not by cell proliferation. Feeding of the normal diet during the 3-month therapy period stabilized the existing degree of sHPT, while the challenge diet further aggravated it. However, the rescue diet fully corrected serum PTH, femoral BMD, and bone turnover to baseline control levels in hyperparathyroid VDR mutants, but not the increased PTH mRNA levels. The normalization of PTH secretion was associated with a significant 25% reduction in parathyroid gland area, which was mainly caused by a decrease in cell size, not by cell apoptosis. We conclude 1) that vitamin D has no essential function in the control of parathyroid cell proliferation, 2) that correction of extracellular calcium in this model of sHPT fully normalizes PTH secretion and reduces parathyroid gland size, and 3) that functional adaptation in the parathyroid glands of mature mice occurs mainly by regulation of cell size.

Apoptosis of Osteoblasts Is Increased in Patients with Mild Primary Hyperparathyroidism and Preserved Cancellous Bone. H. Zhou[1], D. W. Dempster[1], R. Lindsay[1], S. J. Silverberg[2], J. P. Bilezikian[2]. [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Department of Medicine, Columbia University, New York, NY, USA.

We have previously demonstrated that cancellous bone microarchitecture is preserved in patients with mild primary hyperparathyroidism (PHPT) and that this is due, in part, to an anabolic effect of PTH, resulting in increased thickness of bone packets formed in each remodeling cycle. One hypothesis proposed to account for the anabolic action of exogenous PTH is that the life span of osteoblasts is prolonged due to suppression of osteoblast apoptosis. We tested this hypothesis in 2 groups of patients with PHPT.

In Group I, 9 women with PHPT underwent tetracycline-labeled transiliac bone biopsy before (age=52 yrs) and after (age=62 yrs) parathyroid surgery (n=6) or medical management (n=3). In Group II, 6 premenopausal women with PHPT (age =35 yrs) were biopsied and compared with 12 age-matched controls. Apoptotic osteoblasts and osteocytes were detected in bone biopsy sections using the TUNEL method. Apoptotic osteoblasts were expressed as the number of TUNEL-positive osteoblasts over the total osteoblast-covered perimeter (A.Ob/Ob.Pm #/mm) on cancellous, endocortical or intracortical envelopes. Apoptotic osteocytes were expressed as the number of TUNEL-positive osteocytes over the total number of osteocyte lacunae (empty plus occupied) (A.Cty/Lac, %) in cancellous and cortical bone.

In Group II, A.Ob/Ob.Pm was 596, 2104 and 486% higher in PHPT than control on cancellous, endocortical, and intracortical surfaces ($0.05> p< 0.01$) respectively. This was accompanied by a 110% higher mineralized perimeter (Md.Pm) ($p< 0.01$) and a trend towards a higher bone formation rate (BFR)(58%) and activation frequency (Act.F)(55%). Treatment (Group I) resulted in a 74 and 80% decrease ($p<0.05$) in A.Ob/Ob.Pm on cancellous and endocortical surfaces, respectively, accompanied by a 45% decrease ($p< 0.05$) in Md.Pm and a trend towards a decrease in BFR (-43%) and Act.F (-25%). A similar trend was seen on the intracortical surface. There was no significant change in the A.Cty/Lac in PHPT compared to controls or after treatment, although the trend was in the same direction as for osteoblasts.

We conclude that the anabolic action of continuous PTH excess in mild PHPT does not appear to be associated with increased osteoblast life span due to suppressed osteoblast apoptosis. On the contrary, osteoblast apoptosis was increased in PHPT and this was reversed by treatment. These observations are consistent with the hypothesis that enhanced osteoblast number and/or activity seen with continuously elevated PTH in PHPT is associated with enhanced osteoblast attrition.

Treatment of Parathyroid Carcinoma with ABX10241, a Monoclonal Antibody to Parathyroid Hormone. D. M. Shoback[1], R. H. Arends*[2], L. Roskos*[2], S. Shetty*[2], M. Wyres*[2], S. Huang*[2], N. Raie*[2], G. M. Bell[2]. [1]Endocrinology, San Francisco VA Medical Center, University of California, San Francisco, San Francisco, CA, USA, [2]Abgenix, Inc, Fremont, CA, USA.

ABX10241 is a fully human, high-affinity, monoclonal antibody directed against the 1-34 amino acid region of parathyroid hormone (PTH) that neutralizes the activity of PTH in vitro and in vivo. This report describes the use of ABX10241 to treat a 38 year-old male with a 14-year history of inoperable parathyroid carcinoma. The patient had been treated with calcitonin (severe allergic reaction), bisphosphonates (pamidronate and zoledronic acid) and cinacalcet without control of his disease. In February 2004, hemodialysis was initiated to treat progressive renal insufficiency. Following atraumatic, bilateral femoral neck fractures, treatment with ABX10241 was initiated under an emergency use IND. ABX10241 was administered by intravenous bolus at increasing doses over a two-week period to normalize plasma unbound PTH or serum iCa, whichever occurred first. ABX10241 was administered in doses of 25 mg (Day 1), 50 mg (Day 4), 100 mg (Day 8), and 200 mg (Day 11, Day 22, Day 32, and approximately weekly thereafter). Plasma unbound PTH (measured using the Nichols Intact Assay), collagen N-telopeptides (NTx), and 1,25 $(OH)_2$ vitamin D (vit D) and pharmacokinetic samples were obtained before each dose, 24 hours post-dose and approximately 24 hours prior to the next dose during the dose-escalation phase. Serum iCa was obtained every 8 hours during the dose-escalation phase. The patient continued to receive 3-4 times weekly hemodialysis and intermittent doses of zoledronic acid. Treatment with ABX10241 resulted in a profound, dose- and exposure-dependent reduction in plasma unbound PTH from a pre-dose level of 1196 pg/ml to the normal range (range 30 pg/ml - 100 pg/ml) at a final dose of 200 mg per week. Plasma NTx levels were reduced following each dose of ABX10241 suggesting bone turnover was impacted by the treatment (see graph). In addition, vit D levels were reduced by the treatment. Serum iCa fluctuated with hemodialysis but remained elevated. No drug related toxicities were observed during or after the administration of ABX10241 and the patient reported improvement of his bone pain. These findings support the potential benefit of ABX10241 in the treatment of hyperparathyroidism secondary to parathyroid carcinoma.

Altered Geometry of the Proximal Femur Reduces Cortical Bone Strength in Pediatric Crohn Disease. J. M. Burnham*[1], J. Shults*[2], E. Semeao*[1], M. A. Petit*[3], T. J. Beck*[4], B. S. Zemel[1], M. B. Leonard[1]. [1]Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, USA, [2]Epidemiology, The University of Pennsylvania School of Medicine, Philadelphia, PA, USA, [3]Department of Health Evaluation Sciences, Penn State University, Hershey, PA, USA, [4]Radiology, Johns Hopkins University, Baltimore, MD, USA.

Crohn disease (CD) is associated with decreased DXA bone mineral density and increased risk of fracture. Our objective was to characterize cortical bone geometry relative to body size and lean mass in children and young adults with CD.

DXA proximal femur scans (Hologic QDR 2000) were obtained in 89 subjects with CD (55 M, 34 F) and 130 healthy controls (52 M, 78 F), ages 4-26 years. Subperiosteal and endosteal diameter, cortical cross-sectional area (CSA), cross-sectional moment of inertia (CSMI), and section modulus (Z) of the proximal femoral shaft were estimated using hip structural analysis software. Lean mass was assessed using whole body DXA. Bone measures and lean mass are strongly influenced by growth, so these variables were expressed as sex-specific standard deviation scores (SDS) relative to subject height derived from linear regression models in the controls. SDS results in CD were compared with controls, adjusted for age, race and Tanner stage. Bone outcomes were then adjusted for lean mass SDS to determine if deficits in bone strength were associated with decreased biomechanical loading.

CD was associated with decreased height and body mass index for age ($p < 0.001$). Lean mass SDS in CD was significantly decreased ($p < 0.001$), compared with controls. Bone geometry SDS in CD are summarized in the Table. CD was associated with significantly decreased subperiosteal diameter, endosteal diameter, and CSMI; Z was marginally decreased. Adjustment for lean mass SDS attenuated the deficits in CSMI and Z; however, CSMI remained significantly decreased in CD ($p = 0.04$), compared with controls.

After adjustment for decreased stature, CD was associated with altered cortical bone geometry, which may result in decreased resistance to bending and torsion. Reduced endosteal expansion counteracted the decreased periosteal dimensions and preserved cortical CSA. However, these structural changes resulted in decreased CSMI and marginally decreased Z. Bone strength deficits may be associated with decreased biomechanical loading in CD.

Proximal Femoral Shaft SDS Relative to Height in CD

Variable	SDS*	95% CI	p
Subperiosteal Diameter	-0.85	-1.20, -0.49	< 0.001
Endosteal Diameter	-1.00	-1.45, -0.55	< 0.001
Cortical CSA	-0.20	-0.53, 0.13	> 0.2
CSMI	-0.53	-0.86, -0.20	0.002
Z	-0.30	-0.63, 0.04	0.08

Vitamin D Status and Measurements of Bone in Perinatally HIV-Infected Children and Adolescents in New York City. S. Arpadi[1], M. Horlick[1], D. McMahon*[2], E. Abrams*[3], S. Bakshi*[4], M. Bamji*[5], R. Lazell*[6], E. Engelson*[7], E. Shane[2]. [1]Pediatrics, Columbia University, New York, NY, USA, [2]Medicine, Columbia University, New York, NY, USA, [3]Pediatrics, Harlem Hospital, New York, NY, USA, [4]Pediatrics, Bronx-Lebanon Hospital Center, New York, NY, USA, [5]Pediatrics, Metropolitan Hospital Center, New York, NY, USA, [6]Pediatrics, St. Lukes-Roosevelt Hospital Center, New York, NY, USA, [7]Medicine, St. Lukes-Roosevelt Hospital Center, New York, NY, USA.

Alterations in bone and mineral metabolism and bone mass accrual are reported in children and adolescents with HIV infection. The purpose of this study is to evaluate Vitamin D status and its relationship to bone mass measurements in HIV infected children and adolescents.

Fifty-six HIV-infected subjects ages 6-16 yr (mean 10.8) were enrolled from 4 New York City outpatient treatment programs. Serum 25-hydroxyvitamin D (25-OHD), total body (TB) and spine (S) bone mineral content (BMC), bone area (BA) and bone mineral density (BMD) by dual x-ray absorptiometry (DXA, Hologic Delphi A) were measured in a cross-sectional study performed between August 2003-March 2004. HIV viral load and CD4+lymphocytes were also measured. No subjects receiving systemic corticosteroids, tenofovir, or with clinically evident bone disease were included. Separate multiple regression analyses were used to test whether BMC, BA, or BMD were significantly associated with serum 25-OHD concentration while adjusting for known or suspected effect modifiers.

Thirty female and 26 males were enrolled including 37 (66%) African-Americans and 19 (34%) Hispanics. All subjects had prior treatment with antiretroviral medication (ARVs) and 51/56 (91%) were receiving ARVs at enrollment. Mean CD4 count and CD4% were 720 ± 349 and 29 ± 10 respectively. Viral load was non-detectable in 14 (25%) with a mean of $13{,}386 \pm 45{,}725$ copies/ml in those with measurable HIV. Median serum 25-OHD concentration was 24 ng/ml (normal: 20-65 ng/ml); 18 (32%) were below normal, including 13 (23 %) with insufficiency (25-OHD > 12 and < 20 ng/ml) and 5 (9%) with frank deficiency (25-OHD < 12 ng/ml). Multiple regression analyses found that serum 25-OHD was significantly associated with TBBMC ($p = 0.05$) and TBBA ($p = 0.04$), but not with SBMC, SBA or SBMD in models that included age, sex, height, weight, race/ethnicity, Tanner stage, HIV viral load, and CD4%.

In conclusion, vitamin D deficiency and insufficiency are highly prevalent in a sample of perinatally HIV-infected children and adolescents living in New York City. Moreover, vitamin D status was a significant predictor of TBBMC and TBBA. Studies of vitamin D supplementation to enhance bone accrual in children and adolescents infected with HIV are warranted.

Whole Body Bone Deficits in Children with Sickle Cell Disease. A. Buison[1], D. Kawchak*[1], J. I. Schall*[1], K. Ohene-Frempong*[2], V. A. Stallings*[1], M. B. Leonard[3], B. S. Zemel[1]. [1]Gastroenterology and Nutrition, Children's Hospital of Philadelphia, Philadelphia, PA, USA, [2]Hematology, Children's Hospital of Philadelphia, Philadelphia, PA, USA, [3]Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Children with sickle cell disease (SCD) experience impaired growth and delayed skeletal and sexual maturation. Deficits in bone mineral content (BMC) have not been well characterized in this population. Our primary objective was to assess whole body BMC (WBBMC) in children with SCD, type SS (SCD-SS) compared to healthy controls with adjustments for height. The secondary objective was to examine the relationship between WBBMC and growth, nutrition, body composition and hematological measures in children with SCD.

WBBMC and body composition were measured using the Hologic QDR 2000 DXA (Bedford, MA) in 90 children with SCD-SS and 198 healthy controls, ages 4 to 19 years old. Skeletal maturation (bone age - chronological age) was determined in children with SCD-SS only. Z-scores for weight (WAZ), height (HAZ), and body mass index (BMIZ) were generated using national reference data. WBBMC and whole body bone area (WBBA) results in the controls were used to generate gender-specific WBBMC z-scores relative to age (WBBMC-age-z) and height (WBBMC-ht-z and WBBA-ht-z). Growth and bone status were compared by Student t-tests. Associations between growth status and hematological measures and WBBMC-ht-z and WBBA-ht-z were assessed by Pearson's correlation coefficient. Multiple linear regression models were developed using log-transformed WBBMC and WBBA and height.

Children with SCD-SS had significantly lower HAZ (-0.5 ± 1.0 vs. 0.3 ± 1.1, $p<0.01$), WAZ (-0.8 ± 1.1 vs. 0.39 ± 1.2, $p<0.01$), and BMIZ (-0.77 ± 1.19 vs 0.29 ± 1.15, $p<0.01$) compared with healthy controls. SCD-SS was associated with significant deficits in WBBMC ($p< 0.001$), adjusted for height, age, pubertal status, and lean body mass. WBBMC-age-z and WBBMC-ht-z were -2.7 ± 7.6 and -0.5 ± 1.0, respectively. They also had deficits in WBBA-ht (mean z-score of -0.6 ± 0.9). Among the children with SCD-SS, WBBMC-ht-z was significantly associated with skeletal maturation ($r=0.53$, $p<0.001$), total hemoglobin ($r=0.23$, $p<0.05$) and hematocrit levels ($r=0.30$, $p<0.001$). After accounting for height, these children have narrow bones (low WBBA-ht) and reduced bone mass (low WBBMC-ht), indicating that they have less cortical bone strength. This suggests that children with SCD-SS achieve suboptimal peak bone mass and may be subject to future bone fractures.

Low Bone Mass by DXA and QCT in Children with Sickle Cell Disease. E. B. Fung[1], A. Lal*[1], B. Kammen*[2], Z. Pakbaz*[1], E. Vichinsky*[1]. [1]Hematology/Oncology, Children's Hospital Oakland, Oakland, CA, USA, [2]Radiology, Children's Hospital Oakland, Oakland, CA, USA.

Multiple factors compromise bone mineralization in patients with sickle cell disease (SCD) including growth and pubertal delay, decreased vitamin D, reduced physical activity, inflammation, and bone marrow expansion. A pilot project was initiated to determine the prevalence of low bone mass in children (9 to19 years) with severe manifestations of sickle cell disease (Hb SS) and to compare dual-energy x-ray absorptiometry (DXA) with quantitative computerized tomography (QCT) in assessing bone mineral density (BMD). All subjects had one or more severe manifestations including multiple hospitalizations, chronic transfusion therapy, growth failure, and/or avascular necrosis. BMD was evaluated by DXA of lumbar spine (L2-4) and hip, and age, gender and ethnic specific Z-scores calculated. Bone mineral apparent density (BMAD) was calculated using published equations. L2-4 BMD was also measured by QCT, and Z-score estimated independently. Dietary calcium intake was evaluated by a standardized questionnaire. Twenty-five children have been recruited of which n=11 are on chronic transfusion therapy. Over 50% of subjects consumed less than the recommendation for calcium intake (diet + supplements). DXA L2-4 BMD Z-score was reduced in 80% of subjects (< -2.0 in n=13; -1.0 to -2.0 in n=7), whereas BMAD Z-score was reduced in 68% of subjects (<-2.0 in n=12; -1.0 to -2.0 in n=5). The total hip BMD Z-score was reduced in 63% (< -2.0 in n=11; -1.0 to -2.0 in n=4). The L2-4 BMD Z-score assessed by QCT was reduced in only 20% of subjects (< -2.0 in n=4; -1.0 to -2.0 in n=1). The BMAD Z-score values obtained by DXA were significantly different from QCT ($p=0.002$, Wilcoxon rank test), but discordant results were more common in subjects receiving transfusion therapy for >6 months ($p =0.028$, chi square). Further analysis of the DXA L2-4 spine BMAD showed reduced values in 77% of girls vs. 58% of boys; 75% of subjects under 14 years of age; 70% of those with poor dietary calcium intake and 82% of the chronically transfused patients. In summary, the majority of children with severe manifestations of SCD evaluated by DXA in this study had low bone mass (Z-score < -1.0). Z-scores measured by QCT were higher than BMAD Z-scores measured by DXA, however discordant results were observed mostly in patients on red cell transfusions for >6 months. BMAD values derived from DXA might prove more appropriate in assessing BMD in children with SCD. Screening for low bone mass in patients with SCD should take place by second decade of life, particularly for patients with severe manifestations of SCD.

Decreased Acid-Induced Bone Resorption in COX-2 Knockout Mice. K. K. Frick, N. S. Krieger, K. LaPlante*, S. B. Smith*, D. A. Bushinsky. Medicine/Nephrology Unit, University of Rochester School of Medicine, Rochester, NY, USA.

Metabolic acidosis initially stimulates physico-chemical bone mineral dissolution, which is followed by cell-mediated bone resorption. Prostaglandin biosynthesis is central to this acid-induced, cell-mediated bone resorption as inhibition of cyclooxygenase activity, the rate limiting step for prostaglandin production, with indomethacin suppresses both the acid-induced stimulation of PGE_2 and consequent calcium (Ca) release. Cyclooxygenase is present in both a constitutive (COX-1) and an inducible (COX-2) form. We utilized two model systems to determine the contribution of COX-2 to cell-mediated, acid-induced bone resorption: mice engineered to have a null mutation in COX-2 and cultured calvariae from normal mice treated with a specific inhibitor (NS398) of this enzyme. To assess the role of COX-2 in acid-induced bone resorption in knockout mice, heterozygotic parents were mated, genotypes of resulting pups were determined by PCR and individual calvariae were incubated in either neutral medium (NTL, pH ~ 7.4, $[HCO_3^-]$ ~ 24 mM) or medium made acidic by a primary reduction in $[HCO_3^-]$ (ACID, pH ~ 7.1, $[HCO_3^-]$ ~ 12 mM) to model metabolic acidosis. Medium was changed at 24 and 48 hr for determination of Ca flux. At 24 hr, Ca efflux in NTL from heterozygotes (+/-) was less than that from wild type (+/+) and efflux from knockouts (-/-) was less than either +/+ or +/-. This graded response in unstimulated calcium release from bone indicates that COX-2 is instrumental in setting the baseline level of bone resorption. In ACID, there was a significant stimulation of net Ca efflux from all genotypes at 24 hr, a time in which acid-induced physico-chemical dissolution predominates. After 48 and after 51 hr, again Ca efflux in NTL from +/- was less than that from +/+ and flux from -/- was less than either +/+ or +/-. In ACID at 48 and 51 hr, when cell-mediated bone resorption predominates, while there was a significant stimulation of net Ca efflux from +/+ and +/- compared to NTL, there was less efflux from -/-. The graded response of acid-induced net Ca efflux to genotype indicates the essential role of COX-2 in this response to acidosis. We then determined the effects of incubating calvariae from normal mice in NTL or ACID, with or without 1 μM NS398. After 48 hr and after 51 hr, ACID induced a significant increase in both medium PGE_2 levels and net Ca flux compared to NTL. NS398 significantly inhibited both the acid-induced increase in PGE_2 and net Ca efflux. Thus genetic deficiency of COX-2 or its specific pharmacologic inhibition significantly decreases the net Ca efflux induced by metabolic acidosis, demonstrating the central role of this enzyme in acid-induced, cell-mediated bone resorption.

Ultrastructural Localisation of Lanthanum in Bone of Chronic Renal Failure Rats Loaded with Lanthanum Carbonate. G. J. Behets*[1], S. C. Verberckmoes[1], L. Oste*[1], A. R. Bervoets*[1], M. Salome*[2], M. E. De Broe*[1], P. C. D'Haese*[1]. [1]Nephrology - Hypertension, University of Antwerp, Wilrijk, Belgium, [2]Id21, European Synchrotron Radiation Facility, Grenoble, France.

We have shown that administration of $La_2(CO_3)_3$ at high doses to CRF rats can induce a mineralisation defect, secondary to an important phosphate depletion due to the pharmacological action of the phosphate binder, rather than being a direct effect of La on bone. In order to further elucidate this finding localisation of La deposited in bone is necessary.

The scanning X-Ray fluorescence microscopy set-up at beamline ID21 of the European Synchrotron Radiation Facility achieves the necessary resolution and sensitivity to localise La that is present at relatively low levels (< 5 μg/g) in bone. A fixed energy X-Ray beam (6.3 keV) was focussed using a Fresnel zone plate to a 1μm probe. X-Ray fluorescence was detected using a solid state Ge detector placed at a 90° angle to the incident beam. Ca and La could be mapped simultaneously using energy windows of 3.52 to 4.12 keV (Ca $K\alpha$ and K_β) and 4.92 to 5.93 keV (La $L_{\beta1}$ and $L_{\beta2}$). Serial Goldner stained sections were used to visualise the scanned area using conventional light microscopy.

In CRF rats loaded orally with $La_2(CO_3)_3$ (12 weeks, 2000 mg/kg/day), bulk bone La concentrations reached values up to 5 μg/g wet weight. La could be demonstrated at the edge of the mineralised bone, at both actively mineralising and quiescent sites. No correlation with the presence of unmineralised osteoid, or the underlying bone pathology (mineralisation defect, hyperparathyroid bone disease or normal bone) could be found. In the presence of hyperparathyroid bone disease, La was also distributed homogeneously throughout the mineralised trabecular bone, and occasionally in resorption areas. Preliminary data in biopsies of patients treated with $La_2(CO_3)_3$ up to 4 years show a similar pattern.

These results suggest no direct correlation between the localisation of La in bone and the presence of either a mineralisation defect or other type of renal osteodystrophy, thereby further strengthening our hypothesis that La does not exert a direct effect on bone metabolism in CRF.

Reversibility of Impaired Mineralisation Associated with Lanthanum Carbonate Induced Phosphate Depletion in Chronic Renal Failure (CRF) Rats. A. R. Bervoets*, L. Oste*, G. J. Behets*, P. C. D'Haese*, M. E. De Broe*. Nephrology - Hypertension, University of Antwerp, Wilrijk, Belgium.

Lanthanum (La) carbonate has recently been introduced as a new phosphate-binding agent. We have previously shown that oral administration of La carbonate at high doses (1000 mg/kg/day) during 12 weeks can induce phosphate depletion accompanied by a mineralisation defect in CRF rats. Treatment with sevelamer, a non metal-containing, non absorbed phosphate binder induced a similar effect on bone. This strongly suggests that the mineralisation defect occurred secondary to the phosphate depletion, and was not due to a direct effect of La accumulation in bone.

To further substantiate this hypothesis, male CRF rats (5/6th nephrectomy) received La carbonate for 2 or 6 weeks at a dose of 2000 mg/kg/day. Animals were sacrificed and bone samples for histomorphometry and measurement of the bone La content were taken immediately at the end of the treatment period, and after a washout period of 2 and 8 weeks. Control animals received vehicle only. After 2 weeks of treatment, the bone La level was 1.05 ± 0.11 µg/g (vs. 1.00 ± 1.13 µg/g in controls) and 5 out of 6 animals (83 %) showed signs of impaired mineralisation compared to chronic renal failure controls (1 out 7 animals). After a 2 week washout period, 7 out of 8 animals (87 %) showed normal bone histology in the presence of unchanged bone La levels (1.32 ± 0.35 µg/g); after an 8 week washout period, La levels still remained unchanged, yet 5 out of 6 animals (83 %) had normal bone. A similar evolution was noted in the animals treated with oral La for 6 weeks. Here bone La levels were even slightly increased up to 1.87 ± 0.40 µg/g at 6 weeks (vs. 0.51 ± 0.14 µg/g in controls), and after a 2 week washout period remained at the same level (1.89 ± 0.61 µg/g at 6 weeks). Bone histology, however, showed a reduction in the number of animals with an impaired mineralisation from 4 out of 7 (57 %) at 6 weeks to 1 out of 4 (25 %) after 2 weeks washout, and 2 out of 7 (28 %) after 8 weeks washout. La loading went along with a substantial hypophosphaturia in all animals. These results show that bone histology in CRF animals improved after a 2 and 8 weeks washout period, despite the fact that La remains present in the bone. This provides further support for our hypothesis that the impaired mineralisation is secondary to a phosphate depletion, and is not the direct consequence of La accumulation in bone.

Treatment of a Rat Model of High-turnover Renal Osteodystrophy by Systemic Administration of BMP-7. R. A. Dodds, Y. Wang-Fischer*, A. C. Hughes, D. L. Xu, J. A. Tullai*, F. X. Farrell*. Growth Factors, Johnson&Johnson PRD, Raritan, NJ, USA.

BMP-7 (OP-1) is highly expressed in the kidney during development and in adult life. However, if the kidney experiences an acute injury, e.g., ischemia, BMP-7 mRNA levels decline in parallel with loss of renal.function. Chronic renal failure (CKF) is a progressive disorder leading to end stage renal disease. Present treatments (ACE inhibitors) do not impact the deleterious effects of CKF, including renal osteodystrophy (RO). Skeletal abnormalities in patients with CKF include high bone turnover, fracture and pain. This study evaluated the efficacy of BMP-7 in preserving renal function as well as preventing RO in the rat CKF 5/6 nephrectomy model. Rats (250g) were nephrectomized (NPX): a right contra-lateral NPX was followed in 10 days by left total NPX. Sham surgery was the same procedure minus NPX. The rats received BMP-7 (100 ug/kg), or vehicle i.v, weekly, 10 days after the 2nd surgery, for 6 weeks. Ten and three days before sacrifice, rats were injected (sc) with demeclocycline and calcein, and the proximal tibia processed for histomorphometry. BMP-7 improved renal function (increased GFR, elimination of hematuria, leucocyturia and proteinuria). PTH levels (pg/ml ± SD) were increased in the CKF group v sham (254.7 ± 74 v 405.1 ± 38). The levels were normalized in the BMP-7 group (272.8 ± 43). % Tb.Ar was 18% higher in CKF v sham*, and further increased (34% v sham) in the BMP-7 group. This resulted from an increase in Tb.N, and caused a 26% decrease (CKF-BMP-7 v sham) in Tb.Sp. There was a significant increase in %O.Pm (56%*) which was reduced in the BMP-7 group (-22%) to sham levels. There was an increase (22%) in % Er.Pm in the CKF v sham, that was normalized in the BMP-7 group. Oc.No. was the same in all groups. There was a 15%* increase in MAR in the CKF group v sham that was maintained in the BMP-7 group. BFR/BV/BPm were significantly increased* in the CKF group v sham. These parameters were lowered in the BMP-7 group (to sham level). Elevation of BFR/TV reflects de novo modeling, a feature of PTH action; there was a 47 and 45% increase* in BFR/TV in the CKF and BMP-7 treated group respectively (v sham). There was an 83%* increase in Ac.F in the CKF group v sham, which was reduced by 32% in the BMP-7 group. Wall width (W.Wi) was unchanged in the CKF groups v sham, but was significantly increased v sham in the BMP-7 group (6%*). In summary, CKF resulted in an increase in trabecular bone mass, attributed to an increase in bone turnover (2^0 hyperparathyroidism), with bone formation exceeding bone resorption. With BMP-7 treatment, bone turnover decreased (reduced PTH), but de novo bone formation and an increase in mean W.Wi resulted in the maintenance of increased bone mass (BMP-7 effects). *p<0.02 v sham

RANKL and TRAP-5b Are Markers of Bone Destruction in Two Rat Models of Inflammatory Arthritis. P. J. Kostenuik[1], M. Stolina*[2], B. Bolon*[3], S. Adamu*[1], F. Asuncion*[1], S. Morony[1], G. Schett*[4], S. Middleton*[2], U. Feige*[2], D. Zack*[2]. [1]Metabolic Disorders, Amgen, Inc., Thousand Oaks, CA, USA, [2]Inflammation, Amgen, Inc., Thousand Oaks, CA, USA, [3]Pathology, Amgen, Inc., Thousand Oaks, CA, USA, [4]Rheumatology, Medical University of Vienna, Vienna, Austria.

Inflammatory arthritis is associated with local bone erosions and systemic bone loss. We hypothesize that RANKL is an important and common mediator for both forms of bone loss. RANKL is elevated in the serum of arthritic patients, and serum RANKL levels correlate with joint destruction. RANKL mRNA is also highly expressed within the inflamed joints of arthritic rats and mice. We measured RANKL in the serum and joint extracts of rats, using two distinct models of inflammatory arthritis that are associated with bone erosions and systemic osteopenia.

Adjuvant arthritis (AdA) was induced in male Lewis rats using heat-killed mycobacteria in paraffin oil, while CIA was induced in female Lewis rats with collagen II in incomplete Freund's adjuvant. Rats (n = 8 arthritic and 2 healthy control/day) were necropsied intermittently from 5 days before disease onset to onset + 27 days. Inflammation (paw swelling) and skeletal destruction (bone erosions and osteoclasts) were quantified, and RANKL and TRAP-5b (an osteoclast-specific enzyme) were measured in sera and in joint extracts throughout disease progression.

RANKL was increased by 2-3 fold in the serum and by more than 10 fold in arthritic joint extracts of AdA and CIA rats. The induction of RANKL preceded the onset of bone erosions and the appearance of newly activated osteoclasts in arthritic joints. TRAP-5b, a novel bone resorption marker, increased by more than 10 fold in paws of both AdA and CIA. Concomitantly, progressive and significant bone loss was observed locally (in arthritic joints) and systemically (lumbar vertebrae) in both models. The AdA model was typically associated with more dramatic changes in each of these endpoints compared to the CIA model.

RANKL levels are increased significantly in both serum and joint extracts during early disease progression in two distinct rat models of rheumatoid arthritis. TRAP-5b, a novel osteoclast marker, was also significantly elevated in arthritic joints. These data suggest that bone resorption is elevated locally and systemically during the early stages of inflammatory arthritis. Time course analysis of biochemical markers and bone histomorphometry suggest that RANKL plays a pathogenic role in these processes.

Bone Mass Changes and Bone Turnover in Children with Early Juvenile Idiopathic Arthritis and Healthy Controls. G. Lien*[1], A. M. Selvaag*[1], B. Flatø*[1], M. Haugen*[2], O. Vinje*[1], D. Sørskaar*[1], K. Dale*[1], T. Egeland*[1], Ø. Førre*[1]. [1]Department of Rheumatology, Rikshospitalet University Hospital, Oslo, Norway, [2]Norwegian Institute of Public Health, Oslo, Norway.

The aim of this study was to explore early changes and predictors of bone mass in children with juvenile idiopathic arthritis (JIA) in order to identify patients who will develop bone mass reductions.

We conducted a prospective, cohort study of 108 children with early JIA (ages 6 to18, mean disease duration 19.3 months), and 108 healthy children randomly selected from the National Population Register, individually matched for age, gender, race, and county of residence. Bone mass and changes in total body, spine, femur and forearm bone mineral density (BMD), bone mineral content (BMC), and body composition were measured with DXA scanner (Lunar Expert) at base-line and follow-up a mean of 24 months later. Disease activity, growth, nutrition, physical activity and biochemical parameters of bone turnover were examined as possible predictors for the bone mass changes. Low bone mass was defined as z score <1SD below the age-specific mean for healthy individuals.

Among the 200 children participating at follow-up, the 100 healthy children had accelerated gains in total body BMC (P=0.035), distal radius BMC (P<0.001) and total body lean mass (P=<0.001), compared to the 100 JIA children by paired sample T-test. Low total body BMC was observed in 24% of the patients, and in 12% of the healthy children (P=0.045). Bone formation, bone resorption and weight-bearing activities were decreased in the patients compared to the healthy children (P<0.001, P<0.001 and P=0.013 respectively). The presence of JIA, serum bone-specific alkaline phosphatase, serum C-telopeptide-1, and weight-bearing activities were statistical significant predictors for the change in total body BMC by multiple regression analysis. Age-and sex adjusted total body BMC were lower in patients with polyarticular than with oligoarticular disease onset (P=0.023). JIA patients had moderate, but clinically important reductions in bone mass, bone turnover and lean mass early in the disease course. The most important independent predictors of bone mass changes were markers of bone turnover and weight-bearing physical activities.

A 2-Year Prospective Study of the Relationship between Bone Biochemical Markers (BBM) and Change in Bone Mineral Density (BMD) in Systemic Lupus Erythematosus (SLE). C. Lee*[1], A. B. Chadha*[1], D. D. Dunlop*[2], O. Almagor*[2], C. B. Langman[3], H. Price*[3], S. Spies*[4], R. Ramsey-Goldman[1]. [1]Division of Rheumatology, Northwestern University, Chicago, IL, USA, [2]Institute for Health Services Research & Policy Studies, Northwestern University, Chicago, IL, USA, [3]Pediatrics, Children's Memorial Hospital, Chicago, IL, USA, [4]Radiology, Northwestern University, Chicago, IL, USA.

The purpose of this study was to determine the relationship between BBM and changes in BMD in women with SLE. 91 women with SLE had BMD measured (hip, spine, distal forearm) at baseline and at 2-years. 3 BBM were measured at baseline: 1) osteocalcin (OC), 2) bone alkaline phosphatase (BAP), and 3) urine N-telopeptide (NTX). Women completed a self-administered lifestyle questionnaire and medication survey. Data on disease features, including disease duration, renal involvement, the American College of Rheumatology/Systemic Lupus International Collaborative Clinics Damage Index (ACR/SLICC-DI) excluding osteoporosis, were collected. Pearson correlations coefficients were determined to assess the strength of the relationship between individual BBM and change in BMD. Women with SLE had a mean age at study visit of 43.9 ±11.4 years, 16.5% were African-American, and had a mean BMI of 26.8 ±7.3 kg/m^2. The mean age at SLE diagnosis was 34.7 ±12.4 years with a mean ACR/SLICC-DI of 1.2 ±1.8. 44% reported currently taking corticosteroids (CS) (mean dose 11.0 ±11.3 mg/day), mean duration of use was 6.7 ±6.9 years, mean daily calcium intake was 1289.8 ±752.9 mg/day, 9.9% were currently smoking, 52.7% reported drinking alcohol and 82.0% reported drinking caffeine. Baseline values for all BBM were near normal limits: 1) OC (8.3 ±8.0 ng/ml), 2) BAP (17.0 ±7.7 U/L), and 3) NTX (36.7 ±38.9 nM/mM). Higher baseline values of OC and NTX were significantly associated with less change in BMD over 2 years at the distal forearm irrespective of menopause status, current CS or plaquenil (PLQ) use. However, only higher baseline value of BAP was significantly related to less change in distal forearm BMD in post-menopausal women (r = -0.36, p=0.04) and in those taking PLQ (r = -0.54, p < 0.0001).

BMD Site	Baseline BMD* (SD)	Mean change in BMD* (SD)	Correlation coefficients for BBM and Change in BMD over 2-years for women with SLE					
			OC		BAP		U-NTX	
			r	p	R	p	r	p
Hip	0.901 (±0.15)	-0.007 (±0.04)	0.10	0.35	0.09	0.39	0.10	0.37
Spine	0.983 (±0.14)	0.009 (±0.05)	0.13	0.24	0.12	0.26	0.06	0.60
Distal forearm	0.680 (±0.07)	-0.012 (±0.03)	-0.37	**0.006**	-0.14	0.20	-0.43	**<0.0001**

*g/cm^2

BBMs at baseline were near normal. A limited relationship between baseline OC, BAP, and NTX with change in BMD at hip and spine was noted, however, higher levels of BBM maybe associated with increased change in distal forearm BMD.

SA515

A 2-Year Prospective Study of the Relationship between Measures of Calcium Homeostasis (MCH) and Change in Bone Mineral Density (BMD) in Systemic Lupus Erythematosus (SLE). C. Lee*[1], A. B. Chadha*[1], D. D. Dunlop*[2], O. Almagor*[2], C. B. Langman[3], H. Price*[3], S. Spies*[4], R. Ramsey-Goldman[1]. [1]Division of Rheumatology, Northwestern University, Chicago, IL, USA, [2]Institute for Health Services Research & Policy Studies, Northwestern University, Chicago, IL, USA, [3]Pediatrics, Children's Memorial Hospital, Chicago, IL, USA, [4]Radiology, Northwestern University, Chicago, IL, USA.

The utility of MCH to assess bone health in SLE is not known. The purpose of this was to determine the relationship between MCH and changes in BMD in women with SLE. 91 women with SLE had BMD measured (hip, spine, distal forearm) at baseline and at 2-years. Two MCH measured at baseline included: 1) 25-hydroxyvitamin-D (25-OH-D) and 2) intact parathyroid hormone (PTH). All women completed a self-administered lifestyle questionnaire and medication survey, including use of plaquenil (PLQ). Data on disease features, including disease duration, renal involvement, and the American College of Rheumatology/Systemic Lupus International Collaborative Clinics Damage Index (ACR/SLICC-DI) excluding osteoporosis, were collected. Pearson correlations coefficients were determined to assess the strength of the relationship between individual MCH and change in BMD. Women with SLE had a mean age at study visit ±SD of 43.9 ±11.4 years, 16.5% were African-American (AA), and had a mean BMI of 26.8 ±7.3 kg/m^2. The mean age at SLE diagnosis was 34.7 ±12.4 years with a mean ACR/SLICC-DI of 1.2 ±1.8. 44.0% of women reported currently taking corticosteroids (CS) with a mean dose of 11.0 ±11.3 mg/day and the mean duration of use was 6.7 ±6.9 years. For all women, the mean daily calcium intake was 1289.8 ±752.9 mg/day, 9.9% were currently smoking, 52.7% reported drinking alcohol, and 82.0% reported drinking caffeine. The mean baseline value for 25-OH-D (13.3 ±6.3 ng/mL) was low, but PTH (29.1 ±20.9 pg/ml) value was normal. Baseline values of 25-OH-D and PTH demonstrated no significant correlation with mean changes in BMD at the hip, spine or distal forearm over 2-years. Mean baseline values for 25-OH-D and PTH were not significantly related to mean changes in BMD at any of the three anatomical sites regardless of current (PLQ) use.

BMD Site	Baseline BMD* (SD)	Mean change in BMD* (SD)	Correlation coefficients for MCH and change in BMD at 2-years for women with SLE			
			25 (OH)-D		PTH	
			r	p	r	p
Hip	0.901 (±0.15)	-0.007 (±0.04)	0.09	0.43	0.08	0.47
Spine	0.983 (±0.14)	0.009 (±0.05)	0.05	0.66	0.09	0.40
Distal forearm	0.680 (±0.07)	-0.012 (±0.03)	-0.06	0.56	-0.14	0.22

*g/cm^2

In summary, there appears to be no significant relationship between MCH at baseline with change in BMD over 2 years in women with SLE.

Disclosures: ***C. Lee****, None.*

SA516

Longitudinal Analysis of Change in Bone Mineral Density (BMD) in Women with Systemic Lupus Erythematosus (SLE). C. Lee*[1], A. B. Chadha*[1], D. D. Dunlop*[2], O. Almagor*[2], C. B. Langman[3], H. Price*[3], S. Spies*[4], R. Ramsey-Goldman[1]. [1]Division of Rheumatology, Northwestern University, Chicago, IL, USA, [2]Institute for Health Services Research & Policy Studies, Northwestern University, Chicago, IL, USA, [3]Pediatrics, Children's Memorial Hospital, Chicago, IL, USA, [4]Radiology, Northwestern University, Chicago, IL, USA.

There is limited prospective data on change in BMD in SLE. The purpose of this study was to compare change in BMD over a 2-year period at the hip, lumbar spine and distal forearm between SLE (LW) and control women (CW). LW (n=97) and CW (n=97) matched on age, race, and menopause status underwent BMD measurements (hip, spine, distal forearm) at baseline and at 2-years. All women completed a self-administered lifestyle questionnaire and medication survey. Data on disease features, including disease duration, renal involvement, and the American College of Rheumatology/Systemic Lupus International Collaborative Clinics Damage Index (ACR/SLICC-DI) excluding osteoporosis, were assessed. 2-year changes in BMD from baseline values were compared for LW and CW using generalized estimating equations (GEE) to account for the matched case/control design. Case/control differences in 2-year change and 95% confidence intervals (CI) from GEE were calculated. LW and CW were similar in their mean current age (46.6 ±11.5 vs. 47.0 ±11.2 years) and proportion of women who were: African-American (AA) (17.5% vs. 17.5%), menopause status (40.2% vs. 38.1%), and current smoking (9.3% vs. 13.3%). For LW, mean age at SLE diagnosis was 34.6 ±12.6 years with a mean ACR/SLICC-DI of 1.2 ±1.8, 54.6% had disease duration ≥5 years, and 25.8% had renal disease. LW compared with CW reported more corticosteroid (CS) use (75.3% vs. 1.0%) and mean daily calcium intake of (1269.1 ±756.8 vs. 1015.8 ±639.1 mg/day). Mean duration of CS use in LW was 7.05 ±7.0 years with an average CS dose of 14.8 ±11.7 mg/day. LW and CW experienced minimal change in BMD at all sites over 2 years. Similar findings for mean change in BMD were observed for pre-/post-menopausal, Caucasian and AA women with and without SLE.

	Mean change in BMD* measurements over 2-years ±SD		Case/Control Difference in 2-Year Change in BMD* (95% CI)

Effects of Neurotrophic Factors on Osteoblast Growth and Mineralization. C. Moran*[1], J. Farley[2], T. Linkhart[3]. [1]Anatomy, Loma Linda University, Loma Linda, CA, USA, [2]Biochemistry, Loma Linda University, Loma Linda, CA, USA, [3]Pediatrics, Loma Linda University, Loma Linda, CA, USA.

Numerous clinical and experimental studies indicate that the nervous system influences the regulation of bone growth, remodeling, and repair. Intact neural innervation appears to be essential for proper bone maintenance; bone deprived of neural innervation demonstrates significantly altered growth, repair, and remodeling. Bone receives innervation from both sensory and autonomic nerves. Neuropeptides found commonly in sensory nerves in bone include calcitonin gene-related peptide (CGRP) and Substance P. We investigated the effects of these neuropeptides on mouse osteoblast growth and differentiation in vitro. Murine calvarial osteoblasts were isolated and cultured using standard techniques. Osteoblasts were randomly plated in multi-well plates and grown with and without neuropeptides. Experimental wells received either CGRP or Substance P at concentrations of 0.1-10 micrograms/ml. Cellular alkaline phosphatase and total cell protein levels were measured after 24-hours and 48-hours of treatment. CGRP induced a dose-dependent increase in alkaline phosphatase levels (71%, $p< 0.017$) and total cell protein levels (65%, $p< 0.0004$) in calvarial osteoblasts. Alkaline phosphatase and cell protein were modestly but not significantly increased in calvarial osteoblasts treated with Substance P. MC3T3-E1 cells were used to determine the effect of CGRP and Substance P on osteoblastic mineralization. MC3T3-E1 cells were grown in mineralization media with and without addition of neuropeptides. After 1-3 weeks of treatment, cells were fixed and stained with alizarin red. Both CGRP and Substance P reproducibly increased the rate and extent of mineralization in MC3T3-E1 cells as shown by increased staining with alizarin red (Figure 1). These findings suggest that neuropeptides released from neurons in bone are involved with the regulation of osteoblast growth and mineralization.

Calcitonin Treatment Rescues Calcitonin-null Mice from Excessive Bone Resorption during Lactation. J. P. Woodrow[1], A. O. Hoff[2], R. F. Gagel[2], C. S. Kovacs[1]. [1]Memorial University of Newfoundland, St. John's, NF, Canada, [2]University of Texas MD Anderson Cancer Center, Houston, TX, USA.

We are exploring the role of calcitonin (CT) and calcitonin gene-related peptide (CGRP) in regulating maternal bone metabolism during lactation. Using CT/CGRP gene ablated (*Ct*-null) mice and PIXIMUS bone densitometer, we have reported that *Ct*-null mice lose more trabecular bone mineral content (BMC) during lactation than wt siblings, and recover fully after weaning. Expressed as percent of peak total spine BMC at term, *Ct*-null mice dropped during lactation to 49.3% while wt mice dropped to 70.5% of BMC ($p<0.0002$ by ANOVA).

We now present further studies designed to elucidate the mechanism of the loss and to determine if it can be prevented by treatment with calcitonin.

Urinary excretion of deoxypyridinoline (corrected for creatinine) was no different between *Ct*-null and wt at baseline or during pregnancy, but was increased during lactation in *Ct*-null versus wt (11.9 ± 1.4 versus 2.6 ± 1.8, $p<0.004$ by ANOVA on all time points). Serum osteocalcin increased slightly in lactation but was no different between genotypes. Compared to pre-pregnancy, serum PTH was suppressed normally during pregnancy in both *Ct*-null and wt, but was increased only in *Ct*-null during lactation (55.6 pg/ml ± 11.9 versus 8.9 ± 12.4 pg/ml, $p =0.069$). Micro-CT demonstrated increased trabecular thinning and spacing during lactation which was even greater in *Ct*-null than in wt ($p<0.01$).

Further experiments have used salmon calcitonin versus saline versus CGRP administered once daily intramuscularly to pregnant mice beginning at delivery and throughout 21 days of lactation. Implantable pumps were not used due to the inhibitory effect on lactation that surgery would impose. A mean dose of 10 IU of calcitonin was determined in preliminary experiments to be effective in reducing lactational bone mineral content losses. To date 6 *Ct*-null mice have received a full course of calcitonin treatment and 3 have received a full course of saline injections; none have yet completed a full course of CGRP treatment. Compared to peak of pregnancy, *Ct*-null mice treated with saline dropped to $59.5 \pm 2.1\%$ of BMC while *Ct*-null mice treated with calcitonin dropped to 70.1 ± 1.5 % ($p<0.005$).

In summary, *Ct*-null mice lose more trabecular BMC during lactation through a mechanism that involves increased bone resorption and possibly increased PTH secretion. This excess bone resorption appears to be specific to loss of calcitonin since treatment with calcitonin reduced the lactational loss to a value that was no different than the normal wt value.

We conclude that one role of calcitonin is to regulate the losses in BMC that occur during lactation; in its absence, the losses are more severe.

CGRP Decreases Osteoprotegerin Expression in Human Osteoblast-Like Cells. E. Mrak*[1], I. Villa*[2], A. Rubinacci[2], F. Guidobono*[1]. [1]Dept. of Pharmacology Chemotherapy and Medical Toxicology, University of Milano, Milano, Italy, [2]Bone Metabolic Unit, Scientific Institute H San Raffaele, Milano, Italy.

Among the neuropeptides described in bone, calcitonin gene-related peptide (CGRP) was shown to exert an effect on bone metabolism. In our previous study we have demonstrated that CGRP induces cell proliferation and cAMP accumulation in human osteoblast-like cells (hOB). cAMP is one of the second messenger systems that modulates osteoprotegerin (OPG) production, an endogenous inhibitor of osteoclastogenesis produced by hOB. We therefore studied if CGRP anabolic action on bone could be exerted by regulating the OPG/RANKL/RANK system through the stimulation of cAMP production. First we demonstrated by Reverse Transcriptase PCR that hOB express the CGRP receptor, formed of the calcitonin receptor like receptor (CRLR) and its accessory protein, the receptor activity modifying protein-1 (RAMP-1). Then we treated the cells with human CGRP at different concentrations (0.1nM-10nM), and we determined OPG in the conditioned media of the cells by Elisa immunoassay after 24h and 48h treatment. While after 24h treatment there is no evidence of a change in the OPG secretion, after 48h treatment CGRP inhibited OPG secretion in a dose dependent manner with a maximal effect at the concentration of 10nM. To assess whether or not the effect of CGRP on OPG secretion was on the protein expression we analysed OPG mRNA levels after 6h and 24h of CGRP treatment by Real-Time PCR. OPG mRNA decreased in a significant manner ($p<0.05$) after 6h and remained suppressed for 24h after CGRP (10nM) treatment, thus indicating that the peptide acts on OPG protein expression.

In conclusion CGRP seems to have a potential pro-osteoclastogenic effect, reducing the hOB expression of OPG, the decoy receptor of RANKL. It is therefore likely that the bone anabolic action of CGRP also involves the regulation of bone formation/resorption coupling by inducing a shift of the enhanced bone remodeling to a positive balance.

PTH Regulates Akt/PKB Activity in Opossum Kidney (OK) Cells. P. Sarkar*, E. Dillard*, J. A. Cole. Microbiology and Mol Cell Sciences, University of Memphis, Memphis, TN, USA.

The G protein-coupled receptor (GPCR) agonist PTH activates receptors (PTH1R) coupled to adenylyl cyclase (AC) and phospholipase C (PLC) with cAMP/PKA and/or Ca^{2+}/PKC mediating PTH responses in target tissues. ERK1/2 (ERK) represents a point of signaling convergence for growth factor- and GPCR-dependent regulation of proliferation and differentiation. Several studies have shown that PTH increases ERK activity in kidney and bone. In addition, EGF receptor (EGFR) transactivation plays a role in PTH-induced ERK stimulation in proximal tubule-like OK cells (*Endocrinol 140: 5571-5579)* and TMOb osteoblasts (*Mol Endocrinol 17:1607*). GPCRs agonists also converge on growth factor signaling by activating the pro-survival ser/thr kinase Akt and inhibiting apoptosis. In this study we assessed Akt activation by PTH and the role of AC, PLC and the EGFR in mediating PTH responses. Changes in Akt activity were determined by Western analysis with an activation-specific anti-phosphoSer^{473}Akt antibody. ERK activity was also monitored with an activation-specific anti-phosphoThr^{203}-phosphoTyr^{204} antibody. PTH-stimulated Akt activity increased within 1min and persisted for at least 60 min. PTH doses as low as 10^{-11} M increased Akt activity and maximal responses occurred at 10^{-7} M. ERK activation by PTH displayed a similar time- and dose-dependency. EGF also caused dose-dependent Akt activation with a time course similar to that of PTH. Treatment with the AC activator forskolin or the PKC activator PMA stimulated Akt phosphorylation, suggesting cAMP and/or PKC mediate the PTH response. The Ca^{2+} ionophore ionomycin increased Akt activity while chelation of intracellular Ca^{2+} with EGTA-AM reduced Akt activation by ionomycin and PTH. These data suggest Ca^{2+} mediates at least part of PTH-dependent Akt and ERK activation. ERK activation was similarly affected by ionomycin and EGTA-AM. The PI 3-kinase (PI3K) inhibitors wortmannin and LY294002 and the EGFR-selective inhibitor AG1478 reduced both PTH- and EGF-dependent Akt and ERK activation. Thus PI3K and the EGFR appear to lie downstream of the PTH1R and upstream of Akt and ERK. These results indicate that PTH activates Akt through multiple signals including cAMP, PKC, Ca^{2+} , PI3K and the EGFR. In addition, these data may indicate a role for PTH in protecting kidney cells from apoptosis by activating cell survival pathways.

Endogenous PKI$_\gamma$ Regulates PTH-induced Immediate Early Gene Expression. X. Chen[1], J. C. Dai[1], S. A. Orellana*[2], E. M. Greenfield[1]. [1]Orthopaedics, Case Western Reserve University, CLeveland, OH, USA, [2]Pediatrics, Case Western Reserve University, CLeveland, OH, USA.

Parathyroid hormone (PTH) stimulates both bone resorption and bone formation primarily by activating cAMP/protein kinase A (PKA) signaling and affecting the expression of immediate-early genes, such as IL-6 and *c-fos*. Our previous results showed that the primary mechanism responsible for termination of PKA activity, CREB phosphorylation, and immediate-early gene expression following PTH stimulation acts downstream of receptor desensitization, adenylyl cyclase activation, and cAMP degradation (Am J Physiol Cell Physiol 283:1432-40, 2002). We hypothesized that inhibition of PKA activity by the protein kinase inhibitor (PKI) family terminates transcription factor phosphorylation and gene expression. We found that PKI$_\gamma$ mRNA and protein are constitutively expressed in osteoblasts and fibroblasts at high levels, while PKIα and PKI$_\beta$ are weakly expressed. Therefore, to test our hypothesis, *in vitro* transcribed siRNA duplexes directed against the PKI$_\gamma$ coding region were transfected into ROS17/2.8 cells. Knock down of PKI$_\gamma$ mRNA and protein was virtually complete after 24 hours. Knock down resulted in increased levels of IL-6 and *c-fos* mRNAs induced by PTH at early time periods (≤ 1 hour). Knock down also extended the duration of mRNA induction (≥ 6 hours vs. 2 hours in mock-transfected cells). The effects of PKI$_\gamma$ knock down were confirmed using ROS17/2.8 clones stably transfected with PKI$_\gamma$ antisense constructs in the Tet-Off expression system. After 48 hours of tetracycline withdrawal, two independent antisense clones exhibited effects similar to those observed with siRNA. Controls included antisense clones with tetracycline as well as sense and irrelevant clones + tetracycline. PKI$_\gamma$ contains a potent nuclear export signal (NES) and likely inhibits PKA activity to terminate its effects on PTH-induced gene expression and then transports PKA out of the nucleus since we found that (1) PKI$_\gamma$ and all three isoforms of the catalytic subunit of PKA are rapidly re-exported to the cytoplasm following PTH-induced nuclear translocation, (2) PKI$_\gamma$ knock down blocks nuclear export of PKA, and (3) although PKA catalytic subunits lack a NES, the NES inhibitor, Leptomycin B, blocks nuclear export of both PKI$_\gamma$ and PKA. However, Leptomycin B has no effect on nuclear PKA activity, CREB phosphorylation, or immediate-early gene expression. Nuclear export is therefore not required and PKI$_\gamma$ binding is sufficient to terminate nuclear PKA signaling. These findings are the first in any cell type showing that endogenous PKI$_\gamma$ regulates PKA signaling.

Parathyroid Hormone (PTH) Is Not Required to Restore Skeletal Mineral that was Lost During Lactation. K. L. Buckle[1], N. J. Fudge*[1], A. C. Karaplis[2], C. S. Kovacs[1]. [1]Memorial University of Newfoundland, St. John's, NF, Canada, [2]McGill University, Montreal, PQ, Canada.

During lactation, the maternal skeleton temporarily demineralizes to provide calcium to milk, and then the mineral is fully restored after weaning. The demineralization occurs due to the effects of PTH-related protein (PTHrP), produced by mammary tissue, which acts in concert with lower estrogen levels during lactation to stimulate bone resorption. In contrast, the mechanism controlling the restoration of mineral after weaning is not established. Limited data from humans has shown increases in serum PTH after weaning, which has led to speculation that PTH may regulate restoration of mineral to the maternal skeleton during that time frame.

To determine if PTH is required for normal mineral homeostasis during pregnancy and lactation, and in particular, for restoration of mineral after weaning, we studied mice that lack PTH (*Pth* null) and compared them to their wt and *Pth*+/- sisters.

Pth mice were backcrossed into Black Swiss for at least 4 generations and maintained by mating *Pth*+/- mice together. All mice consumed a standard chow containing 1% calcium. First degree relatives were chosen for study beginning at 12 weeks of age, after sexual maturity and the attainment of peak bone mass in mice. Total body and regional (spine, femur) bone mineral content (BMC) was measured by DXA (PIXImus, Lunar) every other day during 70 day reproductive cycles (baseline, pregnancy, lactation, post-weaning). Blood and urine were collected for serial assessment of minerals and hormones.

Pth null mice were hypocalcemic with ionized calcium of 0.89 ± 0.04 mmol/l versus 1.28 ± 0.04 mmol/l in wt. The ionized calcium did not change significantly during pregnancy, lactation and post-weaning in *Pth* null mice or siblings. Compared to their respective pre-pregnancy BMC values, total body BMC rose during pregnancy to a peak of 112 ± 3% in *Pth* nulls (112 ± 3% in wt and 114 ± 2% in *Pth*+/-, p=NS), and fell during lactation to a trough value of 91 ± 5% in *Pth* nulls (83 ± 3% in wt and 86 ±3% in *Pth*+/-, p=NS). Regional BMC values were also no different among genotypes. All BMC values returned to baseline within three weeks, with no significant differences among the time to recovery by genotype.

In summary, *Pth* null mice were hypocalcemic and this did not change during pregnancy or lactation. As compared to their siblings, *Pth* null mice achieved a similar increment in BMC during pregnancy, lost a comparable amount of BMC during lactation, and recovered fully to baseline without any delay.

In conclusion, PTH is not required to maintain mineral homeostasis in the pregnant or lactating mouse, and in particular, is not required to restore skeletal mineral content that was lost during lactation.

The Skeletal Anabolic Effect Of Parathyroid Hormone Is Not Dependant On Nitric Oxide. J. Davies*, C. J. Jagger*, J. W. Chow. Cellular Pathology, St George's Hospital Medical School, London, United Kingdom.

Parathyroid hormone (PTH) is currently the only anabolic agent licenced for treatment of osteoporosis. It is considered to act via the cAMP-protein kinase A and protein kinase C pathways, as well as calcium-signalling pathways. Nitric oxide (NO) is a well-recognised signal transduction molecule. Although no effect has been observed with PTH on bone cells *in-vitro*, NO release has been demonstrated in PTH-treated endothelial cells. To investigate whether the anabolic action of PTH is mediated by NO, we analysed the bone formation response to intermittent administration of PTH in eNOS $^{-/-}$ mice .

PTH (40 ugram/kg sc) was given once daily to 19 week old eNOS $^{-/-}$ and wild-type mice for 6 days. Animals were killed after 8 days, following two spaced fluorochrome lables. Bone histomorphometry was performed on the tibial metaphysis. We found a 4 fold increase in cancellous bone formation rate in PTH-treated wild-type mice compared with vehicle-treated animals. eNOS $^{-/-}$ mice showed a similar increase in bone formation rate as wild-type animals. There was no difference in response between males and females. There was no significant increase in cancellous bone volume after this short period of PTH administration.

The lack of blunted osteogenesis in eNOS $^{-/-}$ animals suggests that the anabolic effect of PTH is not dependant on nitric oxide.

Arrestin Mobilization Is Facultative for PTH Receptor Endocytosis. W. B. Sneddon[1], P. A. Friedman[2]. [1]Dept. of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [2]Depts. of Pharmacology and of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

Arrestins are adaptor proteins that play a critical role in desensitizing and internalizing G protein coupled receptors. Agonist occupied receptors activate cognate G proteins, which in turn activate various downstream effectors, propagating the signal. The transduction cascade is terminated, i.e., desensitized, by receptor phosphorylation followed by arrestin binding. High affinity arrestin binding not only uncouples the receptor from its G protein as part of the desensitization process, but also targets the receptor for endocytosis in clathrin-coated pits. The role of arrestin mobilization in G protein coupled receptor signal termination varies depending on the receptor and the cell in which it is expressed. The parathyroid hormone type I receptor (PTH1R) is found primarily in kidneys and bone. In recent work we showed that PTH(7-34), which doesn't activate or desensitize the PTH1R but efficiently promotes its endocytosis. This raised the question of whether arrestins are required for the internalization of PTH1Rs that are not activated or desensitized. We examined the role of arrestin mobilization in ligand-induced PTH1R internalization and desensitization in mouse kidney distal convoluted tubule (DCT) cells, where PTH regulates calcium absorption. PTH(1-34), which activates, desensitizes, and internalizes the PTH1R promoted ßarrestin2 movement from the cytoplasm to the plasma membrane within 2 minutes. After 15 minutes, arrestin appeared in a punctate fashion in the cytoplasm. PTH(7-34) which does not activate the PTH1R but promotes its endocytosis did not induce arrestin trafficking. Furthermore, PTH(1-34) but not PTH(7-34) enhanced coimmunoprecipitation of ßarrestin1 with the PTH1R. Deletion of the C terminus of the PTH1R reduced the interaction between arrestin and the PTH1R but did not interfere with PTH(1-34) or PTH(7-34)-induced PTH1R endocytosis. Thus, PTH1R interacts directly with ß-arrestin by its intracellular C terminal tail. The clathrin-binding domain of ßarrestin1 acts as a dominant negative (dnArr) preventing trafficking of arrestin-associated proteins to clathrin-coated vesicles for endocytosis. dnArr did not inhibit PTH1R internalization by PTH(1-34) in DCT cells but blocked isoproterenol-induced ß-adrenergic receptor internalization. Furthermore, dnArr inhibited PTH1R internalization in HEK293 cells. We conclude that arrestin mobilization is facultative and not obligatory for PTH1R internalization. Arrestin trafficking, in response to activating PTH peptides, is consistent with a role in mediating PTH1R desensitization.

Amino-terminal Structure of Non-(1-84) PTH Fragments Secreted by Parathyroid Glands of Patients with 1^{ary} and 2^{ary} Hyperparathyroidism. P. D'Amour[1], J. Brossard[1], L. Rousseau*[1], C. Lazure*[2], J. R. Lavigne[3], R. J. Zahradnik[3]. [1]Hôpital Saint-Luc, Centre de recherche du CHUM, Montreal, PQ, Canada, [2]Institut de recherches cliniques de Montréal, Montreal, PQ, Canada, [3]Immutopics Inc., San Clemente, CA, USA.

Non-(1-84) parathyroid hormone (PTH) are large circulating carboxyl-terminal (C) fragments with a partially preserved amino-terminal (N) structure. hPTH(7-84), a synthetic surrogate, has been demonstrated to exert biological effects in vivo and in vitro through a C-PTH receptor which are opposite to those of hPTH(1-34) on the PTH/PTHrP type I receptor. To determine the N- structure of non-(1-84) PTH fragments, we have incubated parathyroid cells isolated from glands obtained at surgery from 3 patients with 1^{ary} hyperparathyroidism (HP) and 3 patients with 2^{ary} HP with ^{35}S-Methionine and ^{3}H-Leucine to internally labeled their secretion products. Incubations were performed for 8 hr at the patient ionized calcium concentration and in the presence of various protease inhibitors (Roche Diagnostic). The supernatant was fractionated by HPLC and fractions were analyzed with a (1-4) and (13-34) PTH assay from Immutopic (San Clemente, CA). The serum of each patient was similarly analyzed. Peaks of immunoreactivity identified were submitted to sequence analysis (Procise model 494, Applied Biosystem) to recover the ^{35}S-Methionine residues in position 8 and 18 and the ^{3}H-Leucine residues in positions 7, 11 and 15. Four regions of interest were identified with PTH assays corresponding to non-(1-84) PTH fragments (regions 3 and 4), a peak of N-PTH reacting mainly in the (1-4) PTH assay (region 2) and a peak of immunoreactivity corresponding to the elution position of standard hPTH(1-84) (region 1). The last corresponded to a single sequence starting at position 1. Region 2 gave similar results most of the time (a sequence starting at position 1) but also sometimes a small amount of a sequence starting at position 4. Region 3 and 4 always identified major sequences starting at positions 7 and 15 and sometimes at positions 8 and 10 also. Surprisingly a sequence starting at position 1 was also present in region 3. The HPLC profile obtained from of a given patient parathyroid cells was similar to the one obtained from serum in each case. These results indicate that non-(1-84) PTH is composed of a family of fragments which are generated by progressive cleavage at their N-region, starting at position 4 and progressing to position 15. This is a process similar to the one described for smaller C-PTH fragments a number of years ago, suggesting a similar generation process and source for all PTH fragments. This work was granted by CIHR and NPS Pharmaceuticals.

Identification of the Response Element That Controls Transcriptional Activation of CCAAT Enhancer Binding Protein Beta by PTH In Osteoblastic Cells. P. Dhawan*[1], X. Peng*[1], Y. Liu*[1], S. Williams*[2], S. Christakos[1]. [1]Biochemistry, University of Medicine and Dentistry of New Jersey, Newark, NJ, USA, [2]Dept. of Cell Biology and Biochemistry, Texas Tech University Health Sciences Center, Lubbock, TX, USA.

We earlier reported that CCAAT enhancer binding protein β (C/EBPβ) is a $1,25(OH)_2D_3$ target in osteoblastic cells and also that C/EBPβ enhances vitamin D receptor (VDR) mediated 24(OH)ase transcription. Our findings indicated that not only $1,25(OH)_2D_3$ but also PTH can induce C/EBPβ in osteoblastic cells and suggested a role for C/EBPβ in the cross talk between PTH and $1,25(OH)_2D_3$ that involves enhancement of PKA induced VDR transcription. To examine the mechanisms involved in induction of C/EBPβ by $1,25(OH)_2D_3$ and PTH, UMR osteoblastic cells were transfected with different deletion constructs of the C/EBPβ promoter -1,400/+16. These constructs were unresponsive to $1,25(OH)_2D_3$ (10^{-9} - 10^{-7}M), suggesting possible post transcriptional regulation of C/EBPβ by $1,25(OH)_2D_3$. However a region located at -120/-60 was found to be required for the activation of the C/EBPβ promoter by PTH (1 - 25 nM; maximal induction at 25 nM, 10 ± 1.5 fold). The protein kinase A inhibitor H89, a dominant negative CREB as well as the inducible cAMP early repressor (ICER) blocked the PTH dependent effect on the C/EBPβ promoter activity, suggesting that PTH activation occurs via a PKA dependent pathway. The PKC inhibitor Go-6983 did not affect PTH dependent induction of C/EBPβ transcription. Mutation constructs of the C/EBPβ promoter demonstrated that the activation of the C/EBPβ promoter by PTH is mediated through a CREB binding site at -111/-107. Gel mobility shift assays indicate that both control and PTH treated (10 nM, 1h) nuclear extracts bind to this site. Significantly more protein-DNA complex was produced when extracts from PTH treated cells were used. An anti-CREB specific antibody markedly reduced protein binding indicating that this complex contains CREB. Thus we conclude that PKA dependent CREB activation mediates the PTH dependent effect on C/EBPβ transcription. In addition, studies using immunocytochemistry and fluorescence microscopy suggest that PTH can also stimulate the nuclear accumulation of C/EBPβ. Under control conditions C/EBPβ was diffusely distributed within the cell but after 2 h of PTH treatment (10 nM) the protein was predominantly nuclear. These findings provide a mechanism for the first time for PTH induction of C/EBPβ and suggest that stimulation of C/EBPβ transcription and C/EBPβ nuclear translocation may be important for other actions of PTH than can affect osteoblast function.

The Anabolic Bone Response to Low Dose PTH Is Attenuated by Reduced Physical Activity. T. E. Hefferan[1], G. L. Evans*[1], M. Zhang*[1], E. Morey-Holton[2], R. T. Turner[1]. [1]Orthopedics, Mayo Clinic College of Medicine, Rochester, MN, USA, [2]Ames Research Center, NASA, Moffett Field, CA, USA.

Bone loss is a widespread problem facing the aging population and can be influenced by lifestyle factors such as reduced physical activity. Disuse results in uncoupled bone turnover where bone resorption is increased and bone formation decreased. Intermittent parathyroid hormone (PTH) increases bone formation, and is an approved treatment for osteoporosis. Thus, we examined the effectiveness of PTH in preventing bone loss that occurs with disuse. A 2-week dose response study was performed using 6 month old male Fisher rats that were hindlimb unloaded (HLU) and injected subcutaneously with PTH 0, 5, 20, or 80 ug/kg/d. The bone response was measured by dynamic histomorphometry and Northern blot analysis of bone matrix genes. All doses of PTH significantly increased bone formation rates (BFR/BS) ranging from a 2 fold increase, $p<0.01$, with the lowest dose (5 ug/kg/d) to a 6.5 fold increase, $p<0.0001$, with the highest dose (80 ug/kg/d) compared to normal loaded control. The 80 ug/kg/d dose significantly increased mRNA levels for type I collagen 10 fold ($p<0.0001$), osteonectin 4 fold ($p<0.001$) and osteocalcin 7 fold ($p<0.0001$). These findings indicate that the daily doses for PTH typically administered to rats are greatly in excess of that necessary to maintain normal bone formation in HLU rats. Therefore, a second study was conducted using a lower dose of PTH 1 ug/kg/d. Six month old intact male Fisher rats were assigned to HLU or normal weight bearing groups and treated for 2 weeks with 1 ug/kg/d PTH or vehicle. PTH treatment of normal weight bearing rats resulted in a significant increase in bone volume ($p<0.01$), trabecular thickness ($p<0.05$) and trabecular number ($p<0.05$), and a significant decrease in trabecular separation ($p<0.01$). HLU significantly decreased mineral apposition rate ($p<0.05$) and bone formation rate ($p<0.0001$), while PTH treatment of the HLU animals maintained mineral apposition and bone formation rates at the same level as the normal weight bearing control. Mineral apposition and bone formation rates were significantly increased (31%, $p<0.05$ and 230% $p<0.0001$) in the PTH treated normal weight bearing animals compared to vehicle control. Two-way ANOVA demonstrated that PTH had significant stimulatory effects while unloading had significant inhibitory effects on bone formation. In addition, there was a strong interaction term demonstrating that normal weight bearing potentiates the stimulatory effects of PTH. These studies suggest that while PTH therapy is beneficial, it may be less effective in patients with impaired physical activity.

HSP-70 Expressed on the Surface of Cancer Cells Binds Specific PTHrP Peptides In Vitro. J. J. Grzesiak*[1], D. W. Burton[2], L. J. Deftos[2], M. Bouvet[1]. [1]Department of Surgery, University of California, San Diego and Veterans Affairs San Diego Healthcare System, San Diego, CA, USA, [2]Department of Medicine (Endocrinology), University of California, San Diego and Veterans Affairs San Diego Healthcare System, San Diego, CA, USA.

Recent studies confirm that the functions of parathyroid hormone-related protein (PTHrP) and its derived peptides cannot be attributed solely to binding of the classical 7 membrane-spanning and G protein coupled PTH/PTHrP receptor. The present study focused on elucidation of other proteins that might be involved in PTHrP binding and signal transduction at the cell surface. Using affinity chromatography techniques, we coupled different PTHrP-derived peptides to Sepharose 4B, including 1-34, 37-86 and 140-173; and applied octyl-ß-D-glucopyranoside solubilized extracts of cell-surface biotinylated Mia-PaCa-2 pancreatic adenocarcinoma, Saos-2 osteosarcoma and DU-145 prostate cancer cell lines over the affinity columns. After washing, the columns were sequentially eluted with 1 mg/ml of the corresponding free peptide, 10 mM EDTA, 1 M NaCl and 8 M Urea. Fractions analyzed by electrophoretic techniques revealed the presence of a major band of about 70 kDa that was elutable with the corresponding free peptide, along with other PTHrP binding proteins. MALDI analyses and immunoblotting revealed that the major PTHrP-binding protein was heat shock protein-70 (HSP-70). Other binding proteins identified by MALDI included HSP-90. Immunoprecipitation binding assays with radiolabled PTHrP peptides confirmed the binding of HSP-70 to specific fragments of PTHrP but not to others and not to control peptides. HSP-70 as well as other molecular chaperones normally expressed exclusively inside the cell are expressed on the cell surface in cancer. Taken together, these data suggest that PTHrP interacts with the proteins identified by these studies, and that these novel PTHrP-protein interactions may be involved in the transmission of PTHrP signals not currently attributable to the PTH/PTHrP receptor.

Role of Voltage Dependent Calcium Channels in Carboxyl-Terminal Parathyroid Hormone Receptor Signaling. A. Selim*, M. J. Mahon, H. Jueppner, F. R. Bringhurst, P. Divieti. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Parathyroid hormone (PTH), an 84-amino-acid polypeptide, is a major systemic regulator of calcium homeostasis and bone remodeling and elicits its classical functions by activating PTH/PTHrP receptors (PTHRs) on target cells. Carboxyl (C) fragments of PTH, secreted by the parathyroids in a calcium-dependent manner or generated by PTH proteolysis in the liver, circulate in blood at concentrations much higher than intact PTH(1-84) but cannot activate PTHRs. Receptors specific for C-PTH fragments (CPTHRs), distinct from PTHRs, are expressed by bone cells, especially osteocytes, in which they may regulate intercellular communication and cell survival. Activation of CPTHRs previously was reported to modify intracellular calcium within chondrocytes.

To further investigate the mechanism of action of CPTHRs in osteocytes, cytosolic free calcium, (Ca_i^{++}) was measured in the PTHR-null osteocytic cell line OC 59, which expresses abundant CPTHRs but no PTHRs. Ca_i^{++} was assessed by single-cell ratiometric microfluorimetry in Fura -2 loaded OC 59 cells that were pretreated for 16 h with 0.3 mM 8Br-cAMP, which increases CPTHR expression in these cells A rapid and transient increase in Ca_i^{++} was observed in OC59 cells in response to the CPTH fragment hPTH(53-84) (250 nM). Similar results were obtained using analogs of longer CPTH fragments, such as hPTH(13-84) and hPTH(23-84). No Ca_i^{++} signal was observed in COS-7 cells, in which CPTHR binding also cannot be detected. A mutant CPTH analog, [Ala^{55-57}]hPTH(53-84), which does not to bind to CPTHRs, also failed to elicit an increase in Ca_i^{++} in OC59 cells, as did hPTH(1-34).

The Ca_i^{++} response to hPTH(53-84) required the presence of extracellular calcium and was blocked by inhibitors of voltage-dependent calcium channels (VDCC), including nifedipine (100 nM), ω-agatoxin IVA (10 nM) and ω-conotoxin GVIA (100 nM). Interestingly, VDCC inhibitors also decreased specific binding of the radioligand ^{125}I-[Tyr^{34}]hPTH(19-84) to CPTHRs on OC59 cells.

We conclude that activation of CPTHRs in OC59 osteocytic cells leads to a rapid increase in influx of extracellular calcium, most likely through opening of VDCCs. VDCCs could interact directly with CPTH ligands or with CPTHRs. Alternatively, they may be required to maintain Ca_i^{++} levels necessary for CPTHR binding to extracellular CPTH ligands. Calcium influx through VDCCs may play a critical role in CPTH receptor signaling in bone cells.

Creation of lacZ-PTHrP Knock-in Allele in the Mouse. X. Chen[1], B. E. Dreyer*[1], V. Hammond*[2], W. M. Philbrick*[1], A. E. Broadus[1]. [1]Department of Medicine, Endocrine Division, Yale University, New Haven, CT, USA, [2]Howard Florey Institute, University of Melbourne, Parkville, Australia.

PTHrP gene expression is tightly regulated by a combination of transcriptional and post-transcriptional mechanisms, as befits its cytokine-like function in many locations. The transcriptional mechanism is due to a variety of positive and negative regulatory elements operating on one or more promoters and the post-transcriptional regulation to multiple instability elements in PTHrP mRNA 3' UTRs. These mechanisms account for the generally low level of PTHrP products, which are frequently at the limit of detection of in situ hybridization histochemistry (ISHH) and immunohistochemistry (IH).

We have created mice with an allelic PTHrP-lacZ insertion. We targeted exon 3 of the mouse gene, comprising the bulk of the PTHrP coding region, and worked with 12kb of strain 129/Sv DNA flanking this exon. After extensive mapping, we settled on a 5.8-kb KpnI-SacI fragment from intron 2 and a 3.6-kb Sac1-BamHI fragment from intron3 as the long and short arms of homology, respectively. The B-galactosidase (gal) coding region was preceeded by stop codons in all three reading frames and a picornaviral internal ribosomal entry site. A nuclear localization sequence was not included. SV40 small t polyadenylation/termination sequences were used in place of the PTHrP 3' UTR, providing the transcription product with the t ½ of B-gal (estimated at 8 hr) rather than the 30-to 120-min t ½ of PTHrP mRNA. The combination of enhanced stability and the sensitivity of X-gal staining should increase detection sensitivity by 10-to 100-fold as compared to PTHrP ISHH or IH.

Some 200 W9.5 (129/Sv (S1)) ES clones resistant to G418 and gangcyclovir were selected and homologous integrants confirmed by PCR and Southern blotting. Two of these were karyotyped and injected into C57BL/6J blastocycts and the line with the highest percentage chimerism in F_0 mice bred to BL/6 mice to produce allelic F_1 mice at a 50% frequency (27/54).

We plan to use the PTHrP-lacZ allele for three principal purposes: 1) to localize PTHrP expression in previously difficult-to-detect locations such as keratinocytes, bone cells and the CNS/PNS, 2) to substitute for a null PTHrP allele in gene-replacement studies, enabling detection of PTHrP-expressing cells in such experiments, and 3) as readout in mouse experiments designed to study PTHrP gene responsiveness to physiological and pathophysiological stimuli. The mice will be made available to other investigators.

Anabolic Effects of Intermittent Parathyroid Hormone-Related Protein (107-139) (Osteostatin) on Human Osteoblastic Cells in Vitro. A. R. de Gortázar*, V. Alonso*, P. Esbrit. Bone and Mineral Metabolism Laboratory, Fundación Jiménez Díaz-UTE, Madrid, Spain.

The C-terminal fragment of parathyroid hormone-related protein (PTHrP) 107-139, referred to as *osteostatin*, has been shown to directly iinhibit osteoclastic-mediated bone resorption. Recent data suggest that this fragment also affects osteoblastic cell function. We performed an *in vitro* study to an assess the influence of exposure time on the effects of this fragment -compared with those of PTHrP (1-36)- on different osteoblastic markers. Subconfluent human osteoblastic osteosarcoma MG-63 cells were treated with PTHrP (107-139), or PTHrP (1-36), for several hours during several consecutive 48-h incubation cycles. Transient exposure of MG-63 cells to PTHrP (107-139), or PTHrP (1-36), at 100 nM, for the first 6-24 h of only one cycle stimulated alkaline phosphatase activity (1.5-fold over control) in these cells. Using a similar intermittent treatment for 3 cycles, both peptides failed to significantly affect core binding factor-α1 (Cbfa1) activity, but stimulated bone nodule formation, and also osteocalcin mRNA and osteoprotegerin (mRNA and protein) expression (maximal 2-fold over control, at 100 nM) in MG-63 cells. Moreover, transient exposure to PTHrP (107-139) during cell growth increased the PTH1 receptor (PTH1R) protein expression. These anabolic effects of this peptide were abolished by the PKC inhibitor bisindolylmaleimide I (25 nM) but not by a neutralizing anti-IGF-I antibody in these cells. In contrast, this antibody abolished these effects induced by PTHrP (1-36) in MG-63 cells. Both PTHrP peptides, within 0.1-100 nM, when added transiently to MG-63 cells, inbited (by 50%) receptor activator of NF-kappaB ligand (RANKL) protein levels in MG-63 cell membrane extracts. Thus, intermittent treatment with these PTHrP peptides significantly increased the OPG/RANKL ratio in these cells. Continuous treatment of MG-63 cells with each peptide for 3 cycles failed to induce these effects; and did not affect those triggered by the transient exposure to the other peptide.

These results indicate that intermittent exposure of human osteoblastic cells to *osteostatin* induces anabolic effects through a PTH1R-independent mechanism.

PTHrP as a Mediator of DNA Repair in Cancer. N. Ilievska*, S. Bouralexis*, R. J. Thomas-Mudge*, T. J. Martin, M. T. Gillespie. Bone, Joint and Cancer, St. Vincent's Institute of Medical Research, Fitzroy, Australia.

Parathyroid hormone-related protein (PTHrP) is widely expressed in many tumors and its production by cancer metastases in bone promotes osteolysis. In addition, PTHrP affects cellular functions including differentiation, proliferation and apoptosis. To determine the potential roles of PTHrP within the progression of breast and other cancers, we have examined the effect of PTHrP expression by and upon breast, prostate and osteosarcoma cell lines. As a consequence of PTHrP overexpressing in the breast cancer cell lines (MCF-7, MDA-MB-231 and MCF-10A), several DNA repair (XPG, BRCA1, BRCA2 and Rad51), cell cycle (p21 and p53), and apoptosis-related genes such as Bcl-2 were determined to be regulated, both at the mRNA and protein level: the DNA repair genes were elevated. To determine whether this was a result of an intracrine or autocrine action of PTHrP, a range of PTHrP peptides were assessed for their ability to alter gene expression in breast (MCF-7, MDA-MB-231, MCF-10A), osteosarcoma (MG63, Saos, U-2 OS) and prostate (DU145, PC3) cells. PTHrP peptides 1-34, 1-108, 106-139 or 122-139 did not affect mRNA or protein levels for these target genes, whilst PTHrP peptides (107-139 or 107-111 at 100 nM) encompassing osteostatin (TRSAW: 107-111) upregulated the expression of mRNA levels for these genes, as well as for PTHrP, within 4 to 24 hrs: changes were also noted in protein levels. Mutant peptides of osteostatin (TRSPW, TRGAW, PRSAW, YRSAW, TKSAW and TASAW) identified a requirement for Thr107 and Ser 109 for activity on DNA repair genes in MCF-10A cells.

To determine the signal transduction pathway(s) involved in osteostatin-induced regulation of DNA repair genes, MCF-10A cells were treated with the NFkB inhibitor (N-acetyl-L-cystine), PKA inhibitor (H89) or PKC inhibitor (chelerythrine chloride) with and without TRSAW (100nM). These inhibitors indicated involvement of the PKA and PKC pathways for TRSAW effects on DNA repair genes.

Finally, to determine if PTHrP was indeed responsible for DNA repair, the ability of osteostatin or mutants peptides to protect against etoposide induced DNA damage was assessed by COMET assays. TRSAW and peptides that elevated DNA repair gene expression protected against etoposide-induced DNA damage, whilst peptides that had no effect upon DNA repair gene expression did not induce DNA repair.

Combined, these data indicate a new function for PTHrP to protect against as well as mediate DNA damage repair, and this activity may well account for the widespread distribution of PTHrP, and its association as a prognostic indicator of survival in patients with breast cancer.

Regulation of Parathyroid Hormone Secretion: Putative Role of the Multiligand Endocytic Receptor Megalin. L. Cianferotti[1], S. Lisi*[1], T. Giacomelli*[1], R. Botta*[1], F. Cetani*[1], P. Miccoli*[2], A. Pinchera*[1], C. Marcocci[1], M. Marinò*[1]. [1]Endocrinology, University of Pisa, Pisa, Italy, [2]Surgery, University of Pisa, Pisa, Italy.

Megalin, a multiligand endocytic receptor belonging to the low density lipoprotein receptor superfamily, is expressed by several epithelial tissues, including parathyroid cells. The role of megalin in the parathyroids has not been established, although it was proposed that megalin may be involved in the regulation of parathyroid hormone (PTH) secretion. Here we investigated the possible role of megalin in PTH secretion, using primary cultures of human parathyroid cells. Cells were prepared from parathyroid tissue specimens collected at surgery from patients with sporadic primary hyperparathyroidism. Parathyroid cells in culture were found to maintain features of differentiation for at least 5 days, as shown by their ability to secrete intact PTH. Cells expressed full length megalin, as observed in cell extracts by Western blotting. To investigate the role of megalin in PTH secretion, cells were cultured in 96 well plates and then incubated with two known megalin ligands, namely the human receptor associated protein (hRAP) and human thyroglobulin (hTg). In addition, cells were incubated with three rabbit anti-megalin antibodies, namely A55 (against full length megalin), anti-megalin-GST (against an extracellular epitope in the second cluster of ligand binding repeats), and Rb4 (against the cytoplasmic tail). Normal rabbit IgG and ovalbumin were used as negative controls. After 6 hours of incubation at 37°C, cell media were collected and PTH was measured by immunoradiometric assay. Mean PTH values in the absence of competitors or controls ranged from 619 to 654 pg/well. PTH values were markedly reduced when cells were incubated with A55 (47% inhibition) or hTg (52.7% inhibition), whereas a slight degree of reduction was observed in the presence of hRAP (7% inhibition) or anti-megalin-GST (16% inhibition). No reduction of PTH values was observed with negative controls as well as with Rb4, as expected from the fact that the latter antibody is directed against an intracellular epitope of megalin, and thus should not affect its functions if applied extracellularly. The results suggest that megalin may be indeed involved in PTH secretion by parathyroid cells in a favoring manner, because its inhibition results in a reduction of PTH secretion. The molecular mechanisms underlying megalin function in the parathyroid remain to be investigated.

A Novel Mutation in the Calcium-Sensing Receptor in Familiar Hypocalciuric Hypercalcemia and Neonatal Severe Hyperparathyroidism. S. C. Andrade*, S. K. Kohara*, L. F. D´Souza-Li. Center for Investigation in Pediatrics, State University of Campinas, Campinas, Brazil.

Extracellular calcium concentration is regulated by the calcium sensing receptor (CASR). It belongs to the superfamily of G protein-coupled receptors and has a large amino terminal extracellular domain, seven transmembrane domains and a cytoplasmic carboxyl C-teminal tail. Cloning of the CASR provided insights into the molecular basis of several inherited disorders of Ca^{+2} homeostasis in humans. Inactivating mutations of calcium-sensing receptor are associated to Familial Hypocalciuric Hypercalcemia (FHH) when individuals have one defective copy of the gene and Neonatal Severe Hyperparathyroidism (NSHPT) when individuals have usually two defective copies. The aim of this study was to analyze the molecular genetics of a consanguineous family where the proband presented as a neonatal severe hyperparathyroidism and to correlate the fenotype (clinical findings) with the genotype. We report a boy who presented hypoactivity and poor feeding during the neonatal period. The biochemical profile showed serum Ca^{++} 21.0 mg/dL, phosphorus 1.3 mg/dL, alkaline phosphatase 1107 UI/L, Mg^{++} 2.18 mg/dL and PTH 1550pg/mL. He underwent total parathyroidectomy on the 30th day of life with significant improvement of the symptoms. The PTH level fell to 28 pg/dL and the serum Ca^{++} to 9.8 mg/dL. The serum calcium in the parents was normal in the mother (8.8 mg/dl) and on the higher limit of reference value in the father (10.5 mg/dl). Genomic DNA was isolated from peripheral blood leucocytes and used as a template to amplify the coding region of the *CASR* gene using nine pairs of primers. After purification, the PCR products were directly sequenced. We identified an inactivating mutation at nucleotide 2 of the cDNA (c.2T>G) changing the conserved Methionine of the first protein codon to Arginine (M1R). The proband was homozygous and parents were heterozygous for this mutation. We confirmed the mutation by restriction enzyme digestions since this mutation destroy a Nco I restriction site. Since this mutation disrupt the original Kozak sequence, a cryptic initiation start site will probably be used resulting in a non-functional protein.

Impaired Translocation of Calcium-sensing Receptor Nascent Chains into Endoplasmic Reticulum due to Signal Peptide Missense Mutations in Familial Hypocalciuric Hypercalcemia. S. Pidasheva*[1], W. F. Simonds[2], S. J. Marx[2], G. N. Hendy[1]. [1]Medicine, McGill University, Montreal, PQ, Canada, [2]Metabolic Diseases, NIH, Bethesda, MD, USA.

Inherited disorders of calcium homeostasis, familial hypocalciuric hypercalcemia (FHH) and neonatal severe hyperparathyroidism (NSHPT) are caused by inactivating mutations in the calcium-sensing receptor (CASR). This cell-surface glycoprotein plays a key role in calcium homeostasis. Here, we report that a CASR allele from a patient with FHH had a point mutation in the s ignal sequence replacing Leu (TTG) with Ser (TCG) at position 11 (L11S). The proband is a 43-yr-old male who underwent 2 unsuccessful neck explorations. A third parathyroidectomy significantly improved his condition. Pre-operative clinical data were: ionized calcium 1.59 mmol/l (ref:1.17-1.31); iPTH 120 pg/ml (10-65); total calcium 2.7 mmol/l (2.05-2.5); urinary calcium/creatinine clearance ratio, 0.022. Previously, an L13P mutation was found in a family with FHH/NSHPT. We engineered both mutants into a c-Myc tagged CASR cDNA and transfected them into human embryonic kidney (HEK293) cells. Wild type and mutant CASR proteins were analyzed by western blot, showing the mutants were much less well expressed than the wild type. Neither mutant was expressed at the cell surface as evaluated by immunofluorescence and confocal microscopy. Both mutants were transcribed and translated comparable to the wild type in an in vitro assay. Insertion into the endoplasmic reticulum (ER) and glycosylation status of wild type and mutants were analysed. Transcribed sense RNA strands were translated in a rabbit reticulocyte lysate cell-free system in the absence or presence of increasing concentrations of canine pancreatic microsomal membranes. Proper glycosylation of wild type receptor was confirmed by digestion with endoglycosidase H. However, both mutants failed to be glycosylated. We next used a co-translational translocation assay in which CASR RNAs were translated with microsomal membranes followed by incubation with proteinase K alone or in combination with Triton X-100. Wild type CASR was protected from protease digestion as it had translocated to the ER, but neither mutant CASR was protected. These results indicated that the mutant receptors' nascent chains do not translocate into the ER. The mutations occur in the CASR hydrophobic signal peptide core which is highly conserved among species. Thus, both mutations resulted in markedly impaired processing of the CASR, accounting for parathyroid dysfunction, and emphasizing the key role of the signal peptide in preprotein targeting.

Interleukin-1beta Stimulated Increase in Parathyroid, Thyroid and Kidney CASR Expression in Vivo Is Mediated by NF-kappaB Elements in the CASR Gene Promoters. L. Canaff*, G. N. Hendy. Medicine, McGill University, Montreal, PQ, Canada.

The calcium-sensing receptor (CASR), expressed in parathyroid gland, thyroid C-cells and kidney tubule, is essential for maintenance of calcium homeostasis. Hypocalcemia is common in critically ill patients in whom circulating pro-inflammatory cytokines are increased. We have investigated whether pro-inflammatory cytokines, via NF-κB activation upregulate transcription of the CASR gene. This would reduce the set-point for PTH suppression by extracellular calcium likely leading to the observed hypocalcemia and hypoparathyroidism. We show that after a single intraperitoneal injection of IL-1β in rats, parathyroid and thyroid CASR mRNA levels rose 2-2.5 fold and kidney CASR mRNA levels rose 1.5 fold over basal levels at 15 hours. Thyroid CASR mRNA levels had not returned to base line at 24 hours. Western blot analysis showed that kidney and thyroid CASR protein levels were also increased at 15 and 24 hours. Serum calcium and PTH levels were decreased significantly at 15 and 24 hours. Transcription of the human CASR gene is driven by two promoters (P1 and P2) yielding transcripts having alternative 5' untranslated regions (1A and 1B), but encoding the same receptor protein. Nuclear run-on assays performed on extracts of human proximal tubule kidney (HKC) cells and thyroid C-cells (TT) cultured with and without IL-1β for 8 hours showed that CASR exons 1A, 1B and 2 transcripts were all stimulated >2-fold, as was cyclooxygenase-2 gene transcription in both cell types. GAPDH was unaffected by IL-1β treatment. Previously, we showed that when human CASR promoter reporter gene constructs were transfected into HKC cells, IL-1β stimulated transcriptional activity of both P1 and P2 promoters 2-fold over basal. The CASR gene promoters have 4 potential NF-κB elements and the responsiveness to IL-1β was reduced or lost when the P1, exon 1A or P2, but not exon 2, NF-κB elements were mutated. P1, exon 1A and P2 NF-κB elements conferred IL-1β responsiveness to a heterologous promoter. Cotransfection of CASR reporter gene constructs with NF-κB proteins in HKC cells led to increased transcriptional activity with p65 only and the p50/p65 combination. Cotransfection with I-κB or pretreatment of HKC cells with a cell-permeable peptide containing the NF-κB nuclear localization sequence abrogated the responsiveness of P1 and P2 to IL-1β. In electrophoretic mobility shift assays, complexes comprising p65/p65, p65/p50 or p50/p50 dimers, formed on three of the four NF-κB elements. In conclusion, NF-κB elements in the CASR gene promoter mediate transcriptional up-regulation by pro-inflammatory cytokines, contributing to the hypocalcemia of the critically ill.

Ca^{2+}-sensing Receptor of Mozambique Tilapia (tCaR): cDNA Expression, Signal Transduction, and Salinity-Dependent mRNA Expression in Vivo.
D. M. Shoback[1], C. Pollina*[2], W. Chang[1], S. Pratt*[1], S. Hyodo*[3], Y. Takei*[3], C. A. Loretz*[2]. [1]San Francisco VA Medical Center, University of California, San Francisco, CA, USA, [2]National Science Foundation Tokyo Regional Office, Minato, Tokyo, Japan, [3]Ocean Research Institute, University of Tokyo, Nakano, Tokyo, Japan.

A CaR cDNA from the kidney of the euryhaline Mozambique tilapia was identified through PCR cloning. The cDNA of tCaR, with 5' and 3' UTRs, is an ≈3.3 kb transcript predicted to encode a 940 amino acid protein with 84% and 93% similarity to mammalian and teleost CaRs. tCaR lacks two stretches of amino acids present in mammalian CaRs -- comparable to residues 367-377 in the extracellular domain (ECD) and 923-1085 in the intracellular (IC) tail of bovine parathyroid (bp) CaR. By RT-PCR, expression of tCaR was strong in brain, gill, and kidney and less in heart, stomach, intestine and urinary bladder; this suggested a physiological role in barrier epithelia. Since tilapia adapts to fresh (FW) and seawater (SW), we considered the hypothesis that tCaR might be involved in responses to salinity change. Tissues from FW-adapted (< 10 mosmol/L, 0.4 mM Ca^{2+}) and SW-adapted (1000-1020 mosmol/L, 10 mM Ca^{2+}) tilapia were harvested. Changes in tCaR mRNA were assessed in kidney and intestine by PCR. Kidney and intestine demonstrated opposite expression patterns as a function of acclimation to salinity. In FW tilapia, kidney tCaR mRNA was 3-fold greater than that in SW fish (N=6-7; $p < 0.001$). In contrast, tCaR mRNA in intestine was elevated ≈3-fold in SW tilapia ($p < 0.01$). Because one of the regions missing in tCaR is in the ECD, which mediates Ca^{2+}-sensing, and the other is in the C-terminal IC tail, which is important in activation of phospholipase C (PLC), we tested tCaR signaling in response to changes in the extracellular $[Ca^{2+}]$ ($[Ca^{2+}]_e$). cDNAs encoding the bpCaR and tCaR were transfected into HEK-293 cells. PLC activation was assessed by ^{3}H-InsP accumulation after raising $[Ca^{2+}]_e$ from 0.5 mM to levels shown (see Table). ^{3}H-InsP increased less in tCaR- vs bpCaR-expressing cells ($p < 0.001$). ED_{50} values were 6 vs 3 mM Ca^{2+} for tCaR and bpCaR, respectively ($p < 0.001$). This suggests that tCaR may have a physiological role in responding to salinity change and that changes in the ECD of tCaR may alter its conformational changes in response to high $[Ca^{2+}]_e$.

TABLE. Fold-Increase in ^{3}H-InsP at $[Ca^{2+}]$ Shown vs 0.5 mM Ca^{2+} (N=3)

[Ca2+] mM	bpCaR	tCaR
2.5	7.2+/-0.6	1+/-0.1
5.0	15.8+/-0.6	5.6+/-0.4
7.5	18.3+/-0.8	10.4+/-0.9
10	17.1+/-1.4	10.9+/-1.2

Expression Levels of the Calcium Receptor Affect Responses to Calcimimetics.
W. L. Heaton*[1], P. S. Jacobson*[1], N. Lloyd*[1], T. Le-Capling*[2], B. T. Brinton*[2], E. F. Nemeth[2], K. J. Krapcho*[1]. [1]NPS Pharmaceuticals, Salt Lake City, UT, USA, [2]NPS Pharmaceuticals, Mississauga, ON, Canada.

The type II calcimimetic compound cinacalcet (Sensipar™) is the first FDA approved allosteric modulator of any G protein-coupled receptor. This compound acts preferentially on the parathyroid cell Ca^{2+} receptor (CaR) to rapidly lower circulating levels of parathyroid hormone (PTH). A seemingly identical CaR regulates calcitonin secretion from thyroid C-cells, yet in rodents and humans, type II calcimimetics are at least 40-fold more potent at regulating PTH secretion than calcitonin secretion. To determine if receptor density affects the potency and efficacy of calcimimetics, CaR expression levels were varied in a heterologous expression system using a tetracycline inducible promoter (TRex-HEK293). Characterization by Western and Northern analysis showed that addition of tetracycline (5 to 100 ng/ml; 24 h) to CaR TRex-HEK293 cultures resulted in concentration-dependent increases in CaR mRNA and protein expression. CaR activation was monitored by fluorimetric measurements of cytoplasmic Ca^{2+}. The potencies and efficacies of type I (Ca^{2+}, Mg^{2+}, Gd^{3+}, spermine) and type II calcimimetics (NPS R-568, NPS 1377, NPS R-467) were dependent on the level of CaR expression, with greater induction levels corresponding to increased potency and efficacy. Increasing levels of CaR expression increased the Hill coefficient of type I, but not type II, calcimimetics. In contrast, the potency and efficacy of carbachol, acting on natively expressed muscarinic receptors, was unaffected by treatment with tetracycline (Table). Increases in cytoplasmic Ca^{2+} evoked by extracellular Ca^{2+} in the absence of induction appear to be CaR mediated because the responses were potentiated by NPS R-467 but not by equimolar concentrations of its less potent stereoisomer NPS S-467. Extracellular Ca^{2+} at concentrations up to 5 mM had no effect in untransfected TRex-HEK293 cells. In conclusion, the density of CaRs profoundly affects the potencies and efficacies of calcimimetic ligands. The relatively high levels of CaR expression in parathyroid glands, compared to other tissues, might explain or contribute to the preferential effects of cinacalcet on PTH secretion.

	No Induction	10 ng/ml tetracycline	100 ng/ml tetracycline
Agonist	EC_{50} / Relative Efficacy	EC_{50} / Relative Efficacy	EC_{50} / Relative Efficacy
Ca^{2+}	2.78 mM / 37.0%	1.86 mM / 86.3%	1.08 mM / 100%
Mg^{2+}	>50 mM / 4.8%	3.6 mM / 66.5%	1.6 mM / 103%
Gd^{3+}	45.5 uM / 10.3%	15.6 uM / 61.0%	10.5 uM / 94.5%
Spermine	>5 mM / 4.5%	151 uM / 62.0%	24.3 uM / 103.2%
NPS 1377	>10 uM / 3.3%	191 nM / 51.5%	24.2 nM / 107.5%
Carbachol	2.1 uM / 31.0%	1.7 uM / 38.6%	1.5 uM / 27.6%

Relative Efficacy is the magnitude of the response as a percent of the maximal Ca^{2+} response with 100 ng/ml tetracycline.

A New Class of Non-competitive Antagonists of the Human Calcium-sensing Receptor Releasing Parathyroid Hormone (PTH) from Parathyroid Glands.
K. Seuwen*[1], C. Halleux[2], R. Bouhelal*[3], M. Kneissel[2], R. Gamse[2], T. Buhl*[2], R. M. Wolf*[1], G. Breitwieser*[4], R. Beerli*[2], S. Weiler*[2], L. Widler*[2]. [1]Gpcr ep, Novartis Institutes for Biomedical Research, Basel, Switzerland, [2]Bone Metabolism, Novartis Institutes for Biomedical Research, Basel, Switzerland, [3]Discovery Technologies, Novartis Institutes for Biomedical Research, Basel, Switzerland, [4]Dep. of Biology, Syracuse University, Syracuse, NY, USA.

Parathyroid glands express a calcium-sensing receptor (PCaR) which acts as the principal regulator of plasma calcium concentration. Lower than normal calcium levels lead to reduced signalling of the receptor, which is translated into increased release of the calcium-mobilising hormone PTH. This effect can be mimicked by PCaR antagonists (calcilytics). As pulsatile administration of PTH has anabolic effects on the skeleton, calcilytics may become useful for the treatment of osteoporosis. Known calcilytics are structurally related to ligands of adrenergic receptors, and molecules of this class are undergoing clinical trials. Their clinical usefulness will strongly depend on pharmacokinetic parameters.

We have used a sensitive high throughput screening approach to find new chemical structures inhibiting PCaR function. One class of molecules identified is related to biarison, a compound which is in clinical use as an anti-inflammatory agent. Chemical derivatisation resulted in highly potent, specific, and efficaceous compounds active at the human and rat receptor. Using receptor modelling and site-directed mutagenesis we identified a specific binding site for biarison-type calcilytics in a hydrophobic pocket within the seven transmembrane domaine of the receptor molecule. This site is different from the site employed by the calcilytics described before.

Compound NVP-AEB032 inhibited calcium-induced inositol phosphate production and mobilisation of intracellular calcium mediated by human PCaR non-competitively with an IC50 of 160 nM and 410 nM, respectively.

Upon i.v. administration to female Sprague Dawley rats, NVP-AEB032 transiently increased plasma PTH dependent on dose. Applied at 3 mg/kg, the compound increased PTH levels from < 50 pg/ml to 480 pg/ml, peaking at 5 minutes and declining back to baseline within 40 minutes. This profile is similar to that produced by i.v. administration of low doses of PTH.

Thus, biarison-type calcilytic molecules have the potential to generate pulsatile PTH release profiles required for anabolic action on the skeleton.

The Calcimimetic Cinacalcet Suppresses Parathyroid Hormone Secretion in Primary Hyperparathyroidism *in vitro* and *in vivo*.
T. Kawata*[1], Y. Imanishi[1], K. Kobayashi*[1], T. Kenko*[2], M. Wada*[3], N. Onoda*[4], H. Tahara[1], E. Ishimura*[5], T. Miki[6], N. Nagano[3], T. Ishikawa*[7], A. Arnold[8], M. Inaba[1], Y. Nishizawa[1]. [1]Department of Metabolism, Endocrinology and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan, [2]Osaka City University Medical School for Technical Assistance, Osaka, Japan, [3]Kirin Brewery Co., Ltd., Takasaki, Japan, [4]Department of Oncology, Osaka City University Graduate School of Medicine, Osaka, Japan, [5]Department of Nephrology, Osaka City University Graduate School of Medicine, Osaka, Japan, [6]Department of Geriatrics and Neurology, Osaka City University Graduate School of Medicine, Osaka, Japan, [7]Department of Surgical Oncology, Osaka City University Graduate School of Medicine, Osaka, Japan, [8]Center for Molecular Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Cinacalcet HCl (cinacalcet), calcium-sensing receptor (CaR) agonist (calcimimetic), is a promising agent for the treatment of hyperparathyroidism secondary to uremia that acts by suppressing parathyroid hormone (PTH) secretion. To investigate cinacalcet's suppressive effect on PTH secretion in primary hyperparathyroidism both *in vitro* and *in vivo*, we investigated its effects on primary cultured human parathyroid cells obtained from 3 PHPT patients, and PTH-*cyclin D1* transgenic mice (PC2) as models of primary hyperparathyroidism. Studies were approved by the institutional ethics and animal care committees. Cinacalcet dose-dependently suppressed PTH secretion from cultured parathyroid cells. The IC_{50} of this compound in the cells was almost the same as that of cells prepared from normal bovine parathyroid glands. CaR expression determined by immunohistochemistry was reduced in the PHPT parathyroid glands compared with the normal glands obtained from thyroid carcinoma patients.

A single administration of 30 mg/kg BW cinacalcet significantly suppressed serum calcium levels by 2 h after administration in 65-85 week-old PC2 mice with chronic biochemical hyperparathyroidism. The percent reduction in serum PTH was significantly correlated with CaR hypo-expression. In older PC2 mice (93-99 weeks old) with advanced hyperparathyroidism, serum calcium and PTH levels were not suppressed by 30 mg/kg BW cinacalcet. However, serum calcium and PTH levels were significantly suppressed by 100 mg/kg BW cinacalcet, suggesting that higher doses of this compound could overcome the resistance developed in severe hyperparathyroidism.
To conclude, cinacalcet has efficacy in models of primary hyperparathyroidism, both *in vitro* and *in vivo*, in spite of any presumed endogenous CaR activation by hypercalcemia and hypo-expression of CaR in the parathyroid glands.

Chondrocyte Calcium-Sensing Receptor and PTHrP are Up-Regulated in Osteoarthritis and Promote Matrix Catabolism. D. W. Burton, M. Foster*, K. Johnson*, L. J. Deftos, R. Terkeltaub. Medicine, University of California and SDVAMC, San Diego, CA, USA.

Growth plate chondrocytes up-regulate calcium-sensing receptor (CaR) expression as they mature to hypertrophy. In cells other than chondrocytes, calcium-sensing via the CaR functions partly to promote expression of parathyroid hormone-related protein (PTHrP). Moreover, PTHrP, which is up-regulated in human OA cartilages, is a critical regulator of growth plate development and is believed to promote both chondrocyte proliferation and osteophyte formation in OA. Hence, our objective was to examine the potential role in the pathogenesis of osteoarthritis (OA) of CaR-mediated calcium-sensing in the chondrocyte. Studying spontaneous knee OA in aging Hartley guinea pigs, we observed that PTHrP and CaR immunostaining *in situ* concurrently increased between 2 and 12 months age as cartilage degeneration developed in the medial tibial plateau. Furthermore, PTHrP secretion by cultured chondrocytes from the guinea pig knees increased 3-fold over this period. Thus, we analyzed functional activities of calcium-sensing including modulation of the effects of PTHrP, using primary bovine knee chondrocytes and clonal immortalized human knee articular chondrocytes (Ch-8 cells) that expressed expressed PTH/PTHrP receptor and CaR. We incubated the primary chondrocytes and Ch-8 cells with the CaR calcimimetic agonist NPS R-467, or with physiologic (1.8 mM) or lesser or greater extracellular calcium concentrations. Firstly, NPS R-467 increased PTHrP expression dose-dependently. NPS R-467 also increased levels of MMP-13, and these effects were shared by treatment alone with elevated extracellular calcium (3 mM). Secondly, progressive elevation of extracellular calcium (from 1.8 mM to an excess level of 3.0 mM) extinguished basal expression of the broad matrix metalloproteinase inhibitor TIMP-3. NPS R-467 directly exerted the same attenuating effect on TIMP-3 expression. Lastly, the PTH/PTHrP receptor-binding peptide PTHrP 1-34 markedly suppressed TIMP-3 expression, but only did so under conditions where calcium-sensing was stimulated by either elevated ambient calcium or directly by the calcimimetic CaR agonist. Our results demonstrate that CaR and PTHrP expression increase *in situ* in spontaneous knee OA. Furthermore, calcium-sensing via the CaR promotes MMP-13 expression and tissue insufficiency of TIMP-3 and modulates the expression and biologic activities of PTHrP. Our results identify heightened calcium-sensing via the CaR as a novel mediator of cartilage catabolism in OA.

1,25D3-MARRS: Molecular Identity and Functional Link to Phosphate Uptake in Intestinal Cells. I. Nemere[1], M. C. Farach-Carson[2], B. Rohe*[2], T. M. Sterling*[1], S. E. Safford*[3]. [1]Nutrition and Food Sciences, Utah State University, Logan, UT, USA, [2]Biological Sciences, University of Delaware, Newark, DE, USA, [3]Biology, Lincoln University, Lincoln University, PA, USA.

We used a ribozyme loss-of-function approach to demonstrate that the protein product of a cDNA encoding a multifunctional membrane-associated protein binds the seco-steroid $1,25(OH)_2D_3$ and transduces its stimulatory effects on phosphate uptake. These results are paralleled by studies in which the ability of the hormone to stimulate phosphate uptake in isolated chick intestinal epithelial cells is abolished by preincubation with Ab099 directed against the amino terminus of the protein. We now report the complete sequence of the cloned chicken cDNA for the $1,25D_3$-MARRS (membrane associated, rapid response steroid-binding) protein and reveal it to be identical to the multifunctional protein ERp57. Functional studies showed that active ribozyme, but not a scrambled control, decreased specific membrane-associated $1,25(OH)_2D_3$ binding, but did not affect binding to the nuclear receptor for $1,25(OH)_2D_3$. Seco-steroid dependent stimulation of protein kinase C activity was diminished as $1,25D_3$-MARRS protein levels were reduced in the presence of the ribozyme, as judged by Western blot analyses. Phosphate uptake in isolated cells is an index of intestinal phosphate transport that occurs during growth and maturation. While cells and perfused duodena robustly responded to $1,25(OH)_2D_3$ in preparations from young birds, older animals no longer responded with stimulated phosphate uptake or transport. The age related decline was accompanied by a decrease in $1,25D_3$-MARRS mRNA that was apparent up to 1 yr of age. Together, these studies functionally link phosphate transport in the chick duodenum with the $1,25D_3$-MARRS protein, and point to a new role for this multifunctional protein class.

The Hairless Gene Product (Hr) Is a Vitamin D Receptor Corepressor, and Several Mutations in Hr that Cause Alopecia in Humans Compromise this Function. J. L. Dawson*[1], J. C. Hsieh[1], S. A. Slater*[1], J. M. Sisk*[2], P. W. Jurutka[1], G. K. Whitfield[1], G. Hsieh*[1], M. L. Thatcher*[1], T. K. Barthel[1], C. A. Haussler[1], C. M. Thompson*[2], M. R. Haussler[1]. [1]Biochemistry & Molecular Biophysics, University of Arizona, Tucson, AZ, USA, [2]Neuroscience, Johns Hopkins University School of Medicine & Kennedy Krieger Institute, Baltimore, MD, USA.

The vitamin D receptor (VDR) and retinoid X receptor (RXR) are both required for hair cycling, and signal by forming a heterodimeric complex that binds to vitamin D responsive elements (VDREs) in the upstream promoter region of genes regulated transcriptionally by 1,25-dihydroxyvitamin D_3 (1,25D). We show that the hairless gene product (Hr), a nuclear protein expressed primarily in skin and brain which is known to interact with the thyroid hormone receptor (TR) and orphan nuclear receptor ROR, also associates physically with VDR in GST pulldown and immunoprecipitation experiments. Both rat Hr (rHr) and human Hr (hHr) function as repressors of basal and 1,25D-VDR-stimulated transcription of a VDRE-containing, natural human CYP24 promoter-reporter construct in cotransfected COS-7 and human keratinocyte cells. Thus, similar to its role with TR and ROR, Hr acts as a VDR corepressor, possibly cooperating with VDR-RXR to silence a gene encoding a tonic inhibitor of the hair cycle. Naturally occurring mutations in hHr cause alopecia in humans, and we probed the impact of several of these mutations on the ability of Hr to repress VDR. Twelve of the hHr point mutations known to elicit alopecia were introduced into the positionally conserved codons of the rHr cDNA, namely P95S, C422Y, A596V, E603V, E611G, R640Q, C642G, N988S, D1030N, A1040T, V1074M and V1154D. The rHr point mutants sort into 3 classes: equivalent to wild type (P95S, C422Y, E611G, R640Q, A1040T, V1074M), markedly reduced in ability to repress 1,25D-VDR-mediated transcription (C642G, N988S, D1030N, V1154D), or proteolyzed (A596V, E603V). The four functionally compromised rHr mutants interact normally with VDR in GST pulldown and coimmunoprecipitation studies. Therefore, the C642G, N988S, D1030N, and V1154D mutations that abolish the ability of Hr to repress VDR appear to blunt downstream signaling by the RXR-VDR-Hr complex to drive the hair cycle. Since histone deacetylases (HDACs) are likely downstream effectors of Hr mediated repression, we postulate that the compromised Hr mutants are defective in their interaction with an HDAC(s). This characterization of naturally occurring Hr mutants that cause alopecia provides evidence for the pathobiologic significance of Hr-VDR corepressive signaling in the mammalian hair cycle, and reveals the importance of downstream factors that execute gene repression.

Combined Impact of Two Common Vitamin D Receptor Gene Polymorphisms on Transcriptional Signaling by $1,25(OH)_2D_3$. M. J. Kaczmarska*[1], G. K. Whitfield[1], C. A. Haussler[1], M. L. Thatcher*[1], P. W. Jurutka[1], M. L. Brandi[2], P. J. Malloy*[3], D. Feldman[3], M. R. Haussler[1]. [1]Biochemistry & Molecular Biophysics, University of Arizona, Tucson, AZ, USA, [2]Clinical Physiopathology, University of Florence, Florence, Italy, [3]Medicine, Stanford University, Stanford, CA, USA.

The vitamin D receptor (VDR) is a transcriptional regulator that, with its 1,25-dihydroxyvitamin D_3 (1,25D) ligand, signals calcium and phosphate absorption, cell differentiation, detoxification and hair cycling. The human (h)VDR gene has common polymorphic variants, two of which are relevant to this study. The first, in exon II, creates two alternative translation start sites, designated *F* and *f*. Data suggest that the *F* hVDR isoform is intrinsically more active in stimulating gene expression, likely as a result of enhanced binding to basal transcription factor IIB. A second, unlinked exon IX polymorphism generates varying lengths of a singlet (A) repeat in the 3' UTR of the hVDR mRNA, classified according to the number of A's in the repeat (≤15 A's designated "short" (*S*) and ≥17 A's considered "long" (*L*)). Although *L/S* alleles do not affect the VDR protein sequence, results indicate that human fibroblasts with the *L* allele have higher VDR activity. To understand the mechanism whereby the *L/S* variation affects activity, saturation binding assays were performed using [^{3}H]1,25D to quantitate the endogenous VDR. Pairs of fibroblast lines were chosen that possessed the same *F/f* genotype, but opposite *LL* vs. *SS* genotypes. Binding plots yielded values for B_{max} which indicated that *LL* lines consistently expressed higher amounts of hVDR than did *SS* lines. We conclude that the *L/S* polymorphism affects the quantity of receptor, rather than its intrinsic activity. To assess the combined effect of *F/f* and *L/S* variations, 19 human fibroblast lines with various VDR genotypes were tested for endogenous VDR activity using a reporter construct containing the 1,25D-responsive natural promoter from the human CYP24 gene. To integrate the combined impact of these polymorphic alleles, the fibroblast genotypes were expressed as an "allele score" of 0-4, with *F* and *L* alleles each scored as 1, and *f* and *S* alleles each scored as 0. The results support previous data that cell lines with a higher allele score exhibit greater VDR potency. Analysis of the results using an ordered logistic regression model yielded a statistically significant P-trend of 0.005 for escalating VDR transcriptional activity with increasing allele score. We propose that the combined influence of these two unlinked hVDR polymorphisms is additive, and significantly affects the ability of 1,25D to elicit bioresponses crucial to the prevention of osteoporosis as well as various epithelial cell cancers.

A Novel Model System Useful for Dissection of Vitamin D Receptor Functional Domains. M. E. Valrance*, J. E. Welsh. Biological Sciences, University of Notre Dame, Notre Dame, IN, USA.

The active form of vitamin D, 1,25-dihydroxyvitamin D3 (1,25D) exerts anti-proliferative and pro-differentiating actions on both stromal and epithelial derived cells, but the exact mechanisms underlying these effects have yet to be defined. The goal of this project is to identify the functional domains of the vitamin D receptor (VDR) that are necessary for the regulation of cancer cell proliferation, invasion, and apoptosis. Towards this goal, we have developed a novel model system consisting of epithelial cell lines that were established from mammary tumors generated in VDR knock-out (KO) mice and their wild-type (WT) littermates. Two of these cell lines, WT145 and KO240 have been characterized with respect to morphology, growth, and apoptosis in relation to VDR function. Both cell lines are estrogen receptor positive, invasive in vitro, and tumorigenic in vivo. The WT145 cells were shown to express the nuclear VDR, and exhibit 1,25D-mediated induction of 24-hydroxylase promoter luciferase activity in transient transfection assays. WT145 cells are also dose-dependently growth inhibited by 1,25D and synthetic vitamin D analogs. 1,25D induces apoptotic morphology, caspase activation, and PARP cleavage in WT145 cells. KO240 cells, as expected, do not express the nuclear VDR, and 1,25D does not induce 24-hydroxylase promoter luciferase activity in these cells. KO240 cells do not exhibit growth inhibition or apoptosis in response to 1,25D or analogs at concentrations up to 1 μM. No apoptotic morphology, caspase activation or PARP cleavage is seen in KO240 cells following vitamin D treatment. At doses of 5-10 μM, 1,25D and the synthetic analogs CB1093, EB1089, KH1230, and MC1288 do inhibit growth of KO240 cells, indicating non VDR-dependent growth inhibitory pathways can be triggered by vitamin D compounds at micromolar doses. These tumorigenic cell lines that differentially express VDR will be exploited to further define the role of VDR in cancer cell regulation. We show that transient transfection of a human VDR into the KO240 cells restores 24-hydroxylase induction, indicating that 1,25D-mediated signaling pathways can be recapitulated. Reconstitution of 1,25D-mediated signaling in VDRKO cells using VDRs with specific point mutations will enable assessment of functional domains that impact on proliferation, apoptosis, invasion, and tumorigenesis. The above data indicate that the WT145 and KO240 cell lines comprise a unique model system, useful for clarification of the impact of VDR ablation and mutation on breast cancer biology both in vitro and in vivo.

GATA-1 Mediates Strong Repression of Both VDR and 1-OHase Promoter Activities in Kidney Proximal Cells and Blocks 1-OHase Gene Expression by PTH. D. Iyer*, A. Bajwa*, M. J. Beckman. Biochemistry, Virginia Commonwealth University, Richmond, VA, USA.

Renal vitamin D activation results in a temporary decrease in gene expression for the $1,25(OH)_2D_3$ receptor (VDR) as the 1α-hydroxylase (1α-OHase) transcript increases. VDR transcriptional repression is relieved after serum calcium levels are restored to normal. Down-regulation of VDR has been found to be specific to the proximal convoluted tubule (PCT) and is proposed to be regulated by PTH. In this study, the globin activator of transcription (GATA-1) was found by GeneChip microarray and promoter analyses to be a candidate transcriptional regulator of VDR and 1α-OHase promoters. Quantitative Real-Time RT-PCR analysis showed the degree of differential regulation for GATA-1 gene expression in rat kidney cortex was 4-fold higher in low Ca compared to high Ca status ($p<0.01$). Two separate human proximal kidney cell lines, HK-2 and HKC-8, were positively identified for the presence of PTH receptors (PTHR1) using confocal immunofluorescence. Gel shift analysis confirmed the presence of GATA-1 protein in the proximal kidney cells. Using a transient transfection procedure GATA-1 was overexpressed in both cell types with luciferase constructs of null and either the VDR or the 1α-OHase promoter, respectively, and in the presence or absence of PTH (50 nM). To ensure there was no influence of extracellular Ca, the media was reduced to 0.1 mM Ca. The VDR and 1α-OHase gene expressions, were analyzed separately. The significant interaction effects demonstrated that: (1) GATA-1 forcefully down regulated both VDR and 1α-OHase, and (2) In the presence of PTH, 1α-OHase was up regulated, while VDR was even more forcefully down regulated. This was highly significant in the HKC-8 cell type, which to date is utilized more in scientific research concerning the vitamin D endocrine system than the HK-2 cell type. Furthermore, it was found that GATA-1 forcefully decreased VDR expression and blocked full activation of 1α-OHase gene expression in response to PTH. The differences were also statistically significant for comparisons between null constructs and GATA-1 constructs when transfected in the absence of PTH. In conclusion, GATA-1 is capable of forcefully down regulating renal proximal VDR and 1α-OHase, however, it is questionable whether the experiment accurately mimicked the real actions that occur on the organismic level, where additional co-regulators may exert a role. Future studies will concentrate on putative GATA-1 binding sites on the VDR and 1α-OHase promoters and work towards determining the specific binding sites and factors that are utilized in the PCT regulation of VDR and 1α-OHase.

The Vitamin D Receptor Is a Low Affinity Sensor of Dietarily Essential Unsaturated Fatty Acids. P. W. Jurutka[1], N. Hall*[2], K. Eichhorst*[2], G. K. Whitfield[2], M. Gurevich*[2], T. K. Barthel[2], J. C. Hsieh[2], C. A. Haussler[2], M. R. Haussler[2]. [1]Life Sciences, Arizona State University West, Phoenix, AZ, USA, [2]Biochemistry & Molecular Biophysics, University of Arizona, Tucson, AZ, USA.

The nuclear vitamin D receptor (VDR) mediates the actions of 1,25-dihydroxyvitamin D_3 (1,25D) to alter gene transcription, thereby effecting bone mineral homeostasis, hair cycling, xenobiotic detoxification and epithelial cell differentiation. Recently, lithocholate was found to be a novel VDR ligand, and also the retinoid X receptor (RXR) heterodimeric partner of VDR was shown to bind oleic and docosahexaenoic acid (DHA). We therefore tested a panel of steroidal and nonsteroid compounds as potential new ligands for VDR, using reporter gene and mammalian two hybrid systems. DHA (10^{-4} M) and 1,25D (10^{-9} M) activated transcription similarly via endogenous VDR in ROS 17/2.8 osteoblast-like cells transfected with a luciferase reporter vector containing the human CYP24 gene promoter. In mammalian two hybrid assays, human embryonic kidney cells (293) were transfected with expression vectors for VDR and RXR fusion proteins and a GAL4 response element-luciferase plasmid. Modest activation was observed with ω3 fatty acids such as α-linolenic acid, eicosapentaenoic acid (EPA) and DHA at dosages ranging from 10^{-4} to 10^{-5} M. Similar results were obtained with ω6 fatty acids including linoleic acid and arachidonic acid, as well as conjugated derivatives of linoleic acid (CLAs). Competition binding with radiolabeled 1,25D confirmed that these ω3 and ω6 fatty acids bind directly to VDR, obviating the possibility that these fatty acids are acting only via RXR. In contrast, several other compounds, such as 8S-hydroxyeicosatetraenoic acid, pregnenolone, lanosterol, α-tocopherol, and the PXR ligands, vitamin K_2 and hyperforin, did not activate VDR. A dietary requirement for polyunsaturated fatty acids (PUFAs) is well known, and deficiency of these fatty acids in VDR target tissues leads to clinical manifestations, including decreased bone mineralization and calcium absorption, cessation of growth, dermatitis, and hair loss. Some of these effects have been attributed to the role of PUFAs in maintaining cell membrane integrity/fluidity, and also to the fact that PUFAs are precursors of prostaglandins (PGs). However, administration of PGs in PUFA-deficient animals does not relieve the associated symptoms. The present results support a novel hypothesis that implicates VDR as a nutritional sensor of circulating essential fatty acids. Thus, PUFA binding to, and activation of, VDR may elicit unique, 1,25D-independent signaling pathways to orchestrate the pleiotropic effects of the ω3 and ω6 fatty acids in bone, skin and hair.

Cell-, Promoter- and Ligand-specific Transactivation Responses of the VDRB1 Isoform. L. M. Esteban, C. Fong*, T. Cock*, S. J. Allison, J. L. Flanagan*, D. Amr*, C. Liddle*, J. A. Eisman, E. M. Gardiner. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

The vitamin D receptor (VDR) mediates the effects of 1,25 dihydroxyvitamin D3, the active form of vitamin D, of which in humans there are two protein isoforms. The VDRB1 isoform differs from the originally described VDR (VDRA) by an N-terminal extension of 50 amino acids. Here we investigate cell-, promoter- and ligand-specific transactivation by the VDRB1 isoform. Transactivation was studied in response to the VDR natural ligand 1,25(OH)2D3 and the secondary bile acid, lithocholic acid (LCA), a cholesterol derivative like vitamin D, recently reported as a VDR activator. Transactivation of cytochrome P450 genes rat CYP24 and human CYP3A4 promoters was studied by transient transfection in COS1 and HEK293 cell lines. On the CYP24, the VDRB1 response to 1,25(OH)2D3 was greater (130%) than that of VDRA in COS1 cells, but similar in response to LCA. In HEK293 cells, the isoforms had similar activity in response to 1,25(OH)2D3, but with LCA VDRB1 was less active (68%) than VDRA. On the CYP3A4 promoter the activity of VDRB1 was lower (60-75%) than that of VDRA in response to either ligand in both COS1 and HEK293 cell lines. The interaction of both isoforms, VDRA and VDRB1, with the vitamin D responsive elements (VDRE) of CYP24 and CYP3A4 were analyzed by gel shift assays in the presence of the heterodimerization partner RXR and 32P-labeled oligonucleotides. The VDR:DNA complex formation was enhanced by the addition of both ligands, and was stronger in the presence of 1,25(OH)2D3 than with LCA. VDRB1 binding to the VDRE1 (proximal DR3) of CYP24 was maximal at a lower concentration of 1,25(OH)2D3 than for VDRA. The reverse-dependence of ligand-receptor binding pattern was evident on the distal DR3 of the CYP3A4 promoter. Increasing concentration of LCA appeared not to have any effect on the VDR:DNA complex formation in either promoter. Transactivation was completely abolished by AF-2 mutations L417S and E420Q in either VDR isoform, on the CYP24 promoter after 1,25(OH)2D3 and LCA treatment. Thus, despite ligand structural differences, VDR mediated transactivation by 1,25(OH)2D3, and LCA shared an AF-2 functional requirement. The present data thus provide new evidence for functional differences between the two VDR isoforms and indicate that these are determined by the promoter and cellular context possibly via differential cofactor interactions, and by the activating ligand.

Low Vitamin D Receptor Level Blunts 1,25 Dihydroxyvitamin D-Mediated Events in Mouse Intestine. Y. Song*[1], C. Gliniak*[1], S. Kato[2], J. C. Fleet[1]. [1]Interdepartmental Program in Nutrition, Purdue University, West Lafayette, IN, USA, [2]Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan.

We tested the hypothesis that low vitamin D receptor (VDR) level causes intestinal calcium (Ca) malabsorption and intestinal vitamin D resistance using wild type (WT) mice and mice with reduced tissue VDR levels (VDR knockout heterozygotes, HT). Duodenal Ca absorption efficiency was upregulated by elevated plasma 1,25 dihydroxyvitamin D ($1,25(OH)_2$ D) caused by feeding 2.0% Ca (0.1%±0.5% absorption), 0.5% Ca (19.8±1.9% absorption), or 0.02% Ca (57.6±3.0% absorption) diets for 7-days (plasma $1,25(OH)_2$ D = 38±5, 134±11, and 244±19 pg/ml, respectively). However, HT mice required higher plasma $1,25(OH)_2$ D levels on the 0.5% Ca (27% higher) and 0.02% Ca (45% higher) diets to maintain calcium absorption at WT levels. This was also reflected in renal 1α hydroxylase mRNA levels (1αOHase) in HT mice on the 0.5% (63% > WT) or 0.02% Ca diets (56% > WT). Regression analysis confirmed that HT mice had lower calcium absorption in response to increasing $1,25(OH)_2$ D levels (slope = 0.31 for WT vs 0.19 HT). The relationship of calbindin D_{9k} (CaBP) protein levels to plasma $1,25(OH)_2$ D was also influenced by VDR level (e.g. CaBP protein slope = 0.045 for WT vs. 0.026 HT). While TRPV6 and CaBP mRNA levels increased significantly after a single $1,25(OH)_2$ D injection (TRPV6 = 22-fold increase at 6 h, CaBP = 5-fold increase at 16 h), there was no difference in response between WT and HT mice. In contrast, $1,25(OH)_2$ D induced 24-hydroxyase (CYP24) mRNA levels were 26-41% lower at 6 h in the duodenum of HT mice depending on dose used. Our data demonstrate that low VDR levels differentially influence $1,25(OH)_2$ D regulated events in mice and suggest that VDR is critical for classical transcriptional regulation (e.g. CYP24), non-classical transcription regulation (e.g. TRPV6), and post-transcriptional regulation (e.g. CaBP) of calcium metabolism. In addition, low VDR level causes resistance of intestinal Ca absorption to $1,25(OH)_2$ D and this may be manifested through post-transcriptional influences of $1,25(OH)_2$ D on CaBP production. Supported by NIH award DK54111-06 to JCF.

PTH and Ca Cause Differential Regulation of the Vitamin D Receptor (VDR) in Mouse Proximal Versus Distal Renal Cells. A. Bajwa*[1], P. A. Friedman[2], M. J. Beckman[1]. [1]Biochemistry, Virginia Commonwealth University, Richmond, VA, USA, [2]Pharmacology, University of Pittsburgh, Pittsburgh, PA, USA.

The $1,25(OH)_2D_3$ receptor (VDR) promoter was characterized in mouse and human species as a TATA-less, GC-rich promoter with Sp1-dependent activation. However, very little is known about the tissue-specific and cell-specific regulation of VDR. The renal nephron offers a unique model for gene expression study of VDR because both proximal and distal tubules are central targets of parathyroid hormone (PTH), calcium (Ca) and $1,25(OH)_2D_3$ activities. The regulation of VDR in response to PTH and Ca was examined in human proximal (HK-2 and HKC-8), mouse proximal (MPCT) and mouse distal (DKC-8) cell lines. Where PTH treatment was used, MPCT cells were transiently transfected with the human type 1 PTH receptor ($PTHR_1$). DKC-8 cells were stably transfected with $PTHR_1$ prior to our experiments. In experiments below, serum free media with calcium (+Ca) or without calcium (-Ca) was used. In cases of additional calcium (Ca^{++}) treatment, (0 - 8 mM) of $CaCl_2$ solution was added to -Ca media. VDR and 1α-OHase gene expressions and promoter activities were measured and analyzed in proximal and distal cells. In DKC-8 cells, PTH_{1-34} treatment (50 nM) significantly increased ($p<0.03$) the relative gene expression of VDR by 6.5-fold while 1α-OHase gene expression was unchanged. Conversely, Ca^{++} concentrations of 2, 4 and 8 mM, decreased VDR gene expression of DKC-8 cells within 2 hours. In MPCT cells, VDR gene expression was suppressed, whereas 1α-OHase gene expression was increased in response to PTH treatment. Ca^{++} exposure of MPCT cells stimulated VDR gene expression and repressed 1α-OHase gene expression in both dose and time-dependent fashion. PTH treatments in human HK-2 and HKC-8 cells demonstrated that PTH is involved in significant ($p<0.05$) down-regulation of VDR. The analysis of promoter activities corresponded with the gene expression data. Additionally, VDR promoter activation was increased in the DKC-8 cells in response to PTH in the absence of a change in 1α-OHase promoter activity. VDR promoter activity in the MPCT cells was decreased with treatment of PTH. In contrast, 1α-OHase promoter activity was increased by PTH in MPCT cells. The differential regulation of VDR in proximal *versus* distal cells suggests several possibilities: (1) distinct promoter usage in the two cell types, (2) an alternative splice pattern of VDR transcription, or (3) the presence of differentially regulated transcription factors in proximal *versus* distal cells. In conclusion, proximal cell VDR is down-regulated by PTH and counterbalanced by opposite effects of extracellular Ca, and in distal cells, PTH potently increases VDR transcription.

Dexamethasone Suppresses Smad3 Pathway in Mouse Osteoblastic Cells. M. Iu*, H. Kaji, H. Sowa, J. Naito*, T. Sugimoto, K. Chihara*. Division of Endocrinology/Metabolism, Neurology and Hematology/Oncology, Department of Clinical Mole, Kobe University Graduate School of Medicine, Kobe city, Japan.

The central to the pathogenesis of glucocorticoid-induced osteoporosis (GC) is the effect of GC on bone formation. However, the mechanism of GC-inhibited bone formation is not well known. The proliferation and differentiation of osteoblasts are included in these events and are controlled by various local growth factors and cytokines produced in bone as well as by systemic hormones. Among them, insulin-like growth factor (IGF) and transforming growth factor (TGF)- β are included in the most important targets of GC in bone formation. We recently reported that Smad3 , a TGF-βsignaling molecule, promotes the production of type I collagen (COLI), alkaline phosphatase (ALP) activity, and mineralization in mouse osteoblastic MC3T3-E1 cells and that PTH-Smad3-axis exerts anti-apoptotic action in osteoblasts (JBC 2002, JBC 2003), suggesting that Smad3 is important for promoting bone formation. However, no reports have been available about the effects of GC on Smad3 in osteoblasts. In the present study, we investigated whether dexamethasone (Dex), an active GC analogue, would affect the expression and activity of Smad3 in mouse osteoblastic cell-line, MC3T3-E1 cells. Dex significantly suppressed Smad3-stimulated ALP activity, although it did not affect TGF-β-inhibited ALP activity in MC3T3-E1 cells. Moreover, pretreatment with Dex suppressed TGF-β-enhanced expression of COLI in these cells. In the luciferase assay using p3TP-Lux with a Smad3-specific response element, Dex significantly suppressed transcriptional activity induced by TGF-β as well as Smad3 in MC3T3-E1 cells. However, Dex did not affect the expression of Smad3 in these cells at both mRNA and protein levels. In conculusion, the present study indicated that Dex inhibits ALP activity and type I collagen expression presumably through suppressing Smad3-induced transcriptional activity, but not through modulating Smad3 expression in mouse osteoblastic cells.

Regulation of Mouse Osteoprotegerin Gene Expression by Steroid Hormones. T. Kondo, R. Kitazawa, S. Maeda*, S. Kitazawa. Division of Molecular Pathology, Kobe University Graduate School of Medicine, Kobe, Japan.

Glucocorticoid-induced osteoporosis is a serious complication of the systemic use of glucocorticoid. It is generally accepted that bone loss is primarily induced by altered osteoblast differentiation, function and by accelerated apoptosis. At the same time, an increase in bone resorption markers is observed during glucocorticoid therapy, indicating that accelerated bone resorption also contributes to glucocorticoid-induced bone loss. To explore the precise mechanism whereby dexamethasone (Dex) stimulates osteoclastogenesis, we analysed the effect of Dex on cis-acting elements of mouse osteoprotegerin (OPG) and of the receptor activator of NF-κB ligand (RANKL) gene. A series of deletion constructs of the mouse OPG promoter (Luc-116, Luc-697, Luc-1125, Luc-1487, Luc-3261) was transfected into ST2 cells and subjected to luciferase assay. Transfected cells were treated with Dex to assess its effect on OPG promoter activity. Mirroring Northern blot analysis, Dex reduced the promoter activity of Luc-1487 to 50%. Transient transfection studies and gel shift assay showed that the c-Jun homodimer bound to the AP-1 binding site (-293/-287) and maintained steady-state transcription of the OPG gene. Furthermore, the mutation of the AP-1 site negated Dex-driven OPG suppression. To assess the effect of Dex on OPG at the protein level, the amount of OPG protein secreted by ST2 cells was measured. Dex downregulated the OPG gene at both mRNA and protein levels. In agreement with the transient transfection studies, the amount of phosphorylated c-Jun protein (p-c-Jun) decreased 1hr after treatment of ST2 cells with Dex, whereas the total amount of c-Jun protein decreased after 12hr. Corresponding to the decrease of p-c-Jun, the amount of phosphorylated p46 isoform of Jun N-terminal kinase (JNK) decreased significantly 30 min after Dex treatment, whereas that of phosphorylated p54 isoform decreased after 12 hr. These data suggest that Dex negatively regulates OPG by transrepressing the OPG gene through the AP-1 site by a reduction in the proportion of the p-c-Jun protein in a JNK-dependent manner and that the reduction was mediated mainly by the decrease in the p46 isoform of JNK. On the other hand, Dex slightly increased the expression of RANKL mRNA. Deletion mutant studies suggested that Dex upregulated RANKL through the putative GRE half sites (-642/-628) or the AP-1 sites in the promoter. We speculate therefore that glucocorticoids per se promote osteoclastogenesis mostly by inhibiting OPG as the main target and partly by concurrently stimulating RANKL reciprocally, thereby enhancing bone resorption.

Glucocorticoids Inhibit Osteocalcin Transcription in Osteoblasts by Suppressing an Egr-binding Cell Type-Specific Enhancer. N. Leclerc*[1], T. Noh*[1], A. Khokhar*[1], E. Smith*[2], B. Frenkel[2]. [1]Biochemistry and Molecular Biology, University of Southern California, Keck School of Medicine, Los Angeles, CA, USA, [2]Orthopaedic Surgery, University of Southern California, Keck School of Medicine, Los Angeles, CA, USA.

Glucocorticoids (GCs) are widely used for the management of rheumatoid arthritis and other autoimmune and inflammatory diseases. A major side effect of GC treatment is osteoporosis, due to the inhibition of bone formation, but the underlying molecular mechanisms are poorly understood. We refined culture conditions, under which the synthetic GC dexamethasone (DEX) strongly inhibits MC3T3-E1 osteoblast differentiation and osteocalcin (*OC*) gene expression. Although OC itself does not play a critical role in osteoblast differentiation and bone formation, *OC* promoter studies contributed to milestone steps made towards our current understanding of transcriptional control mechanisms in osteoblasts. Standard (short-term) transient transfection assays of *OC* promoter-reporter constructs did not recapitulate the strong DEX-mediated repression. Therefore, mapping of negative GC-response elements (nGREs) was performed initially by stable transfections. These assays mapped a nGRE to a 0.1 kb fragment upstream of the binding site for Runx2 (position -138), which itself was not substantially inhibited. Further mapping was achievable by "long-term transient transfection assays", in which transfected cells were allowed to progress to a commitment stage where DEX has been shown to inhibit the osteoblast phenotype. These assays mapped a nGRE to a -161/-147 G:C-rich element and EMSA with this element demonstrated the formation of a protein-DNA complex, which contained an Egr/Krox family member(s). Three copies of the Egr/Krox site conferred 100-fold transcriptional activation on the 147-bp basal *OC* promoter in osteoblasts. Enhancer activity was not observed in 10T1/2 fibroblasts, unless these cells were co-transfected with Runx2. Thus, an Egr/Krox-binding site located immediately upstream of the *OC* Runx2 element was identified as a cell type-specific enhancer, whose activity is inhibited by GCs. Since an additional experimental approach, which employed microarray hybridization, led to the identification of an Egr member, Egr2/Krox20, as the gene most strongly inhibited by GCs in MC3T3-E1 cultures, we suggest that the inhibition of Egr-regulated enhancers in osteoblasts likely contributes to GC-induced osteoporosis.

Glucocorticoid Regulation of Receptor Activator of NF-κB (RANK), Osteoprotegerin (OPG) and RANK Ligand (RANKL) in Mouse Calvarial Bone. C. Swanson*[1], M. Lorentzon[1], H. Conaway[2], U. H. Lerner[3]. [1]Center for Bone Research at the Sahlgrenska Academy (CBI), Department of Internal Medicine, Göteborg University, Göteborg, Sweden, [2]University of Arkansas for Medical Sciences, Department of Physiology and Biophysics, Little Rock, AR, USA, [3]Umeå University, Department of Oral Cell Biology, Umeå, Sweden.

Treatment with glucocorticoids results in a rapid decrease of bone mass in humans. A significant portion of this loss is thought to be due to increased bone resorption. We used a mouse bone resorption model to investigate the effects of glucocorticoids on the expression of RANKL, OPG and RANK. Enhanced release by the glucocorticoid dexamethasone (DEX) of ^{45}Ca from cultured neonatal mouse calvariae was blocked by OPG. Using semi-quantitative RT-PCR, it was found that DEX increased mRNA expression of RANKL, OPG and RANK in calvarial bones. This was at variance from D3, which increased mRNA expression of RANKL and RANK, but decreased that of OPG. DEX also increased mRNA expression of numerous osteoclast markers: tartrate resistant acid phosphatase (TRAP), calcitonin receptor (CTR), cathepsin K and carbonic anhydrase II, enhanced the mRNA expression of the osteoblast marker, alkaline phosphatase, but decreased expression of the osteoblast marker, osteocalcin. Using quantitative realtime PCR, it was found that DEX time- and concentration-dependently stimulated mRNA expression of RANKL, OPG, RANK, calcitonin receptor, cathepsin K and TRAP. When calvariae were stimulated with both D3 and DEX, a supra-additive potentiation of RANKL and CTR mRNA was observed. The stimulation of RANKL, OPG, RANK and CTR mRNA by DEX was blocked by the glucocorticoid receptor antagonist, RU 38486 (mifepristone). These data show that DEX enhances, via a glucocorticoid-receptor mediated mechanism, the expression of two molecules that promote osteoclastogenesis, RANKL and RANK. The observation that OPG, an inhibitor of osteoclast formation, was also increased by DEX may explain why bone resorption caused by glucocorticoids is not as great as that seen with resorptive agents like PTH or D3. Furthermore, the synergistic stimulation of RANKL by DEX and D3 may also explain why there are such significant enhancements of osteoclast formation and bone resorption when these two agents are combined.

Development of a Rapid Assay to Assess the Effects of Glucocorticoid Analogs on the Differentiation of Human Osteoblasts. M. L. Millham*, L. Buckbinder. Cardiovascular and Metabolic Diseases, Pfizer Inc., Groton, CT, USA.

Glucocorticoids (GC) are used to treat inflammatory diseases, however, many serious side effects limit chronic use. The osteoblast (Ob) is a major target for bone side effects. One hypothesis is that GC stimulate differentiation and deplete the precursor Ob pool, leading to osteoporosis. To better describe this phenomenon we have studied effect of GC on the differentiation of cultured primary human Obs. Nodule formation and mineral deposition were assessed after 28 days of GC treatment in confluent Ob cultures by micrographic analysis with von Kossa or alkaline phosphatase staining. Cells treated with GC showed marked dose-dependent increase in mineral deposition. To facilitate assessment of GCs and new analogs, we developed a novel 96-well colorimetric assay to detect alkaline phosphatase activity in cultures after only 7 to 10 days of treatment and demonstrated correlation with the 28 day micrographic results. We have established a facile method predictive for Ob differentiation and, we propose, bone safety.

Transgenic Mice Over-expressing 11beta-Hydroxysteroid Dehydrogenase Type 2 (11betaHSD2) Under the Col 1 alpha (I) Promoter Provide a Model to Test Direct Effects of Exogenous Corticosteroids on Osteoblasts. K. J. Brennan*, H. Zhou, J. de Winter*, C. R. Dunstan, M. J. Seibel. Bone Biology Unit, ANZAC Research Institute, Sydney, Australia.

Endogenous Glucocorticoid (GC) levels are systemically regulated via the hypothalamic-pituitary-adrenal axis. However, cytokines, growth factors and certain enzymes are able to modulate this control at the local level. Within specific tissues, two isoforms of 11beta-hydroxysteroid dehydrogenase (11betaHSD) control cytoplasmic GC levels independent of circulating GC concentrations. 11betaHSD type 1 predominantly converts inactive cortisone to active cortisol. In contrast, 11betaHSD2 unidirectionally catalyses the conversion of active GCs to their inactive metabolites. The relative activities of 11betaHSD1 and 11betaHSD2 determine the availability of active ligand (i.e. cortisol or corticosterone) for the GC receptor. The aim of this study was to determine if mice over-expressing 11betaHSD2 in osteoblasts are relatively protected from direct bone effects when treated with corticosterone (the rodent analogue of cortisol). Four week old transgenic male mice or wild type littermates over-expressing 11betaHSD2 under the regulation of the Col1alpha(I) 2.3 kb promoter were treated with vehicle or corticosterone (0,5, 2, or 10mg/kg/d, n = 4 - 5) for 14 days. At the end of this time bones were removed for assessment of endogenous 11betaHSD 1 and 2 and 11betaHSD2-transgene expression in bone, and histological assessment of bone volume and osteoclast and osteoblast lined surfaces in the lumbar vertebrae and proximal tibia. Endogenous 11betaHSD2 expression was not detectable in the bones of wild type mice. The 11betaHSD2 transgene was abundantly expressed in tibia of the transgenic mice with no changes seen over the duration of the study or with corticosterone treatment. 11betaHSD1 was constitutively expressed in the bones of mice and was not altered by transgene expression or corticosterone dosing. 11betaHSD2 transgenic mice tended to have a lower bone volume compared to transgenic in both the vertebral bodies and proximal tibia though this did not reach significance. Wild type mice appeared to lose proportionally more bone in the proximal tibia than transgenic mice at the 2mg/kg dose, though this effect was lost at the highest dose. Osteoclast and osteoblast surfaces were similar at all doses as were bone formation and bone resorption markers. 11betaHSD2 transgenic mice provide a potential model for evaluating the osteoblast specific actions of both endogenous and exogenous glucocorticoids.

Inhibition of Interleukin-11 Gene Transcription by Glucocorticoid. Y. Ito, S. Kido, D. Inoue, T. Matsumoto. Department of Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medicine, Tokushima, Japan.

Glucocorticoid (GC) excess causes osteoporosis (GIO: glucocorticoid-induced osteoporosis) in part through suppression of bone formation, but the mechanism is still largely unknown. We have reported that GC inhibits expression of an osteogenic cytokine, interleukin (IL)-11, which has been shown to stimulate bone formation and thereby increase bone mass in vivo. Moreover, IL-11 inhibits apoptosis of osteoblasts induced by GC. Therefore, decreased IL-11 expression may be involved in the pathogenesis of GIO. In the present study, we aimed to clarify the mechanism by which GC inhibits IL-11 gene expression. Deletion analysis with mouse IL-11 promoter revealed that both FSS (fluid shear stress) and PTH promoted IL-11 gene transcription in a manner dependent on the AP-1 binding site, which we previously identified as a key element for serum and TGF-β-stimulated transcription, following induction of fos family members such as δosB. We found that dexamethasone (DEX) strongly inhibited IL-11 gene transcription induced by PTH and FSS also in an AP-1-dependent manner. DEX had no effect on induction of fosB/δfosB or upstream signals including ERK activation. Inhibitory effects of DEX on IL-11 gene transcription appeared steroid-specific, because no inhibition was observed with other steroid hormones such as progesterone, 17 β -estradiol and dihydrotestosterone. DNA precipitation experiments with AP-1 binding sequences on the mouse IL-11 promoter demonstrated that JunD and ΔFosB were actually bound to the AP-1 site. We found that GR (glucocorticoid receptor) was also co-precipitated with the DNA/AP-1 complex in a ligand-dependent manner. However, GC treatment did not cause any appreciable changes in the amount of the other transcription factors bound to the AP-1 site. We therefore con-

clude that GR inhibits IL-11 gene transcription in an AP-1-dependent manner probably by direct interaction with AP-1 and recruitment of co-repressors. Further elucidation of the molecular mechanism by which GC inhibits AP-1-dependent transcription in osteoblasts will help us better understand tissue-specific actions of GC, and may contribute to the development of SGRM (selective GR modulator).

1αOH Vitamin D_2: Primary Functions in Energy Metabolism. N. J. Fleming*[1], C. Corley-Mastick*[2], R. S. Fredericks[1]. [1]Endocrine Associates, Reno, NV, USA, [2]Biochemistry, University of Nevada Reno, Reno, NV, USA.

The role of calcitropic hormones to influence mineral metabolism is widely recognized. Concomitant effects on energy metabolism have received less attention. Vitamin D in particular appears to participate in both mineral and energy modulation. As an ancient signal, recognition of novel actions of Vitamin D should shed light on the origins of receptor-ligand function. We have found 1αOH Vitamin D to have unexpected actions when administered to patients with normally function kidneys. These effects appear to be associated with increases in circulating leptin, while both 1-25 D and PTH are reduced. In developing models of signaling structure to explain these findings, the possibility that $1\alpha D_2$ could have direct effects on adipocyte function has been considered. Primary rat epidydimal adipocyte cultures utilizing exposure to 1-25 D and $1\alpha D_2$ in the presence and absence of a PPARγ agonist, rosiglitazone, demonstrate discordant actions of $1\alpha D_2$ and 1-25 D, where the effects of $1\alpha D_2$ are only seen in the presence of rosiglitazone. Liganded VDR has been demonstrated to interact with PPARγ in the cytoplasm. We propose that $1\alpha D_2$ is able to induce a similar action, but does not act as a functional ligand for nuclear expression regulating gene transcription. Such a mechanism could be primitive and account for the natural selection of 1αhydroxylation of Vitamin D in adaptive behavior in response to inadequate environmental phosphate, as well as selection of receptors as a means to mediate these actions through non-nuclear mechanisms. This concept for Vitamin D as a regulator of energy metabolism as well as mineral metabolism is likely to resolve clinical questions related to thermogenesis, behavior, and phenotypic expression of disease, including diabetes and coronary artery disease.

Leptin secretion over 96 hours (pg/ml)

Rosiglitazone	35.9
1αOH Vitamin D	32.1
1,25 Vitamin D	63.4
Rosiglitazone + 1αOH D	65.0

Effects of Noncalcemic Vitamin D Analogues on PTHrP Production in Prostate and Lung Cancer Cells. S. Tu*[1], D. Burton[1], R. H. Hastings[2], P. Clopton*[3], L. J. Deftos[1]. [1]Medicine, University of California and SDVAMC, San Diego, CA, USA, [2]Anesthesiology, University of California and SDVAMC, San Diego, CA, USA, [3]Research, SDVAMC, San Diego, CA, USA.

We and other investigators have shown that parathyroid hormone-related protein (PTHrP) can directly stimulate tumor cell growth and promote metastases to the skeleton. Therefore, down-regulation of PTHrP expression may provide therapeutic benefits for cancer patients. 1α,25-dihydroxyvitamin D_3 (1,25 D), the active form of vitamin D, decreases PTHrP expression in prostate cancer cells, and it also inhibits proliferation of breast, lung and prostate cancer cells. To reduce the development of hypercalcemia and hyperphosphatemia, the major side effects of vitamin D treatment, synthetic vitamin D receptor ligands are being developed for various medical applications. In an attempt to evaluate even more effective vitamin D analogues for application in selected cancers, we used human prostate cancer (PC-3) and squamous lung cancer cells (BEN) to evaluate the effects of 11 different vitamin D analogues (generously provided by BioXell, Inc. and Leo Pharma) on PTHrP secretion. These cell lines were selected because they robustly express PTHrP. The cells were cultured in the presence or absence of the vitamin D analogues (0-10 nM) for 48 hrs in triplicate dishes in 4 separate experiments. Conditioned media were collected and secreted PTHrP 1-34 was determined by radioimmunoassay. Of the analogues analyzed, the most effective vitamin D analogues in suppressing PTHrP secretion were EB 1089, RO 27-2094, and RO 27-2310. In PC-3 cells these vitamin D analogues suppressed PTHrP by 24-42% and in BEN cells they decreased PTHrP levels by 61-64% compared to vehicle control. In contrast, the 1,25 D was less effective in suppressing PTHrP, reducing PTHrP levels in PC-3 and BEN cells by 3% and 33%, respectively, compared to vehicle controls. From these results, we found that EB 1089, RO 27-2094, and RO 27-2310 were more effective than 1,25 D in down-regulating PTHrP expression in PC-3 and BEN cells. Some of these compounds may prove useful for the management of selected human cancers.

Rapid Responses to 1,25-Dihydroxyvitamin D3 Require Phospholipase A2 Activating Protein for Functional Activation of ERp60 Signaling. B. D. Boyan[1], L. Wang[1], E. A. Graham*[2], V. Sylvia[3], Z. Schwartz[1]. [1]Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, USA, [2]Periodontics, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, [3]Orthopaedics, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

$1,25(OH)_2D_3$ acts through two main pathways: via nuclear vitamin D receptors (VDR) and through rapid membrane-associated signaling pathways, including activation of PLA_2, PLC, PKC and MAP kinase. The membrane-associated $1,25(OH)_2D_3$ binding protein ERp60 (also called 1,25-MARRSbp) is present in growth plate chondrocytes but is functional only in cells from the prehypertrophic and upper hypertrophic zones (growth zone, GC). Here we used antibodies directed to the N- and C-terminals of rat ERp60 and verified that it mediates the effect of $1,25(OH)_2D_3$ on this signaling pathway. We evaluated the role of PLA_2 activating protein (PLAA) in the cell-maturation specific response. RT-PCR and Western blots confirmed that PLAA mRNA and protein were present in confluent cultures of rat costochondral GC cells; Northern blot analysis showed that PLAA expression was not regulated by $1,25(OH)_2D_3$ at 10 min, 12 hours, or 24 hours. PLAA levels in vivo were assessed by in situ hybridization and by immunolocalization of costochondral cartilage from rats as well as from wild-type and nuclear VDR knockout mice. In situ hybridization showed that PLAA was expressed in undifferentiated chondrocytes in 16-day rat fetuses. However, in adult rats PLAA mRNA and protein were found only in the prehypertrophic and upper hypertrophic cartilage. Moreover, both wild type and VDR knockout mice showed the same pattern of expression. PLAA increased PLA_2 specific activity in both plasma membranes and the matrix vesicles and regulated arachidonic acid turnover in a manner similar to $1,25(OH)_2D_3$. Effects of PLAA on alkaline phosphatase and PKC specific activities and proteoglycan production ($[^{35}S]$-sulfate incorporation) were also like those of $1,25(OH)_2D_3$. Inhibitor studies showed that both PLAA and $1,25(OH)_2D_3$ acted through PLA_2, PLC-beta, and PKC-alpha, and that PGE_2 mediated the response through its EP1 receptor and Gq. These results show that PLAA is a critical link between ERp60 and downstream cell-maturation specific signaling in growth plate chondrocytes.

Protein Partners in the Intracelluar Binding and Transport of Vitamin D. R. F. Chun, M. A. Gacad, L. Nguyen, J. S. Adams. Division of Endocrinology, Burns and Allen Research Institute, Cedars-Sinai Medical Center, UCLA School of Medicine, Los Angeles, CA, USA.

In proximal kidney tubular epithelium, vitamin D is internalized by LDL- receptor (megalin)-mediated endocytosis. However, the proteins involved in the post-endocytotic intracellular traffic of vitamin D are less well studied. In previous findings (JBMR 17:S292; 2002) we observed increased uptake of a fluorescently labeled 1,25-dihydroxyvitamin D (1,25D) in HKC-8 cells transfected with plasmid expressing human hsc70 (member of hsp70 family of chaperones) and reduced uptake with ATPase domain-mutated hsc70 compared to HKC-8 transfected with vector alone. This result is consistent with the known role of hsc70 in clatherin uncoating of endocytic vesicles. Besides assisting internalization, hsc70 may also serve to bind and transport vitamin D intracellularly. Suggestive evidence of this includes: hsc70 can be detected in pull-downs with GST-C terminal megalin but not with GST alone and specific binding of 25-hydroxylated vitamin D metabolites (25D and 1,25D) to hsc70 can be measured. To further confirm and characterize hsc70's specific vitamin D binding ability and the role of ATP, binding assays were performed in the presence and absence of ATP. A several-fold, significant increase ($p<0.05$) in specific binding for 25D and 1,25D was observed when 2 μM ATP was included in the reaction mixture; interestingly, specific binding of cholesterol to hsc70 was also enhanced by ATP ($p<0.05$) indicating that cholesterol may share hsc70 as a trafficking chaperone. Vitamin D metabolic activity occurs in mitochondria; thus, an hsc70-like protein residing in mitochondria would be a candidate for involvement in subcellular vitamin D trafficking. The mitochondrial hsc70 equivalent, grp75, fits this description. We synthesized holo-grp75 and various domain-deletion mutants in *e. coli* and purified them with HIS-tag/Ni affinity chromatography. An expression construct of grp75 missing the first 63 amino acids (i.e. minus the mitochondrial targeting sequence) produced a protein that retained specific binding for 25D and 1,25D, while a C-terminal fragment of grp75 did not. We also detected grp75 in GST-C-terminal 1-hydroxylase pull-down assays of whole cell protein extracts suggesting a protein-protein interaction between grp75 and vitamin D-1-hydroxylase. Taken together, our current working model for vitamin D traffic holds that it enters the cell via LDL-receptor mediated endocytosis and is picked up by cytoplasmic hsc70. Vitamin D metabolite can then be passed to VDR (nuclear destined transcription factor) or grp75 that may facilitate transfer to mitochondria-localized vitamin D hydroxylases for hormone metabolism or catabolism or both.

1,25-dihydroxyvitamin D_3 Increases Hypoxia Inducible Factor-1alpha and Vascular Endothelial Growth Factor mRNA Expression and Release via Phosphatidylinositol-3-Kinase. M. J. Levine*, J. Noll*, D. Teegarden. Foods and Nutrition, Purdue University, West Lafayette, IN, USA.

Previously we reported phosphatidylinositol 3-kinase (PI3K) plays a role in 1,25 dihydroxyvitamin D_3 (1,25D) induced vascular endothelial growth factor (VEGF) release, in part by activating the VEGF promoter at 24 hrs in C3H10T½ cells. Here, we examine the role of PI3K in 1,25D stimulation of VEGF release (ELISA) and mRNA expression (RT-PCR). 1,25D significantly increased VEGF release 2-fold by 8 hrs and remained elevated at 24 hrs. 1,25D-induced VEGF release involves transcription, as it was blocked by actinomycin D. 1,25D stimulation of VEGF mRNA levels and release are abrogated by PI3K inhibition at 8 hrs. Since no known vitamin D response element exists on the VEGF promoter, we investigated if transcription factors nuclear factor κB (NFκB) and hypoxia inducible factor-1α (HIF-1α), a subunit of HIF-1, which may regulate VEGF via PI3K, mediate the effect of 1,25D. While PI3K mediated 1,25D induction of NFκB activity, NFκB did not mediate 1,25D-induced VEGF release since it was unaffected by a constitutively active mutant construct of IκB that impedes NFκB activity. 1,25D increased levels of a protein immunoreactive with the HIF-1α antibody 2.6-, 1.6-, and 3.2-fold at 0.5, 2, and 4 hours. Further, PI3K inhibition modestly suppressed 1,25D's increase of HIF-1α. In conclusion, PI3K is involved in 1,25D induction of HIF-1α and is required for 1,25D to increase VEGF mRNA and release. The Coordinated Action of Parathyroid Hormone and 1,25-Dihydroxyvitamin D_3 Is Essential for Endochondral Bone Formation and Postnatal Survival. Y. B. Xue, A. C. Karaplis, G. N. Hendy, D. Goltzman, D. S. Miao. Medicine, McGill University, Montreal, PQ, Canada.

We previously generated, by targeted gene ablation, mouse models homozygous for either the PTH ($PTH^{-/-}$) or 1α-hydroxylase (1α-$(OH)ase^{-/-}$) null alleles. Although both animal models developed post-weaning hypocalcemia on a normal calcium diet, they were viable. In the current study, we generated double "knockout" mice which are homozygous for both the 1α-hydroxylase and PTH null alleles (1α-$(OH)ase^{-/-}PTH^{-/-}$). Double knockout mice appeared normal at birth but died 1-3 weeks postnatally, prior to the end of weaning with severe tetany. Serum calcium concentrations at two weeks of age, were 2.5±0.02, 1.7±0.07, 2.2±0.08 and 1.2±0.05 mmol/L in wild-type, $PTH^{-/-}$, 1α-$(OH)ase^{-/-}$ and 1α-$(OH)ase^{-/-}PTH^{-/-}$ mice, respectively. mRNA and protein expression levels of epithelial calcium channel 1 (EcaC1), calbindin-D_{9K}, calbindin-D_{28K} and Na^+/Ca^{2+} exchanger 1 (NCX1) in kidney and calbindin-D_{9K} gene expression in intestine were decreased in $PTH^{-/-}$ mice, more markedly reduced in 1α-$(OH)ase^{-/-}$ mice and dramatically diminished in 1α-$(OH)ase^{-/-}PTH^{-/-}$ mice. Overall body and long bone size were reduced in all three mutant mice at 2 weeks of age, compared to wild-type controls, however, the reductions were most severe in the double mutants. Epiphyseal cartilaginous growth plates were widened in 1α-$(OH)ase^{-/-}$ mice and double mutants had reduced secondary ossification centers. Double mutants, with the lowest serum calcium/phosphate product, showed diminished mineralization of cartilage and bone. Trabecular bone volume was moderately diminished in $PTH^{-/-}$ mice and 1α-$(OH)ase^{-/-}$ mice, but markedly decreased in 1α-$(OH)ase^{-/-}PTH^{-/-}$ mice in association with reduced osteoblast number and diminished expression levels of alkaline phosphatase, type I collagen and osteocalcin. Osteoclast number and RANKL levels were also decreased. The results demonstrate that alteration in PTH and 1,25-$(OH)_2D_3$ levels in PTH and 1α-(OH)ase deficiency can modulate the expression of critical genes in the transcellular calcium transport system that contribute to severe hypocalcemia and reduced survival. The results also demonstrate: that 1,25-$(OH)_2D_3$ regulates epiphyseal growth plate development, that a low calcium/phosphate product can impede cartilage and bone mineralization, that PTH and 1,25-$(OH)_2D_3$ together regulate trabecular bone formation, and that combined deficiency of these modulators leads to severe defects in endochondral bone formation.

Candidate Genes for Novel Vitamin D-Dependent Proteins in the Mouse Kidney. R. A. Meyer, M. H. Meyer. Department of Orthopaedic Surgery, Carolinas Medical Center, Charlotte, NC, USA.

The mammalian kidney is known to express three vitamin D-dependent proteins: calbindin D_{9K}, calbindin D_{28K}, and C/EBPβ (Christakos *et al.*, J Cell. Biochem. 88: 238, 2003). To search for novel vitamin D-dependent transcripts, we have examined the Affymetrix MOE 430A and 430B whole-genome microarrays (>40,000 transcripts). The experimental model was to find transcripts which were down-regulated in response to the acute deprivation of 1,25-dihydroxyvitamin D_3 which occurs when X-linked hypophosphatemic (*Hyp*) mice are fed a low phosphate diet. Normal and *Hyp* mice at 10 weeks of age were fed control or low phosphate diet for 3 days. Three mice were pooled for each of six microarrays per treatment group. Normal mice showed a significant rise in 25-hydroxyvitamin D-1α-hydroxylase mRNA transcript levels when fed a low phosphate diet. In contrast, the 25-hydroxyvitamin D-1α-hydroxylase transcript level fell in *Hyp* mice fed the low phosphate diet ($P = 0.02$) to 0.044 times that of *Hyp* mice fed the control diet. This was the largest proportional decrease among all genes examined. The transcript level for calbindin D_{9K} had the second largest fall in *Hyp* mice on low phosphate diet to 0.17 times the level of *Hyp* mice fed the control diet ($P < 0.001$). Seven other genes also had stable or increased transcript levels in normal mice fed the low phosphate diet, while, in *Hyp* mice fed the low phosphate diet, their transcript levels decreased to 0.25 to 0.33 times that of *Hyp* mice fed the control diet (all decreases were significant at $P < 0.05$). These seven genes (GenBank entries: AV369309, BB660640, BM194786, BB046307, AW913782, BB732233, and AK016112) are all relatively weak expressors, are unnamed, and are of unknown function. In conclusion, a whole genome search of transcript levels of genes expressed in the mouse kidney has revealed seven candidate genes for novel vitamin D-dependent proteins.

Vitamin D Status: Long-Term Variability in Postmenopausal Women. A Follow Up Study. L. Rejnmark[1], A. L. Lauridsen*[2], P. Vestergaard[1], C. Brot*[3], L. Heickendorff*[2], L. Mosekilde[1]. [1]Dept of endocrinology and metabolism C, Aarhus Amtssygehus, Aarhus, Denmark, [2]Dept of Clinical Biochemistry, Aarhus Sygehus, Aarhus, Denmark, [3]The Osteoporosis Research Centre, Hvidovre Hospital, Hvidovre, Denmark.

Measurements of plasma 25-hydroxyvitamin D (25OHD) levels are often used in patients to determine vitamin D status. Our aim was to investigate whether individual plasma 25OHD- and vitamin D-binding protein (DBP) levels are stable over a period of 5 years in healthy postmenopausal women. We followed 187 women who were perimenopausal at baseline for five-year. At baseline, 89 women were allocated to treatment with Hormone replacement therapy (HRT). Measurements were performed at baseline and after one-, two-, and five-years of follow up. Use of HRT increased plasma levels of DBP (+8%) but did not affect 25OHD levels. At baseline, 25OHD levels were higher in women who reported that they often went sunbathing and in those using vitamin D supplements, whereas smoking was inversely associated with 25OHD levels. Analyses on within-patient variability revealed a high coefficient of variation (CV) on 25OHD measurements (app. 20%); mostly due to a large biological variation (18.9%). Among those classified in the lowest tertile at baseline, only 40% remained in the lowest tertile during all subsequent time-points of measurements. Similarly, only 32% of those classified in the highest baseline tertile remained in the highest tertile during all following measurements. Use of the free vitamin D index (molar ratio of 25OHD- to DBP-levels) showed similar results. No independent predictors of changes in vitamin D tertiles during follow up were identified. Thus, in healthy postmenopausal women, individual measurement of a single plasma 25OHD level is not a reliable predictor of vitamin D status during the following five-year. Measurements of 25OHD levels should be restricted to patients with symptoms and signs of hypovitaminosis D. Our results do not exclude the use of 25OHD measurements in groups of patients. In the general population, 25OHD levels may be useful to identify factors influencing vitamin D status in order to determine how to improve vitamin D status.

The Effect of Calcium Intake on the Vitamin D Requirement. R. Y. Goussous*[1], L. Song*[2], G. Dallal*[3], B. Dawson-Hughes[2]. [1]Division of Endocrinology, Tufts-New England Medical Center, Boston, MA, USA, [2]Bone Metabolism Laboratory, JM USDA HNRCA at Tufts University, Boston, MA, USA, [3]Biostatistics Department, JM USDA HNRCA at Tufts University, Boston, MA, USA.

It has been postulated that a low calcium intake may increase the vitamin D requirement. This study was conducted to examine the effect of increasing calcium intake on the rise in serum 25-hydroxyvitamin D [25(OH)D] levels in response to supplemental vitamin D3.

The subjects were 52 healthy men and postmenopausal women with a mean age of 61.7 ± 8.5 (SD) years, and with screening 25(OH)D levels restricted to the range of 22.5 to 63.0 nmol/l. They were randomly assigned to either calcium (500 mg twice daily with meals) or placebo tablets for 90 days. All participants were placed on 800 IU per day of vitamin D3. Serum 25(OH)D measurements were made at baseline and on days 30, 60 and 90. The study was approved by the Investigation Review Board.

The basal mean calcium intake was 521 ± 341 mg/day in the calcium group and 634 ± 352 mg/day in the placebo group (P=0.251). The mean baseline 25(OH)D values were 48.0 ± 15.8 nmol/l in the calcium group and 49.0 ± 16.8 nmol/l in the placebo group (P=0.808). The change in 25(OH)D during the study didn't differ significantly in the two groups (ANOVA P = 0.700). The mean change from day 1 to day 90 was 16.2 ± 14.8 nmol/l in the calcium group and 16.6 ± 17.4 nmol/l in the placebo group (P=0.923 for difference, 95% CI (calcium-placebo) = (-9.5, 8.7) nmol/l). Both groups increased significantly over time (P< 0.001). We conclude that in healthy older men and women, the level of calcium intake, within the range of 550 to 1500 mg per day, doesn't affect the rise in serum 25(OH)D that occurs in response to the frequently recommended dose of 800 IU per day of vitamin D3.

Post-Translational Means of Regulating 25-Hydroxyvitamin D-1-Hydroxylase Activity. S. Wu, L. Nguyen*, R. F. Chun, J. S. Adams. Endocrinology, Cedars-Sinai Medical Center, Los Angeles, CA, USA.

The vitamin D-1-hydroxylase is a mitochondrial-based cytochrome P450 enzyme. It is the product of the CYP-1α gene and preferentially catalyzes the conversion of 25-hydroxylated vitamin D substrates to their cognate 1α-hydroxylated metabolite. Expression of 1-hydroxylase enzyme activity in both renal and extrarenal sites is regulated at the level of CYP-1α transcription and post-translationally based on 1] the cellular site of residence of the enzyme and its access to required accessory proteins, 2] the presence and amount of competitive CYP-24 (24-hydroxylase) gene product and 3] the delivery of substrate to the 1-hydroxylase. With regard to the latter, we have recently shown that cellular uptake of a 25-hydroxylated vitamin D metabolite and expression of 1-hydroxylase enzymatic activity is enhanced in cells

overexpressing the cytoplasmically-based intracellular vitamin D trafficking protein, hsc70. Because hsc70-bound vitamin D metabolite does not enter the mitochondrial compartment, we theorized that 1] substrate 25-hydroxyvitamin D (25-D) may be passed from hsc70, bearing a relatively low affinity for 25-D, to the relatively high-affinity substrate binding domain of the 1-hydroxylase in the cell cytoplasm and 2] it is the substrate-"preloaded", inner membrane-targeted 1-hydroxylase that determines the yield of product 1,25-dihydroxyvitamin D (1,25-D). Using gst-pulldown, a protein-protein interaction between the C-terminal domain of hsc70 and the 1-hydroxylase was demonstrated in the human kidney cell line HKC-8, confirming the potential for hsc70 to pass substrate 25-D to the 1-hydroxylase. In order to support the hypothesis that it is 1-hydroxylase "preloaded" with substrate-in the cell cytoplasm that determines 1-hydroxylating potential of the cell, the holo human 1-hydroxylase (1-522) and truncated, but substrate binding competent, 1-hydroxylase (94-522) missing the N-terminal mitochondrial-targeting domain were transiently over-expressed in HKC-8 cells. Compared to vector-alone-transfected cells, specific 25-D uptake was increased significantly, 61% (p=0.03) and 75% (p=0.02), in holo and N-terminally-truncated 1-hydroxylase-transfected cells, respectively. However, transient overexpression of the N-terminally-truncated 1-hydroxylase significantly squelched endogenous 1-hydroxylase activity in either 24-hydroxylase-competent HKC (p=0.006) or 24-hydroxylase-incompetent, macrophage-like HD11 cells (p=0.01). Contrary to current dogma, these data suggest that the 25-D substrate-1-hydroxylase interaction may occur in the cell cytoplasm prior to enzyme trafficking to the inner mitochondrial membrane.

Characterization of Recombinant CYP2C11: A Vitamin D 25-Hydroxylase and 24-Hydroxylase. M. Rahmaniyan*[1], K. Patrick*[2], N. H. Bell[1]. [1]Medicine, Medical University of South Carolina, Charleston, SC, USA, [2]Medical University of South Carolina, Charleston, SC, USA.

Studies were performed to further characterize rat male-specific hepatic recombinant microsomal vitamin D-25-hydroxlase CYP2C11 expressed in baculovirus-infected insect cells and whether it also is a vitamin D-24-hydroxylase, a physiologically significant alternative pathway of vitamin D_2 metabolism. CYP2C11 is not expressed in livers of female rats. 25- and 24-hydroxylase activities were compared to those of ten other rat recombinant hepatic microsomal cytochrome P-450 enzymes expressed in baculovirus-infected insect cells. Each of them 25-hydroxylated vitamin D_2, vitamin D_3, 1α-hydroxyvitamin D_2 [1αOHD_2] and 1α-hydroxyvitamin D_3 [1αOHD_3]. CYP2C11 had the greatest activity except for vitamin D_3 where it had the same activity as 4 of the other enzymes. CYP2C11 25-hydroxylated 1αOHD_3, 1αOHD_2, vitamin D_2, and vitamin D_3 in declining order. Each of the recombinant cytohrome P-450 enzymes 24-hydroxylated 1αOHD_2 and CYP2C11 had the greatest activity. 24-Hydroxylation of 1αOHD_3 was very low and there was none with vitamin D_3. Only CYP2C11 24-hydroxylated vitamin D_2. Rat liver microsomes and CYP2C11 also 26-hydroxylated 1αOHD_2 and 1αOHD_3. K_m and V_{max} values for 24-, 25- and 26-hydroxylation of 1αOHD_2 and 1αOHD_3 by recombinant CYP2C11 were determined. Structures of vitamin D metabolites including 24-hydroxyvitamin D_2, 1,24*(S)*-dihydroxyvitamin D_2, 1,24-dihydroxyvitamin D_3, 1,26-dihydroxyvitamin D_2, and 1,26-dihydroxyvitamin D_3 were confirmed by HPLC and gas chromatography retention times, and characteristic mass spectrometric fragmentation patterns. In male rats, hypophysectomy significantly reduced body weight, liver weight, hepatic CYP2C11 mRNA expression and 24- and 25-hydroxylation of 1αOHD_2. It is concluded that CYP2C11 is male-specific hepatic microsomal vitamin D-25-hydroxylase that hydroxylates vitamin D_2, vitamin D_3, 1αOHD_2, and 1αOHD_3. CYP2C11 also is a vitamin D 24-hydroxylase.

Evidence for a Gastrointestinal-Kidney Axis Modulating Phosphate Effects on Vitamin D Metabolism. B. Yuan*[1], Y. Xing*[1], R. Achyutharao*[1], J. F. Collins*[2], F. K. Ghishan*[2], M. K. Drezner[1]. [1]Medicine, University of Wisconsin, Madison, WI, USA, [2]Pediatrics, University of Arizona Health Sciences Center, Tucson, AZ, USA.

Alteration of the serum phosphorus (P) concentration, due to dietary phosphate loading or depletion, modulates renal 25(OH)D-1α-hydroxylase activity, suggesting that circulating P levels regulate vitamin D metabolism. However, when aberrant Na^+-dependent phosphate transport underlies hyperphosphatemia (Tumoral Calcinosis) or hypophosphatemia (X-Linked Hypophosphatemia), the disease phenotype does not include expected changes in calcitriol production. Thus, it remains unclear if serum P directly influences renal 25(OH)D-1α-hydroxylase activity. Therefore, we compared 25(OH)D-1α-hydroxylase mRNA (RT-PCR), protein (Western) and enzyme activity in male 8-12 week old C57BL/6J normal and phosphate loaded mice with that in similarly aged male C57BL/6J transgenic (*KAP* [**K**idney **A**ndrogen-responsive **P**rotein]-*Npt2*) mice with hyperphosphatemia, due to *Npt2* over-expression and consequent enhanced renal Na^+-dependent phosphate transport. Mice were fed a similar diet (0.8% P) until 10 days before study when phosphate loaded mice received a P (1.5%) enriched ration. The serum P level in transgenic (8.9±0.3 mg/dl) and phosphate loaded mice (8.9±0.1 mg/dl) was similar and significantly elevated (p<0.001) above that in normal mice (6.1±0.2 mg/dl). In contrast, compared to normal mice, phosphate loaded mice exhibited a 2.5-fold suppression (p<0.001) of 25(OH)D-1α-hydroxylase mRNA while transgenic mice displayed normal mRNA levels (fold change: 1.0±0.04 vs 0.4±0.03 vs 1.1±0.08). Similarly, 25(OH)D-1α-hydroxylase protein was selectively decreased (p<0.001) in the phosphate loaded mice (fold change: 1.0±0.1 vs 0.4±0.1 vs 1.0±0.2) as was the enzyme activity (5.6±0.2 vs 3.8±0.4 vs 5.6±0.7 fmoles/mg/min; p<0.002). These data indicate 25(OH)D-1α-hydroxylase activity is not uniformly influenced by the serum P level, possibly due to hyperphosphatemia of variable cause impacting differently on proximal tubule cell cytosolic events or to a direct effect of the GI system on kidney function. We excluded the former possibility by discovering that hyperphosphatemia in phosphate loaded and transgenic mice equally stimulates mRNA transcripts of renal PEX19 (fold change: 1.0±0.1 vs 1.3±0.1 vs 1.2±0.2; p<0.05), a peroxisomal farnesylated protein, which initiates a cascade of cytosolic events regulating Npt2 endocytosis. These observations establish that circulating P levels do not directly modulate renal 25(OH)D-1α-hydroxylase activity and suggest that regulation of vitamin D metabolism may depend on unique modulating effects of the Gastrointestinal-Kidney axis.

C-3 Epimerization of Vitamin D_3 Metabolites in Osteoblast like cells. M. Kamao*[1], S. Hatakeyama*[2], N. Kubodera[3], T. Okano[1]. [1]Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, [2]Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, [3]Chugai Pharmaceutical Co. Ltd., Tokyo, Japan.

Purpose: We have demonstrated that 25-hydroxyvitamin D_3 [25(OH)D_3] and 1α,25-dihydroxyvitamin D_3 [1α,25$(OH)_2D_3$] are metabolized into their epimers of hydroxyl group at C-3 of the A-ring in hepatoblastoma and osteosarcoma cell lines. In the present study, we examined the C-3 epimerization during differentiation in osteoblast-like cells and the basic properties of the enzyme responsible for the C-3 epimerization of vitamin D_3.

Materials and Methods: UMR-106 [rat, osteosarcoma] and MC3T3-E1 [mouse, calvaria] cells were cultured for 28 days with 50 μg/mL ascorbic acid and 10 mM β-glycerophosphate. Amounts of 25(OH)D_3 metabolites were determined by HPLC and the mRNA levels of alkaline phosphatase (ALP) and osteopontin (OP) were measured by real time RT-PCR. The degree of mineralization was assessed by Arizarin Red S staining. The microsome fraction of UMR-106 cells was incubated with vitamin D_3 compounds in the presence of NADPH-generating substrates.

Results: In UMR-106 cells, C-3 epimerization activity was increased until day 15 and maintained its level throughout the period. On the other hand, C-24 hydroxylation activity was increased for 28 days. The mRNA level of ALP reached the maximal level at day 15. Mineralization was observed after 10 days. In MC3T3-E1 cells, maximal level of C-3 epimerization activity was observed at day 5. The expression of ALP was gradually decreased until day 28 and mineralization was observed after 15 days. In both cell lines, C-3 epimerization activity was not related to the expression level of OP and the production ratio of C-3 epimer to C-24 hydroxide at day 5 was the highest. Vmax values for 1α,25$(OH)_2D_3$, 25(OH)D_3, 24,25-dihydroxyvitamin D_3 [24,25$(OH)_2D_3$] and 22-oxacalcitriol (OCT) were 1.52, 2.34, 0.51 and 0.03 pmol/min/mg protein, respectively and Km values for 1α,25$(OH)_2D_3$, 25(OH)D_3, 24,25$(OH)_2D_3$ and OCT were 98.9, 73.7, 200.1 and 24.2 μM, respectively. These results indicate that 25(OH)D_3 has the highest specificity for C-3 epimerization among the four compounds. In addition, C-3 epimerization activity was not inhibited by various cytochrome P450 inhibitors or anti serum of NADPH cytochrome P450 reductase. C-3 epimerization activity was not induced by 1α,25$(OH)_2D_3$ in UMR-106 cells.

Conclusion: C-3 epimerization activity may be altered during osteoblast differentiation. The enzyme responsible for the C-3 epimerization of vitamin D_3 are thought to differ from already-known cytochrome P450 related vitamin D metabolic enzymes and not induced by 1α,25$(OH)_2D_3$.

The Microsomal Vitamin D_3-25 Hydroxylase, *CYP2R1*, Is Expressed in the Normal Human Liver and Kidney and its Hepatic mRNA Levels are Negatively Correlated with the Circulating 1,25$(OH)_2$D Concentrations. M. Gascon-Barré, C. Demers*. Hopital Saint-Luc, Centre de recherche du CHUM, Montreal, PQ, Canada.

Vitamin D (D) must be hydroxylated in the liver at C-25 before acquiring its full hormonal potential in the kidney. A mitochondrial D_3 C-25-hydroxylase (CYP27A1) has been described and shown to play a substantial role in human. Lately, the orphan microsomal *CYP2R1* has been proposed as a potential D-25-hydroxylase. The purpose of our study was to evaluate the *CYP2R1* gene expression levels in adult and foetal human livers and kidneys. In addition, to probe the role of 1,25$(OH)_2D_3$ in its regulation, *CYP2R1* mRNA levels were evaluated in two human hepatoma cell lines following exposure to vehicle or 1,25$(OH)_2D_3$. Adult subjects referred for hepatic or renal surgery were recruited. In addition, 5 normal foetuses (16-20 wks of gestation) were obtained following voluntary termination of pregnancy. All mRNA levels are presented as *CYP2R1/GAPDH* ratios. The *CYP2R1* gene transcript was found to be clearly expressed in liver and kidney of both adult and foetal specimens. However, mean *CYP2R1* mRNA levels were found to be 2.3 times higher in liver than in kidney of adult specimens (p<0.05), and no correlation was observed between the expression of *CYP2R1* and *CYP27A1*. *CYP2R1* mRNA levels were also found to be twice as high in adult than in foetal livers. In adult subjects, hepatic *CYP2R1* mRNA levels were shown to decrease logarithmetically as serum 25OHD increased (n=12, r^2 = 0.392, p<0.05) which resulted in a significant difference between patients presenting low serum 25OHD (<37 pmol/L) and those with normal D status (*CYP2R1* levels 1.2±0.1 vs 0.4±0.1, p<0.001). In patients with serum 1,25$(OH)_2$D concentrations above 50 pmol/L, a significant negative linear correlation was observed between circulation 1,25$(OH)_2$D concentrations and hepatic *CYP2R1* mRNA levels (n=9, r^2 = 0.567, p<0.05). In addition, the hepatoma cell line HEP3B which expresses very low *CYP27A1* mRNA levels exhibited a 3 times higher *CYP2R1* expression levels than the HEPG2 cell line which expresses normal levels of the *CYP27A1* gene transcript. Moreover, 1,25$(OH)_2D_3$ but not D_3 was shown to negatively regulate the expression of the *CYP2R1* gene transcript in HEP3B (p<0.05) while it had no effect in the HEPG2 cell line. Our findings illustrate that the microsomal *CYP2R1* is expressed in the human adult and foetal liver and kidney and that a negative relationship between *CYP2R1* mRNA levels and 1,25$(OH)_2D_3$ is present in both *in vitro* and *in vivo* conditions.

Prostate Cells Express Vitamin D-25-Hydroxylases and Can Synthesize 1α,25-Dihydroxyvitamin D_3 from Vitamin D_3. J. N. Flanagan*, M. V. Young*, L. W. Whitlatch*, J. S. Mathieu*, K. S. Persons*, M. F. Holick, T. C. Chen. Department of Medicine, Boston University School of Medicine, Boston, MA, USA.

The biologically active form of vitamin D, 1α,25-dihydroxyvitamin D (1,25D), plays essential roles in calcium homeostasis, and regulates proliferation and differentiation of a variety of cells, including prostate cells. Two hydroxylation steps catalyzed by vitamin D-25-hydroxylase (25-OHase) in the liver and 25-hydroxyvitamin D (25D)-1α-hydroxylase (1α-OHase) in the kidneys are required for the activation of vitamin D to 1,25D. Previously, we reported that 1α-OHase is also expressed in extra-renal tissues, including prostate cells, suggesting that local production of 1,25D could provide an important cell growth regulatory mechanism. Now, we present evidence that prostate cells also possess 25-OHase and are capable of metabolizing vitamin D_3 to $1,25D_3$ in the immortalized PZ-HPV-7 cells derived from normal prostate tissue. Three types of 25-OHase, one mitochondrial (CYP27A1) and two microsomal (CYP3A4 and CYP2R1), have been described. Using real-time PCR we found that CYP2R1 was expressed two-fold greater in normal human prostate tissue, 3-fold greater in PZ-HPV-7 cells and 6-fold greater in LNCaP prostate cancer cells than in normal liver tissue, whereas CYP27A1 was expressed 10-fold greater in normal liver tissue than in normal prostate tissue. Very little or no expression of CYP27A1 was found in PZ-HPV-7, LNCaP and PC-3 cells. PC-3 cells also expressed very little or no CYP2R1. The presence of 25-OHase in PZ-HPV-7 cells was further supported by the use of functional assays: (1) the addition of vitamin D_3 caused a dose-dependent up-regulation of 24-hydroxylase (CYP24A1) and IGF-BP3 mRNA, two genes known to be sensitive to 1,25D regulation in prostate cells, (2) vitamin D_3 at 10^{-6} M caused a 40% inhibition of ^{3}H-thymidine incorporation into DNA. These data suggest that vitamin D_3 was converted to $25D_3$, which in turn was further converted to $1,25D_3$ before exerting biological actions in prostate cells. The higher expression of CYP2R1 in prostate cells than in liver cells may have chemo-preventive relevance in prostate cancer, since CYP2R1 has been recently identified by a gene mutation analysis of a vitamin D deficient patient as a biologically relevant 25-OHase. Our results suggest that maintaining adequate levels of serum vitamin D or 25D by oral supplementation or sun exposure can be a safe and effective chemo-preventive measure to decrease the risk of prostate cancer.

Vitamin D Metabolism in Human Osteoblasts. G. J. Atkins[1], P. H. Anderson*[2], K. Welldon*[1], A. C. W. Zannettino*[3], H. A. Morris*[4], D. M. Findlay[1]. [1]Orthopaedics and Trauma, University of Adelaide, Adelaide, Australia, [2]Div. of Endocrinology, Institute of Medical and Veterinary Science, Adelaide, Australia, [3]Div. of Haematology, Institute of Medical and Veterinary Science, Adelaide, Australia, [4]Hanson Institute, Adelaide, Australia.

Circulating 1α ,25-dihydroxyvitamin D_3 (1,25D) derives from conversion of 25-hydroxyvitamin D_3 (25D) by the kidney 1α -hydroxylase (CYP27B1). 1,25D exerts a number of effects on human osteoblasts, including inhibition of proliferation and differentiation, and effects on gene expression, including stimulation of RANKL, osteocalcin (OCN) and bone sialoprotein (BSP). We have examined vitamin D_3 metabolism in human osteoblastic cells, and found that primary normal human osteoblasts (NHBC) and human osteosarcoma cell lines, including MG-63, SaOS-2, HOS, G-292, all up-regulate the negative regulator of 1,25D, the 24-hydroxylase (CYP24), in response to 1,25D exposure. Additionally, all of these cell types expressed CYP27B1 mRNA, implying that human osteoblasts are capable of metabolising 25D into 1,25D. We have investigated this possibility and found that NHBC exposed to physiological concentrations of 25D (10 - 100 nM) in the absence of serum, exhibit up-regulated transcription of the downstream genes RANKL and OCN. Unlike 1,25D, 25D did not elicit a vigorous CYP24 response except at high concentrations (10^{-7} - 10^{-6} M). Consistent with this, NHBC treated with high concentrations of 25D secreted detectable 1,25D into the culture supernatant. We also found that NHBC express the 25-hydroxylase, and treatment with 1-hydroxyvitamin D_3 (1D), resulted in a gene expression response qualitatively similar to 25D. Inhibition of CYP activity using ketoconazole (10 μ M) resulted in an elevated response to 1,25D, probably due to inhibition of the catabolic activity of CYP24. Results to date indicate that the activity of 1D is CYP-dependent, since ketoconazole abolished its effects. However, 25D effects at low concentrations were unaffected by ketoconazole, indicating that 25D may have direct effects in osteoblasts independent of its conversion to 1,25D. Our results suggest that vitamin D_3 metabolism represents an intrinsic autocrine/paracrine pathway in these cells. Thus, vitamin D metabolites may regulate key functions in human osteoblasts independently of circulating levels of 1,25D.

Auto/Paracrine Action of Vitamin D in Bone: Evidence for 1alpha-Hydroxylase Expression and Activity in Human Osteoblasts. M. van Driel*[1], C. J. Buurman*[1], M. Koedam*[1], H. Chiba*[2], H. A. P. Pols[1], J. P. T. van Leeuwen[1]. [1]Internal Medicine, Erasmus MC, Rotterdam, Netherlands, [2]Pathology, Sapporo Medical University School of Medicine, Sapporo, Japan.

Vitamin D is metabolised by sequential hydroxylations in liver and kidney. 25-Hydroxyvitamin D_3 ($25\text{-}(OH)D_3$) formed in the liver is metabolised to the active metabolite $1\alpha,25\text{-}(OH)_2D_3$ ($1\alpha,25\text{-}(OH)_2D_3$) in the kidney by the enzyme 1α-hydroxylase. However, 1α-hydroxylase expression or activity has also been reported at several extrarenal sites like skin, lymph nodes, and colon at which local synthesis of $1\alpha,25\text{-}(OH)_2D_3$ appears to fulfil autocrine or paracrine functions. Over 20 years ago also $1,25\text{-}(OH)_2D_3$ production by osteoblasts was reported but this was never further explored and functionally tested. Recently, we observed a significant increase in osteocalcin mRNA expression after short-term incubations of human osteoblasts with $25\text{-}(OH)D_3$. Aim of the current study was to extend the data on $25\text{-}(OH)D_3$ effects on human osteoblast differentiation and to study 1α-hydroxylase expression and $1\alpha,25\text{-}(OH)_2D_3$ production in human osteoblasts. Moreover, to assess expression of cubilin and megalin, mediators of cellular uptake of the $25\text{-}(OH)D_3$-vitamin D-binding protein (DBP) complex, in human osteoblasts.

Short-term treatment of differentiating human osteoblasts (SV-HFO) with $25\text{-}(OH)D_3$ (1 μM) increased alkaline phosphatase activity and 24-hydroxylase mRNA expression throughout the three weeks osteoblast differentiation process.

We found 1α-hydroxylase mRNA expression in human osteoblasts and human bone biopsies. Incubation of SV-HFO cells for 48 hrs with $25\text{-}(OH)D_3$ (1 μM) resulted in the production of about 600 pM $1,25\text{-}(OH)_2D_3$ (assayed using radioimmunoassay). The $1,25\text{-}(OH)_2D_3$ formed from $25\text{-}(OH)D_3$ exerted comparable effects as equimolar concentrations freshly added $1,25\text{-}(OH)_2D_3$. Time-course studies showed that already after one hour $25\text{-}(OH)D_3$ incubation 50 pM $1,25\text{-}(OH)_2D_3$ could be detected. Production of $1,25\text{-}(OH)_2D_3$ showed a clear substrate-concentration dependency. 1α-Hydroxylase activity decreased during osteoblast differentiation. $1\alpha,25\text{-}(OH)_2D_3$ did not change 1α-hydroxylase mRNA expression nor did 24 hours $1,25\text{-}(OH)_2D_3$ pre-incubation affect 1α-hydroxylase activity in human osteoblasts. Finally, cubilin and megalin mRNAs were expressed in human osteoblasts.

In conclusion, we show that human osteoblasts express 1α-hydroxylase and $25\text{-}(OH)D_3$-DBP receptors and are capable to produce $1\alpha,25\text{-}(OH)_2D_3$ concentrations that regulate osteoblast activity. Thereby, these data provide evidence for an autocrine and/or paracrine vitamin D endocrine system in human osteoblasts and bone.

Regulation of the Renal Vitamin D 1alpha-Hydroxylase Cytochrome P450 (CYP27B1) mRNA and Protein by Dietary Phosphorus in Young and Adult Rats. H. J. Armbrecht, M. A. Boltz*. Geriatric Center, St. Louis VA Medical Center, Saint Louis, MO, USA.

Previous studies have shown that the capacity of rats to adapt to low dietary phosphorus declines with age. Young rats adapt to a low phosphorus diet by increasing plasma levels of 1,25-dihydroxyvitamin D (1,25D), which increase intestinal phosphate and calcium absorption, but adult and old animals do not. The purpose of this study was to determine whether this decreased adaptation was due to decreased expression of the renal 1alpha-hydroxylase (1-OHase), which synthesizes 1,25D. Young (2 month) and adult (12 month) male F344 rats were placed on a low phosphorus (0.1%) or high phosphorus (1.0%) diet for 2 weeks. Plasma 1,25D was markedly increased by the low phosphorus diet in young animals but not in adults. To determine whether this difference was due to decreased 1-OHase expression, mRNA levels of the terminal cytochrome P450 (CYP27B1) of the 1-OHase were measured by ribonuclease protection assay. In young animals, the low phosphorus diet increased renal CYP27B1 mRNA levels 8-fold compared to the high phosphorus diet, but there was no increase in adults. Protein levels of renal CYP27B1 were measured by Western blotting, using a specific anti-peptide polyclonal antibody. Interestingly, CYP27B1 protein levels were not increased by the low phosphorus diet in either age group in these experiments. In parallel experiments, feeding a low calcium diet markedly increased CYP27B1 protein levels in young rats but not in adult rats. The effect of low dietary phosphorus on plasma calcium, phosphate, and parathyroid hormone levels was similar in both age groups. These results demonstrate that the decreased adaptation to low dietary phosphorus in adult rats can be accounted for by decreased CYP27B1 mRNA levels. The results also demonstrate that the decreased adaptation in the adult is not due to changes in the major regulators of 1-OHase activity. Finally, they suggest that adaptation to low dietary phosphorus is fundamentally different than adaptation to low dietary calcium with regard to CYP27B1 expression.

Early Screening and Characterization of Osteopenia in Middle-Aged Women. P. G. Masse[1], J. Jougleux*[1], J. Dosy*[1], S. M. Donovan[2]. [1]Nutrition, Université de Moncton, Moncton, NB, Canada, [2]Nutrition, University of Illinois, Urbana, IL, USA.

Fifty-eight healthy, active, Caucasian women living at latitude 46º 7'North were recruited based on the following criteria: BMI <30 kg/m2, non-smoker, not using estrogen, drugs, nutritive supplements, vegetarian or special diet and with no history of bone fracture. BMD (g/cm2) was measured by Lunar DXA at 13 different lumbar and femoral sites. Subjects were then classified into two groups: **A**) control: normal BMD; **B**) osteopenic on the basis of clinical WHO criterion (BMD between 1.1 and 2.5 SD below the average value

(T-score) of the peak bone of healthy young adults for one lumbar site or more. Osteopenic subjects (68.9%) were further divided into two subgroups **B** and **B-** according to reference absolute values used in bone research, **B-** subjects being more osteopenic with BMD <0.9 g/cm2 for one lumbar spine site or more combined to 0.795 g/cm2 for at least one femur site. Fasting morning plasma and urinary double markers of bone formation and resorption (expressed per mmol **Cr**eatinine) were used to assess bone metabolism in addition to IGF-1. The 3 groups were well-matched in terms of: age, serum estradiol, height, body weight and frame, dietary protein, vitamin D, Ca and P intakes and their ratio (as assessed from 3-d records). IGF-1 was significantly lower in both osteopenic groups. There was no difference between the two B groups. Osteocalcin (OC) was significantly higher only in the most severe osteopenic group. All other bone markers, calciotropic hormones [PTH, $1,25(OH)_2D_3$] and plasma minerals showed no significant differences. The present study confirmed that bone loss declined in middle age. It also demonstrated that: 1) IGF-1 was the most sensitive biochemical indicator of bone metabolism; 2) OC was the earliest specific biochemical marker to vary, a finding indicating that osteoblasts increased this protein synthesis at an early stage of bone mineral loss; 3) absolute BMD values (g/cm2) for lumbar site combined to femur are more sensitive criteria for the diagnosis of osteopenia than WHO criterion.

Lifetime Recreational Gymnastics and Selected Risk Factors for Osteoporotic Fractures, Prospective 6-year Follow-up Study. K. Uusi-Rasi, H. Sievänen*, A. Heinonen, I. Vuori*, P. Kannus*. UKK Institute, Tampere, Finland.

High bone mass and good physical fitness are important factors in prevention of fragility fractures. We studied effects of lifelong recreational gymnastics (at least 20 years of recreational gymnastics ≥ 2 times a week) on maintenance of bone mass and physical performance.

Initially 223 postmenopausal women were enrolled in the study. Six years later, 217 of them (107 gymnasts and 110 sedentary referents) with mean age of 68 years (SD 5) participated in the follow-up measurements. Mean height and weight were 161 (5) cm and 67 (10) kg at baseline with no differences in changes.

Bone mineral content (BMC) of the femur was measured with DXA, and cortical density (CoD) and cortical area (CoA) of the tibial midshaft, and trabecular density (TrD) of the distal tibia with pQCT. Physical performance was estimated by measuring maximal isometric strength, dynamic power, agility and 2-km walking time. Analyses of covariance were used to analyze the between-group differences and changes by time.

Bone mass decreased at a similar rate in both study groups. The overall decline (95% CI) in the femoral neck BMC was 3.4% (2.2% to 4.7%) for the gymnasts and 3.8% (2.6% to 5.0%) for the referents. In the tibia, the changes were small. TrD of the distal tibia declined by 0.6% (0.1% to 1.2%) and 1.0% (0.4% to1.6%) among the gymnasts and referents, respectively. CoD declined by about 2% in both groups and CoA did not change significantly. However, the gymnasts had greater bone mass both in the femur and tibia, although the intergroup difference did not reach statistical significance in all bone sites. The mean BMC differences were 3.4% (0.0% to 6.9%) in the femoral neck and 3.2 (-0.3% to 6.8%) in the trochanter, and in the tibia 3.7% (-0.2% to 7.8%) for the TrD, 0.4% (-0.3% to 1.1%) for CoD and 3.6% (0.8% to 6.4%) for CoA.

Compared to the referents, the gymnasts were in better physical condition, but the mean decline in physical ability was similar in both groups. Leg extensor power decreased 11% (8% to 14%) and 10% (7% to 13%) among the gymnasts and referents, respectively, while the decline in isometric muscle strength was insignificant. Agility decreased 3% (2% to 5%) in both groups, and the 2 km-walking time increased by 1 minute.

In conclusion, despite the similar rate of decline in bone mass and physical performance, the gymnasts had maintained the benefits achieved with lifelong gymnastics. In consequence of their greater bone mass and better physical ability, their risk of falling and fragility fracture is likely to be lower compared to their sedentary counterparts.

Dietary Fish Oil Mitigates Aging-induced Bone Loss in Middle-Aged Male Rats. C. Shen*[1], D. M. Dunn*[1], J. K. Yeh[2]. [1]Pathology, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [2]Medicine, Winthrop-University Hospital, Mineola, NY, USA.

Recent studies indicated that n-3 polyunsaturated fatty acids (PUFA) prevented bone loss in ovariectomized rats and postmenopausal women. The present study investigated the effects of dietary n-3 PUFA on bone mineral density (BMD) and bone histomorphometry in middle-aged male rats (n=21, 12 mo) fed diets containing either 20% menhaden oil (M diet, rich in n-3 PUFA) or 20% safflower oil (S diet, rich in n-6 PUFA) for 20 wks. Another 7 rats were euthanized at the beginning of the study as baseline (B group). Aging was found to decrease total bone mineral contents and BMD in femur, but did not affect DEXA-total area of femur. Compared to the S diet, rats fed the M diet had higher bone mineral contents in femur, but lower osteoclastic activity in lumber vertebra. The results of pQCT scans in the metaphyseal region of rat femoral bones were similar to those of DEXA scans in terms of the following: (i) aging caused a significant decrease in the total density, and (ii) rats given the n-3 PUFA tended to result in higher values of cortical + subcortical than those fed the n-6 PUFA (P = 0.088). Based on the results of bone histomorphometry, aging resulted in a significant decrease in the trabecular bone volume (Tb Ar) and the cortical bone area (%Ct Ar) of all the dietary groups. Compared to the S group, M group had a significant higher Tb Ar. The higher Tb Ar was because M diet resulted in a decreased bone formation rate/bone periosteal perimeter (BFR/B.Pm) (11.19 mcm/d) compared to the S diet (17.55 mcm/d). Our study also demonstrated that M diet had a significant higher %Ct Ar (80.8%) compared to the S group (78.9%). It seemed that M diet resulted in an increase in the periosteal bone formation as well as a decrease in the endosteal bone turnover rate. The present data suggest that n-3 PUFA mitigate aging-induced bone loss in middle-aged male rats through modulating both periosteal and endosteal bone turnover rate.

Decreased Self Renewal of Mesenchymal Stem Cells Underlies the Senescence-Associated Bone Loss in Two Independent Murine Models: p53 +/m (Activating Mutation) and SAMP6. R. L. Jilka[1], M. Dumble*[2], R. A. Wynne*[1], A. M. Parfitt[1], L. Donehower*[2], S. C. Manolagas[1]. [1]Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA, [2]Depts. Of Molecular Virology and Microbiology, and Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX, USA.

Mesenchymal stem cells (MSC) serve as a reservoir of osteoblasts in the bone marrow by virtue of their ability to both self-renew (i.e. produce identical daughter cells) and differentiate into osteoblasts. Age-related bone loss is characterized by a deficit in the number of osteoblasts needed to refill resorption cavities created during bone remodeling. Earlier work in rodents and humans had shown an age-related decline in the number of MSCs, as measured by colony forming osteoblast progenitors (CFU-OB) in *ex-vivo* cultures. Here, we have investigated whether the decline in MSC number is due to a reduction in their self-renewal capacity using two murine models of premature aging that exhibit a decrease in skeletal mass. In the p53 +/m mouse, early senescence is caused by an activating mutation of the transcription factor p53. This protein plays a key role in the induction of replicative senescence or apoptosis in response to cell stress and DNA damage, which may contribute to the aging phenotype. Femoral marrow cell cultures were established from 4-6 month old p53 +/m mice, and wild type littermates, and used to determine the number of CFU-OB, as well as their ability to produce identical daughter cells. We found that CFU-OB number in p53 +/m mice was significantly decreased as compared to wild type littermates (34.8 ± 12 vs 47.5 ± 11 per 10^6 marrow cells, respectively, P<0.05 by Students t-test). CFU-OB from p53 +/m mice increased only 3.3 ± 0.6-fold during 6 days of culture, whereas wild type CFU-OB increased 6.5 ± 0.6 fold (P<0.05). Moreover, the hindlimb and vertebral BMD of p53 +/m mice was significantly reduced by 17 ± 1% and 12 ± 1%, respectively, as compared to wild-type mice. In the second model, SAMP6, earlier studies had linked a reduction in CFU-OB number to a decrease in bone mass, which is associated with 7 genetic loci as determined by QTL mapping. CFU-OB from SAMP6 mice increased by 2.3 ± 0.5 fold during 6 days of culture, whereas CFU-OB from SAMR1 controls increased 8.7 ± 1.3-fold (P<0.05). These findings, obtained with two independent murine models of premature aging, strongly support the hypothesis that diminished MSC replication, perhaps secondary to p53-mediated replication arrest or apoptosis, can lead to exhaustion of the osteoblast reservoir needed for orderly bone remodeling, thereby contributing to age-related bone loss.

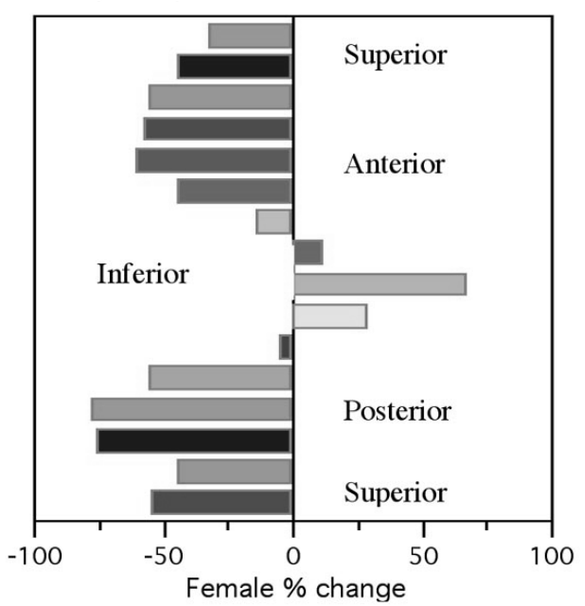
Walking tall Is Poor Long-term Protection against Hip Fracture. P. Mayhew*[1], D. Thomas*[2], J. Clement*[2], N. Loveridge[1], W. Bonfield*[1], T. Beck[3], J. Reeve[1]. [1]Medicine & Materials Science, University of Cambridge, Cambridge, United Kingdom, [2]Dental Science, University of Melbourne, Melbourne, Australia, [3]Radiology, Johns Hopkins, Baltimore, MD, USA.

Background: Hip fractures rise 10 fold every 20 years but this is only partly accounted for by reduced BMD (aBMD). Bone can fracture by buckling under compression, when Critical Buckling Stress (CBS) is exceeded. We wondered if CBS declines markedly with ageing in the supero-lateral cortex (SLC) of the femoral neck that takes the compressive load in a sideways fall.

Methods: We measured ex vivo with high-resolution CT (Densiscan, 0.25mm res.) the distribution of bone in the mid-femoral neck of 77 proximal femurs from unselected cases of sudden death aged 20-95 (35 F). We calculated CBS around the cortex of each femoral neck at its pre-defined mid point, in 16 cortical sectors using the conventional equation CBS=E*t/{R*sqrt(3*[1-u2])} where t=the thickness of each cortical sector (adjusted for the partial volume effect by Hangartner's method), E=the elastic modulus of bone tissue (estimated from the bone density in the inferior sector using the Carter & Hayes equation), R=the sector's distance from the centre of gravity of the cross section and u=the usual Poisson's ratio of 0.3. The CBS data were modelled by MANOVA for all 16 sectors with age as the independent variable.

Results: aBMD decreased by 27% from age 20 to 80 in women. However, the thin SLC thinned more still and lost 60-75% of its CBS in women, slightly less in men over the same time frame. Meanwhile the CBS in the inferior cortex increased about 30% on average (fig). Comparing femoral neck bone from 22 hip fracture patients with 24 age matched controls, the cases had levels of critical buckling stress that were symmetrically reduced by 20-30% around the whole mid-femoral neck.

Interpretation: As we age, risk of buckling-type failure upon a sideways fall increases greatly in the SLC. This might result from the limited variety of western physical activity (80+% walking), during which gluteal contraction locally neutralises ground reaction forces in the SLC predictably leading to underloading. The fragile zones in healthy bones might be kept stronger with mechanical loading targeted to the SLC, as occurs when extending the flexed femur under load. A targeted lifelong physical activity intervention might substantially reduce hip fractures.



Change in CBS between 20-80y

3D Volumetric Analysis of Age-Related Change in Cortical Porosity at the Human Anterior Femoral Mid-shaft. D. M. L. Cooper*[1], J. G. Clement*[2], C. D. L. Thomas*[2], B. Hallgrímsson[3]. [1]Archaeology, University of Calgary, Calgary, AB, Canada, [2]School of Dental Science, University of Melbourne, Melbourne, Australia, [3]Cell Biology & Anatomy, University of Calgary, Calgary, AB, Canada.

Relatively little is known about age dependent variation in the 3D structure of porosity within cortical bone. Accordingly, this study examines 3D volumetric age-related change in cortical porosity (on the level of osteonal canals) in the human anterior femoral mid-shaft. The sample included 42 individuals, 18 females and 24 males, spanning 20 to 85 years of age. The mean (+/- SD) ages for the males and females were 56.7 (+/- 18.5) years and 50.4 (+/- 21.4) years, respectively. Cortical blocks, 5 mm wide and 8 mm long were micro-CT (SkyScan 1072) scanned at 7 μm isotropic resolution. Cylindrical volumes of interest, 3 mm in diameter and 3 mm long, adjacent to the periosteal surface, were isolated from the scan data for quantitative analysis. Cortical porosity (%), mean canal diameter (μm), and mean canal separation (μm) were measured using model independent 3D stereological methods. Cortical porosity averaged 7.7 (+/-5.0) % for the males while females were relatively more porous at 14.4 (+/-14.0) %. Linear regression revealed significant positive relationships between age and cortical porosity for both males $R^2 = 0.243$ ($p = 0.014$) and females $R^2 = 0.718$ ($p < 0.001$). The average mean canal diameter followed a similar pattern, with males at 96 (+/- 47) μm and females at 161 (+/-137) μm. A significant positive linear relationship was found between mean canal diameter and age in females $R^2 = 0.686$ ($p < 0.001$) while this relationship was not significant $R^2 = 0.156$ ($p = 0.056$) for males. The average mean canal separation was 337 (+/- 38) μm for males and 328 (+/-55) μm for females. Significant negative linear relationships were found between age and mean canal separation for both males $R^2 = 0.365$ ($p = 0.002$) and females $R^2 = 0.447$ ($p = 0.002$). The results revealed two distinct trajectories for 3D age-related change in cortical porosity for the sexes. Females exhibited a dramatic increase in cortical porosity with age which occurred through the coalescence of larger canals with progressively less bone between them. For males, cortical porosity increased only slightly with age, canal separation decreased, and canal diameter did not change. From these findings we infer that the increase in porosity in males was a result of an increase in the number of canals (transverse and longitudinal) with age. 3D reconstructions of the canal networks provided qualitative evidence for this conclusion which is in contrast with previous 2D studies that have found that greater porosity in older specimens is due to greater canal size rather than a larger number of canals.

Growth Hormone Receptor/Binding Protein-Null Mice Indicate That Growth Hormone Plays a Role in Normal Bone Function in Young, Adult, and Aged Mice. R. W. Pamenter, M. S. Bonkowski*, J. S. Rocha*, M. M. Masternak*, K. AlRegaiey*, A. Bartke*. Internal Medicine, Southern Illinois University, School of Medicine, Springfield, IL, USA.

Growth hormone receptor/binding protein knock out (GHR-KO) mice are deficient in growth hormone signaling, have reduced insulin-like growth factor I levels, and are long-lived (~50%) compared to wildtype (WT) siblings. This study investigated the body composition and bone characteristics using dual-energy x-ray absorptiometry (DEXA) (PIXIMUS, Lunar GE, Madison, WI) in young (6-8 weeks), adult (7-10 months), and aged (28-32 months) GHR-KO and WT mice. Three-way ANOVA and post hoc testing was used to determine significant differences. Body weight was significantly different ($P<0.0001$) comparing WT and GHR-KO phenotypes, as previously reported. Percent fat across age groups was significantly higher in GHR-KO mice compared to WT ($P<0.0001$). Whole animal bone mineral density (BMD) increased with age ($P<0.0001$) and GHR-KO mice had reduced BMD ($P<0.0001$) compared to WT. Femur length increased across age groups in WT mice while GHR-KO mice had a numerical but not significant reduction in femur length at old age. Femur BMD was increased with age ($P<0.0001$) regardless of sex or phenotype, but reduced ($P<0.0001$) in GHR-KO compared to WT mice. Lower lumbar BMD was reduced ($P<0.0001$) in GHR-KO mice compared to WT. Lower lumbar BMD increased from young to adult regardless of phenotype or sex ($P<0.0001$). There was a decrease ($P<0.0006$) in lower lumbar BMD when comparing aged with adult WT male mice (0.061±.003 vs. 0.075±0.003, respectively). The decreased femur length linear growth in GHR-KO mice with advancing age indicates that growth hormone influences bone metabolism throughout the lifespan. In addition, bone characteristics and body composition of aged GHR-KO mice more closely matches values measured in young WT mice consistent with previous results of delayed growth and aging in GHR-KO animals.

Males

SU008

Geometric Effects that Occur with Ageing and Osteoporosis Have an Impact on the Local Buckling Capacity of Bone at the Femoral Neck. T. Lee*[1], B. W. Schafer*[2], M. M. Daphtary*[1], T. J. Beck[1]. [1]Radiology, Johns Hopkins University, Baltimore, MD, USA, [2]Civil Engineering, Johns Hopkins University, Baltimore, MD, USA.

Osteoporotic fragility is ascribed to structural change in the amount and distribution of essentially normal bone material in ways that reduce density. But density declines with age by net bone loss and by expansion of volume due to periosteal apposition with opposing effects on mechanical strength. If declining bone density is actually homeostatic, why do bones become fragile? Since an expanding bone requires less material to achieve the same bending strength, it is conceivable that certain skeletal sites become locally unstable when expansion/thinning proceeds beyond stability thresholds. While it is known that Euler buckling does occur in the failure of individual trabeculae it is less obvious that whole bones may become unstable since they do not meet slenderness criteria. However, if one considers the possibility of local buckling of the bone cross-section then variations in the cross-section geometry become of primary importance. Local buckling is a phenomenon whereby the cross-section undergoes bending deformation as it destabilizes. Combinations of compressive bending and axial compression applied to the thinnest cortical region are potentially the most damaging. These conditions are likely at the thin lateral femoral neck in a fall on the greater trochanter. Using a tool specifically developed for investigating the local buckling of thin-walled members, i.e., elastic buckling analysis by classical finite strip method (CUFSM, Schafer 2003) we examined the local buckling characteristics of simulated femoral necks. Published cortical dimensions were used to simulate, femoral necks of young (20-29y), and old (80-89y) women with and without femoral neck fracture. Results indicate a strong sensitivity to the local geometry change that occurs with aging - the stress at which local buckling occurs decreases by a factor of 2.4 from a 20 year old to an 80 year old woman in those who do not fracture and a factor of 2.9 in those who fracture at the femoral neck. Geometric effects that occur with ageing clearly have a significant impact on the local buckling capacity of osteoporotic bones. However, the magnitude of the predicted local buckling stresses still remains relatively high in these crude simulations- and whether or not these large reductions trigger instabilities leading to fracture or are a secondary contributor remains unknown. Modeling sensitivity to material and geometric assumptions is being investigated, as are more realistic three-dimensional models of the proximal femur over a range of geometries observed in aging subjects.

SU009

Increased Bone Loss During Disuse in Aged Animals May Be Due to Impaired BMP Responsiveness. D. S. Perrien, N. S. Akel, F. L. Swain*, R. A. Skinner*, L. J. Suva, E. E. Dupont-Versteegden*, D. Gaddy. Physiology and Biophysics, Orthopaedic Surgery, and Geriatrics, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Aging is associated with functional changes in many tissues, such as a decline in muscle mass and strength, and reduced bone density. We previously reported that 4 weeks of hindlimb suspension decreases BMD in the long bones of 6 month old Sprague Dawley rats, as measured by DEXA. To determine if aging enhances the rate of bone loss associated with disuse, and to examine the cellular basis of any age-related effects, a well-characterized model of musculoskeletal aging (Brown Norway/Fisher 344 rat) was utilized. Young adult 6 mo. old and aged 32 mo. old rats were hindlimb suspended (HS) for 2 weeks. Serial DEXA measurements of the hindlimb were obtained before HS and at sacrifice. Bone marrow cells were harvested from the femurs and cultured in osteogenic medium in the presence or absence of 100 ng/ml BMP2 or 200 ng/ml Noggin for 10 days. Recruitment of stromal cells to the osteoblastic lineage was assessed by alkaline phosphatase (AP) staining of CFU-F and determination of AP+ colony number. Unsuspended control young (CONY) and old (CONO) animals demonstrated similar increases in BMD in the proximal tibiae by DEXA analysis (P>0.05). However, rapid and significant decreases were observed in the BMD of proximal tibiae of old rats during 2 weeks of HS (HSO), compared with unsuspended control rats (p<.05) (CONO). However, HS did not have a significant effect on BMD in young adult animals (HSY) compared to CONY animals. As expected, osteoblastogenesis in bone marrow cells from CONO animals is under endogenous BMP control *in vitro*, since Noggin significantly suppressed the formation of AP+ colonies (P<0.05). Similarly, HS reduced the number of AP+ colonies in marrow cultures established from both old (HSO) and HSY animals, indicating decreased osteoblastogenesis as a consequence of disuse. Bone marrow cells from HSY animals maintained their responsiveness to exogenous BMP2, as indicated by increased numbers of AP+ colonies. In contrast, bone marrow cells from HSO animals were not responsive to either exogenous BMP2 or Noggin. These data suggest that, unlike younger animals, recruitment of HSO marrow cells into the osteoblast lineage is not under endogenous BMP control *in vitro*. Together, these data indicate that aging increases the rate of bone loss during disuse, and that this may be due to impaired response of marrow cells to the osteogenic effects of BMPs.

Age-Related Trabecular and Cortical Bone Loss in the Proximal Femur. C. E. Cann, J. K. Brown*. Mindways Software Inc, San Francisco, CA, USA.

Bone loss in the proximal femur with aging is well described as measured by dual x-ray absorptiometry (DXA), but no in vivo data are available about the age-related loss of trabecular versus cortical bone within specific regions such as the femoral neck. Such information could be useful in interpreting the role of age-related femoral bone loss in the increased risk of hip fracture. We have used 3D quantitative computed tomography scans projected as a DXA-like analysis to determine the fraction of trabecular versus cortical bone in the femoral neck and total hip regions of interest as a function of age in normal US women.

Six hundred sixteen normal women age 20-80 were recruited from 11 centers across the US. All were scanned using a standard 3D QCT proximal femur protocol. Quality control phantoms were used at each center to normalize all results to a common reference. QCT data were projected to a DXA-like 2D image using commercial software (CTXA Hip, Mindways Software, Inc, San Francisco, CA), and the area BMD measurements for Total Hip and Femoral Neck were segmented into "trabecular" and "cortical" compartments using a fixed threshold of 350 mg/cm3 as the upper limit for the trabecular bone. Area BMD in g/cm2 was calculated for each compartment with their sum equal to the standard DXA-like total bone BMD.A linear model was used to fit age-related bone loss for all compartments.

Age-related loss in the total bone for Total Hip and Femoral Neck regions of interest was -0.042 and -0.045 g/cm2/decade respectively. Cortical loss was -0.033 and -0.036 g/cm2/decade, and trabecular loss was -0.009 and -0.009 g/cm2/decade respectively. There were no significant differences between rates of loss in Total Hip vs. Femoral Neck regions, and cortical loss was significantly greater than trabecular loss ($p<0.01$). The cortical fraction of the total hip decreased from 66.8% at age 20 to 62.6% at age 80 and from 69.3% to 62.1% in the femoral neck ($p<0.02$).

Bone loss with age in the proximal femur is primarily due to loss from the "cortical" compartment comprised of the cortex and endocortical bone. While trabecular loss does occur with aging, it is relatively less. Use of this compartmental analysis in fracture rather than normal populations as done here may provide useful insight into the pathophysiology of hip fracture independent of simple total BMD measurements.

Revitalization of Structural Allografts via Immobilized Recombinant Adeno-Associated Virus. M. Koefoed*[1], H. Ito[1], J. J. Goater*[1], R. E. Guldberg*[2], A. Lin*[2], R. J. O'Keefe[1], X. Zhang[1], E. M. Schwarz[1]. [1]Orthopaedics, University of Rochester, Rochester, NY, USA, [2]Georgia Institute of Technology, Atlanta, GA, USA.

Introduction: Due to their lack of osteogenic potential, structural allografts often result in catastrophic failure. To the end of generating a remodeling structural allograft we developed a murine femoral model, and a novel approach in which recombinant adeno-associated virus (rAAV) can be freeze-dried onto the cortical surface to mediate in vivo gene transfer. The aim of this study was to evaluate the transduction efficiency of immobilized rAAV in vitro and in vivo, and determine the effects of BMP gene therapy on allograft healing using this approach.

Methods: *In vitro* transduction of rAAV-LacZ was determined by freeze-drying 5 x 10^7 particles onto the surface of a stainless steel pin, which was incubated on a monolayer of 293 cells for 72hr. *In vivo* gene transfer to processed allografts was assessed by freeze-drying rAAV-LacZ onto the cortical surface, and transplantion into 8 week-old C57BL/6 mice. The mice were sacrificed at 2-weeks and transduction was assessed from X-gal staining. The effects of BMP gene therapy was evaluated by coating allografts with rAAV expressing a constitutively active Alk2 receptor (caAlk2) vs rAAV-LacZ controls, via X-ray, histomorphometry and micro-CT.

Results & Discussion. *In vitro* analysis of freeze-dried rAAV-LacZ revealed that storage of the vector at -80^{0}C had no effect on infectivity as determined by ß-gal assay. X-gal staining of the cultures demonstrated a mosaic transduction pattern both proximal and distal to the coated pin, indicating that the virus rehydrates and infects cells following passive diffusion in the culture media. X-gal staining of rAAV-LacZ coated allografts 2-weeks after transplantation revealed that the vector transduces ~5% of the cells in the immediate proximity of the allograft, as well as stromal cells in the fracture callus. To formally evaluate the efficacy of transferring BMP signals to the cortical surface of processed allografts we coated femoral allografts with rAAV-LacZ and rAAV-caAlk2 and evaluated their healing at 2, 4 and 6-weeks. Several remarkable features of rAAV-caAlk2 coated allograft healing were observed including: i) the absence of a foreign body reaction that normally encases the allograft in inflammatory tissue, ii) endochondral bone formation directly on the allograft surface, iii) a new bone collar that extends the entire length of the allograft, and iv) osteoclastic resorption of the allograft. Micro-CT analysis of the allografts at 6-weeks revealed the significant effects of the rAAV-caAlk2 vs rAAV-LacZ on bone formation around the allograft ($2.25 + 0.54mm^3$ vs $0.90 + 0.32mm^3$; $p<0.005$).

Regulation TGF-b/BMP Signaling by Smurfs and Arkadia. T. Imamura*, S. Maeda, M. Hayashi*. Department of Biochemistry, The JFCR Cancer Institute, Tokyo, Tokyo, Japan.

Smurf1, a HECT type E3 ubiquitin ligase, interacts with Smad1 and Smad5, and induces their poly-ubiquitination, with subsequent enhancement of turnover of Smads1 and 5. In addition, Smurf1 associates with type I receptors for TGF-b and BMP via inhibitory Smads (I-Smads), and induces poly-ubiquitination and degradation of the receptors. Thus, Smurf1 inhibits TGF-b superfamily signaling in cooperation with I-Smads. Here we show that Arkadia, a RING type E3 ubiquitin ligase, physically interacts with I-Smads and induces their poly-ubiquitination and degradation, but fails to associate with receptors. Overexpressed Arkadia enhances transcriptional activities induced by TGF-b and BMP. Silencing of the Arkadia gene by siRNA results in repression of TGF-b/BMP signaling. Arkadia may thus play an important role as an amplifier of TGF-b superfamily signaling.

Interferon-γ Inhibits Smad Signaling and Osteoblast Differentiation. F. A. Sylvester[1], N. Wyzga*[1], S. Varghese[2], E. Canalis[2]. [1]Digestive Diseases & Nutrition, Connecticut Children's Medical Center, Hartford, CT, USA, [2]Research, Saint Francis Hospital & Medical Center, Hartford, CT, USA.

Factors secreted by activated T cells regulate bone cell function and differentiation. We have shown that interferon (INF)-γ, a factor synthesized by activated $CD4^+Th_1$ T cells, inhibits the differentiation of primary bone marrow stromal cells into mature osteoblasts. However, the mechanisms involved are not known. We hypothesized that INF-γ blocks osteoblast differentiation by interfering with bone morphogenetic protein (BMP)-2 activity and signaling. For this purpose, we used ST-2 cells, a mouse bone marrow stromal cell line that is responsive to BMP-2. ST-2 cells were treated with BMP-2 at 1 nm in the presence and absence of INF-γ at 5 ng/mL under osteoblastogenic conditions. Cells treated with BMP-2 formed calcified nodules, whereas those treated with INF-γ did not. Furthermore, INF-γ altered the effect of BMP-2 so that the cultures did not develop discrete mineralized nodules, exhibited a reticular pattern of calcium precipitation, and did not express osteocalcin transcripts. INF-γ did not alter the number of viable cells and cell number was not different in cultures treated with BMP-2 with or without INF-γ. To test mechanisms responsible for the inhibitory effect of INF-γ on ST-2 cell differentiation, we examined whether it modified BMP-2 signaling. BMP-2 induced the phosphorylation of Smads 1/5/8, and this effect was decreased by INF-γ. Furthermore, transient transfection experiments with the BMP-responsive 12xSBE-OC-pGL3 plasmid, containing 12 repeats of Smad recognition sequences directing luciferase expression, revealed that its transactivation was significantly decreased in cells treated with INF-γ. BMP-2 induced luciferase β-gal activity was reduced from (means ± SEM) 43.5 ± 7 to 12.7 ± 2 ($p < 0.01$) by INF-γ. The expression of the inhibitory Smads 6/7 was not increased in INF-γ-treated cells, as determined by Western immunoblots. To investigate the possibility that INF-γ inhibits BMP-2 Smad-independent signaling, we studied the activation of MAP kinases p38, ERK, and JNK by BMP-2, in the presence and absence of INF-γ. BMP-2 did not enhance p38, ERK, and JNK phosphorylation, and INF-γ had no effect either. In conclusion, INF-γ inhibits the differentiation of ST-2 stromal cells into mature osteoblasts by a mechanism involving the inhibition of BMP-2 Smad-dependent signaling. INF-γ inhibits the differentiation of ST-2 stromal cells into mature osteoblasts. This effect is explained by an inhibition of BMP Smad signaling, although other mechanisms may also be operational.

Quantitative in Vitro Assay for Osteoinductivity of Human Demineralized Bone Correlates with in Vivo Assay. S. Honsawek*[1], R. M. Powers*[2], L. Wolfinbarger[2]. [1]Biochemistry, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [2]Research & Development, LifeNet, Virginia Beach, VA, USA.

Demineralized bone matrix (DBM) has been extensively utilized in orthopaedic, periodontal, and maxillofacial applications and widely investigated as a material to promote new bone formation. Many studies have demonstrated that DBM comprises bone morphogenetic proteins (BMPs) that are substantial regulators for endochondral bone formation. The purposes of the present study were to quantitate BMP-4 in protein extracts of DBM and assess the osteoinductive potential of DBM preparations using in vitro and in vivo assays. Bone samples of 40 donors were ground and demineralized by exposure to 0.5 N HCl and then extracted by collagenase digestion. BMP-4 in protein extracts from DBM could be detected by Western blot analysis and measured using enzyme-linked immunosorbent assay (ELISA). The extractable BMP-4 levels were variable and averaged 3.70 ± 0.21 ng BMP-4/g of DBM. In the study of the effect of residual calcium on extractability of BMP-4, we found that the less residual calcium left in DBM increased the extractability of BMP-4. In the donor age and gender study, the extractable BMP-4 content appears to be age-dependent, with DBM from younger donors being most likely to have greater BMP-4 quantity. In contrast, no difference in the quantity of extractable BMP-4 was observed between male and female donors. In the in vitro dose-response studies, DBM protein extracts enhanced alkaline phosphatase activities of human periosteal cells in a dose-dependent fashion. Morphologic and histochemical analysis revealed osteoblast-like cells in the DBM protein extracts treated cells. Additionally, the osteoinductivity of DBM from the same donors quantitated by BMP-4 ELISA were assessed by histomorphometric analysis of new bone formation in an in vivo athymic mouse bioassay. The results revealed that DBM exhibiting high osteoinductivity in the nude mouse assay contained higher amounts of extractable BMP-4 than DBM samples possessing low levels of osteoinductivity. There was a good positive correlation between the quantitative BMP-4 in vitro assay and osteoinduction determined by the implantation of DBM in the in vivo nude mouse bioassay with a correlation coefficient of 0.7397 ($p < 0.001$).

Evaluation of New Drug Delivery System for rhBMP-2 in a Rabbit Lumbar Spine Fusion Model. T. Namikawa*, H. Terai, E. Suzuki*, M. Hoshino*, H. Toyoda*, H. Nakamura*, S. Miyamoto*, K. Takaoka. Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan.

The purpose of this study is to achieve solid posterolateral intertransverse process lumbar fusion with use of an artificial osteoinductive implant without using autologous bone grafting. In this study, we use beta-tricalcium phosphate (β-TCP, Olympus. Co., Ltd.) and poly-D,L-lactic acid with random insertion of p-dioxanone and polyethylene (PLA-DX-PEG, Taki Chemical Co., Ltd.) composite paste implant added with low dose of an osteoinductive cytokine rhBMP-2 (Yamanouchi Pharmaceutical Co., Ltd.) as a potential bone graft substitute in a rabbit model. Thirty-six New Zealand white rabbits were used for this study. The rabbits were divided into six groups and underwent L5-L6 posterolateral intertransverse process lumbar fusion by using β-TCP and PLA-DX-PEG composite containing rhBMP-2 implants indicated in Table. The animals were examined for bone formation at the operated site every two weeks by radiographs, and evaluated by manual palpation, biomechanical testing and histological examination at 6 weeks after surgery. Radiographs demonstrated homogeneous calcified shadow between the transverse processes in all animals of group 1, 2 and in part of group 3 at 6 weeks. However, radiographs at 2 and 4 weeks, it was hard to assess fusion mass because of the β-TCP radiopacity. Fusion rate evaluated by manual palpation was 100% in the group 1and 2, 40% in the group 3 and 5. None (0%) had solid fusion in the group 4. Results of biomechanical testing correlated well with those of manual palpation. Histological section of L5-L6 intertransverse region of achieved solid fusion showed new bone formation between the L5-L6 transverse process and cortical rim around fusion mass. These results showed the efficacy of β-TCP powder and PLA-DX-PEG as a carrier of rhBMP-2 compared with those of reported previously (e.g., bovine type I collagen) from the standpoint of reducing the dose of rhBMP-2. We concluded that, with use of β-TCP powder and PLA-DX-PEG as a carrier of rhBMP-2, 15μg per each side of rhBMP-2 was enough to achieve posterolateral intertransverse process lumbar fusion at 6 weeks in a rabbit model. This artificial biomaterial containing rhBMP-2 can be useful as a autologous bone graft substitute.

Table: Summary of composition of implants per each side and fusion ratio

Group	rhBMP-2(μg)	β-TCP(mg)	PLA-DX-PEG(mg)	Fusion ratio
1	30	300	300	5/5
2	15	300	300	5/5
3	7.5	300	300	2/5
4	0	300	300	0/5
5	Autologous iliac bone graft (1-1.5g)			2/5

Defective Trafficking of BMP Receptor in Fibrodysplasia Ossificans Progressiva. P. C. Billings*[1], J. L. Fiori*[1], L. Serrano de la Pena*[2], R. Caron*[1], E. M. Shore[1], F. S. Kaplan[1]. [1]Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA, [2]Genetics, Rutgers University, Piscataway, NJ, USA.

Fibrodysplasia ossificans progressiva (FOP) is a devastating genetic disease characterized by congenital malformations of the great toes and progressive heterotopic ossification of connective tissues. There is no cure for this condition and only limited palliative treatment options are currently available. Although the molecular mechanisms giving rise to this disorder have not been elucidated, we have hypothesized that defects in the BMP signaling pathway play an important role in the pathophysiology of FOP. Previously, we demonstrated that BMP receptor IA (BMPRIA) is elevated 6-10 fold on the surface of FOP cells compared with control cells. Further, in the presence of BMP4 ligand, BMPRIA is rapidly degraded in control cells, but not in FOP cells. In this study, we used immunofluorescence to analyze BMPRIA in response to BMP4. All human cells were obtained from patients following IRB approved protocols. We found that treatment of normal cells with BMP4 induces BMPRIA clustering and internalization. However, under the same conditions, BMPRIA remains on the surface of FOP cells. Control and FOP cells bind transferrin protein and internalize transferrin receptor, indicting that this receptor internalizes similarly in both cell types. Our results suggest that the molecular defect in FOP is closely linked with BMP-receptor trafficking and supports the hypothesis that promiscuous BMP signaling in FOP cells results from increased BMPRIA density on the cell surface, thus giving rise to bone formation. Analysis of the molecular pathology of the human BMP4 pathway in FOP will elucidate the molecular mechanisms leading to abnormal ossification in these patients.

rhBMP-2/CPM Accelerates Metaphyseal Trabecular Bone Formation in a Non-Human Primate Core Defect Model. X. Li, D. Gavin*, C. Wallace*, L. Li*, J. M. Wozney, H. J. Seeherman. Women's Health & Bone, Wyeth Research, Cambridge, MA, USA.

The efficacy of rhBMP-2/calcium phosphate matrix (CPM, ETEX Corporation, Cambridge, MA) (BMP/CPM) to accelerate trabecular bone formation was evaluated using a metaphyseal core defect model in 12 adult male cynomolgus monkeys. One core defect (n = 6) was treated with 1.5 mg/mL BMP/CPM in the distal radii, proximal tibiae and proximal femora. The contralateral core defects were treated with 4.5mg/mL BMP/CPM. Core defects in the remaining 6 animals were treated with CPM on one side and were untreated on the contralateral side (SXCT). Four weeks prior to the 8 week study termination, bilateral core defects created in the distal femora were injected with corresponding treatments. Histomorphometry was used to evaluate the regions surrounding and within the core defects. Values were significant ($p<0.05$) unless stated otherwise.

Results were equivalent for both BMP concentrations and for the CPM and SXCT groups except for mineral apposition rate (MAR). At 4 weeks, there was no difference in Tb.V between BMP/CPM and the CPM and SXCT groups in the region surrounding the core defects. However, O.V (osteoid volume) was increased by 25.6 fold and O.S (osteoid surface) by 14.4 fold (80.6 ± 18.6% vs. 5.69 ± 2.27%) in the BMP/CPM group compared to controls. The MS (mineralized surface) was 7.4 times greater in the surrounding region in the BMP/CPM compared to CPM and SXCT animals (64.1 ± 13.1% vs. 8.6 ± 3.4%). MAR also increased by 1.6 fold in the BMP/CPM-treated animals compared to SXCT. MAR of the CPM animals was 1.2 times greater than SXCT. Residual CPM was 88% vs. 60% in the CPM vs. BMP/CPM groups.

At 8 weeks, Tb.V for all anatomic locations treated with BMP/CPM was 1.7 times greater in the region surrounding the core defects compared to the combined CPM and SXCT groups. Increased Tb.V resulted from increased Tb.Th (trabecular thickness) and O.V on existing trabeculae, as well as new trabecular bone formation. O.S was increased from 12.8 ± 8.6% in the control groups to 61.0 ± 18.0% in the BMP/CPM animals. The increase in Tb.Th was due to a 5.2 fold increase in MS (70.8 ± 14.3% vs. 13.9 ± 6.7%) and a 1.6 fold increase in MAR in the BMP/CPM group compared to SXCT. MAR of the CPM group was 1.2 times greater than SXCT. Residual CPM was 67% vs. 26% in the CPM vs. BMP/CPM groups.

These results indicate that BMP/CPM induces rapid increases in O.V, O.S, MS and MAR in the region surrounding the core defects as early as 4 weeks. These increases were sustained at 8 weeks leading to increased Tb.Th and Tb.V. There was also considerable new trabecular bone formation within the core defects and the surrounding region. This study provides support for evaluating BMP/CPM to accelerate metaphyseal fracture repair and increase bone density.

NF-kB, p65 Represses BMP2 Signaling by Interfering with the Interaction of Smad and CBP. E. Jimi[1], T. Katagiri[2], F. Okamoto*[1], H. Fukushima[1], T. Tada[1], H. Kajiya[1], K. Okabe[1]. [1]Physiological Science and Molecular Biology, Fukuoka Dental College, Fukuoka, Japan, [2]Biochemistry, Showa University, Tokyo, Japan.

Bone morophogenetic proteins (BMPs) are members of the transforming growth factor-b (TGF- b) superfamily and control proliferation, differentiation and apoptosis of various cell types. Previous studies have shown that BMPs induce not only bone formation in vivo but also osteoblast differentiation of mesenchymal cells in vitro. On the other hand, transcription factor NF-kB is critical for the expression of inducible genes involved in immune reactions and inflammation, and BMPs and NF-kB have opposite biological functions during inflammatory processes and apoptosis. To clarify the regulatory mechanisms of NF-kB on BMP signaling pathway during osteoblast differentiation, we examined the effect of p65 (a subunit of NF-kB) expression on BMP2-induced osteoblast differentiation using p65 deficient (p65-/-) mouse embryonic fibroblasts (MEF). BMP2 induced more alkaline phosphatase (ALP) positive cells in p65-/- MEF than in wild-type MEF. BMP2-induced expression of osteoblast differentiation markers, such as ALP or osteocalcin was also enhanced in p65-/- MEF. Expression of p65 failed to affect receptor-dependent formation of heteromers containing Smad proteins (intracellular signaling molecules in the BMP signal transduction pathway) as well as the DNA-binding activity of Smad proteins. Overexpression of p65 in p65-/- MEF inhibited BMP2-responsive promoter activity despite a lack of direct interactions between p65 and Smad proteins. Furthermore, this p65-mediated inhibition of BMP2- and Smad-responsive promoter activity was restored after inhibition of NF-kB by overexpression of the dominant negative form of IkB. Overexpression of the transcriptional coactivator CBP suppressed the inhibitory effect of p65 on the BMP2-responsive promoter. Overexpression of p65 interfered with the interaction of Smad and CBP. These results suggest that NF-kB represses the BMP2 signaling through at transcriptional level by competing for transcriptional coactivators.

Transcriptional Profiling of Murine Marrow Stromal Fibroblast Cultures Treated with Noggin. S. P. Suriyapperuma*, I. Kalajzic*, J. Glynn*, N. Boucher*, A. Kaur*, W. Krueger*, D. Rowe. Genetics and Developmental Biology, Univ. of Connecticut Health Center, Farmington, CT, USA.

Bone morphogenetic proteins (BMPs) have an important role in controlling mesenchymal differentiation. Important mechanisms of regulation of BMP action are BMP antagonists that prevent BMP's from binding to its receptors and therefore control BMP signaling. Previous studies described the biological effects of BMP antagonists on osteoblast lineage differentiation, but did not provide the broad spectrum of the modulation of gene expression induced by these agents. We have previously shown that primary marrow stromal cell (MSC) cultures grown under osteoblast inductive conditions, in the presence of continuous with 250ng/ml of noggin for 9 or 20 days fail to achieve full osteoblast differentiation (J. Cell Biochem. 88:1168, 2003). To identify the gene regulation triggered by noggin, we performed cDNA transcriptional profiling of noggin treated cultures. Total RNA from untreated and treated cultures was extracted on day 9 (N9 Vs C9) and day 20 (N20 Vs C20). RNA was amplified to make antisense RNA and hybridized to four UCHC Mouse 6K Chip each consisting of transcripts in quadruplicate. Noggin treated and control RNA was comparatively hybridized to provide comparisons in a loop design (N9 Vs C9), (N20 Vs C20), (N20 Vs N9), and (C20 Vs C9). The data was statistically validated by Confidence Analysis (CA-95%) and Significance Analysis of Microarrays (SAM-5%).

Comparison of N9 with C9 generated 13 and 22 up regulated genes and 3 and 2 down regulated genes by CA and SAM respectively. N9 showed down regulation of early markers of bone lineage (Akp2 and fibromodulin) and inhibition of Col2a1, a chondrocyte specific gene. N20 Vs C20 revealed more pronounced regulation of genes with 135 and 239 (up to 33 fold) up regulated genes and 131 and 812 down regulated genes by CA and SAM. Cartilage directed (Col2a1, Col11a1and FGFr3) and bone associated genes (Bmp1, Wnt4, Col1a1 and Dkk1) were down regulated. Among up regulated genes were myogenic genes i.e., Foxk1, Fhl2 and Spnb2. Preliminary data on C20 Vs C9 showed 76 up regulated and 86 down regulated genes by CA. Increased levels of Wnt1, Wnt4, Col1a1 and decreased levels of Myh11, Tmp2, Spnb2 and other skeletal genes validated the control cell cultures. Comparison of N20 Vs N9 identified 43 up and 79 down regulated transcripts. Longer exposure to noggin had stronger inhibitory effects on osteoblast and chrondocyte differentiation and accentuation of myogenic precursor cells. Our data validates the multi-lineage potential of MSCs and suggests that noggin inhibits mesenchymal lineage differentiation at the stage prior to bifurcation of progenitor cells into the chondrocyte and osteoblast lineage.

Modulation of BMP2-Induced Osteoblast Differentiation by Heparin and Heparin Sulfate Proteoglycans (HSPGs). X. Jiao*[1], E. M. Shore[2], F. S. Kaplan[3], D. L. Glaser*[1]. [1]Orthopedic Surgery, University of Pennsylvania, Philadelphia, PA, USA, [2]Orthopedic Surgery ,Genetics, University of Pennsylvania, Philadelphia, PA, USA, [3]Orthopedic Surgery, Medicine, University of Pennsylvania, Philadelphia, PA, USA.

Heparin and heparan sulfate proteoglycans (HSPGs) may interact with bone morphogenetic proteins (BMPs) during bone formation. However, the precise mechanisms remain unknown. This study examined the effects of both cell surface HSPGs and exogenous heparin on BMP2-induced osteoblast differentiation.

To examine the effects of exogenous heparin, C2C12 cells were cultured for 6 days with 0-300 ng/ml BMP2 and 0-2 mg/ml heparin added simultaneously. Osteoblast differentiation was assessed at day 7 by the expression of alkaline phosphatase (ALP), collagen type I, Cbfa1/Runx2 and osteocalcin. Messenger RNA levels of these markers were detected by semi-quantitative RT-PCR, and ALP activity was measured histochemically. Heparin at concentrations up to 2 µg/ml increased while at higher concentrations significantly inhibited BMP2 signaling as demonstrated by phosphorylated SMAD1 levels and ALP activity. At 2 mg/ml, heparin blocked the BMP2 mediated increase of mRNAs of osteoblast markers including osteocalcin, Cbfa1/Runx2, collagen type I and ALP. To study effects of cell surface HSPGs on BMP2 signaling, C2C12 cells were pretreated with either 0-80 mM sodium chlorate for 48 h or 0-6 SU Heparinase III for 2 h to deplete HSPGs and then cells were incubated with BMP2 for 6 days. Depletion of cell surface HSPGs by both methods enhanced BMP2 signaling in a dose-dependent manner indicated by increased ALP activity and pSMAD1. To investigate HSPGs' effects on BMP2 internalization, cells treated either with sodium chlorate and/or antibodies against BMPRIA were incubated with labeled BMP2. The internalization of BMP2 was monitored by fluorescence microscopy. In the presence of intact BMPRIA, ALP was induced but the cell surface BMP2 binding capacity was significantly reduced when HSPGs were depleted. When cells were treated with antibodies against BMPRIA, ALP induction was blocked; however, BMP2 still could be internalized through HSPGs. These results suggested that cell surface HSPGs mediated BMP2 internalization without signaling and thus competitively inhibited BMP2 signaling. With cell surface HSPGs intact, free heparin has a biphasic effect on BMP2 signaling, being stimulatory at low concentration and inhibitory at high concentration. Since BMPs play an important role in ectopic bone formation, exogenous heparin or alteration of endogenous HSPGs has a potential to block debilitating ectopic bone formation, as in fibrodysplasia ossificans progressiva (FOP).

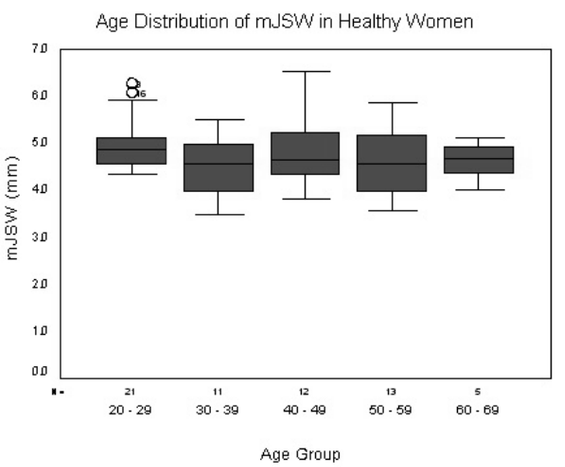
The Relation of Medial Minimum Joint Space Width to Age in the Knees of Healthy and Osteoarthritic Women. K. A. Beattie[1], P. Boulos*[1], J. Duryea*[2], J. O'Neill*[1], M. Pui*[1], C. L. Gordon[1], J. D. Adachi[1], C. E. Webber[3]. [1]McMaster University, Hamilton, ON, Canada, [2]Dept. of Radiology, Brigham & Women's Hospital, Boston, MA, USA, [3]Hamilton Health Sciences, Hamilton, ON, Canada.

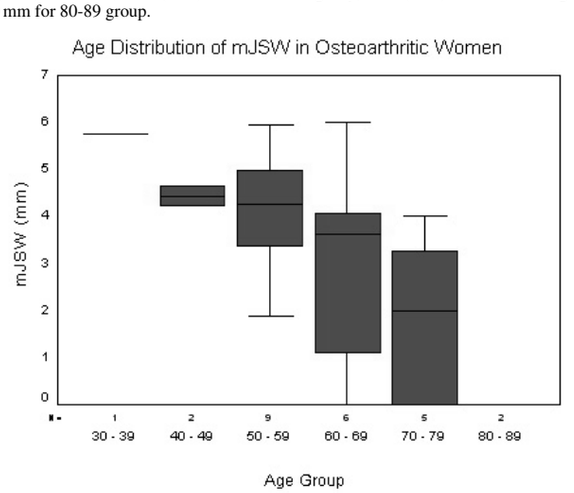
The purpose of this study was to evaluate medial minimum joint space width (mJSW) in the knees of healthy women of various age groups and compare these values with osteoarthritic women.

The group of healthy women included 20-69 year olds with no knee pain, bone/joint disease or knee injury. Women in the osteoarthritis (OA) group had been clinically diagnosed with OA by a rheumatologist. All volunteers underwent a single, fixed-flexion knee radiograph. Radiographs were graded using the Kellgren-Lawrence (K-L) scale and digital films were analyzed using a computer algorithm.

The 2 groups consisted of 62 healthy and 25 osteoarthritic females. Age distribution of healthy females included 21 aged 20-29, 11 aged 30-39, 12 aged 40-49, 13 aged 50-59 and 5 aged 60-69 with a mean (SD) age of 39.1 (13.6) years and a mean (SD) BMI of 24.2 (4.3) kg/m^2. K-L grading of healthy knees revealed 43 grade 0 and 19 grade 1 films with no differences in mJSW between grades 0 and 1. Analyses for age groups revealed the following mean (SD) mJSWs: 5.00 (0.54) mm for 20-29, 4.49 (0.69) mm for 30-39, 4.82 (0.74) mm for 40-49, 4.57 (0.76) for 50-59 and 4.61 (0.44) mm for 60-69.



Age distribution in the OA group included 1 aged 30-39, 2 aged 40-49, 9 aged 50-59, 6 aged 60-69, 5 aged 70-79 and 2 aged 80-89. The mean (SD) age was 62.2 (11.7) years and mean (SD) BMI was 28.0 (5.8) kg/m^2. K-L grading yielded 3 grade 0, 4 grade 1, 9 grade 2, 3 grade 3 and 4 grade 4. mJSW decreased significantly as K-L grade increased. Analyses revealed the following mean (SD) mJSWs: 5.75 mm for 30-39, 4.43 (0.28) mm for 40-49, 4.12 (1.22) for 50-59, 3.07 (2.18) mm for 60-69 group, 1.85 (1.83) mm for 70-79 group and 0 mm for 80-89 group.



These data suggest that a "normal" range of mJSW for a healthy women lies between 4.55 and 5.00 mm. In OA patients, mJSW decreases with age and these values are smaller than healthy women in the same age group.

An Automated High-Resolution Technique for Volumetric Fluorescence Imaging of Large Bone Specimens. G. J. Kazakia*[1], J. J. Lee*[1], T. M. Keaveny[2]. [1]Mechanical Engineering, University of California, Berkeley, CA, USA, [2]Mechanical Engineering & Bioengineering, University of California, Berkeley, CA, USA.

Three-dimensional reconstruction of fluorescent labels is often crucial in the detailed study of biological structures and processes. Currently available techniques for fluorescence imaging cannot provide high-resolution volumetric reconstructions of large specimens. We describe a new system, based on the CNC milling technique, for generating high-resolution, 3D reconstructions of fluorescent signals within bone tissue specimens. This method produces images with resolution independent of specimen size, and with fluorescent signals segmented by emission spectra such that components labeled with different fluorochromes may be visualized individually (a single wavelength band) or as a unit. Biological specimens are stained in bulk with fluorescent dyes to reveal various matrix and cellular components, and are then embedded in an opaque resin. The specimen surface is then milled away at very small increments by a computer-controlled moveable specimen stage and milling machine. After each milling pass, a computer-controlled imaging station excites the exposed fluorochromes and captures the emitted fluorescence through a series of filters chosen specifically for the specimen. Through post-processing the 3D volume is reconstructed, allowing the researcher to visualize the stained components at a very high resolution (on the order of a few microns). To investigate both the qualitative and quantitative capabilities of this fluorescence imaging technique, we imaged damage within an 8 mm x 10 mm cylinder of bovine trabecular bone stained with the chelator xylenol orange. Autofluorescence was exploited to capture the geometry of the bone tissue; a UV excitation filter was coupled with a DAPI emission filter to image bone. Xylenol orange fluorescence was imaged using a TRITC filter set. Two 5x6 arrays of 30 images each were captured for each exposed surface - one array using the UV-DAPI filter set and one using the TRITC filter set. Using a 4x objective an in-plane resolution of 3 microns/pixel was achieved. An out-of-plane resolution of 7 microns was obtained by removing 7 microns of material during each pass of the milling tool. The volume representing xylenol orange-stained regions was superimposed onto the volume representing the bone, and then rendered to create a 3D map of damage throughout the volume. Our volumetric reconstruction of this specimen provides a visual map of the volume of damage present through the entire cylinder. These data also provide quantitative measures of damage distribution, which greatly add to the information derived from traditional 2D analysis.

Structural Characterization of Cortical Bone Microarchitecture on Microcomputed Tomography Images: Correlation with Mechanical Analysis. C. Chappard[1], A. Basillais*[1], S. Bensamoun*[2], B. Brunet-Imbault*[1], M. Ho Ba Tho*[2], G. Lemineur*[3], C. Benhamou[1]. [1]Ipros, Université d'Orléans, Orleans, France, [2]Laboratoire de Biomécanique et Génie Biomédical, Université de Technologie de Compiègne, Compiègne, France, [3]Lesi, Université d'Orléans, Orleans, France.

Microcomputed tomography (µCT) is largely used to analyze trabecular bone. Cortical bone is made of compact bone including a network of pores (canals and resorption spaces). Its porosity is a major parameter conditioning bone strength. The morphological and topological arrangement of this network remains to be evaluated.

Nineteen cortical samples from 3 human femurs were scanned by a µCT (Skyscan ® 1072) with an isotropic 7.81 µm resolution. After reconstruction and thresholding, three dimensional (3D) cortical bone volumes were available. After inversion of the image, the algorithms developed for trabecular bone analysis were applied in order to characterize the network of pores.

The pore volume (BV/TV equivalent) was labelled PoV/TV. PoN (pore number, TbN equivalent) and DA (degree of anisotropy) were measured by the Mean Intercept Length method. PoDm (pore diameter, TbTh equivalent) and PoSp (pore spacing, TbSp equivalent) were derived from the Hildebrand method, PoS/PoV (pore surface on volume, BS/BV equivalent) from triangulation method, and FD (fractal dimension) by box counting analysis. Ultrasound measurements were performed by contact transmission technique to measure longitudinal velocities. Elastic coefficient C_{33} and Young modulus E_{33} were derived from ultrasound measurement at 2.25 MHz and 75 kHz respectively and apparent densities calculated from the ratio of bone mass to bone volume.

The morphological parameters showed a wide range of values especially for the mean CaDm 44 to 493 µm, the lowest values corresponding to Haversian and Volkman canals and the highest to resorption spaces. All the structural parameters were significantly correlated to the mechanical parameters (Spearman coefficients are given in the table below).

The 3D rendered volume revealed the porosity structure in details, and the parametric analyses quantitatively describe the microstructural organization of the porosity. This structural analysis of cortical bone is related to mechanical values. This analysis could bring new and pertinent insight on cortical bone evaluation.

r values	PoV/TV (%)	PoS/PoV (mm^{-1})	PoDm (µm)	PoSp (µm)	PoN (mm^{-1})	DA	FD
C_{33}	-0.94 [a]	0.78 [a]	-0.80 [a]	0.76 [b]	0.88 [a]	-0.53 [b]	0.79 [a]
E_{33}	-0.92 [a]	0.80 [a]	-0.77 [b]	0.74 [b]	-0.86 [a]	-0.54 [b]	0.78 [b]

NanoSIMS as an Analytical Tool for Trace Metal Detection in Bone and Liver from Haemodialysis Patients. J. Denton*[1], F. Hillion*[2], F. Horreard*[2], A. G. Cox*[3]. [1]Osteoarticular Pathology, University of Manchester, Manchester, United Kingdom, [2]CAMECA, Paris, France, [3]University of Sheffield, Centre Analytical Sciences, Sheffield, United Kingdom.

The purpose of this study is to investigate the potential of the NanoSIMS instrument in the identification of metals in bone and soft tissues at an ultrastructural level coupled with high sensitivity to PPB levels. It is the intention of this submission to demonstrate the capabilities of the instrument and not to demonstrate the presence of aluminium in bone as this has been described earlier. The technique of NanoSIMS was developed by CAMECA Paris and the first instrument installed in St Louis USA in 1999. There are 10 instruments in the world to date. The ability to extend the SIMS analysis to extremely small areas or volumes (50 nm beam diameter cesium, 150 nm oxygen) while maintaining extremely high sensitivity at High Mass Resolution is possible. Five masses or elements can be collected simultaneously by the instrument allowing true superimposition of ion maps.

Bone and liver specimens from an end stage renal failure patient treated by haemodialysis and receiving aluminium containing oral phosphate binders and whole blood transfusion were used as test specimens. They were formalin fixed and Araldite embedded. A block 10mm diameter and 100micron thick was taken, polished by diamond abrasion techniques and gold coated.

Using a 200nm diameter primary negative oxygen beam areas 40x40micron were examined by raster mapping.

There was significant deposition of iron and moderate deposition of aluminium in the liver specimen, however there was limited co-localisation of the two metals.

In contrast to the intracellular deposition of the metals in liver the accumulation of the metals in the bone was concentrated in the matrix of bone in a lamellar or banded pattern. The metal accumulation was mainly within bone concentrating at the cement or reversal lines.

The NanoSIMS instrument offers the ability to map ions in mineralised and non-mineralised tissues at extremely low concentrations <1 ppm with a spatial resolution of between 50 (Cs) and 150 nm (O)depending on the ion beam, no other instrument has this capability

Mathematical Modeling of ^{3}H-tetracycline and ^{45}Ca Metabolism as Bone Resorption Markers in Rats. Y. D. Zhao, J. M. K. Cheong*, B. R. Martin, C. M. Weaver. Department of Foods and Nutrition, Purdue University, West lafayette, IN, USA.

Urinary ^{3}H-tetracycline has been used as a bone resorption marker in pre-labeled animals. Changes in urinary ^{3}H-tetracycline are used to evaluate effectiveness of interventions to reduce bone loss. We used mathematical modeling to explore ^{3}H-tetracyline metabolism and to determine bone resorption rates from urinary ^{3}H-tetracycline data. Furthermore, the labeling efficiencies of ^{3}H-tetracyline and ^{45}Ca in cortical and trabecular bones were investigated. In our first study, 4-month-old female rats were injected with ^{3}H-tetracycline intravenously followed by 4-day serum kinetics at 13 time points and 4-day urine and fecal collection. Serum, urinary, fecal, and whole skeletal ^{3}H data revealed two exchangeable compartments (rapid and slow) between serum and bone ^{3}H-tetracycline pools. Using the ^{3}H-tetracylcine transfer rates derived from the modeling we were able to determine the bone resorption rates from urinary ^{3}H data of other rats. In another study, twelve 9-month-old OVX rats were injected subcutaneously with both 50 µCi ^{45}Ca and 20 µCi ^{3}H-tetracycline by single injection or multiple injections (twice a week for 6 weeks). Rats were sacrificed either 1 week or 6 weeks after single injection or after the last dose of multiple injections. Proximal tibia, femur midshaft, lumbar vertebrae (L1-L4), and the remaining skeleton were analyzed for ^{3}H, ^{45}Ca and calcium content. The total skeletal retention of ^{3}H-tetracycline in the multiple injection group (6.19±0.92%) was significantly higher than the single injection group (4.74±0.86%), whereas ^{45}Ca skeletal retention did not differ between the two injection groups. Among the bone sites, the labeling efficiencies (% dose/g Ca) of ^{45}Ca and ^{3}H were significantly higher in proximal tibia than those of femur midshaft. The ratio of ^{45}Ca to ^{3}H in bones varies by bone site, thus indicating that ^{3}H-tetracycline labels the skeleton differently from ^{45}Ca. In conclusion, kinetic modeling of ^{3}H-tetracycline enabled us to quantify the bone resorption rate from urinary ^{3}H-tetracycline data. Trabecular bones were labeled much more efficiently than cortical bones for both ^{45}Ca and ^{3}H.

New Nano-CT Technology Allows Ultrastructural Study of Bone Quality Including Microcracks and Osteocyte Lacunae. P. L. Salmon, A. Y. Sasov. Skyscan, Aartselaar, Belgium.

A nano-CT scanner has been developed which promises new capabilities relevant to the study of bone ultrastructural quality, such as 3d imaging of osteocytes and micro-cracks. The device employs advanced x-ray technologies and new physical phenomena for signal detection. The highest nominal resolution (lowest isotropic voxel size) is about 140 nm, superior to synchrotron tomography. The instrument uses an x-ray source with a spot size of 300-400 nm. At these scanning parameters, small-angle x-ray scattering plays a significant role in the image formation, accentuating structure edges to sharpen image detail (a desirable "artefact") while on the other hand making density measurement based on x-ray absorption less accurate. This is analogous to phase contrast in optical microscopy. Detail detectability is 150-200 nm. An object manipulator allows positioning and rotation with an accuracy of 100 nm, and the intensified CCD x-ray detector has photon-counting sensitivity. Images obtained from the current prototype (figure 1, 530 nm voxel) show clearly osteocyte lacunae and cracks in a mouse fibula. Inspection of cracks in 3d suggests that they may propagate along paths between osteocytes.

Evaluation of Mineralization During Fetal Development in the IGF-I Deficient Mouse. A. Burghardt*[1], Y. Wang*[2], H. Z. ElAlieh*[2], X. Thibault*[3], D. D. Bikle[2], F. Peyrin[3], S. Majumdar[1]. [1]Radiology, University of California, San Francisco, San Francisco, CA, USA, [2]University of California, San Francisco and Veterans Affairs Medical Center, San Francisco, CA, USA, [3]ESRF/CREATIS, Grenoble, France.

Insulin-like growth factor I (IGF-I) has previously been established as an important regulator of skeletal metabolism. However the role of IGF-I during embryonic bone development has not been evaluated in detail. Here we investigate the role of IGF-I during embryonic mineral formation in the spinal ossification center and proximal metaphysis of the tibia using the von Kossa stain method and synchrotron based micro-computed tomography (SR μCT).

Lumbar spine and tibia were harvested from 6 IGF-I deficient (IGF-I -/-) mouse embryos (18 days gestational age) along with their wild type controls. SR μCT images were obtained in a 3D parallel beam geometry with an isotropic voxel size of 0.97μm and a 1mm field of view. A two phase model for x-ray attenuation in bone was used to relate the mean bone linear attenuation to mineral density (DMB). Histological sections (5μm) were obtained from a second group of animals and prepared using the standard von Kossa staining procedure.

Von Kossa staining of the proximal metaphysis of the tibia showed a comparable degree of silver nitrate substitution in control and knockout animals. In contrast, virtually no stain precipitation was observed in the lumbar ossification center of knockout animals while controls were found to have considerable staining. Surprisingly, DMB as determined by SR μCT, was found to have only a minor reduction (6.8%, $p < 0.0001$) in the knockout lumbar spine. In the tibia, DMB was determined to be slightly higher (8.2%, $p < 0.001$) in IGF-I -/- animals.

At 18 days, IGF-I deficient embryos were found to have significant material differences from their controls in both the lumbar spine and proximal tibia. However, the degree of differentiation was dependent on anatomic site and method used to assess mineralization. Specifically, we were surprised by the disparity between von Kossa staining and densitometric SR μCT seen in the spinal ossification center. Subtle differences in mineral chemistry or structure during embryonic mineral formation might explain this result. Implications for the interpretation of von Kossa specificity as well as the role of IGF-I during fetal development should be investigated further. Fourier transform infrared imaging and electron microscopy could help characterize the state of calcium phosphate crystallinity in this model. Additionally, experiments at different gestational time points will be an important next step in better understanding the role of IGF-I during fetal development.

Mineralization in the Mouse Calvarial Cell-seeded Nano-fibrous Scaffolds. K. Woo*[1], J. Jun*[1], V. Chen*[2], J. Baek[1], S. Seo*[1], G. Kim*[1], S. Ko[3], P. X. Ma[4]. [1]Dept. of Craniofacial Cell and Developmental Biology, Seoul National University, College of Dentistry, Seoul, Republic of Korea, [2]Dept. of Biomedical Engineering, Univ. of Michigan, Ann Arbor, MI, USA, [3]Kangnung National University, College of Dentistry, Kangnung, Republic of Korea, [4]Dept. of Biologic and Materials Sciences, Univ. of Michigan, Ann Arbor, MI, USA.

Poly(L-lactic acid) nano-fibrous scaffolds with interconnected pores were developed under the hypothesis that synthetic nano-fibers, mimicking the structure of natural collagen fibers, could create a more favorable microenvironment for cells. In this work, the biological properties of the nano-fibrous scaffolds were evaluated in vitro in terms of the potential use for bone tissue engineering. Under electromicroscopic examination, mouse calvarial cells seeded on nano-fibrous scaffolds were found to connect to each other by forming a network of slender cell processes that were intermingled with the nanofibers of the scaffolds. Biomineralization was enhanced in the nano-fibrous scaffolds as revealed by transmission electromicroscopy and von Kossa staining. Consistent with histological results, the expression of bone sialoprotein transcripts in nano-fibrous scaffolds was much higher than that in solid-walled scaffolds. We inhibited collagen fibril formation by adding 3,5-dehydroproline to culture and examined the expressions of alpha 2 integrin and osteogenic markers in the nano-fibrous scaffolds and control (solid-walled) scaffolds. Nano-fibrous scaffolds supported the expressions of alpha 2 integrin and osteogenic markers (osteocalcin and bone sialoprotein), while the solid-walled scaffolds suppressed the expressions of the alpha 2 integrin and the osteogenic markers. These results indicate that the nano-fibrous architecture serves as superior scaffolding for biomineralization, and suggest that the synthetic nanofibers may function similarly to natural collagen fibers to osteoblasts.

Fourier Transformed Infra-red Imaging Spectroscopic Analysis of the Mineral Phase Generated during *in Vitro* Matrix Vesicle Mineralization. R. Garimella[1], N. Camacho*[2], J. Sipe*[1], H. Clarke Anderson[1]. [1]Pathology and Laboratory Medicine, University of Kansas Medical Center, Kansas City, KS, USA, [2]Research Division, Hospital for Special Surgery, New York, NY, USA.

The process of skeletal mineralization is tightly regulated and displays unique spatial relation to the underlying organic matrix. Membrane-bound extracellular matrix vesicles (MVs) play an important role in the *de novo* initiation and propagation of biological mineral in calcifying cartilage, bone, dentin, and in pathologic calcification. Phosphatases of MVs including alkaline phosphatase (ALP), ATPase, 5' AMPase and inorganic pyrophosphatase (PPiase) promote MV-initiated mineralization. Phosphoester substrates such as ATP, AMP and PPi are hydrolyzed by MV phosphatases, thereby increasing the local concentration of orthophosphate (Pi) and thus initiating calcification. Characterization of the phase, composition, and crystal size and perfection provides valuable insight into the mechanism of bone mineral deposition. The hypothesis tested here, was that hydrolysis of AMP or β-GP, monophosphoester substrates of MV-5' AMPase (substrate: AMP) and ALP (substrates: AMP, β-GP), yields orthophosphate (Pi) which leads to the formation of mature crystalline, apatite mineral while the hydrolysis of ATP, a substrate for MV-ALP, ATPase or nucleoside triphosphate pyrophosphohydrolase (NTPPase) leads to the formation of immature mineral and not crystalline hydroxyapatite. MVs were isolated from collagenase-digested rachitic rat growth plate cartilage by differential ultra-centrifugation thus separating MVs from intact chondrocytes and larger cell fragments, e.g. nuclei, mitochondria and lysosomes. *In vitro* calcification was initiated by incubating 30 μg samples of MV protein in a calcifying solution (pH 7.65) containing 2.2 mM Ca^{+2} and 1.6 mM PO_4^{-2}, in the presence of 1 to 3 mM phosphoester substrate, e.g. 1 mM ATP, 3 mM AMP or 3mM β-GP, at 37°C for 5.5h. The calcified MV precipitates were pelleted by centrifugation at 8800g for 30 min. To identify the mineral phase formed, Fourier transform infrared imaging spectroscopy (FT-IRIS) was carried out on 1 μm sections of spurr-embedded MV after exposure to calcifying solution. FT-IRIS showed the presence of a hydroxyapatite-like phase associated with matrix vesicles when AMP or β-GP was used as a phosphatase substrate, while with ATP no identifiable crystalline mineral phase was present. The production of a hydroxyapatite-like mineral phase by the monophosphate substrates of alkaline phosphatase or AMPase supports earlier data indicating a significant role for these monophosphoesterases in biological mineralization.

Evidence for a Serum Factor that Initiates the Re-calcification of Demineralized Bone. P. A. Price, H. H. June*, N. J. Hamlin*, M. K. Williamson. Biology, University of California, La Jolla, CA, USA.

The present studies show for the first time that demineralized bone re-calcifies rapidly when incubated at 37°C in rat serum: Re-calcification can be demonstrated by Alizarin red and von Kossa stains, by depletion of serum calcium, and by uptake of calcium and phosphate by bone matrix. Bone re-calcification does not occur in a carbonate buffer that maintains the ionic milieu of serum, however, which indicates that re-calcification is driven by specific agent(s) in serum.

Re-calcification is specific for the type I collagen matrix structures that were calcified in the original bone, with no evidence for calcification in periosteum or cartilage. Re-calcification ceases when the amount of calcium and phosphate introduced into the bone matrix is comparable to that present in the original bone prior to demineralization, and the re-calcified bone is comparable in weight to the original bone and is palpably hard. Radiographs of fully re-calcified rat tibias are indistinguishable from radiographs of control tibias, and re-calcified bone mineral is comparable to the original bone mineral in calcium to phosphate ratio and in FTIR and XRD spectra.

The serum activity responsible for re-calcification is sufficiently potent that the addition of only 1.5% serum to DMEM causes bone re-calcification. This putative serum calcification factor has an apparent molecular mass of 55 to 150kDa and is inactivated by trypsin or chymotrypsin. The serum calcification factor must act on bone for 12h before re-calcification can be detected by Alizarin red or von Kossa staining, and before the subsequent growth of calcification will occur in the absence of serum. The first observable effect of the serum factor is the formation of numerous, discrete mineral foci within the collagenous bone matrix.

The speed, matrix-type specificity, and extent of the serum-induced re-calcification of demineralized bone suggest that the serum calcification factor identified in these studies may participate in the normal calcification of bone.

Glutamate Signalling Regulates Skeletogenesis and Bone Growth. J. H. Burford[1], D. S. Perrien[2], A. Horner*[1], E. A. Bowe*[1], T. Notomi*[1], L. J. Suva[2], T. M. Skerry[1]. [1]Royal Veterinary College (VBS), London, United Kingdom, [2]Center for Orth. Res., University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Intercellular communication in the bone microenvironment controls cell function, regulating bone mass and strength. Evidence has emerged for a role in this communication for the excitatory amino acid glutamate, acting via cell membrane receptors on osteoblasts, osteoclasts and precursors. Here we show that skeletogenesis and bone growth in vitro and in vivo are regulated by AMPA gated glutamate receptors.

In fetal mouse limb buds, immunocytochemistry was used to demonstrate expression of AMPA receptors in cells within mesenchymal condensations that precede the formation of skeletal elements and in the apical ectodermal ridge. Treatment of explanted limb buds from 10.5 d.p.c fetuses with the non-competitive AMPA type glutamate receptor antagonist CFM-2 led to 70% and 90% inhibition of expression mRNA for the chondrogenic markers Sox-9 and aggrecan respectively. There was no effect on 12.5 d.p.c. explants. In micromass cultures of 10.5 d.p.c limb bud cells, cartilage nodule formation, aggrecan and collagen II expression were significantly inhibited by CFM-2, but at 12.5 d.p.c the same treatment was associated with a significant increased cartilage formation. Similar dose-dependent inhibition was also observed with the competitive AMPA antagonist, NBQX.

CFM-2 treatment of adult murine bone marrow cells cultured under osteogenic conditions was associated with a reduction in colony formation. Similarly siRNA knockdown of the AMPA receptors iGluR2 and iGluR3 of these cells resulted in a 100% and 90% inhibition respectively of AP-positive colony formation.

To test these findings in vivo, two groups of female CD1 mice (bw 22g +/- 2g) received

NBQX (approximately 20ug/kg/h), or saline via subcutaneous osmotic pumps for 9 days. NBQX was chosen on the basis of solubility, and its demonstrated inability to cross the blood-brain barrier.
Micro CT analysis of the proximal tibiae showed a highly significant increase in trabecular thickness (p=0.002), while Bone Surface/Bone Volume (p=0.007), and SMI (p=0.021) were significantly decreased. These data are indicative of thicker, more plate-like metaphyseal trabeculae, with reduced trabecular spacing and improved mechanical competence. BV/TV, trabecular number, and connectivity density were not significantly altered.
These effects demonstrate a direct influence of glutamate mediated signalling on bone cells, rather than effects mediated by the central and peripheral nervous systems. Collectively, these data demonstrate that glutamate regulates skeletogenesis, osteoblast progenitor differentiation and bone formation in vivo.

Cardiovascular Risk Factors in Osteoporotic Women: Association between Fractures and Aortic Calcifications. G. Rajzbaum*[1], Y. Bézie*[2], M. Chauffert*[3], P. Bréville*[1], F. Roux*[1], M. Safar*[4], J. Blacher*[4]. [1]Rheumatology, Fondation hôpital Saint-Joseph, Paris, France, [2]Pharmacie, Fondation hôpital Saint-Joseph, Paris, France, [3]Biochimie, Fondation hôpital Saint-Joseph, Paris, France, [4]Hôpital Hôtel-Dieu, Paris, France.

Association between aortic calcifications (AC) and osteoporosis has been described but remains controversial. There is no data about the relation between osteoporotic fractures and CV diseases after adjustment on all potential cofounders. Our aim was to examine the multiadjusted relation between previous osteoporotic fractures and abdominal AC, an established CV risk factor.
We investigated correlation between AC, evaluated on lateral lumbar spine X-rays, and osseous parameters in 221 consecutive postmenopausal out patients consulting for osteoporosis between January 2000 and June 2003 in a French general hospital. Multiple linear regression with forward and backward selection of variable was used to assess the independent determinants of AC. Adjusted odds-ratio with Wald confidence intervals were estimated from multiple logistic regression.
Compared with women without AC (n=137), women with AC (n=84) were on the average almost 7-year older (69 $\pm$ 8.8 versus 61.6 $\pm$ 7.8 years ; $p< 10^{-6}$) . They presented a more deleterious CV risk profile : premature menopause (38% versus 24%, $p\leq0.05$), higher dyslipidemia (27 ± 32% vs 20 ± 15% ; p=0.002) and higher pulse pressure (58.3 ± 14.9 mmHg vs 52.9 ± 15.1 mmHg ; p=0.001), and a more severe osteoporosis : increased osteoporotic fractures (49% versus 27% p<0.001), lower lumbar T score and femoral BMD (respectively -2.44 $\pm$ 1.17 versus -2.06 + 1.39 SD, p<0.05, and 0.728 $\pm$ 0.12 versus 0.761 + 0.11 g/cm², p<0.05). Women with AC were smaller (154.2 cm $\pm$ 18.4 versus 158.1 cm $\pm$ 6.3, p<0.05), with a significant height loss (4.28 cm versus 2.27, p<0.001). Free desoxypyridinoline but not cross-laps were higher in women with AC (9.4 $\pm$ 3.73 versus 8.01 $\pm$ 3.14, p<0.05). No difference has been found for the osteoprotegerin concentration (6.45$\pm$3.1 vs 6.9$\pm$2.9 pmol/L, p=0.6). Concerning the AC, adjusted odds-ratio (OR) is 2 for previous osteoporotic fracture (95% IC 1.1-3.6), and 2.4 for the age, for a 1-SD increase (95% IC 1.7-3.4).
In this study, osteoporotic fractures are statistically correlated with the presence of AC, independently of the age and all other cofounders. The relationship between osteoporosis and atherosclerosis has not yet been clarified. Additional research is needed to further characterise the relationship between these two common illnesses of elderly. Prevention strategies would entirely differ.

Up-regulation of Alkaline Phosphatase Activity and Bone Sialoprotein Gene Expression in PC-1 Mutant Periodontal Cells, in vitro. S. Sato[1], M. Kitagawa*[2], M. Miyauchi*[2], B. Foster[1], M. Somerman[1], T. Takata*[2]. [1]Department of Periodontics, University of Washington, Seattle, WA, USA, [2]Department of Oral Maxillofacial Pathobiology, Hiroshima University, Hiroshima, Japan.

Abnormal hypermineralization has been reported in mutant mice exhibiting mutations in genes regulating the level of extracellular pyrophosphate, e.g., plasma cell membrane glycoprotein-1 (PC-1), tissue-nonspecific alkaline phosphatase (TNAP) and the multiple-pass transmembrane protein ankylosis (ANK). However, while most of these studies have focused on cartilage/bone, effects on cells within the periodontal region have only begun to be examined. Teeth obtained from PC-1 mutant mice show a marked increase in cementum thickness on root surfaces of teeth as compared to wild-type. In this study, cultured periodontal cells established from PC-1 and wild-type mice were compared for cell proliferation rate, alkaline phosphatase activity and osteocalcin (OCN) and bone sialoprotein (BSP) gene expression. Primary cultures of PC-1 mutant and congenic wild-type periodontal cells, isolated from 8-week-old mice, were cultured in α-MEM supplemented with 20% FBS. For the cell proliferation assay, cells were plated at a density of 5 x 10^3 cells per well of 24 well-plates, and were counted every two days for 10 days. Alkaline phosphatase activity was determined after 4, 8 and 10 days by a p-nitro phenyl-phosphate method. Osteocalcin (OCN) and bone sialoprotein (BSP) mRNA expression were measured by RT-PCR at day 7. Results demonstrated that PC-1 mutant cells proliferated at a 1.5 fold greater rate when compared with wild type cells and this difference was apparent by day 6, a trend that continued through out the 10 day period. Further, PC-1 cells exhibited markedly higher alkaline phosphatase activity and BSP expression, as compared to wild-type controls. These findings suggest that the PC-1 gene mutation may affect mineralization through alteration of alkaline phosphatase activity and BSP mRNA expression, in addition to altering the phosphate (Pi) and pyrophosphate (PPi) levels. It has been reported that PC-1 mutant mice have decreased levels of extracellular PPi, and alkaline phosphatase hydrolyzes the mineralization inhibitor PPi. Currently, we do not know if phosphate has a direct role in the observed up-regulation of alkaline phosphatase activity and BSP expression, but BSP itself, consider to promote mineralization, may play a role in the enhanced mineralization noted in cementum of PC-1 mutant teeth.

Low Phosphate Intake Induces Hypertrophic Chondrocytes Survival and Transdifferentiation in Normocalcemic Rats with Hypophosphatemic Rickets. V. Lascau-Coman*[1], G. Mailhot*[1], F. Moldovan*[2], N. Dion[1], M. Gascon-Barré[1], L. G. Ste-Marie[1]. [1]Hopital Saint-Luc, CHUM Research Centre, Montreal, PQ, Canada, [2]Faculty of Dentistry, Université de Montréal, Montreal, PQ, Canada.

Calcium (Ca) and phosphorus (P) play important roles in endochondral ossification and bone development. It was previously observed that young rats fed a low Ca diet depleted in D (Ca-D-) exhibit growth retardation. However, we showed that young rats fed a D depleted diet but high in Ca (Ca/P ratio: 4/1) developed rickets due to hypophosphatemia which partially inhibited chondrocytes apoptosis and impaired terminal differentiation (J Bone Miner Res 2003; 18 Suppl. 2: S189). In this study, we investigated the effect of dietary P on the fate of hypertrophic chondrocytes (HC) in the growth plate. Ca-D- rats were repleted for 14 days with diets presenting various Ca/P ratios. Three groups were studied with Ca/P ratios of: 4/1 (Ca++); 4/1.5 (P+); 4/3 (P++). Rats paired for age and fed a regular rat chow diet served as controls. In the Ca++ animals, chondrocytes were found in doublets or triplets (clones) in intact lacunae. This zone of clones was separated from the late HCs by a transitional zone with elongated chondrocyte-like cells (ECLC). These findings were not observed in the controls. Using immunohistochemistry, some clones were shown to be in division (expressing PCNA). In addition, some clones showed asymmetric cell division with one cell positive for Tunel while the other expressed type I collagen. Endothelin-1 which has been shown to be involved in the control of proliferation and probably in the differentiation of chondroprogenitors into chondroblasts or osteoblasts, was highly expressed in ECLCs. Safranin O staining demonstrated a loss of proteoglycans in the transitional zone. Goldner's trichrome was suggestive of osteoid tissue surrounding the clones indicating osteoid production by these cells. Compared to the controls, HCs of the Ca++ rats acquired osteogenic potential by switching from a maturational step to cell division and transdifferentiated into bone-forming cells. In the P+ group, partial onset of rickets was demonstrated without clones, while the P++ diet completely prevented the rachitic phenotype and HC division and transdifferentiation. Taken together, these data suggest that dietary P plays a role as an important metabolic mediator that contributes to the modulation of the fate of hypertrophic chondrocytes in the rat growth plate.

Regeneration of Cartilage Tissue from Bone Marrow Cells using an RWV Bioreactor System. N. Kida*[1], H. Kojima[1], T. Taguchi*[2], J. Tanaka*[2], T. Uemura[1]. [1]ADRC(Age Dimension Research Center), AIST (National Institute of Advanced Industrial Science and Technology), Tsukuba, Ibaraki, Japan, [2]BMC(Biomaterials Center), NIMS(National Institute of Materials Sciences), Tsukuba, Ibaraki, Japan.

Cartilage tissue regeneration attracted much attention not only in bone biologists but also clinicians having interests in treating bone diseases such as osteoarthritis. However, problems such as necrosis of cells due to high-density cell culture and shear stress by gravity have not yet been solved. Thus, we examined an RWV (Rotating Wall Vessel) bioreactor that simulates a micro-gravity environment with low shear stress for cartilage tissue regeneration. An RWV bioreactor generates stress by horizontal rotation of a cylindrical vessel equipped with gas exchange membrane to compensate the effect of gravity, resulting in homogenous cell growth and differentiation without sinking, and cells aggregate and form a three dimensional tissue. In this study, we established a three-dimensional culture technique for construction of large and homogenous cartilage tissues without necrosis by culture of bone marrow mesenchymal stem cells using RWV bioreactor.
Bone marrow cells were collected from rabbit long bones. The cells were cultured for 3 weeks in DMEM with 10% FBS. The cells were subcultured by trypsinization, and resuspended in DMEM supplemented with TGF-beta etc. The cell suspension was seeded in the cylindrical vessel of an RWV reactor, and rotatory culture was performed for 4 weeks. Cartilage function of the cultured tissues was examined by quantitative RT-PCR of aggrecan and type II collagen mRNA, safranin-O staining of paraffin-embedded sections, immunostaining, and measurement of the marker of matured cartilage, ALP activity. In addition, the elastic modulus of the formed cartilage tissue was measured.
Large cell aggregate with a longer diameter of about 1.4 cm was formed by rotatory culture of bone marrow cells in an RWV bioreactor, and the size of aggregates was maintained throughout 4 weeks.
The mRNA expression of aggrecan and type II collagen was detected, and homogenous production of the two proteins was confirmed in whole tissue by immunostaining. The tissue formed a cartilage cavity, differentiated into matured cartilage cells. Furthermore, no necrotic cell was observed in the formed tissue. Large and homogenous three-dimensional cartilage tissues were successfully generated by culture of bone marrow cells in a pseudo micro-gravity environment in an RWV bioreactor.

Distinct Roles of Smad Pathways and p38 Pathways in Cartilage-specific Gene Expression in Synovial Fibroblasts. H. Seto*[1], S. Kamekura*[1], H. Chikuda[1], H. Hiraoka*[1], T. Imamura[2], K. Miyazono[3], H. Oda*[1], H. Kurosawa*[4], K. Nakamura*[1], H. Kawaguchi[1], S. Tanaka[1]. [1]Orthopaedic Surgery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, [2]Department of Biochemistry, The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Japan, [3]Molecular Pathology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [4]Orthopaedic Surgery, Juntendo university, Tokyo, Japan.

Synovium is a thin tissue, which lines the nonarticular surfaces of diarthrodial joints. There is accumulating evidence that synovial tissues(STs) contain multipotent cells with chondrogenic potential that might be involved in the repair process of articular cartilage defects and therefore might provide a good source for engineering articular cartilage. In the present study, we analyzed downstream cascades of TGF-ß/BMP signaling in synovial fibroblasts (SFs) using the adenovirus vector-mediated gene transduction system. STs were obtained from the knee joints of patients at the time of operation under written informed consents, and SFs were isolated from STs by enzymatic digestion. After 3 - 5 passages, SFs were infected with adenovirus vectors , and chondrogenic phenotypes of the cells were examined by Northern blotting or real time-PCR of chondrocytic marker genes as well as histological staining. Overexpression of constitutively active activin receptor-like kinase 3 ($ALK3^{CA}$) dramatically increased type II collagen and aggrecan expression in SFs, while LacZ or $ALK5^{CA}$ expression had no effects. Chondrogenic differentiation via $ALK3^{CA}$ expression was also observed in SFs subcutaneously transplanted into nude mice. To analyze downstream cascades of ALK3 signaling, we utilized adenovirus vectors carrying either Smad1 to stimulate Smad pathways or constitutively active MKK6 ($MKK6^{CA}$) to activate p38 pathways. Smad1 expression had a synergistic effect on $ALK3^{CA}$, while activation of p38 MAP kinase pathways alone by transduction of $MKK6^{CA}$ accelerated terminal chondrocytic differentiation, leading to type X collagen expression and enhanced mineralization such as positive Alizarin Red staining. Overexpression of Smad1 prevented $MKK6^{CA}$-induced type X collagen expression and maintained type II collagen expression. In model mouse of osteoarthritis, activated p38 expression as well as type X collagen staining was detected in osteochondrophytes and marginal synovial cells. These results suggest that SFs can be differentiated into chondrocytes via ALK3 activation and that stimulating Smad pathways and controlling p38 activation at the proper level can be a good therapeutic strategy for maintaining the healthy joint homeostasis and treating degenerative joint disorders.

Effects of Irradiation Therapy on Primary Rat Chondrocytes *In Vitro*. B. S. Margulies*, J. A. Horton*, Y. Wang*, M. J. Allen, T. A. Damron*. Orthopedic Surgery, S.U.N.Y. Upstate Medical University, Syracuse, NY, USA.

Introduction: Radiation therapy in pediatric patients may negatively impact the growth plate resulting in crippling therapy-related growth arrest and deformity. Negative irradiation effects on the growth plate observed in our Sprague-Dawley rat model suggest an acute chondrocyte irradiation sensitivity. The chondrocyte response to specific irradiation doses remains unknown. To address negative radiation therapy effects in the clinically relevant range below 20 Gy, we employed our cell culture model system to evaluate the acute irradiation effects on chondrocyte proliferation and cytotoxicity; while examining terminal differentiation, the induction of apoptosis, alterations in cell synthetic activity, and changes in the expression of PTHrP, PTHrP-receptor, Ihh, collagens II & X, VEGF, FGF 2, TGF-β, Bax and Bcl-2. We hypothesized that irradiation alters growth plate chondrocyte synthetic activity resulting in decreased mineral formation, while preferentially increasing the incidence of terminal differentiation over cell death. **Methods:** Primary rat chondrocytes were exposed to a series of single fraction irradiation doses using a clinical radiotherapy unit. Standard colorometric assays and flow cytometry were used to assess proliferation, cytotoxicity, terminal differentiation and apoptosis. RT-PCR and western blotting were used to demonstrate changes in mRNA and protein expression. **Results:** Radiation therapy reduced cell proliferation and increased cytotoxicity (Fig. 1); while increasing the induction of apoptosis and G_0/G_1 cell cycle arrest (Fig. 2). Irradiation decreased mineralization and expression of collagen II & X (Fig. 3), while increasing the expression of Ihh, TGF-β and FGF 2. **Discussion:** The irradiation doses employed in this study inhibited chondrocyte proliferation and increased cytotoxicity; except at the 1 Gy dose were there was no significant cytotoxicity. Evidence of terminal differenatiation was observed through dose and time dependent increases in alkaline phosphatase, TGF-β, FGF 2, Ihh and G_0/G_1 arrest. Decreases in collagen expression and mineral formation following irradiation suggest an alteration in synthetic activity when compared to the non irradiated chondrocytes and in contrast to the markers of terminal differeniation observed to increase in the irradiated chondrocytes.

Lack of Indian Hedgehog Disrupts Pre- and Post-natal Development of Murine Craniofacial Skeleton. B. Young*[1], N. Minugh-Purvis*[2], M. Iwamoto*[1], E. Koyama*[1], M. Pacifici[1]. [1]Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA, [2]Anatomy and Cell Biology, University of Pennsylvania, Philadelphia, PA, USA.

Incontrovertible evidence shows that Indian hedgehog (Ihh) has major roles in development of long bones, where it regulates chondrocyte proliferation in growth plates and ossification in intramembranous bone collar and endochondral shaft. Surprisingly little is known about potential roles of Ihh in craniofacial skeletal development. Here we carried out an extensive analysis of embryonic and neonatal mice homozygous- or heterozygous-null for Ihh (St. Jacques, et al., 1999), focusing on cranial vault and base. Litter analyses revealed that Ihh-/- embryos were identifiable not only by their dwarf limbs, but also by a foreshortened snout starting around E15.5. Alizarin red/alcian blue staining showed little effect on frontal bones of null embryos, whereas more posterior cranial vault regions showed growth delays. By far, the most dramatic defects were seen in cranial base, a largely endochondral structure. In wild-type E17.5 and E18.5 specimens, spheno-occipital and mid-sphenoidal synchondroses displayed their normal, striking and bipolar organization consisting of back to back growth plates with typical zones of chondrocyte maturation. The cells expressed characteristic molecular markers, including Ihh in pre-hypertrophic zone and collagen X and osteopontin in hypertrophic zone. By E18.5, wild-type synchondroses displayed abundant endochondral bone and marrow, with extensive vascularization. In Ihh-null littermates, the cranial base did form, but the synchondroses were completely disorganized. Presumptive growth plates lacked obvious zones of maturation before E16.5 but displayed collagen X-and osteopontin-positive hypertrophic chondrocytes scattered randomly by E17.5, and failed to undergo endochondral ossification thereafter. In addition, the growth plates were essentially devoid of proliferating chondrocytes, as indicated by histone C4 in situ analyses. Similar analyses of heterozygous Ihh+/- animals showed fairly normal embryonic craniofacial development. However, postnatal follow-up revealed defects in cranial base which became more pronounced with age, consistent with importance of spheno-occipital synchondrosis in postnatal growth. In sum, this is the first report showing that Ihh clearly plays major roles in craniofacial skeletal growth and development, and targets of its direct or indirect action appear to include the largely intramembranous bones of cranial vault as well as endochondral elements of cranial base. Supported by: NIH RO1AR47543.

Identification of PTHrP Target Genes in Chondrocytes Using cDNA Microarray. J. Hoogendam[1], E. Parlevliet*[1], R. Miclea*[1], C. Löwik[2], J. Wit*[1], M. Karperien[3]. [1]Pediatrics, LUMC, Leiden, Netherlands, [2]Endocrinology, LUMC, Leiden, Netherlands, [3]Pediatrics and Endocrinology, LUMC, Leiden, Netherlands.

Parathyroid Hormone related Peptide (PTHrP) is an essential regulator of the pace of chondrocyte differentiation. To gain more insight into the molecular mechanisms of action of PTHrP, we performed microarray analysis using the chondrogenic ATDC5 cell line to identify PTHrP target genes.

ATDC5 cells were cultured in micromasses to stimulate chondrocyte differentiation. During this process the PTHrP Receptor becomes expressed. The responsiveness of cells to PTHrP increases with differentiation as shown by a dose and time dependent increase in the generation of cAMP after a challenge with PTHrP. At day 8 of culture the cells have deposited an alcian blue positive matrix and express collagen type II and type IX mRNA as well as low levels of collagen type X mRNA. This time point represents cells in the transition zone of the growth plate, the main target cells for PTHrP, and was chosen for identification of PTHrP target genes. ATDC5 cells were stimulated with 10^{-7} M PTHrP, and RNA was extracted at 0h, 1h, 2h, 4h and 8h after stimulation. Samples were reverse transcribed, amplified and labelled with Cy5 and Cy3. All samples were hybridized against 0h in three, four or five fold using competition hybridization on a mouse 15k cDNA array. A list of approximately 50 genes ($p< 10^{-3}$), which were significantly regulated by PTHrP was generated. About 30% of the genes were up- and 70% were downregulated. Cluster analysis identified several patterns of response to PTHrP, including immediate early up- and downregulated genes (peak of regulation between 1-4 hours) and intermediate up- and downregulated genes (peak of regulation at 8 hours). Most of the identified genes were implicated in signal transduction and transcription regulation. Among the targets was RGS2, which was upregulated by PTHrP and is implicated in turning off PTHrP receptor signalling. Among the regulated genes were various proteins known to be involved in regulation of hormonal responsiveness, suggesting that PTHrP may influence the responsiveness of growth plate chondrocytes to hormones like GH and sex steroids.

Peroxisome Proliferator Activated Receptor-gamma Represses Thyroid Hormone Signaling in Growth Plate Chondrocytes. L. Wang*, Y. Shao*, R. T. Ballock. Orthopaedic Research Center, Department of Biomedical Engineering, The Cleveland Clinic Foundation, Cleveland, OH, USA.

Peroxisome proliferator activated receptors (PPARs) are DNA-binding nuclear hormone receptors and are upregulated in response to high fat diets. PPARs may compete with thyroid hormone receptors (TRs) for binding to the preferred heterodimerization partner, the retinoid X receptor (RXR). The purpose of this study was to investigate if PPARs are inducible repressors of thyroid hormone signaling in growth plate chondrocytes.

Epiphyseal chondrocytes were isolated from distal femoral growth cartilage of neonatal

rats. Chondrocytes were transiently transfected with a reporter plasmid containing a single copy of a thyroid hormone response element (DR+4) inserted upstream of a thymidine kinase promoter fused to a luciferase cDNA. Overexpression of a PPARγ cDNA or addition of the PPARγ activator ciglitazone each resulted in a decrease in TRα1-mediated transcriptional activation in the presence of T3. These inhibitory effects of PPARγ stimulated by ciglitazone or its endogenous ligands were attenuated by BADGE, an antagonist for PPARγ. Co-transfection of a RXRα expression vector in the growth plate cells partially restored the inhibition of transcriptional activation by PPARγ. The T3-induced increases in alkaline phosphatase activity associated with terminal differentiation of growth plate chondrocytes were suppressed by forced overexpression of a PPARγ cDNA in the cells. Electrophoretic mobility shift assay (EMSA) with nuclear extracts of growth plate chondrocytes demonstrated retarded bands of TR/RXR heterodimers and TR/TR homodimers binding to DR+4 probes. The formation of TR/RXR complexes was disrupted when chondrocytes were transfected with PPARγ plasmid before nuclear protein extraction.
In conclusion, PPARγ activation in growth plate chondrocytes represses TR-mediated gene transcription and inhibits the biological effects of thyroid hormone. This cross-talk between the peroxisome proliferator and T3 signaling pathways most likely occurs via competition for available heterodimeric partner RXRs. These findings may have important implications for development of an obesity-related hip disorder in children known as slipped capital femoral epiphysis.

Heparanase Expression in Cartilage: A Novel Regulator of Heparin Binding Growth Factor (HBGF) Delivery. A. J. Brown*[1], C. Kirn-Safran*[1], M. C. Roy*[2], D. Marchetti*[2], M. C. Farach-Carson*[1], D. D. Carson*[1]. [1]Department of Biological Sciences, University of Delaware, Newark, DE, USA, [2]Department of Comparative Biomedical Sciences - SVM, LSU-Baton Rouge, Baton Rouge, LA, USA.

Heparanase, an endoglucuronidase that cleaves heparan sulfate (HS) chains from various proteoglycans, has been identified in a wide variety of tissues. Despite the ability of heparanase to release active heparan sulfate binding growth factors (HBGFs) in various tissues, the role that heparanase plays in chondrogenesis has not been determined. We developed an antibody to a synthetic peptide corresponding to a conserved sequence in mouse and human heparanase. The antibody recognized partially purified heparanase and heparanase in crude cell extracts. The antibody was used to localize heparanase in growth plate and articular cartilage. Following immunohistochemistry, heparanase was predominantly detected in the perichondrium and periosteum and in the growth plate. The location of heparanase in actively growing regions of bone suggests a functional relationship between growth factors such as (basic) fibroblast growth factor-2 (FGF-2) and heparanase. To examine the normal function of heparanase in the growth plate, we have begun to investigate the role of heparanase in HBGF delivery. Western blots, quantitative PCR (Q-PCR) and activity assays were used to monitor changes in heparanase expression and activity during *in vitro* chondrogenic differentiation of mouse ATDC5 cells. Q-PCR showed that heparanase transcript expression is transiently increased 60-fold in maturing chondrocytes. Western blot analysis confirms the presence of heparanase in total protein extracts, but the changes are of lower magnitude than seen by Q-PCR. Heparanase activity assays show robust heparanase activity throughout the differentiation period. Surprisingly, during the mid-point of chondrogenic differentiation in this system (day 15), overall heparanase activity was decreased although protein expression was still evident. The mechanism for this functional decrease has not been elucidated. Collectively, our data indicate that chondrogenic differentiation may be, in part, regulated by changes in heparanase expression and activity. Taken together, our results support the notion that heparanase is a regulated enzyme in the growth plate likely to be involved in HBGF delivery. Perturbing normal patterns of heparanase expression is expected to impact HS-dependent processes during cartilage differentiation.

Wnt9a BAC Transgenes Drive Reporter Gene Expression in Developing Synovial Joint Articular Cartilage In Vivo. K. J. McDermott*, R. L. Chandler*, D. P. Mortlock*. Molecular Physiology and Biophysics, Vanderbilt University, Nashville, TN, USA.

More insight into the molecular events that regulate synovial joint development could help further the understanding of arthritis etiology, or lead to novel therapeutic approaches to modify cartilage differentiation. Surprisingly, little is known about the molecular regulation of joint development. The Wnt gene family encodes secreted glycoproteins utilized in many developmental processes. In both mouse and chick embryonic limb buds, Wnt9a is expressed in stripes of mesenchyme that mark interzones, the presumptive synovial joint-forming regions. Recently, retroviral expression of Wnt9a was reported to upregulate synovial joint markers in chick, implying a functional role for the Wnt pathway in joint induction. However, the upstream signaling components regulating Wnt9a expression have yet to be identified. To identify Wnt9a cis-regulatory sequences that could interact with key transcription factors or signaling pathways involved in joint specification, we used bacterial "recombineering" to insert LacZ reporter cassettes into Wnt9a bacterial artificial chromosome (BAC) transgenes. The resulting BACs were used to generate transgenic mouse embryos by pronuclear injection. Of the two BAC constructs tested, one clone that contains extensive Wnt9a 3' flanking sequence was able to drive LacZ expression in digit, carpal/tarsal and elbow/knee joints specifically in differentiating articular cartilage at 15.5 days post-coitus and in connective tissue adjacent to tendons. A BAC that carried much less 3' sequence failed to drive digit joint expression, suggesting that some key cis-regulatory sequences required for proper joint expression may lie in the 108 kb genomic region 3' to Wnt9a. Although this segment overlaps at least two adjacent genes, several noncoding stretches in this region are highly conserved across species. rVISTA analysis was used to identify conserved transcription factor binding sites in the Wnt9a BAC sequences. This revealed binding sites for several factors implicated in cartilage patterning, such as Hox, DeltaEF1, Gli, Smad, and Lef/TCF. Our data suggest long-range cis-regulatory sequences may control Wnt9a expression in developing joints. These results demonstrate new joint-specific transgene vectors and indicate Wnt9a BAC constructs should be useful for refining critical Wnt9a cis-regulatory sequences. Also, Wnt9a BACs can be engineered for future experiments that require targeted expression of desired gene products to developing joint cartilage, which will be useful for studies to determine whether Wnt ligand inhibitors (such as Sfrp/Frzb) can regulate interzone formation or differentiation.

Chondrogenic, Osteogenic and Adipogenic Differentiation of Pluripotent Adipose-derived Stem Cells from Type II Collagen Promoter-driven GFP Mice. Z. Huang[1], J. Bryan*[1], W. Horton[2], L. Sandell[1]. [1]Orthopaedic Surgery, Washington University, St Louis, MO, USA, [2]Oregon Health Sciences University, Portland, OR, USA.

Pluripotent adult stem cells such as bone marrow-derived stem cells and adipose-derived stem cells have been successfully isolated from human and other large mammals. Due to limited quantity of bone marrow in mice, it is impractical to obtain sufficient quantities of stem cells from mouse bone marrow. The aim of this study is to isolate pluripotent stem cells from mouse fat tissues and verify pluripotency of these adipose-derived stem cells. To expand fat stem cells in vivo, we fed mice with regular diet (9% fat) and high fat diet (42%) for two and half months. Mice were paired by ages from 2 months to 16 months and by gender. Significant weight gains were found in male mice that were placed on high fat diet at the age between 4 and 8 months. Visceral and inguinal fat tissues were excised, minced, and digested with collagenase for 2 hours as 37 °C. After brief centrifugation, cell pellet were resuspended in DMEM medium with 10% fetal bovine serum. After filtered through 70 um cell strainer, cell suspension was then placed in 10 cm dishes overnight. The suspended cells were removed in the following day and fresh medium were added. The attached cells were expanded for two to four passages before used in experiments or frozen down for storage. To test chondrogenic potential of the fat stem cells, cells were cultured in TGF-β containing medium for 28 days. Progression of differentiation was monitored by the appearance of fluorescence of the micro-spheres that were formed and by alcian blue staining. Adipogenic differentiation was induced by a cocktail of reagents including insulin, IBMX, indomethacin and dexamethasone, and was monitored by appearance of oily droplets in the cytoplasm and by oil-red staining. Osteogenic differentiation were induced by a cocktail of reagents including ascorbic acid, β-glycerophosphate, and dexamethasone, and monitored by nodule formation and von Kossa staining. Our data indicate that the cells that we isolated were pluripotent and capable of differentiate into multiple differentiation pathways under inducing reagents. Successful isolation of large amount of mouse stem cells provides a useful tool to explore increasing pools of transgenic mice available.

Intervertebral Disk Degeneration due to Aging and Oxidative Stress. N. Fujita*[1], T. Miyamoto[1], N. Hosogane*[2], M. Yagi*[1], Y. Toyama*[2], T. Suda*[1]. [1]Cell Differentiation, Keio University School of Medicine, Shinjuku, Japan, [2]Orthopaedics, Keio University School of Medicine, Shinjuku, Japan.

Low back pain is one of the most common deseases and constitutes a devastating economic burden on the individual and society. Degeneration of the intervertebral disk (IVD) based on aging is considered as a cause of low back pain, however, the pathophysiologic process of IVD degeneration is still unclear. In this study, we have analyzed the mechanisms of IVD degeneration using rabbit IVD cells. First, to investigate the disk degeneration in 4W, 14W and 160W rabbits, magnetic resonance imaging and histological analysis were performed. The IVD degeneration was obvious in 160W rabbit IVD as observed aged human disk degeneration. The IVD is composed of two distinct tissues: a gelatinous center, known as the nucleus pulposus (NP), and several surrounding lamellae known as the annulus fibrosus (AF). Each cell was separated by blunt dissection and isolated by pronase following collagenase treatment. Subsequently, the number of each AF and NP cell was examined, then RNA was extracted and cDNA was synthesized to analyze the expression pattern of various molecules by RT-PCR. The numbers of both AF and NP cells were reduced in 160W rabbit compared with other young rabbits such as 4W and 14W. The expression of typeI collagen, typeII collagen and aggrecan were also reduced in 160W rabbit, while decorin and lumican were up-regulated. These observations show a characteristic feature of degenerative change in IVD based on aging.
Next, we have examined the effect of oxidative stress as aging stress on the cells from 14W rabbit IVD in vitro whether the radical oxigen stress (ROS) mediate the degenerative changes in cultured cells as observed in vivo. AF cells were isolated from 14W rabbit and cultured for 24 hours with various concentration of hydrogen peroxide. ROS down-regulated the expression of typeIcollagen, typeIIcollagen and aggrecan dose-dependently as observed in aging rabbit and up-regulated the expression of typeX collagen, a marker of terminally differentiated chondrocyte. These results indicate that IVD degeneration based on aging is mediated via ROS. Moreover, we will discuss the possibility of the therapeutic effect of anti-oxidant on the IVD degeneration.

Regeneration of Defects in the Articular Cartilage in Rat Knee Joints by Connective Tissue Growth Factor/Hypertrophic Chondrocyte-Specific Gene Product 24/CCN Family Member 2 (CTGF/Hcs24/CCN2). T. Nishida*[1], S. Kubota*[1], T. Kuboki*[1], K. Nakao*[1], T. Kushibiki*[2], Y. Tabata*[2], M. Takigawa[1]. [1]Biochem. & Mol. Dent., Okayama Univ. Grad. Sch. Med. & Dent., Okayama, Japan, [2]Frontier Medical Sciences, Kyoto University Grad. Sch. Medicine, Kyoto, Japan.

CTGF/Hcs24/CCN2 is a unique growth factor that stimulates the proliferation and differentiation, but not hypertrophy, of articular chondrocytes in vitro. The objective of this study was to investigate the therapeutic use of CTGF/Hcs24/CCN2. The effects of recombinant CTGF/Hcs24/CCN2 (rCTGF/Hcs24/CCN2) on repair of damaged cartilage were evaluated by using both the monoiodoacetic acid (MIA)-induced experimental rat osteoarthritis (OA) model and full-thickness defects of rat articular cartilage in vivo. In the MIA-induced OA model, quantitative real-time reverse-transcription polymerase chain reaction (RT-PCR) assays showed a significant increase in the level of CTGF/Hcs24/CCN2 mRNA; and immunohistochemical analysis and in situ hybridization revealed that the clustered chondrocytes, which clustering indicates an attempt to repair the damaged cartilage, produced CTGF/Hcs24/CCN2. Therefore, CTGF/Hcs24/CCN2 was suspected to play critical roles in cartilage repair. In fact, a single injection of rCTGF/Hcs24/CCN2 incorporated in gelatin hydrogel (rCTGF/Hcs24/CCN2-hydrogel) into the joint cavity of MIA-induced OA model rats repaired their articular cartilage to the extent that it became histologically similar to normal articular cartilage. Next, to examine the effect of rCTGF/Hcs24/CCN2 on the repair of articular cartilage, we created defects (2 mm in diameter) on the surface of articular cartilage in situ and then implanted rCTGF/Hcs24/CCN2-hydrogel or PBS-hydrogel therein with collagen sponge. In the group implanted with rCTGF/Hcs24/CCN2-hydrogel-collagen, new cartilage filled the defect 4 weeks postoperatively. In contrast, only soft tissue repair occurred when the PBS-hydrogel-collagen was implanted. Consistent with these in vivo effects, rCTGF/Hcs24/CCN2 enhanced type II collagen and aggrecan mRNA expression in mouse bone marrow-derived stromal cells, and induced chondrogenesis in vitro. These findings suggest the utility of CTGF/Hcs24/CCN2 in the regeneration of articular cartilage.

MMP13 Is a Component of the Large Latent TGF-β2 Complex Produced by Hypertrophic Chondrocytes. P. M. Mattioli*, R. K. Scott*, M. D'Angelo. Anatomy, Philadelphia College of Osteopathic Medicine, Philadelphia, PA, USA.

Chondrocytes produce transforming growth factor-beta 2 (TGF-β2) and store it in their matrix in a large latent complex (LLC) that includes latent TGF-β binding protein 1 (LTBP1). Large quantities of activated TGF-β2 are produced as a result of hypertrophy in chondrocytes and MMP-13 is involved in the activation of TGF-β2 from its latent complexes produced by these cells. In this study, our lab has made the novel observation that the LLC for TGF-β2 produced by hypertrophic chondrocytes also includes MMP-13. We isolated resting, early stage hypertrophic and late stage hypertrophic sternal chondrocytes and cultured them in serum-free alginate bead cultures as previously described. Conditioned media was collected at day 8 in culture and cells were extracted with 0.5% 3-([3-chlomadipropyl]dimethylammonio)-1-propane-sulfonate (CHAPS) buffer [10mM Tris, 100mM NaCl, 2mM EDTA, pH7.6]. Western blot analysis with antiserum to MMP-13 produced the previously described 59 kDa band and an additional band at approximately 250 kDa. Antisera to LTBP1 and TGF-β2 revealed the same immunoreactive band at approximately 250kDa, corresponding to the LLC. To further investigate whether MMP-13 is present in the hypertrophic chondrocyte-produced LLC, tibial hypertrophic chondrocytes were isolated from day 19 chicks, extracted and immunoprecipitated with antiserum to LTBP1 and MMP-13 and immunoblotted with antiserum to TGF-β2. These blots contained bands of immunoreactivity corresponding to the 250 kDa LLC, the 60kDa b-LAP N-terminus fragment of TGF-β2 and the 25kDa homodimer of TGF-β2. Furthermore, addition of 2.5ng/ml TGF-β2 to hypertrophic chondrocytes grown in serum-free alginate cultures resulted in an increase in mRNA for tissue transglutaminase and MMP-13 as measured by reverse-transcription polymerase chain reaction. These data suggest that the large latent complex for TGF-β2 produced by hypertrophic chondrocytes may include cross-linked MMP-13. The presence of covalently linked MMP-13 in the large latent complex would point to a novel storage process for TGF-β2 produced by hypertrophic chondrocytes. In addition, association of an activating protease with the LLC produced by these cells, suggests a mechanism to regulate the quantity and timing of activated TGF-β2 released from matrix storage by hypertrophic chondrocytes.

Impact of Small Collagen Fragments on Cartilage Cells. S. Oesser*[1], J. Seifert*[2]. [1]Collagen Research Institute, Kiel, Germany, [2]Surgical Research University of Kiel, Kiel, Germany.

The integrity of articular cartilage is dependent on the maintenance of the extracellular matrix (ECM), which is controlled by chondrocytes (Kuettner et al. 1991). Over the past years various degradation products of the ECM have been identified to influence the metabolism of cartilage cells (Huber et al. 2000). The aim of the present study was to investigate the effect of small collagen fragments on the biosynthesis of mature chondrocytes.

For the investigation, a primary cell culture model was used. Porcine chondrocytes were cultured under oxygen reduction and, after a 3-day lag phase, collagen hydrolysate (CH) with a mean MW of 3.3 kDa was supplemented to the culture medium. Type II collagen biosynthesis of the chondrocytes was quantified by means of ELISA technique. Moreover, pericellular proteoglycans were determined by colorimetric assay and immunoassay, respectively. In additional experiments, porcine articular cartilage explants were cultured in the presence of CH and protease activity in the culture media was assayed by gelatin-substrate zymography.

It was shown that the presence of CH in the culture medium led to a significant ($p<0.01$),dose-dependent increase in type II collagen biosynthesis, whereas native collagen and collagen-free hydrolysate failed to stimulate the production of type II collagen in cartilage cells. The amount of pericellular proteoglycans was also significantly ($p<0.05$) increased after CH treatment, indicating that the stimulated cells produce a complete ECM. In contrast, the presence of the CH in the cell medium had no effect on the protease activity of chondrocytes.

These results clearly indicate a stimulatory effect of CH on the type II collagen biosynthesis of chondrocytes and suggest a regulatory mechanism for the regulation of collagen turnover in cartilage tissue. Moreover, the cells seem to synthesize enhanced amounts of a complete ECM after CH treatment. Protease activity was not affected by the administration of such small collagen fragments.

Based on these results CH might be of particular importance for the regulation of chondrocyte metabolism and might help to reduce degenerative alterations in the ECM.

FGF Signaling Inhibits Hypertrophic Differentiation of Chondrocytes by Suppressing Expression of the CDK Inhibitor, $p57^{Kip2}$. M. Stewart, Y. Geng*. Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL, USA.

Fibroblast growth factor (FGF) signaling inhibits hypertrophic differentiation of chondrocytes *in vitro,* while constitutively activating point mutations of the type 3 FGF receptor are responsible for several inherited chondrodysplasias. The cyclin-dependent kinase inhibitor (CDKI) $p21^{Cip1}$ is up regulated by FGF signaling in chondrocytes and has been implicated in the molecular pathogenesis of the FGFR3-mediated chondrodysplasias. The closely related CDKI, $p57^{Kip2}$ has also been implicated in the regulation of hypertrophic differentiation. Both *in vitro* and murine gene deletion studies suggest that p57 is required for collagen type X (Coll X) expression by differentiating chondrocytes. This study was carried out to determine whether FGF signaling influences p57 expression in chondrocytes undergoing hypertrophic differentiation.

Prehypertrophic chondrocytes were collected from the distal femoral epiphyses of neonatal rat pups and isolated by sequential trypsin/EDTA and collagenase digestion. Isolated chondrocytes were cultured as non-adherent aggregates in defined, serum-free medium supplemented with ascorbic acid and antibiotics. Hypertrophic differentiation, induced by 100 ng rhBMP-2/ml, was monitored by expression of Coll X and alkaline phosphatase (ALP), and by ALP bioactivity. FGF-2 and FGF-18 were administered at 10 ng/ml. Gene expression was assessed by Northern and Western blot analyses. Adenoviral vectors were used to exogenously express p57 and p21.

Both FGF-2 and FGF-18 inhibited Coll X and ALP expression in epiphyseal chondrocytes with near-equal potency. Inhibition persisted despite co- or pre-treatment with BMP-2. Concurrently, FGFs suppressed p57 mRNA and protein expression to below-detectable levels. In contrast, both FGFs and BMP-2 up regulated p21 expression. Exogenous adenoviral p57 expression dose-dependently antagonized the effects of FGF on expression of ALP and Coll X in differentiating chondrocytes, whereas parallel expression of p21 had no such effect.

This study demonstrates that FGF signaling inhibits p57 expression in differentiating chondrocytes. This suppression is functionally significant since exogenous expression of p57 abrogates the inhibitory effects of FGF on expression of Coll X and ALP, both markers of the hypertrophic phenotype. These findings are of direct relevance to the molecular basis of the FGFR3-linked chondrodysplasias and suggest a novel mechanism by which excessive FGF signaling, through constitutive receptor activity, interferes with normal chondrocyte differentiation and associated skeletal growth.

***Ror2^{W749X}*, a Mutation Carried by Brachydactyly B Patients, Causes Brachydactyly in the Mouse and Altered Early Cartilage Development.** R. Raz[1], E. Gazzerro[2], J. L. Clor*[1], H. Nistala*[1], R. C. Pereira[2], L. Stadmeyer*[2], X. Wang*[1], W. T. Poueymirou*[1], T. M. DeChiara*[1], G. D. Yancopoulos*[1], E. Canalis[2], D. M. Valenzuela*[1], A. N. Economides[1]. [1]Regeneron Pharmaceuticals, Tarrytown, NY, USA, [2]Department of Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Mutations in *ror2*, a gene encoding a transmembrane tyrosine kinase (TK) related to MuSK and Trk receptors, can cause two different human disorders: recessive Robinow syndrome (RRS), a mesomelic short-limbed dwarfism, and brachydactyly B (BDB). BDB, associated with dominant mutations, is characterized by short or absent middle and terminal phalanges. To examine the molecular mechanisms underlying the two phenotypes associated with dominant and recessive mutations in *ror2*, we generated *knock-in* mice expressing a W749X mutation, predicted to remove the distal Ser-Thr- and Pro-rich domains of ROR2 and found in severe BDB cases.

In contrast to humans, $ror2^{W749X}$ has no effect in heterozygosis in the mouse and causes in homozygosis a mild skeletal phenotype reminiscent to that of $ror2^{V487lacZ/V487lacZ}$, in which the TK domain is also eliminated. Both mutations result in missing middle phalanges, indicating that the TK domain of ROR2 is not sufficient for normal phalanx specification. $Ror2^{W749X/W749X}$ mice are viable, although males exhibit variable degrees of infertility and

germ cell deficiency. Mutant testes can have up to 40% reduction in size, and display focal areas of tubular degeneration.

Ror2$^{W749X/W749X}$ mice exhibit delayed specification and decreased length of all cartilage anlagens, detectable at embryonic day 13, which result in limb shortening, brachyrrhiny and reduced spine length. Despite a delay in the onset of bone development, growth plate architecture is normal and there is no change in the proliferation of growth plate chondrocytes, suggesting that the bone length phenotype stems from defects in early cartilage specification. Confirming that the effects of ROR2 are specific to bone development, bone mineral density measurements and static and dynamic histomorphometry of post-natal and adult femurs do not reveal any abnormality in the mutants. Overall, the phenotype of *ror2*^{W749X} is markedly less severe than that of *ror2*^{V487lacZ}, indicating that the TK domain is an essential mediator of ROR2 function in proliferating chondrocytes. The Ser-Thr- and Pro-rich carboxy-terminal domain of ROR2 may be required for specification of the middle phalanx and for maintenance of spermatogenesis.

Spring Growth in the Vertebrae of Atlantic Salmon (*Salmo salar*) Is Characterized by a Gradual Increase in *ihh* Expression, while a Certain Photoperiod Triggers *shh* Induction. A. S. Wargelius*, U. Nordgarden*, P. Fjelldal*, A. Berg*, T. Hansen*. Institute of Marine Research, Bergen, Norway.

Vertebral column defects are a common problem in salmon aquaculture. To acquire better understanding for how these defects are induced we studied natural and light simulated spring growth in the adult vertebral column. Osteoblast activity was measured following gene expression of proteins involved in bone morphogenesis namely Sonic hedgehog (Shh), Indian hedgehog (Ihh) and Collagen I (ColI). While hedgehog signalling is involved in osteoblast recruitment and differentiation, ColI is a bone matrix protein representing mature osteoblasts. Gene expression was monitored during a growth activation phase from January- to June 2003 in postsmolt Atlantic salmon, where one fish group was kept under constant light (LL) while another group was kept under natural light (NL). The vertebral bodies (n=10) were measured at three time points (Jan, Apr and Jun.) and the size increased with about 55% (length) and 65%(width). The LL group increased 10% more in size compared to the NL group from April-June. To monitor gene expression, vertebrae 40 was sampled monthly from January-June (n=6 group) and expressional level of *shh*, *ihh* and *colI* was measured at each time point. The expression of *ihh* gradually increased throughout the growth phase while the *ihh* expression in June was 8 times higher compared to that of January. Shh expression was induced in February (NL) and March (LL) after which the expression stayed high throughout the experiment. Interestingly, fish exposed to NL have a peak expression of *shh* in February while LL fish lack this expressional peak. Col I expression was essentially at the same level throughout the season, which indicates that osteoblasts produce a constant level of Collagen I. However, since bone volume significantly increased the expressional induction of *shh*, *ihh* may reflect osteoblast recruitment rather than an increased matrix production by individual osteoblasts. In conclusion expression of *shh* and *ihh* is significantly induced during natural bone growth. In addition *shh* expression was triggered by photoperiod in the beginning of the growth phase, however, the biological significance of this photoperiodic induction needs to be further investigated.

Up-regulation of Bone Morphogenetic Protein Receptors Induced by Hepatocyte Growth Factor in the Early Phase of Fracture Repair. Y. Imai*[1], H. Terai*[1], C. Nomura-Furuwatari*[1], K. Matsumoto*[2], T. Nakamura*[2], K. Takaoka[1]. [1]Orthopaedic Surgery, Osaka City University Graduate Shool of Medicine, Osaka, Japan, [2]Division of Biochemistry, Department of Oncology, Biomedical Research Center B7, Osaka University Graduate School of Medicine, Osaka, Japan.

Introduction: The precise mechanisms of the up-regulation of the BMP, BMPRs or other molecules involved in the bone repair remain to be elucidated. In this study, we investigated effects of HGF to facilitate the BMP action through potential local induction of BMP or BMPRs by HGF which could be activated through thrombin-mediated activation of HGF activator (HGFA).

Materials and Methods: Fracture models of ICR mice tibia were produced. Samples were harvested for real time RT-PCR of HGF and BMPRs, for immunohistochemistry of c-Met (receptor for HGF) and for situ hybridization of BMPRs. To investigate the changes in expressions of BMPRs in response to HGF, C3H10T1/2 cells were cultured with or without recombinant human HGF and harvested for real time RT-PCR of BMP4 and BMPRs and for western blot analysis. To detect the contributions of HGF to biological action of BMP2, cells were pre-cultured with rhHGF, then cultured recombinant human BMP2. And alkaline phosphatase (ALP) activity and expression of luciferase gene linked to *Id1* promoter containing BMP responsive element were assayed.

Results: Positive immuno-staining of c-Met and elevation of HGF mRNA expression in the early phase of fracture repair indicated indirect evidence of activation of HGF at the fracture site. Messenger-RNA expressions of BMPRs were increased at day 1 after fracture and were localized in mesenchymal cells at the fracture site. On real time RT-PCR, the expressions of mRNA of BMPRs were elevated by treatment with HGF, but the expression of BMP4 was not altered. Western blot analysis also showed the BMPR2 up-regulation by HGF treatment. The results from luciferase and ALP assays indicated increased responsiveness to BMPs in the group treated by HGF.

Conclusion: This study indicated that HGF was activated and expressed in the fracture site and induced up-regulation of BMPRs in mesenchymal cells and subsequently might facilitate BMP signaling without affecting expression of BMP molecules.

Retroviral Infection of Osteoactivin Induces Osteoblast Differentiation and Function. M. C. Rico[1], M. P. Hurley*[1], E. Nuglozeh*[1], T. A. Owen[2], S. N. Popoff[1], F. F. Safadi[1]. [1]Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, [2]Pfizer Global Research and Development, Groton, CT, USA.

Osteoactivin (OA) is a novel protein expressed by osteoblasts and plays an important role in osteoblast differentiation and bone formation. Previously, our laboratory demonstrated that primary osteoblast cultures treated with OA antisense oligonucleotide exhibited a dramatic decrease in their differentiation. In this study, we utilized a retroviral system to over-express osteoactivin protein in osteoblasts. Retroviruses produced by co-transfection of a packaging retroviral vector pCL-10A1 (IMGENEX®) and a mammalian expression vector (pBabe) provide an effective mechanism to transiently and stably introduce cDNA into dividing cells. These viral particles were used to generate large recombinant retrovirus titers by co-transfection of pCL-10A1 and OA/pBabe in a 293 packaging cell line using a $CaCl_2$ method. A construct containing an osteoactivin DNA insert (1.4 Kb) was ligated into a BamH1 site in the multiple cloning region of the mammalian expression vector pBabe (5.4 Kb). Control retrovirus was produced by co-transfecting 293 cells with the pCL-10A1 and pBabe. We transiently infected the mouse osteoblast cell line, MC3T3-E1, with the media obtained from the 293 cells. Osteoactivin protein was over-expressed (4-fold) in MC3T3-E1 cells infected with OA/pBabe when compared to control cells infected with pBabe as determined by Western blot analysis. MC3T3-E1 cells infected with OA/pBabe showed a significant (2-fold) increase in nodule formation when compared to control cells infected with pBabe. Matrix mineralization, assessed by calcium deposition into the cell-matrix layer, was significantly increased in OA/pBabe infected MC3T3-E1 cells when compared to control cells infected with pBabe. These results confirm an important role of osteoactivin in osteoblast differentiation and function. Future studies will evaluate the potential clinical uses of osteoactivin in the treatment of bone diseases where increased osteoblast differentiation and bone formation are desired.

TRAP Regulates Expression of Osteocalcin and Osteopontin in Cementoblasts, *in Vitro*. E. C. Swanson*[1], B. L. Foster*[1], M. L. Snead[2], M. L. Paine*[2], C. W. Gibson*[3], M. J. Somerman[1]. [1]Department of Periodontics, University of Washington School of Dentistry, Seattle, WA, USA, [2]Center for Craniofacial Molecular Biology, University of Southern California School of Dentistry, Los Angeles, CA, USA, [3]Department of Anatomy and Cell Biology, University of Pennsylvania School of Dental Medicine, Philadelphia, PA, USA.

Recent studies provide evidence that, in addition to their important role in the formation of enamel, amelogenins also act as signaling molecules during formation of dentin and cementum. Moreover, certain mutations in amelogenin protein sequence associated with mineral defects in human enamel have been reported. These single amino acid changes can be found in the tyrosine-rich amelogenin peptide (TRAP), a specific proteolytic cleavage product of the amelogenin N-terminus. This study focused on the role of TRAP and mutated forms of TRAP in regulating cementoblast gene expression in vitro. Two amelogenin TRAP peptides were selected because they are known to be found in patients affected with amelogenesis imperfecta (AI): (a) a single amino acid change that results in Thr^{21} to Ile (T^{21}TRAP) and (b) a protein engineered double amino acid substitution that results in Thr^{21} to Ile and Pro^{41} to Thr change ($T^{21}P^{41}$TRAP).

Clonal populations of immortalized murine cementoblasts (OCCM) were exposed in vitro to wild-type TRAP (wtTRAP), T^{21}TRAP, or $T^{21}P^{41}$TRAP at doses of 0.1, 1, and 10 μg/mL. Total RNA was isolated at 1, 6, 12, and 24 hours after treatment. Quantitative RT-PCR was used to evaluate change in transcripts for osteocalcin (OCN) and osteopontin (OPN).

It was shown that wtTRAP, T^{21}TRAP, and $T^{21}P^{41}$TRAP down-regulated OCN and up-regulated OPN in a time- and dose-dependent fashion. The aforementioned changes of OCN and OPN transcripts can be detected as early as 6 hours after treatment with proteins. After 24 hours of treatment at the highest concentration (10 μg/mL), OCN was down-regulated by wtTRAP (50%), T^{21}TRAP (85%) and $T^{21}P^{41}$TRAP (70%). Conversely, OPN was up-regulated after 24 hours of treatment by wtTRAP (60%), T^{21}TRAP (200%) and $T^{21}P^{41}$TRAP (150%) when compared to vehicle-treated controls.

TRAP appears to have a direct effect on genes associated with cementoblast function, where the cementoblasts seem to be more responsive to the mutated forms of TRAP. Interestingly in earlier studies, leucine-rich amelogenin peptide (LRAP), which has the first 33 amino acid residues in common with TRAP, was shown to regulate cementoblast gene expression in the same fashion, suggesting that the N-terminus is critical for the signaling events in cementoblasts.

Identification of a New Immunoglobulin-like Domain Containing Protein in Bone. Y. Jung*[1], M. Han*[1], J. Jeong*[1], M. Jung*[1], S. Kim*[2], H. Shin[3], S. Kim[3], T. Kwon*[1], I. Kim*[1], J. Choi[1]. [1]Dept.of Biochemistry, Kyungpook Natl. Univ. School of Medicine, Daegu, Republic of Korea, [2]Dept.of Oral and Maxillofacial Surgery, Hallym University, Sacred Heart Hospital, Kyoungkido, Republic of Korea, [3]Skeletal Diseases Genome Research Center, Daegu, Republic of Korea.

We identified a new immunoglobulin (Ig)-like domain containing gene from human chondrosarcoma cell line, HCS-2/8 cDNA library EST database and cloned its full-length cDNAs from both human and mouse chondrocytes HCS-2/8 and ATDC5 cells, respectively. Mouse gene is located in chromosome 4, and consists of 10 exons. We analyzed the structure and domain composition of this protein after in silico translation, and it belongs to Ig superfamily and composed of 442 amino acid residues which containing two Ig-like loops, one transmembrane region and relatively short cytoplasmic tail of 80 amino acid residues. It also has PDZ-domain binding motif in the end of cytoplasmic tail. In multi-alignment analysis, it is similar to CTX family proteins especially in two Ig domains and transmembrane region. This protein is ubiquitously expressed in various tissues including in brain, kidney, liver, cartilage and bone. Originally, the EST clone has been known as adipocyte specific protein 3 without functional study. Based on structural characteristics and its expression pattern, we called it as dual IgG domain containing cell adhesion family molecule (DICAM). The expression of DICAM was increased during chondrocytes and osteoblasts differentiation in ATDC5 and MC3T3-E1 cell culture systems, respectively. In immunohistochemical staining, DICAM was detected in chondrocytes and osteoblasts of growth plates. These results indicate that DICAM is one of Ig-like domain containing molecules which express in chondrocytes and osteoblasts.

Whole Genome Expression Profiling of Fracture Healing Under Rigorous Experimental Design Reveals Novel Pathways: Pleiotrophin and Meox2 in Fracture Healing. C. H. Rundle[1], H. Wang[2], H. Yu*[1], R. B. Chadwick*[1], J. Tesfai*[1], K. H. W. Lau[1], S. Mohan[1], J. T. Ryaby[2], D. J. Baylink[1]. [1]Mdc, J.L. Pettis VAMC, Loma Linda, CA, USA, [2]Research, Orthologic Corporation, Phoenix, AZ, USA.

To better understand the molecular mechanism of fracture healing, we performed whole genome expression profiling by applying rigorous control design to the Agilent low-input labeling system and the large 20K rat oligomer microarray chip. This approach applied the stabilizing K-wire to fractured and unfractured control femurs to: 1) control for bone formation produced by the K-wire in the marrow, and 2) ablate the marrow equally in fractures and controls. The low-input system allowed us to use the low RNA recoveries and avoided pooling samples that can conceal individual variations. RNA was obtained from Sprague-Dawley femur diaphyses at 3 days (n=5), the inflammation and intramembranous bone formation stages, and at 11 days (n=4), the endochondral bone formation stage.

Cluster analysis identified 3398 genes with significant changes in expression ($p<0.05$), 33% of which were unidentified. A large number of Gene Ontology categories were represented, including cell growth/maintenance, apoptosis, adhesion, development, neurogenesis, transcription factors and angiogenesis. In agreement with previous studies, several growth factor gene families were represented, including the IGF1 ($p<0.004$), TGFB ($p<0.027$), FGF ($p<0.016$) and PDGF ($p<0.002$) families. Our study revealed fewer inflammatory and erythrocyte-related genes than previous studies, probably because we minimized the marrow RNA. Genes not previously described in fracture healing were also identified. Meox2, a homeobox gene expressed during embryonic chondrocyte differentiation, was up-regulated 2-fold at 3 days, suggesting that bone repair can indeed recapitulate development. Pleiotrophin was up-regulated 2-fold at 3 days, and possible pleiotrophin pathway genes (PIP3, Akt, ILK, paxillin and Rac/cdc42) were up-regulated at 3 and 11 days. Pleiotrophin shares several genes with the VEGFR3 pathway, suggesting that fracture angiogenesis is initiated early. As a modulator of neurogenic, osteogenic and angiogenic processes, pleiotrophin could also coordinate repair. In conclusion: 1) using a 20K gene chip and controls that normalized marrow RNA input among multiple replicates at two healing times, we identified 3398 genes with significant changes in expression in fracture tissue; 2) two new fracture healing pathways (pleiotrophin and Meox2) were discovered, with one (pleiotrophin) interfacing with a VEGFR pathway. Characterization of such gene expression pathways should facilitate the molecular understanding of normal and impaired fracture repair.

Disclosures: ***C.H. Rundle****, None.*

Transcriptional Activation of Collagenase-3 by PTH: Changes in Chromatin Structure in the Proximal Promoter Region. C. E. Boumah*, N. Selvamurugan, N. C. Partridge. Physiology and Biophysics, University of Medicine and Dentistry of NJ, Robert Wood Johnson Medical School, Piscataway, NJ, USA.

PTH induces collagenase-3 gene transcription in the rat osteoblastic cell line, UMR 106-01, through the protein kinase A pathway and is a secondary effect. The minimal promoter region for PTH responsiveness, identified in the first 148 bp upstream of the transcription start site, contains a conserved AP-1 binding site (-51/-44) as well as a runt domain (RD) binding site (-135/-129). Here, we have investigated the chromatin structure of the collagenase-3 gene and how PTH alters this to induce transcription. Using high resolution indirect end labeling of DNase I digested chromatin, we have mapped DNase I hypersensitive sites (DHS) at three locations in the proximal promoter region: one with very strong hybridization intensity, at -10/-2, a second DHS was found in a small AT-rich section at -166/-154 and the third DHS, of much weaker intensity, was found at -200/-191. PTH (10^{-8}M) activation, however, had no effect on the location of the DHS but rather caused significant increases in signal intensities. These data suggest that the proximal promoter of the collagenase-3 gene in UMR cells exists in a nucleosome structure between -154 and -10. Next, histone acetylation status was monitored using chromatin immunoprecipitation (ChIP) assays combined with quantitative real-time PCR. Two to 3-fold increases in amounts of acetylated histone H4 associated with the proximal promoter, specifically around the RD binding site (-176/-68), were detected as early as 5 min after PTH addition; maximal changes (20-fold) were reached by 60 min. There were no PTH-induced changes in acetylated histone H4 levels in the proximal promoter region containing the AP-1 site, in the distal promoter region (-1237/-970) or within exon 10. We detected no changes in acetylated histone H3 levels until after 120 min of PTH treatment and these were uniform throughout the proximal promoter region. Endogenous histone acetyl transferase (HAT) activity was elevated in UMR 106-01 cell lysates; treatment with PTH caused rapid and transient increases in HAT activity: high within 15 min, remaining so until approximately 60 min but returning to control levels by 90 min. We propose that PTH induces transcription of the collagenase-3 gene by altering the nucleosome structure of its proximal promoter, first by stimulating HAT activity, secondly by initiating histone H4 acetylation at the RD site, thirdly, by increasing histone H3 acetylation throughout the proximal promoter.

Soy Isoflavones May Increase Bone Formation as Seen by Enhanced Osteoblast-Specific Gene Products in Ovariectomized Rat Model of Postmenopausal Osteoporosis. L. Devareddy*, D. Y. Soung, D. A. Khalil, E. A. Lucas, B. J. Smith, A. B. Arquitt*, B. H. Arjmandi. Nutritional Sciences Department, Oklahoma State University, Stillwater, OK, USA.

It is generally believed that soy and its isoflavones improve bone mass, in part, by stimulating bone formation. The aim of the present study was to evaluate the effect of isoflavones on osteoblast-specific gene products including collagen type I, COL: osteocalcin, OC; osteonectin, ON; osteopontin, OP; and alkaline phosphatase, ALP. Sixty 9-month old female Sprague-Dawley rats were either sham-operated (Sham; 1 group) or ovariectomized (Ovx; 5 groups) and fed a semi-purified casein-based diet. After 90 days the occurrence of bone loss was confirmed using dual energy x-ray absorptiometry. Thereafter, rats were assigned to following treatments: Sham, Ovx (control), Ovx + 17β-estradiol (E_2; 10 μg E_2/kg body wt. twice per wk), Ovx + soy protein with normal isoflavone content (Soy; 3.55 mg isoflavones/g protein), and Ovx + soy protein enriched isoflavones (Soy+; 7.10 mg isoflavones/g protein). After 125 days of treatment, rats were sacrificed and bone specimens were collected. Total RNA was extracted from distal femurs and Northern blot analysis was used to measure mRNA levels of interest. cDNA of 18S ribosomal RNA was used as an internal control to normalize gene expression. Data are presented below:

	Sham	Ovx	Soy	Soy+	E_2
AP	0.676 ± 0.120^{c}	0.9247 ± 0.120^{abc}	0.8675 ± 0.120^{bc}	1.239 ± 0.120^{a}	1.133 ± 0.138^{ab}
COL (4.7kb)	0.421 ± 0.065^{b}	0.472 ± 0.065^{b}	0.507 ± 0.065^{b}	0.729 ± 0.065^{a}	0.546 ± 0.065^{ab}
COL (5.7kb)	0.301 ± 0.046^{b}	0.334 ± 0.046^{b}	0.355 ± 0.046^{b}	0.548 ± 0.046^{a}	0.373 ± 0.046^{b}
OC	0.468 ± 0.107^{c}	1.0687 ± 0.107^{ab}	0.958 ± 0.107^{b}	1.320 ± 0.107^{a}	0.601 ± 0.107^{c}
ON	0.596 ± 0.116^{c}	1.008 ± 0.116^{ab}	0.982 ± 0.116^{ab}	1.313 ± 0.116^{a}	0.782 ± 0.116^{bc}
OP	0.799±0.108	0.967±0.108	1.036±0.108	1.147±0.108	0.881±0.108

Data are means ± SE (n=4). Values in a row that do not share the same superscript letters are significantly (P<0.05) different.

The results of our study demonstrate that soy isoflavones may enhance the synthesis of bone matrix proteins and osteoblast activity as indicated by high mRNA levels of osteoblast-specific gene products. Since we have shown that soy isoflavones increase both circulating and bone levels of insulin-like growth factor-1 (IGF-1), we speculate that this upregulation of gene expression is, in part, mediated through IGF-1-dependent pathway.

Gene Expression Within Discrete Compartments in the Growth Plate Using Microarray Analysis. S. Nishimori[1], N. Elmessadi*[2], J. F. Burke*[2], D. Park*[2], G. F. Short*[2], H. M. Kronenberg[1]. [1]Endocrine Unit, MGH, Boston, MA, USA, [2]Microarray Facility, MGH, Boston, MA, USA.

To investigate the molecular underpinnings of the conversion of round chondrocytes to flat columnar and then hypertrophic chondrocytes, microarray analysis provides a powerful tool. We attempted manual microdissection of fresh-frozen tissues under an inverted microscope rather than Laser Capture Microdissection, to obtain as much RNA as possible. After isolating the tibiae of newborn mice, we compared three different treatments: quick freezing, freezing after Zincfix (Scheidl et al. 2002.*Am. J. Pathol.*) treatment, or freezing after RNAlater™ (Qiagen) treatment. Thick cryo-sections of proximal tibiae were used to dissect cells from the three distinct chondrocyte layers, and total RNA was isolated. The Bioanalyzer (Agilent) showed total RNAs with little degradation with the first two methods. We extracted 1.7-2.1 μg of total RNA from 115-147 sections from each layer by the quick freezing method.

We compared conventional RNA amplification of mouse liver and kidney total RNAs, using a T7dT primer (Eberwine et al, 1992.*PNAS*) with a new protocol using T3N9 random primers (Xiang et al, 2003. *Nucleic Acids Res*). We obtained sufficient antisense RNA (aRNA) with one round of the T3N9 protocol (from 1 μg to 56 μg). We evaluated both pro-

tocols by comparing the order of the genes expressed more in one tissue than another using both unamplified and amplified RNA. We evaluated the number of genes not detected at all and measures of slide quality (signal-to-noise ratio and % of detected genes), using two different amounts of aRNA (2 or 5 μg) on an oligo array (15,500 murine genes). The T3N9 protocol and higher amounts of aRNA yielded a higher gene matching ratio and a lower number of missing genes, but with higher backgrounds than ideal.
After optimizing microarray conditions to reduce backgrounds, we screened the genes differentially expressed in round vs. hypertrophic layer, using 8 μg of T3N9-amplified RNA. 221 genes were specific to the hypertrophic layer (fold ratio>2.0), and 211 genes were specific to the round layer (fold ratio<0.5). Success in separating the cell layers was suggested by the identification of genes known to be enriched in the hypertrophic layer, such as Type X collagen (fold ratio 0.06), Mmp13(0.14), Spp1(0.16), Alkphos 2(0.27), TGF-β1 (0.33), and PTH receptor 1(0.38). To validate the candidate genes, we perform real time (RT)-PCR and in situ hybridization. We found that signal intensities are as important as fold ratios, because genes with low signal intensities led to predictions sometimes not verified by RT-PCR. In summary, these procedures should prove useful for studying chondrocyte differentiation.

Targeted Deletion of the SPARC Gene Accelerates Disc Degeneration in the Aging Mouse. H. E. Gruber*[1], E. H. Sage*[2], S. Funk*[2], E. N. Hanley*[1]. [1]Orthopaedic Surgery, Carolinas Medical Center, Charlotte, NC, USA, [2]Division of Basic Science, Hope Heart Institute, Seattle, WA, USA.

Interaction is needed between cells and the extracellular matrix (ECM) in order to maintain the structural integrity of the intervertebral disc. We have recently shown that SPARC (Secreted Protein, Acidic, and Rich in Cysteine) is present in human disc ECM and that it decreases with aging and degeneration. The objective of the present study was to assess whether the targeted deletion of the SPARC gene is deleterious for disc health in the aging mouse. Methods of investigation included quantitative histomorphometry, radiology, electron microscopy and immunohistochemistry. SPARC null and wild-type (WT) control mice were studied at 2-3 and 14-19 months of age. Radiologic examination of spines from 2 month old SPARC null mice showed wedging, endplate calcification and sclerosis, features absent in age-matched WT spines. At age 3 months, the SPARC null disc had a greater number annulus cells than did the WT control (1884.6 ± 397.9 (mean ± S.D.) vs 1500.2 ± 188.2, p=0.031). By age 19 months, however, SPARC null discs contained fewer cells than did the WT (1383.6 ± 363.3 vs 1466.8 ± 148.0, p=0.033; 3 mice/group/time and 5-7 discs/group). Histologic evaluation of mid-sagittal spines showed herniations of lower lumbar discs of SPARC null mice aged 14-19 months (see figure); no herniations were seen in WT age-matched controls. Ultrastructural studies showed that collagen fibril diameters were uniform in the WT annulus but in SPARC null discs fibrils were of variable size and had irregular margins. Immunohistochemistry showed decreased type I collagen in the null vs WT.
In summary, the absence of SPARC adversely affects the number of disc cells in the annulus of older animals, ultrastructural features of collagen fibrils, type I collagen content of the annulus, and spinal structure as reflected in radiologic wedging and endplate changes. Histologic evidence of disc herniations was also present in older null animals. These findings support the heretofore unrecognized role of SPARC in the structural integrity of the disc ECM.

Bone and Cartilage Stimulating Peptide BCSP-1 Induces Collagen Type I Expression in Osteoblasts. D. R. Sindrey[1], J. W. Terryberry*[1], F. Fulde*[2], A. Brunner*[2], V. Ciolfi*[1], E. Plawinski*[1], R. Tommasini*[2]. [1]Millenium Biologix Inc., Mississauga, ON, Canada, [2]Millenium Biologix AG, Zurich, Switzerland.

Decreasing bone and cartilage collagen levels are hallmarks of osteoporotic and osteoarthritic diseases. Increased turnover and excretion of collagen telopeptides are validated as diagnostic markers for osteoporosis and other bone disorders. Investigators have postulated that a drug able to enhance collagen production would facilitate recovery from or slow the development of connective tissue diseases, as well as promote bone repair. Bone and Cartilage Stimulating Peptides (BCSP™) are herein shown to induce the expression of the collagen type I gene in human or rat primary osteoblasts, which is accompanied by an increased production of immunoreactive collagen I. Collagen type I up-regulation was established by genomic arrays using CART-CHIP™ and a lucifierase reporter construct for collagen type I. Briefly, gene expression analysis was performed using CART-CHIP™ 300 microarray (Millenium Biologix) comprising 338 human skeletal tissue relevant oligonucleotides printed on glass substrate. RNA amplification was performed using two micrograms of total RNA from cultures treated with BCSP-1 for 4hrs or 24hrs. Amplified RNA was labeled with fluorescent dye, and hybridized onto CART-CHIP™ followed by fluorescence scanning. Further, human primary osteoblasts were transiently co-transfected with a firefly luciferase reporter construct for collagen type I alpha 2 (COL1A2). Plasmid (pGL3) containing firefly luciferase that integrates a 450 bp fragment of the promoter region COL1A2 and 0.1 μg phRG-TK were used for transfection. Cells were dosed with BCSP-1 17hrs after transfection followed by bioluminescence measurements at 4 and 24 hours post treatment using a Dual-Luciferase reporter assay system. Results showed a 2.5-fold increase in the COL1A2 gene expression in rat osteoblasts 4hrs post treatment with BCSP-1. Human primary osteoblast cells transfected with the luciferase construct for COL1A2 demonstrated a dose dependent increase in bioluminescence with BCSP-1 at 4hrs and 24hrs post treatment. Thus, we have shown specific and pronounced up-regulation of collagen I subunit in primary osteoblast cultures using BCSP-1. This result was confirmed by immunoblots of cell lysates with various anti-collagen I antibodies. Results demonstrated a qualitative increase in total collagen I isoforms, as well as the specific production of a unique collagen I monomer at 90kD. This isoform was detectable only in osteoblast cell cultures receiving BCSP-1. This mechanism may promote the recovery from or delay the onset of connective tissue trauma and disease.

SOX9-Dependent and SOX9-Independent Transcriptional Regulation of Human Cartilage Link Protein. I. Kou*, S. Ikegawa*. SNP Research Center, RIKEN, Tokyo, Japan.

Cartilage link protein is a key component of the extracellular macromolecular environment in cartilage. Transcriptional regulation of the gene encoding cartilage link protein (*CRTL1*) is largely unknown, however. Here, we investigate the regulation of *CRTL1* by SOX9, a key regulator of cartilage matrix genes and chondrogenesis. First, we expressed SOX9 in human non-chondrocytic immortalized cell lines, mesenchymal stem cell and adult dermal fibroblast by mammalian expression vectors or adenovirus vectors. *CRTL1* mRNA was significantly induced by SOX9 in these cells, suggesting SOX9 is also a key regulator of *CRTL1*. Then, we expressed SOX9 with its known transcriptional co-activators, L-SOX5 and SOX6 in these cells. The effect of L-SOX5 and SOX6 to the SOX9-induction of *CRTL1* was cell-type dependent. Next, we performed luciferase assays in several non-chondrocytic cell lines using pCRT1 that contains approximately 1.2-kb of the 5'-flanking region of *CRTL1*. Co-transfection of SOX9 significantly increased transcriptional activity from pCRT1, suggesting the presence of the SOX9-responsive element in the fragment. To localize the cis-acting element(s) in the fragment, we constructed several deletion plasmids of pCRT1. Luciferase assays with the 5'-deletion constructs showed 5'-untranslated region (5'-UTR) of *CRTL1* contained a cis-element that is regulated by SOX9. Electrophoretic mobility shift assays (EMSA) with *in vitro*-translated SOX9 showed that this element bound to SOX9. The element contains the consensus SOX-binding motif and substituting mutations for the motif abolished both enhancer activity and SOX9 binding. These results indicated that this element is critical for SOX9 binding and transcriptional activity, and SOX9 could directly regulate *CRTL1* expression. Interestingly, luciferase assays with 3'-deletion constructs of pCRT1 showed 5'-UTR of *CRTL1* contained another cis-acting element. This element was, however, not regulated by SOX9 and responded in a cell-type-specific manner. EMSA with *in vitro*-translated SOX9 and several cell extracts showed that this element bound to some proteins other than SOX9. These findings suggest the presence of the SOX9-independent enhancer element in *CRTL1*. We further examined whether these enhancer elements were functional in chondrocytes. Luciferase assays in a human chondrosarcoma cell line showed both elements could enhance *CRTL1* transcription. Our results suggest that there are two pathways for the regulation of *CRTL1* transcription; one is SOX9-dependent and the other is SOX9-independent. They might play important roles in mediating differential expression of *CRTL1* during chondrocyte differentiation and maturation.

Fibronectin Is Required for BMP2-Induced Osteoblast Mineralization Through its Role as a Regulator of Assembly of Multiple Bone ECM Proteins. Q. Chen[1], P. Sivakumar[1], D. M. Peters*[2], D. F. Mosher*[2], S. L. Dallas[1]. [1]Univ. of Missouri, Kansas City, MO, USA, [2]Univ. of Wisconsin, Madison, WI, USA.

Fibronectin is an extracellular matrix (ECM) glycoprotein that is important for cell adhesion, migration and angiogenesis. Inhibition of fibronectin signaling via integrins has been shown to block mineralization in primary osteoblast cultures. Mice lacking the gene for fibronectin die at embryonic stage E8.5, prior to the formation of skeletal structures. Therefore, to gain further insights into the role of fibronectin in mineralization, we have used fibroblasts derived from E6.5 fibronectin null (FN-null) embryos and treated them with exogenous fibronectin at defined times to rescue fibronectin fibril assembly. Upon treatment with BMP2, these FN-null fibroblasts differentiate into osteoblasts as determined by induction of alkaline phosphatase and expression of terminal differentiation markers such as osteocalcin. However, these cultures fail to mineralize unless fibronectin is present in addition to BMP2. Time course studies showed that when fibronectin was present for only week 1, week 2 or week 3, mineralization did not occur. Only when fibronectin was present for the entire culture period did mineralization occur. Fibronectin has recently been shown to be critical for assembly of several ECM proteins. We therefore examined whether assembly of bone ECM proteins was compromised in FN-null cells. By immunostaining, we found that assembly of type I collagen, decorin, biglycan, perlecan, fibrillin-1 and latent TGF beta binding protein-1 (LTBP1) were impaired in FN-null cells. Western blotting confirmed that this was not due to a failure in synthesis or secretion. Assembly of ECM proteins was rescued by addition of exogenous fibronectin, but not by fibronectin fragments that were incapable of assembly into fibrils, including an RGD containing fragment that activates integrin signaling. As fibronectin may also be important for stability of ECM proteins, we examined the effect of addition of fibronectin to FN-null cells for 2 days, followed by withdrawal for 3 days. When fibronectin was withdrawn, the fibronectin fibrillar network disassembled. Assembly of other ECM molecules was halted and no further incorportation of collagen I, fibrillin-1, perlecan, biglycan and LTBP1 occurred. In contrast, when fibronectin treatment was continued these ECM proteins continued to assemble into the ECM. These studies suggest that osteoblast differentiation can occur in the absence of fibronectin. However, the continual presence of fibronectin is required for mineralization to proceed. This may be mediated through the function of fibronectin as a key regulator of assembly of multiple bone ECM proteins.

Collagen and Proteoglycan Perturbations in Cartilage of Patients with Morquio A Disease. R. Bank*[1], K. A. Hoeben*[2], J. E. Groener*[3], P. Maaswinkel*[4], H. A. Schut*[5], V. Everts[6]. [1]TNO, Leiden, Netherlands, [2]Cell Biology, AMC, Amsterdam, Netherlands, [3]Biochemistry, AMC, Amsterdam, Netherlands, [4]Pediatrics, Ootmarsum, Netherlands, [5]Physician, Eindhoven, Netherlands, [6]Oral Cell Biology, Academic Centre of Dentistry Amsterdam, Amsterdam, Netherlands.

Morquio A disease, mucopolysaccharidosis type IVA, is a lysosomal storage disease caused by a deficiency of *N*-acetylgalactosamine-6-sulfate sulfatase (GALNS; E.C. 3.1.6.4). This lysosomal enzyme is involved in the digestion of keratan sulfate and chondroitin-6-sulfate and its deficiency gives rise to a lysosomal accumulation of partially digested glycosaminoglycans (GAGs); a phenomenon seen particularly in bone and cartilage. Although Morquio disease is a disorder of connective tissue no reports have appeared on effects of the extracellular matrix. In the present study we analyzed the biochemical properties of collagen of both bone and cartilage of Morquio A patients and the ultrastructure of the cartilage matrix.

Bone and cartilage samples were obtained from two non-related Morquio A patients. The biochemical analyses included (i) the cross-links hydroxylysylpyridinoline (HP) and lysylpyridinoline (LP), and (ii) hydroxylysine (Hyl) and hydroxyproline (Hyp). Bone and cartilage samples of normal individuals (n=41 and 34, respectively) served as controls. For microscopy tissues were fixed in 1% glutaraldehyde and 4% formaldehyde, embedded in plastic and further processed.

Biochemical analyses revealed that in bone samples hydroxylation and cross-linking of collagen did not differ from the controls. Analyses of the cartilage, however, showed remarkable differences. The amount of Hyl residues in the triple helix of cartilage collagen was decreased by approximately 50% and the ratio of HP/LP was strongly increased due to a decreased level of HP and a concomitant increase in LP. Electron microscopy showed, in addition to a high number of vacuoles in the chondrocytes, a wide rim of extremely well ordered layers of proteoglycans surrounding the cells. In this pericellular area collagen fibrils were absent. The fibrils found interchondrally proved to be relatively thin. Our data demonstrate that in Morquio patients the hydroxylation and cross-linking of cartilage collagen, but not of bone collagen, is severely disturbed. In addition we show that the extracellular arrangement of proteoglycans is affected. So it seems that deficiency of GALNS not only disturbs intracellular digestion of GAGs but also affects processing of various extracellular matrix components.

Increased Notch 1 in Osteonectin-null Osteoblasts: A Potential Mechanism for Aberrant Maturation. C. Kessler*, A. M. Delany. Center for Molecular Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Osteonectin (SPARC, BM-40) is a matricellular protein supporting osteoblast formation, maturation and survival. Osteonectin-null mice develop low turnover osteopenia, and in culture, osteonectin-null osteoblasts are less mature and develop more adipocytic characteristics, suggesting that osteonectin could regulate cell fate. We found that, compared to control cells, osteonectin-null osteoblasts have increased levels of Notch 1, a regulator of cell fate determination in multiple systems. A 2-3 fold increase in Notch 1 mRNA and protein was detected at confluence and was maintained throughout in vitro osteoblast differentiation. Moreover, Notch 1 transcripts were increased at the level of gene transcription. The increase in Notch 1 was cell type specific, as it was not observed in confluent cultures of fibroblasts from osteonectin-null mice. Transcripts for Notch 2 and the Notch ligands Jagged 1 and Delta 1 were detectable and equivalent in both control and osteonectin-null osteoblastic cells, indicating the presence of both Notch receptors and ligands in the system. Our laboratory and others have shown that constitutive Notch signaling inhibits osteoblastic differentiation and stimulates adipogenesis. To define the impact of increased Notch 1 on the osteonectin-null osteoblast phenotype, we cultured cells with a gamma secretase inhibitor known to block Notch signaling. Surprisingly, this inhibitor blunted osteoblastic differentiation of the control cells and decreased the adipocytic and osteoblastic markers in the osteonectin-null cells. These data suggest a dual role for Notch signaling in osteoblast differentiation, similar to that recently observed for adipogenesis. In an effort to understand the mechanisms underlying Notch 1 over expression in osteonectin-null osteoblasts, we considered the cAMP pathway. In response to PTH stimulation, osteonectin-null osteoblastic cells exhibit a blunted cAMP response. Further, elevation of cAMP levels using a phosphodiesterase inhibitor decreased Notch 1 mRNA in control and osteonectin-null osteoblasts and fibroblasts, indicating that cAMP decreases Notch 1 expression in both cell types. We hypothesize that osteonectin-null osteoblasts generate less cAMP in response to stimuli, possibly due to decreased adenyl cyclase activity or increased activity of phosphodiesterases. This theory can explain the increased Notch 1 expression in osteonectin-null osteoblasts and could provide a more global mechanism for their diminished osteoblastic maturation.

Osteopontin Regulates TNFα-Dependent Metalloproteinase Activity and NFkB-Dependent Transcription in Aortic Vascular Smooth Muscle Cells. C. F. Lai*[1], J. S. Shao[1], A. P. Loewy*[1], N. Charlton-Kachigian*[1], S. R. Rittling*[2], D. A. Towler[1]. [1]Dept. of Internal Medicine, Washington University School of Medicine, St. Louis, MO, USA, [2]Genetics, Rutgers Univ., Piscataway, NJ, USA.

Osteopontin (OPN) is a phosphorylated cytokine that exists in at least three forms: a calcified matrix-bound form; a circulating, soluble form entrained to the skeletal osteoanabolic response to teriparatide; and a form secreted by epithelia of breast and renal tubule. In aortic vascular smooth muscle cells (VSMCs) OPN gene expression is markedly upregulated in response to diabetes, induced in part via a glucose-activated, SP600125 - sensitive transactivation function in USF1. We wished to characterize the role of OPN in the activity and expression of TNF-α dependent gelatinases that control vascular matrix remodeling. In gelatin zymography, TNF-α upregulated the activity of MMP9 in aortic VSMCs isolated from wild-type male C57Bl/6 (B6.OPN+/+) mice ca. 2-fold. Modest induction of MMP3 (casein zymogram) was also observed, but little regulation of MMP2 was noted. By contrast, TNF-α induction of MMP9 was almost completely abrogated in aortic VSMCs from B6.OPN-/- mice, while upregulation of MMP3 was not affected. To better understand the potential mechanisms whereby OPN modulates MMP9, we examined the effects of purified bovine OPN (bOPN) on MMP9. At 50 nM, bOPN enhanced MMP9 induction by TNF-α ca. 2 fold. Moreover, addition of exogenous bOPN to cultures of B6.OPN-/- VSMCs re-constituted MMP9 activation by TNF-α. Since NFkB signaling mediates many intracellular actions of TNF-α, we examined the effects of OPN deficiency on the regulation of NFkB responsive promoter - luciferase reporter (NFkB-LUC). In transfected B6.OPN+/+ VSMCs, TNF-α enhanced NFkB-LUC activity 3-fold. However, NFkB-LUC induction was completely abrogated in B6.OPN-/- VSMCs. In A7r5 rat aortic VSMCs, the induction of MMP9 activity was highly dependent upon glucose concentration - a key stimulus for endogenous OPN expression. Hyperglycemia - glucose at 30.5 mM -- permits TNFα-dependent MMP9 activation; by contrast, TNF-α. treatment in 5.5 mM glucose/25 mM mannitol exerts little if any effect on MMP9. bOPN also enhances TNF-α upregulation of MMP9 activity, and neutralizing antibody against OPN can inhibit this TNF-α effect. Thus, OPN functions as a co-regulator of TNF-α signaling in primary and A7r5 aortic VSMCs. In A7r5 cells, the JNK pathway inhibitor SP600125 antagonizes MMP9 production and NFkB signaling, while ERK1/2 and p38 MAPK inhibitors have no effect. Hyperglycemia-induced aortic OPN expression may enhance vascular matrix remodeling, sensitizing aortic myofibroblasts to the low-grade macrovascular inflammation induced by diabetes.

The Degree of Posttranslational Modifications of Collagen Is an Important Determinant of the Toughness of Cortical Bone. P. Garnero[1], O. Borel*[2], E. Gineyts*[2], F. Duboeuf*[2], C. Christiansen[3], P. Delmas[2]. [1]Synarc, Inserm Unit 403, Lyon, France, [2]Inserm Unit 403, Lyon, France, [3]CCBR & Nordic Bioscience, Herlev, Denmark.

Bone strength depends on its mass and architecture, but also on the material properties of its matrix. Mineral accounts mainly for pre-yield properties of bone including stiffness and yield strength, and collagen is believed to influence its toughness.

Aim: To analyze the role of posttranslational modifications of collagen on the compressive mechanical properties of cortical bone using an in vitro model where the extent of crosslinking can be modified, keeping constant the size and the mineral content of bone. In this model, we previously showed that collagen crosslinks are associated with bending mechanical properties.

Methods: Calibrated fetal bovine cortical bone specimens (11 animals, 41 samples in total) with a low degree of collagen modifications were incubated for 0, 60, 90 and 120 days at 37°C to increase crosslinking. At each time, compressive mechanical test was performed. The concentration of enzymatic (PYD, DPD) and non-enzymatic (pentosidine) crosslinks of bone matrix was measured by HPLC and the extent of C-telopeptide (CTX) isomerisation was evaluated by ELISA of native (α CTX) and isomerised (β CTX) forms.
Results: After 60 days, there was a significant increase of PYD (+98%, p=0.005), DPD (+42%, p=0.013), pentosidine (+55 fold, p=0.005) and β/α CTX ratio (+4.9 fold, p=0.005), levels reaching those of young adult bone, but remaining lower than levels of old bone. The increase of crosslink concentration was associated with a 2 fold (p=0.005) increase in toughness (energy absorbed after yield). After 60 days of incubation, no significant change of BMD, stiffness (young modulus), yield strength, and maximal strength was observed. As expected, BMD significantly correlated with pre-yield properties (young modulus, yield strength) and maximal strength (p=0.02-0.001), but not with post-yield toughness. In contrast, PYD (r=0.45, p=0.002), DPD (r=+0.35, p=0.02), pentosidine (r=0.46, p=0.002) and the β/α CTX ratio (r=044, p=0.005) were associated with toughness.
Conclusion: These data indicate that the degree of post-translational modifications of collagen plays a significant role in explaining the toughness of cortical bone, an important determinant of bone fragility.

Effect of Adrenalectomy and Glucocorticoid Replacement On Rat Osteocalcin and Lumbar Bone. P. Buckendahl[1], B. Mravec*[2], R. Kvetnansky*[2]. [1]Center of Alcohol Studies, Rutgers University, Piscataway, NJ, USA, [2]Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia.

Glucocorticoid (GC) deficiency and excess both alter skeletal physiology. We previously reported that 2 hr acute foot restraint immobilization of rats (Immo, a mental stressor) rapidly increased plasma osteocalcin (pOC), as well as the stress hormones corticosterone, epinephrine and norepinephrine within 5 minutes of onset of Immo. Daily repetition of this stimulus over a period of 8 weeks blunted pOC response, decreased bone growth and vertebral OC. Here we compare the pOC and on lumbar 3 bone weight and OC concentration in adrenalectomized (ADX) and sham operated rats with and without supplementation of cortisol (cort) at levels physiologically equivalent to corticosterone, the native rodent glucocorticoid. Rats were supplemented for 7 days following ADX or sham ADX (1) with 25 mg/kg/day cort via Alzet minipump, or (2) 15 mg/kg/day in two doses administered i.p.. Controls received isotonic saline. In expt. 1, plasma was obtained during Immo via cannulae implanted in the tail artery. ADX increased basal pOC more than 2.5 fold over sham controls, and was significantly further elevated during 120 min Immo. Basal pOC in cort supplemented ADX or sham rats did not differ from sham control, nor did Immo induced elevations differ among these groups. In expt 2, Non-Immo rats were compared with rats that were Immo for 120 min, and killed after 3 hr recovery. Plasma and L3 vertebrae were harvested. Normal plasma responses to Immo were eliminated by cort. After 3 hr recovery from Immo, pOC in ADXcort control and Immo did not differ from sham control or from each other, while sham Immo rats' pOC was lower than non-Immo controls. Both ADX control and Immo rats' pOC were significantly higher than sham control. Plasma Ca+2 in control or Immo ADXcort rats did not differ from unstressed sham or ADX rats, but was decreased by Immo in sham and ADX rats. Body wt was lower at sacrifice in ADXcort compared with ADX and sham rats; however, L3 dry wt was significantly lower in ADX compared with ADXcort and sham rats. Bone OC concentration was decreased in ADXcort, but not in ADX compared with sham, reflecting the expected decrease in OC synthesis due to cort down-regulation. Cortisol treatment preserved L3 bone wt, consistent with previous reports of prevention of bone loss in ADX rats by supplementation with corticosterone pellets. Plasma data from both experiments support previous reports of increased bone turnover in ADX rats. Cort also returned stress response of pOC in ADX rats to that of sham rats, confirming our previous data suggesting that glucocorticoids are required for return of pOC to normal levels following Immo.

Mice Lacking the Extracellular Matrix Protein Thrombospondin 3 (TSP3) Show Accelerated Skeletal Development. J. A. Meganck*[1], S. Hormuzdi*[2], K. D. Hankenson[3], P. Bornstein*[4]. [1]Mechanical Engineering, University of Michigan, Ann Arbor, MI, USA, [2]Biochemistry, University of Washington, Seattle, WA, USA, [3]Orthopedic Surgery, University of Michigan, Ann Arbor, MI, USA, [4]Medicine, University of Washington, Seattle, WA, USA.

TSP3 is a pentameric protein that is structurally similar to cartilage oligomeric matrix protein (COMP), also known as TSP5. Like TSP5, TSP3 is localized to bone and cartilage, but its role in the skeleton has not been previously examined. Mice with a targeted disruption of *Thbs3* were created to examine its functional significance. The mice were viable and fertile and showed normal skeletal patterning by alcian blue/alizarin red staining. To examine the effect of TSP3 disruption on post-natal bone modeling, femoral specimens were obtained from male and female TSP3-null and wild-type (WT) mice at 9, 15, and 26 weeks. Body weight was measured and femora were harvested into either PBS or ethanol and scanned using micro-computed tomography (μCT). Bone length, the moment of inertia (I), cortical thickness, endosteal and periosteal radii and cross-sectional area were calculated from the resulting images. Histological analysis was also performed using either hematoxylin and eosin (paraffin embedded specimens) or Von Kossa (undecalcified plastic sections). Mechanical properties of the bone tissue were investigated using 4-point bending, and predicted yield stress, σ_y, and predicted Young's modulus, E, were calculated. Results were considered to be significant if $p<0.05$ using the Mann-Whitney U test.
Female 9-w TSP3-null mice showed an increase in weight, I, endosteal and periostal radii, cross-sectional area, yield and failure load, and a decrease in modulus. Similarly, 15-w TSP3-null females had increased I, periosteal radius, cross-sectional area, stiffness, failure load, and post-yield and total work. Higher values for weight, I, endosteal and periosteal radii, stiffness and failure load were also seen in 9-w TSP3-null male mice, but there were no differences by 26-w.
When evaluating μCT scans, we noted that TSP3-null mice developed trabecular bone proximal to the femoral head growth plate earlier than WT mice. In TSP3-null mice trabecular bone was present at 9-w and ossification was completed by 15-w, whereas in WT mice trabeculation was only beginning at 26-w. Histological analysis showed that the WT femoral head was composed of hypertrophic chondroctyes in a calcified matrix until 26-w, while TSP3-null femoral heads showed vascular invasion and ossification beginning at 9-w. Overall, these results show that adolescent male and female TSP3-null mice have greater femoral bone volume and strength and accelerated endochondral ossification of the femoral head.

Biglycan and Fibromodulin Potentially Inhibit Ectopic Ossification in Tendon by Inhibiting the Differentiation of Osteogenic Stem Cells. Y. Bi*, T. Kilts*, M. F. Young. National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD, USA.

Biglycan (BGN) and fibromodulin (FM), two members of Small Leucine-rich Proteoglycans (SLRPs) are co-expressed in tendons. It was previously shown that BGN and FM double deficient mice (DKO) develop ectopic ossification in the tendon. It is also known that SLRPs bind to cytokines and growth factors to modulate their activities in regulating the growth and differentiation of osteogenic stem cells. In the absence of BGN, the differentiation of bone marrow stromal cells (BMSCs) is impaired due to the alteration of BMP-2/4 activity. We therefore hypothesized that BGN and FM inhibit osteogenesis in the tendon by regulating the activity of BMP-2. To test this hypothesis we used bone marrow stromal cells that are of mesenchymal origin and believed to be developmentally related to tendon cells. In this study we compared the osteogenic ability of BMSCs in the presence or absence of BGN and FM. First, we compared the colony forming efficiency (CFU-F) in bone marrow cells from DKO mice to cells from wild type (WT) mice. We found that the number of CFU-F formed from DKO bone marrow cells was increased by 88 ± 4 % (n = 3) compared to WT cells. The size of colonies formed in DKO cultures was bigger than that in WT cultures, suggesting the proliferation and/or survival of BMSCs are increased. Next, we determined the differentiation of BMSCs in response to BMP-2. The expression of alkaline phosphatase was significantly higher (29 ± 3 vs. 18 ± 1 Units/ml, $p<0.05$) in the cultures of DKO BMSCs compared to WT BMSCs. The expression of alkaline phosphatase was up-regulated in both DKO and WT cultures after treatment of BMP-2 for 20 hours. However, the BMSCs from DKO mice were more sensitive to BMP-2 (60 ± 2 vs. 28 ± 2 Units/ml, $p<0.005$) than WT cells. In addition, Western blotting analysis showed that the expression of cbfa1 in DKO cultures is higher compared to WT cultures in the presence or absence of BMP-2. Both experiments demonstrate that the differentiation of BMSCs increased in the absence of both BGN and FM. Based on our findings that BMP-2 activity is increased in BMSCs due to a loss of BGN and FM, we postulate that the SLRPs, BGN and FM, inhibit ossification in tendon by modulating BMP induced osteogenesis.

Bone Sialoprotein Elicits Biomineralization and Ossification in a Bone Defect Model. J. Wang*, H. Zhou, E. Salih*, J. G. Hofstaetter*, M. J. Glimcher. Orthopaedic Research, Children's Hospital, Boston,, MA, USA.

Bone sialoprotein (BSP) is one of the major non-collagenous glycosylated phosphoproteins of the extracellular matrix in bone. Previous *in vitro* precipitation and cell culture studies have suggested that BSP may play a significant positive role in the initiation of calcification. Here, we report for the first time that implantation of BSP-collagen complex into critical sized rat cranial defects, which do not heal spontaneously, elicits mineral deposition followed by osteoblast differentiation and ossification. To explore the biological functions of BSP *in vivo*, especially in a bone defect model. Highly purified bovine BSP linked to type I collagen (prepared from rat-tail tendons) was implanted into surgically created cranial defects (8-mm in diameter) and subcutaneous pouches in the thoracic region of 6-8 weeks old rats. Collagen alone was implanted as a control. All animal procedures were approved by the Animal Care and Use Committee at the Children's Hospital, Boston, MA. The molecular and cellular responses to the implants were evaluated by *in situ* hybridization, quantitative real-time RT-PCR, histochemical, immunocytochemical and histomorphometric analyses. BSP-collagen complex first induced the proliferation of cells in the dura and small mineral deposits at the junction areas between the dura and the BSP implant, which progressed further into the interior of the BSP implant at days 6-7. At this time there was no morphological evidence that the proliferating cells were either chondroblasts or osteoblasts. The proliferating cells in the BSP implants differentiated to osteoblasts at ~ 9-10 days followed by synthesis of bone. Collagen alone implanted into 8 mm rat cranial defects did not stimulate the mineral deposition or ossification in the mid-defect within the same experimental period. At days 10-21, expression levels of bone marker genes in the retrieved cranial BSP-collagen implants were significantly higher than that in the cranial control implants (collagen alone). By day 30, the total mass of new bone formed in the BSP-treated cranial defects was significantly greater than that occurred in the defects filled with collagen alone ($p<0.01$, N=8, Student t-test). BSP-collagen complex implanted into rat subcutaneous tissues did not induce mineralization or bone formation. These results demonstrate that BSP facilitates biomineralization and bone formation in cranial defects, but not in subcutaneous tissues. The site-specific responses to BSP implants suggest that the specificities of local responding cells and/or environment may play important roles in BSP-mediated biomineralization and ossification.

Pressure Modulates OPG, RANK and RANKL in Macrophage/osteoblast Co-cultures. C. E. Evans[1], S. Lewis*[1], A. P. Mee*[2], J. L. Berry*[2], J. G. Andrew*[3]. [1]L.m.a.g., University of Manchester, Manchester, United Kingdom, [2]Medicine, University of Manchester, Manchester, United Kingdom, [3]Salford Royal Hospitals Trust, Salford, United Kingdom.

Mechanical load is crucial to maintenance of skeletal homeostasis, but the mechanism involved is still unclear. Recent research has implicated the OPG/RANK/RANKL triumvirate in bone homeostasis, by modulation of osteoclast activity. We have previously shown that cyclical hydrostatic pressure influenced synthesis by human macrophages of various molecules important in osteoclast activity and bone resorption (1-3). This study further examines this concept, looking at how pressure affects synthesis of OPG/RANK/RANKL.

Co-cultures of human osteoblasts and macrophages were subjected to pressure (5.0psi) for 5 consecutive days; static controls from the same cell population were included for all experiemnts. Cells were immunostained for RANK and culture media assayed using specific ELISAs for sRANKL and OPG.

Cultures subjected to pressure synthesised more RANK than controls (Fig 1a.) and this was further modulated by supplementation with 1,25 dihydroxy cholecalciferol (Fig 1b). A reciprocal relationship between OPG and sRANKL was seen in co-cultures exposed to pressure. Where pressure increased synthesis of sRANKL, OPG was decreased (Table 1); decreased [sRANKL] corresponded to increased [OPG].

In common with our previous findings, samples from different individuals responded differently to pressure (Table1). Comparison with non-poresurised controls showed that 66% of samples showed increased synthesis of OPG in response to pressure.

These data show that cyclical hydrostatic pressure increases RANK synthesis in pre-osteoclasts and modulates the ratio of sRANKL:OPG in co-cultures of osteoblasts and pre-osteoclasts. Our other studies have shown that pressure also stimulates differentiation of macrophages to osteoclasts (In press). These findings suggest a possible transduction mechanism for mechanical load in the skeleton, which has implications for future therapies for skeletal abnormalities such as osteoporosis.

RhoA and Cytoskeletal Disruption Contribute to Altered Differentiation of Human Mesenchymal Stem Cells in Modeled Microgravity. V. E. Meyers*, M. Zayzafoon, J. M. McDonald. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Bone loss during spaceflight, disuse, and aging is due, in part, to reduced osteoblastic differentiation. We have previously described reduced osteoblastic and enhanced adipocytic differentiation of human mesenchymal stem cells (hMSC) following 7 days of culture in modeled microgravity (MMG). The lineage 'decision' of hMSC is influenced by the small G protein, RhoA, which regulates cytoskeletal organization and stress fiber formation in fibroblastic cells. Cell shape and cytoskeletal organization are disrupted in many cell types during spaceflight and in MMG. Therefore, the purpose of our study is to determine the effects of MMG on cytoskeletal organization and Rho activation in hMSC.

To explore the effects of MMG on actin cytoskeletal arrangement, we stained cells with rhodamine-conjugated phalloidin to visualize f-actin. Stress fibers, present in normal gravity, are completely eliminated following 7 days of culture in MMG. There was a concomitant increase in monomeric G-actin in cells cultured in MMG, as determined by Alexa Fluor 488-conjugated deoxyribonuclease I. In addition, Western blot analysis demonstrates reduced total actin in cells cultured in MMG. Interestingly, this disruption in the actin cytoskeleton begins as early as 36 hours after initiation of MMG and is irreversible following return to normal gravity for 7 days. Due to the lack of stress fibers in MMG, we analyzed the activation of RhoA. We demonstrate an 88 $\pm$ 2% reduction in Rho activation in hMSC cultured in MMG. Reduced activation of Rho is known to be associated with adipocytic differentiation of hMSC. Therefore, we examined the lipid content of cells cultured in normal or MMG conditions, using a fluorescent dye, Nile Red. Cells cultured in MMG display a marked increase in lipid staining, compared to hMSC cultured in normal gravity. This is consistent with our previous data demonstrating increased expression of adipocytic genes in MMG, including PPARγ, leptin, and GLUT4 (*Endocrinology* 145:2421-2432). In summary, the data presented here provide a novel mechanism for decreased osteoblastic and increased adipocytic differentiation of hMSC in MMG, namely disruption of the actin cytoskeleton and reduced Rho activity.

Evidence of Anabolic Effects of Physiological Strain Regimen in a New Cancellous Bone Explants Tissue Culture-Loading System. V. David*[1], S. Peyroche*[1], A. Guignandon*[1], N. Laroche*[1], D. Jones*[2], E. L. Smith[3], L. Vico[1]. [1]Lbto, Inserm, St Etienne, France, [2]Exp. Orthopaed. Biomechan., Philipps-Universitat Marburg, Marburg, Germany, [3]Preventive Med, Wisconsin Univ, Madison, WI, USA.

To study coordinated bone cellular responses and the resulting tissue response while avoiding complexity of in vivo situation, as well as live animal experiments, we used a new organ culture model (named "Zetos"; Jones et al., ECM 2003). It provides the ability to culture cancellous bone cores over long periods (until now difficult due to rapid degeneration inside the organ) and to apply specific compressive strains to bone cylinders. We chose a regimen that mimics a jump pattern (4000µS, 1Hz, 300 cycles/d.). Cylindrical bovine biopsies (10mm diameter, 5mm height) from sternum were precisely machined, fitted in chambers and feeded with culture medium in conditions ensuring uniform double fluorochrome labelings within the whole sample. Biomechanical (through Zetos itself), tomographic (µCT40, Scanco Medical), and cellular evaluations were performed on basal control (BC) samples immediately processed, loaded (L), and non loaded (NL) 3-wk cultivated samples.

	BC	NL	L
Young Modulus (MPa)	159.53 ± 57.90	157.72 + 40.95	184.1 + 66.80[a]
Plate/Rod Index	1.25 ± 0.2	1.37 + 0.22	0.87 + 0.20[a]
Tb.Th (µm)	84 ± 16	84 ± 10	104 ± 16[a]
OS/BS (%)	7.05 ± 1.64	9.72 ± 3.67	14.37 ± 2.98[a]
O.Th (µm)	11.43 ± 1.93	10.38 ± 2.85	13.6 ± 3.70[a]
MAR (µm/day)	/	0.71 ± 0.17	0.94 ± 0.17[c]
BFR ($\mu m^2/\mu m^3$/day)	/	0.79 ± 0.30	1.16 ± 0.42[c]
Resorption lacunae. N/BS (%)	15.23 ± 2.50[d]	7.35 ± 2.95	8.52 ± 3.00

Means ± SD, [a]significant vs. NL and BC; [b]vs. L and BC; [c]vs. NL; [d]vs. NL and L. Assessment of bone alkaline phosphatase activity (ALP) in culture medium increased by 30 and 35% in L vs. NL after 5 and 8d., respectively, and no longer differed afterward. Sandwich ELISA for Runx2, osteocalcin, and ALP were performed in harvested bone samples. In L, Runx2 and osteocalcin showed increased levels after 7 and 14d. (Runx2: 322 and 285%; osteocalcin: 90 and 27%, respectively), which normalized thereafter. ALP activity increased (47%) only after 7d. in L. Meanwhile we showed that marrow stromal cells from bovine sternum plated on type I collagen-coated-silicon membranes and submitted to cyclic strain (6000 µS, 1Hz, 10 min/d., FLEXCELL FX-3000 unit) over 14d. showed an increased proliferation the first 3d. of stretch, increased levels of ALP and osteocalcin (147 and 76%, respectively) at 14d. and enhanced Runx2 level (67%) at 3d. In conclusion, mechanosensitive bovine osteoblast lineage cells retain their sensitivity in the Zetos organ culture loading system. Such cellular adaptation results in tissue response evidenced by thicker trabeculae arranged in a more plate-like pattern.

Oxygen, Mechanical Compression and Inflammation in Articular Cartilage. B. Fermor[1], D. S. Pisetsky*[2], J. B. Weinberg*[2], F. Guilak*[1]. [1]Surgery, Division of Orthopaedics, Duke University Medical Center, Durham, NC, USA, [2]Medicine, VA and Duke University Medical Center, Durham, NC, USA.

Articular cartilage is avascular and exists at a reduced oxygen tension which can alter the level of inflammatory mediators such as nitric oxide (NO) and prostaglandin E2 (PGE_2) induced by interleukin 1 (IL-1). Mechanical stress influences cartilage metabolism and can increase the production of PGE_2 and NO. Increased NO production has been observed clinically in arthritis, and the severity of the disease is significantly decreased *in vivo* using nitric oxide synthase (NOS) inhibitors. The aim of this study was to determine how the oxidative state of cartilage affects mechanically induced NO and PGE_2 in the presence and absence of IL-1.

Articular cartilage explants from the femoral condyles of 2 yr old female pigs were cultured in DMEM with 10% FBS, non-essential amino acids, HEPES, penicillin and streptomycin. After 72 hrs in culture at 37ºC, 5% CO_2, 95 % air, explants were incubated in the presence and absence of 10 ng/ml IL-1, and incubated at 37^0C at either 5% CO_2, 95% air, or at 5% CO_2, 5% O_2, 90 N_2, or at 5% CO_2, 1% O_2, 94% N_2. Explants were allowed to equilibrate under a 10 gf tare load for 8 hrs. Intermittent compressive loads were applied at 0.05 MPa, 0.5 Hz for 24 hrs using a modified version of the Biopress system™ (Flexcell International). All controls were cultured in an unloaded state at either 20% O_2, 5% O_2 or 1% O_2 respectively. The effect of the selective NOS2 inhibitor 1400W (2 mM, Alexis) was tested. PGE_2 production was measured with the PGE_2 ELISA kit (R&D Systems), and NO production measured by the Griess reaction. Statistical analysis was performed by ANOVA with Duncan's multiple range test.

Incubating mature articular cartilage at 5% O_2 caused a significant increase ($p < 0.001$) in baseline NO production compared with incubation at 1% or 20% O_2. Mechanical compression caused a significant increase ($p < 0.001$) in NO at 20% O_2 but not at 5% or 1% O_2, and significantly increased ($p<0.001$) PGE_2 production at 20% (50 fold) and 5% (4 fold) but not at 1% O_2. Mechanical compression in the presence of IL-1 caused a significant increase ($p< 0.01$) in PGE_2 production at 5% O_2 only. Application of mechanical compression in the presence of 1400W caused a significant further increase in PGE_2 production at all oxygen tensions.

Our data show the oxidative state of articular cartilage is important in determining the effect of mechanical compression on production of inflammatory mediators. Therefore it is important to consider the avascularity and hence low oxygen tension, characteristic of articular cartilage, in our understanding of inflammation and mechanical loading of cartilage.

Gender Differences in Long Bone Fatigue using a Rat Model. L. D. Moreno*[1], A. M. Cheung[2], M. D. Grynpas[1]. [1]Samuel Lunenfeld Institute, Mount Sinai Hospital, Toronto, ON, Canada, [2]Osteoporosis program, University Health Network and Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada.

Stress fractures can occur because of prolonged exercise and are associated to cyclic loading. This is of special concern for athletes and army recruits. Understanding bone fatigue behavior may give insight into the mechanisms of bone fragility. Existing literature shows that the rates of stress fracture for female athletes and army recruits are higher than for their male counterparts. The objective of this work was to perform a comparative study of the fatigue response of female and male rat tibia. Young 16 weeks Sprague-Dawley rats were used for this study. Excised tibias were loaded at different strains from 0.5% to 1% ε to determine the strain versus cycles to failure curve (S/N curve) at physiological frequency of 2Hz. A set of tibias from male and female rats were monotonically loaded at different stages of the fatigue life (N_f) and the mechanical properties (stiffness, work to fracture and ultimate strength) were determined to assess bone mechanical properties deterioration. A set of tibias that were not fatigued were used as controls. The secant modulus of the tibias was fairly constant throughout the fatigue test; loss of stiffness and cyclic softening was reported only in the later stages of the fatigue life (>90%N_f). Male tibias undergo loss of stiffness for longer periods before fracture. From the S/N curves we inferred the endurance limit. We found that the tibias of the male rats have a higher endurance - about 17% higher. From the cumulative creep data, i.e. from the strain-time curve we found that ε_f (strain-to-failure) of both female and male are not significantly different ($p>0.05$), but for a given non-dimensional stress _/E_o the female bones deteriorate at higher rate than the males (e.g. for an initial peak strain of 0.007_ the steady-state strain rate was 0.035 μ/s and 0.18μ/s for male and females respectively). The results of this rat model suggest that extensive training session with high intensity, even if scaled down to female strength levels would have a detrimental effect on their bones, hence shorter training sessions for females might help to reduce the rates of stress fractures in female athletes.

SU077

Young's Modulus of C57BL/6J Cortical Bone Is Less Than That of Outbred *Col1a1^{oim}* Heterozygotes or Their Wild-Type Littermates. G. E. Lopez Franco[1], D. S. Stone*[2], R. D. Blank[3]. [1]Medicine, University of Wisconsin-Madison, Madison, WI, USA, [2]Materials Science and Engineering, University of Wisconsin-Madison, Madison, WI, USA, [3]Geriatrics Research, Education, and Clinical Center, William S. Middleton Veterans' Hosptital, Madison, WI, USA.

One must distinguish the inherent mechanical properties of the bone tissue from the contributions of bone mass and bone architecture to bone strength in order to understand bone's mechanical performance fully. Nanoindentation provides a means of calculating hardness and Young's modulus independently of the sample's geometry.

Mice harboring the *Col1a2^{oim}* mutation (*oim*) are a well-studied mouse model of osteogenesis imperfecta arising from α2(I) chain deficiency. Mice homozygous for the mutation produce type I collagen composed of α1 homotrimers and suffer from marked skeletal fragility. Mice heterozygous for the mutation suffer reduced type I collagen synthesis and have a much more subtle biomechanical defect.

We performed nanoindentation to compare the hardness and Young's modulus of cortical bone from animals heterozygous for the *oim* mutation, wild-type littermate control, and C57BL/6J, an inbred mouse strain with low bone mineral density and low Young's modulus. Cortical bone from either the tibia or femur was polished from the periosteal surface prior to testing. We performed nanoindentation in conjunction with atomic force microscopy using a Hysitron TriboScope and a diamond Berkovich tip at loads between 3000 and 8000 μN. Comparison among genotypes was performed by ANOVA and Tukey's test.

Cortical Bone Nanoindentation

	C57BL/6J	*oim*/+	+/+
Young's Modulus (GPa, Mean ± SEM)	20.6 ± 0.8	29.0 ± 1.8*	30.6 ± 1.8**
Hardness (GPa, Mean ± SEM)	1.06 ± 0.08	1.45 ± 0.13	1.48 ± 0.18

*P =0.00309 *v* C57BL/6J, **P = 0.00053 *v* C57BL/6J, *oim*/+ *v* +/+ = NS

The results are summarized in the table. C57BL/6J bone had a lower Young's modulus than either *oim*/+ or +/+ littermates. The 3 genotypes did not differ significantly in hardness.

It therefore appears that neither decreased bone modulus nor decreased bone hardness is the source of skeletal fragility in *oim*/+ mice. It is worth noting that the *oim* mutation is maintained on an outbred B6C3 background. Our data suggest that the collective influence of the segregating background genes has a greater impact on Young's modulus of cortical bone than does heterozygosity for the *oim* allele of *Col1a2*.

Disclosures: ***G.E. Lopez Franco****, None.*

QTL Mapping of Bone Quality Measured Using Nanoindentation Technology. Y. Jiao*[1], Z. Fan*[2], H. Chiu*[3], H. Yang*[1], E. C. C. Eckstein*[3], J. Rho*[3], W. G. Beamer[4], W. Gu[1]. [1]Department of Orthopedic Surgery-Campbell Clinic, Univ. of Tennessee Health Science Center, Memphis, TN, USA, [2]Orthopedic and Rehabilitation Engineering Center, Marquette University, Marquette, WI, USA, [3]Department of Biomedical Engineering, University of Memphis, Memphis, TN, USA, [4]The Jackson Laboratory, Bar Harbor, ME, USA.

Using nanoindentation technology to identify QTLs that regulate bone quality represents a novel approach to improving our understanding of molecular mechanisms that control bone matrix properties. So far, nanoindentation appears to be the superb technology for measurement of bone quality. In this study, we investigate the use of nanoindentation measurements in identification of QTLs that regulate bone quality.

Mouse tibiae for comparison of different ages were from C57BL/6J and C3H/HeJ and for QTL mapping were from a F2 population derived from C57BL/6J and C3H/HeJ (provided by WGB at Jax). Those tibiae were from the same population used for the analysis of QTLs of bone mineral density. All tibiae were embedded in epoxy resin without infiltration at room temperature. After using silicon carbide abrasive papers with progressively finer grit sizes, they were polished on micro cloths with a 0.05 μm aluminum suspension. A Triboindenter (Hysitron, Inc. Minneapolis, MN) was used to conduct all indentation tests. The Oliver-Pharr method was used to determine the elastic modulus. Genome scan was performed in The Jackson Laboratory. QTL mapping was conducted using Map Manager QTX software. The analysis procedure followed the instructions in the text at (http://mapmgr.roswellpark.org/mmQTX.html; http://webqtl.roswellpark.org)

We obtained the following results: 1) Mice at 4, 8, 16, 32, and 40 weeks were used for the nanoindentation tests. The data at 16 weeks of age shows a moderated variation among mice within a strain compared with older ages. The data suggest that 16 weeks is sufficient time for mouse tibia to mature; 2) We examined 800 tibiae from F2 mice and compared the data to the two progenitors. Data shows that both Er (stiffness) and Hr (hardness) modulus appears normal distributions, suggesting that multiple genetic factors control the bone quality; and 3) Four QTLs for hardness (chr. 9, 12, 13, and 16) and three for stiffness (two on chr. 12 and one on chr. 16) have been identified. Among the QTLs detected from nanoindentation, the one on chromosome 13 has a similar location with the QTL of bone density. The others are new QTLs that have not been detected.

Our study suggests that using nanoindentation technology to identify QTLs that regulate bone quality represents a novel approach to improving our understanding of molecular mechanisms that control the matrix properties of bone.

Prevalence of Atypical Osteon Characteristics May Reflect Adaptations in Bending Environments and During Growth. S. M. Sorenson*, N. H. Jenson*, J. G. Skedros. University of Utah, Utah, UT, USA.

Basic multicellular units (BMUs) produce 2nd osteons, which mediate microdamage repair, mineral mobilization, and the introduction of interfaces. Since fatigue behavior of cortical bone is significantly different in tension, compression, and shear strain *modes*, histologic adaptations are expected since many limb bones receive consistent tension/compression/shear distributions. BMU-mediated adaptations include variations in 2nd osteon densities and collagen fiber orientation (CFO). Additional important BMU characteristics might include 'atypical' secondary osteons (zonal, connected canal, mature and active drifting, elongated, dumbbell, and multiple canal). If these characteristics correlate with strain-related parameters, then regional variations in these not-often-quantified osteon characteristics (O.C.) may reveal mechanisms (e.g., increasing microstructural complexity/interfaces) that serve to "toughen" bone for relatively more deleterious loading environments (e.g., prevalent tension and shear). O.C. were examined in bones loaded habitually in bending for strain-mode-related correlations. Specimens included mid-third diaphyseal sections of a growth series of calcanei of wild mule deer (older fawns to adults). This model is useful for examining strain-related relationships with microstructural adaptation since the cranial (Cr) cortex receives prevalent compression, the caudal (Cd) cortex receives tension, and the medial/lateral (M/L) cortices receive prevalent shear since they are in proximity of the neutral axis. Regional variations in O.C. were evaluated in backscattered electron images and expressed as "osteon heterogeneity index" (OHI = O.C./total 2nd osteons). Kruskal-Wallis analyses of spatial OHI variations revealed no significant differences among the four cortices in fawns. Sub-adults *and* adults showed these significant differences: Cd vs. L, Cr vs. L, and M vs. L. Although OHI in the whole section (i.e., all cortices) vs. bone length was poorly correlated, the total no.of O.C./area increased with age ($r = 0.538$, $p=0.005$). The increase in these atypical osteon characteristics occurs during the phase of development when osteons may generally serve to enhance toughness and fatigue resistance. The differences between the M cortex and other locations may reflect the fact that the neutral axis is oblique, placing the M cortex in prevalent/predominant shear *and* compression. CFO in this region is also known to be highly oblique, consistent with adaptation for shear/compression. These observations may help understand the mechanisms mediating regional and age-related cortical histologic changes in the complexly loaded human femoral neck.

Trabecular Bone Strength with Virtual Osteoporotic Simulation and Finite Element Analysis. S. Ferreri*, E. Mittra*, B. Gruber, Y. Qin. Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA.

Osteoporosis is a disease that is characterized by low bone density and chronic erosion of the microstructure. As a result, the structural integrity of the affected tissue is compromised and individuals suffering from the disease are at greater risk to develop bone fractures. Clinically, osteoporosis & osteopenia are characterized by decreased apparent bone mineral density (BMD). However, apparent BMD alone does neither explain all variation of the mechanical properties nor does it account for the structural anisotropy of trabecular bone, which might not be sufficient to accurately predict the quality of bone. The ultimate bone strength is directly dependent on bone's quality rather than quantity. In this study osteoporotic conditions are created virtually by decreasing the overall trabecular thickness and maintaining the characteristic microstructure using μCT technology. The response to mechanical loading for both samples is then evaluated using the finite element method.

Four human cadaveric, calcaneus samples with an average age of 76 years (SD ±10.25) were scanned using a μCT-20 scanner (SCANCO Medical) with a resolution of 34 μm. A SCANCO image processing package was used to reconstruct and threshold the scanned images. A ~4 mm cube near the center of the sample was selected for analysis. One third of a voxel was removed from the trabeculae surface using applications available in the SCANCO software. A finite element analysis was then conducted for both the original and simulated diseased samples. The analysis was implemented using ABAQUS (HKS INC.) version 6.3. A 1% compressive strain is applied to nodes on the medial surface with a non-friction boundary condition while nodes on the lateral surface are restricted from motion in the mediolateral direction. Additionally, nodes on the remaining four sides are restricted from moving in the direction of the unit normal to the side.

The ~4 mm cubes of human calcaneus bone had an average bone volume fraction (BVF) of 17.41 % (SD±3.46). For the case of simulated osteoporosis average BVF was 11.20% (SD±1.86). The effect of simulating osteoporosis removes on average 35.56% of bone from the original model. The apparent stress was defined as $\sigma_{33} = (F_{z,max} - F_{z,min})/2*A$, where $F_{z,max}$ and $F_{z,min}$ are the sum of the nodal forces on the top and bottom surfaces of the cube. The average apparent stress for the healthy bone is found to be 55.64 ±24.52MPa. However, under the same loading conditions, the case of simulated osteoporosis experiences an apparent stress of 90.2 ±14.15MPa, nearly 38% greater than that of the original bone. The results of this study suggest that decreasing BVF 35% severely compromises the structural integrity of calcanean trabecular bone.

Repeatability of the Ex-Vivo Bioreactor Bone Organ Culture Chamber and Loading System. H. Ploeg*[1], E. Smith*[2], A. Gerson*[2], S. Garcia*[1], E. Broeckmann*[3], D. B. Jones*[3]. [1]Mechanical Engineering, University of Wisconsin, Madison, WI, USA, [2]Population Health, University of Wisconsin, Madison, WI, USA, [3]Exp. Orthopaedie & Biomechanik, Phillips Universitaet, Marburg, Germany.

The purpose of this study was to determine the repeatability of the Ex-vivo bioreactor Bone organ culture chamber and Loading System (EBLS) over the period of time of at least that of a 30 to 50 day experiment. Three standards were obtained from the Dr. David Jones' Laboratory in Marburg Germany. The standards are closed hollow cylinders open at one end. The apparent elastic moduli ($E=Kh/pi/r^2$, where E is apparent elastic modulus, K is apparent stiffness, h is cylinder height, r is cylinder radius), chosen to cover the expected range of ex-vivo trabecular bone samples, were a result of varying the material modulus and the thickness of the cylinder's end plate. The apparent elastic moduli of the three standards were 325 MPa, 495 MPa and 1590 MPa for the 500 μm thick aluminum, 800 μm thick steel, and 1200 μm thick steel standards, respectively. Thirteen sets of ten repeat measurements were made on three standards over a 90 day period. The coefficient of variation of the apparent elastic modulus was 1.4%, 1.3% and 2.3% for the three standards, in order of increasing apparent stiffness, over a period of 90 days. It is clear from this data that the reliability of the loading system is excellent and will not induce large variations into the ex-vivo bone core data set. Further testing is being carried out to determine the effects of the bone chamber, loading characteristics and specimen characteristics on the apparent elastic modulus measured using the EBLS.

Table 1. Reliability Testing Results for Three Standards (n=130 per standard)

	Force (N)	Displacement (μm)	Apparent Elastic Modulus (MPa)
Aluminum - 500 μm thick endplate			
Mean	148.9	29.62	325.0
Standard Deviation	2.375	0.04883	4.581
Coefficient of Variation	1.595%	0.1649%	1.409%
Steel - 800 μm thick endplate			
Mean	223.7	29.61	494.9
Standard Deviation	4.426	0.07139	6.540
Coefficient of Variation	1.978%	0.2411%	1.321%
Steel -1200 μm thick endplate			
Mean	719.5	29.63	1591
Standard Deviation	16.34	0.05167	0.03592
Coefficient of Variation	2.271%	0.1744%	2.257%

Correlation of Serum TRAcP 5b and Bone Mineral Density with Osteolytic Bone Cancer Pain. A. Gordon[1], J. Boulet*[1], J. Miller*[2], D. Bristol*[2], G. Crumley*[3], S. Gottshall*[1], S. Chaffer*[1], K. Walker*[1], J. Pomonis*[1]. [1]Neuropharmacology, Purdue Pharma, Cranbury, NJ, USA, [2]Biostatistics, Purdue Pharma, Cranbury, NJ, USA, [3]Molecular Pharmacology, Purdue Pharma, Cranbury, NJ, USA.

In patients with malignant disease, bone cancer pain is the most common kind of pain. Upon increased bone tumor burden, a patient's discomfort worsens with clinical presentation of mechanical allodynia, a pain response that occurs when a normal, nonpainful stimulus is perceived as painful. Increased serum tartrate-resistant acid phosphatase 5b (TRAcP 5b) and decreased bone mineral density (BMD) have been shown clinically to correlate to advanced states of osteolytic tumor burden. Moreover, clinical studies suggest both decreased serum TRAcP 5b and increased BMD can signify pharmacologic or analgesic activity and predict pain relief in these cancers.

To confirm the utility of serum TRAcP 5b and BMD as quantifiable correlates of mechanical allodynia, we used an established pre-clinical rat model of bone cancer pain. 3000 MRMT-1 rat mammary gland carcinoma cells were implanted in the tibiae of female Sprague Dawley rats and monitored for progression of osteolytic tumor burden over a 21-day period. Naïve, Hank's Balanced Salt Solution (HBSS) sham and MRMT-1 tumor-bearing rats were tested for von Frey paw withdrawal threshold (VWT) as a measure of mechanical allodynia, immunoassayed for serum TRAcP 5b, and radiographed for BMD prior to surgery and after 7, 10, 14, and 21 days. Increased serum TRAcP 5b levels were seen in MRMT-1 rats as compared to sham rats at 14 and 21 days after surgery. BMD and VWT significantly decreased in MRMT-1 rats as compared to sham rats, beginning 10 days after surgery. A repeated measures analysis of covariance was performed, regressing VWT on BMD, with covariate adjustment for baseline VWT. This analysis demonstrated that the concomitant decrease in BMD and VWT in MRMT-1 rats was statistically significant ($n=8$, $p<0.01$). Furthermore, multiple regression analysis over days 7-21, regressing VWT on serum TRAcP 5b, verified statistical significance of the simultaneous rise in serum TRAcP 5b and fall of VWT in MRMT-1 rats ($n=8$, $p<0.04$). Therefore, our statistical analysis establishes both BMD and serum TRAcP 5b as correlates of VWT.

This is the first study to demonstrate statistical correlation of serum TRAcP 5b levels with quantitative measures of mechanical allodynia in a pre-clinical bone cancer model. Increased serum TRAcP 5b and decreased BMD, known clinical correlates of osteolytic tumor burden, are statistically associated with and may predict more pronounced states of bone cancer pain. Our results will lead to greater understanding of the utility of potential analgesics in this regard.

Bone Mineral Density in Long-term Survivors of Acute Lymphoblastic Leukemia (ALL). V. Vyskocil[1], Z. Cerna*[2], S. Kutilek[1]. [1]Bone Disease Center, Charles University Hospital, Plzen, Czech Republic, [2]Department of PediatricBone Disease Center, Charles University Hospital, Plzen, Czech Republic.

The childhood leukemia has an increasing number of survivors and therefore, more attention is being paid to the long-term side-effects of this disease and its treatment. In patients with ALL, the leukemic process itself together with the treatment are likely to undermine the achievement of peak bone mass 12 children (10 boys and 2 girls) with history of ALL were enrolled in the study. The ALL was diagnosed at the age of 6.1±3.7 years, treated for 2.1±0.3 y (ALL protocol BFM 83, n=2; BFM 90, n=6; BFM 95,n=4). The ALL remmission occurred at mean age 8.2±3.7 years. The first DXA (Hologic Delphi W S/N 70220, CV 1%, LSC 2.7 %) measurement was performed 3.83± 2.89 y after completion of chemotherapy (at mean age 12.0±3.4 y) and after additional 1.22 ± 0.34 y (mean age 13.5±3.6 y). Volumometric bone density (BMD_{vol}) was calculated: BMD_{vol}=BMC/Volume = BMD_{areal} [4/(π Width)],where Width = mean width of vertebral body. The obtained results of BMD_{areal} and BMD_{vol} were expressed as Z-scores. The BMD_{areal} didn´t differ significantly from the reference values at both time points ($p = 0.11$ and 0.25, respectively), neither was there any difference between the results of the two measurements ($p=0.33$). The BMD_{vol} was significantly lower in comparison to the reference data at the respective time-points ($p< 0.001$ and 0.006, respectively), and there was no difference between the results of the two measurements ($p=0.25$) There were no correlations between the basic anthropometric parameters and either BMD_{areal} or BMD_{vol}. Neither were there any correlations between cummulative doses of prednisone and cytostatic drugs (methotrexate, cyclophosphamide) and BMD_{areal} or BMD_{vol}, nor between number of hospital admissions or duration of hospitalisation and BMD. Our results further confirm that ALL survivors have decreased BMD. The estimation of BMD_{areal} is influenced by bone size and can be underestimated in smaller individuals. However, the absence of correlations between normal BMD_{areal} and normal anthropometric parameters suggests that this wasn´t the case in our patients. Furthermore, low BMD_{vol} values confirm the low bone mass in ALL survivors, as volumometric bone density gives more reliable information than the areal data There were no significant changes in BMD Z-scores between the two measurements in a mean time span of 1.22 ± 0.34 years. In conclusion, childhood survivors of ALL are at risk of decreased bone mass. Volumometric bone density gives more reliable information than the areal data

Differential Expression Profile of Haematopoietic Markers in the Giant Cell Tumor Stromal Cells (GCTSCs). E. A. Kaiser[1], A. Jeske*[1], M. Wuelling*[2], G. Delling*[2]. [1]Bone Pathology, Center of Biomechanics, Hamburg, Germany, [2]Bone Pathology, Hamburg, Germany.

Among the giant cell tumor of bone's (GCT) three cellular components, multinucleated giant cells, CD68 positive monocytes and mononucleated fibroblast-like stromal cells (GCTSCs), only the GCTSCs survive in cell cultures thus assuming that they are the neoplastic component of GCTs. In earlier studies the development of GCTs from monocytic/osteoclastic cells was proposed and a GCT cell line (GCT23) with osteoclast-like properties has been presented. Recent papers have suggested a mesenchymal cell as the origin of the GCTSCs. The present study sought to address this controversy. The hypothesis of the existence of pluripotent stem cells that can differentiate into haematopoietic as well as mesenchymal cell types may offer an explanation for the divergent results. The lack of definitive antibodies allowing recognition of pluripotent cells let us to the quantification of the relative gene expression of early haematopoietic (GATA1, 2, 3, 6) and mesenchymal (CD73, CD105, CD166) markers in eight GCTSCs, one primary human mesenchymal stem cell (MSC) population, the giant cell tumor cell line GCT23 and the pluripotent stem cell line V54/2 by Real Time PCR. Comparing the expression profiles of the control cells (MSC, GCT23 and V54/2) revealed that the mesenchymal markers did not differ appreciably between the control cell types. However, the haematopoietic markers displayed a differential expression profile. Matching up control cell expression profiles of the haematopoietic markers with the expression profiles of the GCTSCs identified three GCTSCs that demonstrated a similar expression profile as the GCT23, four GCTSCs that corresponded to the expression profile of MSCs and one GCTSC that related to the expression profile of V54/2. The presented results suggest that GCTs could comprise different entities, but further marker expression profiling, in addition to in vivo and in vitro differentiation studies need to be conducted to assume a pluripotency of GCTSCs.

Supported by Rudolf Bartling Stiftung, GCT23 were provided by Dr. Grano, Bari, Italy and V54/2 were provided by Dr. Huss, Munich, Germany

Estrogen in the Establishment of Peak Bone Mass among Childhood Cancer Survivors. J. E. Mulder[1], C. A. Sklar*[2], A. C. Mertens*[3], L. L. Robison*[3], L. Diller*[4], A. Klibanski*[5], J. P. Bilezikian[1]. [1]Columbia University, NY, NY, USA, [2]Memorial Sloan-Kettering Cancer Center, NY, NY, USA, [3]University of Minnesota, Mpls, MN, USA, [4]Dana Farber Cancer Institute, Boston, MA, USA, [5]Massachusetts General Hospital, Boston, MA, USA.

Advances in multimodality therapy for the treatment of childhood cancers have resulted in markedly improved survival rates for many children. In young adults who have survived cancer, however, therapy and its complications place them at risk for suboptimal acquisition of peak bone mass. In addition to chronic illness, nutritional deficiencies, limited physical activity, and treatment with glucocorticoids, multiagent chemotherapy and radiation; the long-term adverse effects of cancer therapies on endocrine systems, specifically sex steroid and growth hormone deficiencies, are important risk factors for low bone mass in adult survivors of childhood cancer. As part of a study to assess the effects of estrogen dose on bone mineral acquisition in survivors of childhood cancer with premature ovarian failure, we evaluated bone mineral density and markers of bone remodeling in a group of childhood cancer survivors with normal menses. We hypothesized that estrogen status would have the greatest influence on BMD in cancer survivors, and therefore, cancer survivors with normal menses would have normal BMD. Six childhood cancer survivors (mean age 26.5, range 21-30) with normal menarche (mean age 11.8) and regular menses have been studied thus far. No subject had received growth hormone replacement therapy. BMD (DXA) was measured at the lumbar spine (LS), total hip (TH), femoral neck (FN), and 1/3 radial site (R). Markers of bone remodeling, vit D, PTH, androgens, estradiol and progesterone were measured during the luteal phase of the menstrual cycle. Mean height was 158.2 cm (148.6-175.2) Z-score -0.7, mean BMI was 22.7 (20.9-24.3). Mean Z-scores of the LS, TH, FN, and R were -0.87, -0.87, -0.82, and -0.08, respectively. Mean T-scores were -0.92, -0.88, -0.87, and -0.15, respectively. Despite having normal menses, 3 of 6 patients had BMD Z-scores below -1.0 at one or more sites. L-S and TH BMD Z-scores were at or below -2.0 in 2 patients. Markers of bone remodeling, PTH, gonadotropins, and estradiol were normal in all subjects. Serum progesterone levels confirmed ovulation in 4 of 6 patients. Two patients had vit D levels below 20 ng/ml. IGF-1 was normal in all subjects, although the 3 patients with the lowest BMD had lower IGF-1 levels. These 3 patients had received cranial or cranial-spinal irradiation. In summary, the continued presence of regular menses after cancer therapy was not always protective of acquisition of normal bone density in this small sample of childhood cancer survivors.

Oral Squamous Cell Carcinoma Cells Enhance Osteoclast Differentiation and Bone Resorbing Activity. T. Tada[1], E. Jimi[2], S. Ozeki*[1], K. Okabe[2]. [1]Oral and Maxillofacial Surgery, Fukuoka Dental College, Fukuoka, Japan, [2]Physiological Science and Molecular Biology, Fukuoka Dental College, Fukuoka, Japan.

The invasion of oral squamous cell carcinoma (SCC) into maxillary and mandibular bone is a common clinical problem. It is well known that bone destruction by SCC invasion is mediated by osteoclasts. We therefore investigated how SCC cells affect osteoclast differentiation and function. We injected BHY (human oral squamous carcinoma cell line) cells mixed with human gingival fibroblasts into the masseter muscle of nude mice and observed an increased number of osteoclasts and bone destruction on the surface of the mandibular bone. When BHY cells were co-cultured with mouse bone marrow cells, few osteoclasts were formed even though BHY cells express receptor activator of NF-kB ligand (RANKL). However, adding BHY cells to the co-culture of mouse osteoblasts and bone marrow cells markedly increased osteoclastogenesis in the absence of osteotropic factors. This effect was completely abolished by addition of osteoprotegerin (OPG). When co-cultures were separated from BHY cells using transwell culture system and conditioned media collected from BHY cell cultures were added to the co-cultures without any osteotropic factors, osteoclastogenesis was suppressed (up to 20-30%) but we still observed osteoclasts in both culture system. Paraformaldehyde-fixed BHY cells added to co-cultures of mouse osteoblasts and bone marrow cells still could induce small (mostly mono and binuclear) osteoclasts. These results indicate that soluble factors released from BHY cells as well as cell-to-cell contact between BHY cells and osteoblasts cooperatively induce osteoclastogenesis. When purified osteoclasts were cultured for longer than 24 h, most died spontaneously. The addition of either BHY cells or conditioned media from BHY cells markedly increased the survival of osteoclasts. We previously reported that enriched osteoclasts placed on dentin slices form few resorption pits and that their pit-forming activity is greatly increased by adding osteoblasts or BHY cells. Therefore, alteration of both osteoclast differentiation and function is a major factor of bone invasion by SCC.

Risedronate, and its Phosphonocarboxylate Analogue NE10790, both Induce Apoptosis, but have Differential Effects on the Cell Cycle and Protein Prenylation in Human Myeloma Cells. A. J. Roelofs*[1], P. A. Hulley*[1], R. G. G. Russell[1], F. H. Ebetino[2], M. J. Rogers[3], C. M. Shipman*[1]. [1]Nuffield Department of Orthopaedic Surgery, University of Oxford, Oxford, United Kingdom, [2]Procter & Gamble Pharmaceuticals, Cincinnati, OH, USA, [3]University of Aberdeen, Aberdeen, United Kingdom.

Bisphosphonates (BPs) are widely used in the treatment of osteolytic bone disease associated with multiple myeloma (MM). In addition to their beneficial effects on bone disease in MM, BPs have recently been demonstrated to exert anti-tumour effects both *in vitro* and *in vivo*. NE10790 is a phosphonocarboxylate analogue of the potent BP risedronate (RIS), which has a lower affinity for bone mineral and is a weak inhibitor of bone resorption. NE10790 has been shown to specifically inhibit the prenylation of small Rab GTPases in macrophages and osteoclasts. Both RIS and NE10790 strongly reduce skeletal tumour burden in a murine model of breast cancer.

The aim of this study was to determine whether RIS, and its phosphonocarboxylate analogue NE10790, induce apoptosis in human MM cells *in vitro*, and to compare their anti-tumour mechanisms of action.

Both NE10790 and RIS significantly increased apoptosis in NCI H929, JJN-3, and RPMI 8226 MM cells in a dose-dependent manner ($p<0.001$), as determined by characteristic changes in nuclear morphology and by a fluorescence *in situ* nick translation assay. A significant increase in apoptosis was detected following treatment with 1 mM NE10790 ($p<0.01$) and 50 μM RIS ($p<0.05$) in JJN-3 cells. For both RIS and NE10790, induction of apoptosis was found not to be due to calcium chelation.

Flow cytometric analysis of propidium iodide (PI)-stained cells demonstrated that RIS induced an increase in the proportion of cells in S-phase of the cell cycle, before an increase in apoptosis could be detected. In contrast, NE10790 did not cause accumulation of cells in S-phase. Double labelling with BrdU and PI confirmed that DNA replication was partially inhibited after treatment with 10 μM RIS, and completely after treatment with 100 μM RIS.

Western blot analysis showed that RIS dose-dependently inhibited prenylation of both Rap1a (geranylgeranylated by GGTase I) and Rab6 (geranylgeranylated by GGTase II/Rab GGTase) proteins. In contrast, NE10790 only inhibited the prenylation of Rab6. These results demonstrate that RIS, and its phosphonocarboxylate analogue, NE10790, both induce apoptosis in human MM cell lines *in vitro* in a dose-dependent manner. However, effects of RIS are associated with cell cycle arrest in S-phase and general inhibition of protein prenylation, whereas our results suggest that NE10790 may have distinct mechanisms of action involving specific inhibition of prenylation of small Rab GTPases.

Soluble RANK Ligand (sRANKL) and Osteoprotegerin (OPG) in Multiple Myeloma and in Monoclonal Gammopathy of Undetermined Significance. D. Beke*[1], G. Hawa*[2], P. Kudlacek*[3], G. Pohl*[1], K. Brenner*[1], L. Hofbauer*[4], M. Pecherstorfer[1]. [1]1. Department of Medicine and Medical Oncology, Wilhelminenspital der Stadt Wien, Vienna, Austria, [2]Biomedica Group, Vienna, Austria, [3]Department of Medicine, Hospital Barmherzige Brüder, Vienna, Austria, [4]Division of Gastroenterology, Endocrinology and Metabolism, Phillips University of Marburg, Marburg, Germany.

Background: Osteolytic bone disease is a major cause of morbidity in patients with multiple myeloma. The identification of the OPG/RANKL/RANK system as the apparently most important regulator of osteoclastogenesis and osteoclast activity represents a major advantage in bone biology.

Purpose: To evaluate the role of soluble receptor activator of nuclear factor kappa B ligand (sRANKL) and osteoprotegerin (OPG) in patients with plasma cell dyscrasias, we measured the serum concentrations of these parameters in 43 patients with monoclonal gammopathy of undetermined significance (MGUS), 46 patients with newly diagnosed, untreated myeloma (MM) and 90 healthy adults. We used commercially available immuno assays (Biomedica Group, Vienna, Austria). The OPG assay determined the total amount of circulating OPG in serum by measuring free and sRANKL bound OPG.

Results: Serum levels of OPG and sRANKL did not differ between patients with MM or MGUS. OPG levels and sRANKL levels were significantly higher in MM and MGUS patients than in healthy controls.

Conclusion: Patients with MGUS and MM did not differ with regard to serum levels of OPG and serum levels of sRANKL. Therefore, OPG and sRANKL levels were not useful in discriminating MM from MGUS patients in our study population. In patients with MGUS, serum concentrations of OPG and sRANKL were raised when compared to healthy controls. This finding might indicate the presence of already enhanced osteoclast activity in MGUS patients who per definition do not have overt neoplastic bone involvement.

	Multiple Myeloma (n=46)	MGUS (n= 43)	Healthy controls (n= 90)
Osteoprotegerin (pmol/L)	4.94* (1.00 - 17.36)	4.47* (1.00 - 10.99)	2.15 (0.85 -8.55)
sRankl (pmol/L)	0.27* (0.06 - 1.08)	0.24* (0.11 - 3.22)	0.18 (0.01 - 2.67)
Ratio sRankl/osteoprotegerin	0.06 (0.01 - 1.80)	0.06 (0.01 - 0.90)	0.06 (0.01- 1.52)

E1A Oncogene Repression of Parathyroid Hormone-related Protein Gene Expression in Human Prostate Cancer Cell Lines. F. Asadi*[1], B. Boyer*[2], A. Valles*[2], S. C. Kukreja[1], J. L. Cook*[3]. [1]Medicine, University of Illinois at Chicago & West Side VA Medical Center, Chicago, IL, USA, [2]Regulations Cellulaires et Oncogeneses, UMR 146 du CNRS, Institute Curie, Paris, France, [3]Medicine, University of Illinois at Chicago, Chicago, IL, USA.

Previous studies have demonstrated that PTHrP levels are high in prostate cancer and that PTHrP expression is greater in poorly differentiated tumors as compared to that in well differentiated tumors. In the advanced stages, prostate cancer cells become androgen-independent and resist apoptosis. Overexpression of parathyroid hormone-related protein (PTHrP) has been shown to result in resistance to apoptotic injuries in various cells including prostate cancer. In another study, we evaluated the effects of addition of PTHrP (1-34) and its neutralization on cell survival following exposure to trans-retinoic acid (tRA) in LNCaP and C42 and C42b prostate cancer cell lines. Cell survival was assessed by trypan blue exclusion and MTS proliferation assay and apoptosis was examined by intracellular DNA fragmentation analysis, caspase-3 activity assay, and TUNEL assay. In these cell lines, tRA (5μM) treatment reduced cell viability and PTHrP (1-34) (100nM) protected against the tRA-induced loss in cell viability. Similarly, PTHrP had a protective effect against tRA-induced DNA fragmentation and caspase-3 activation in these cell lines. On the other hand, addition of PTHrP (1-36) neutralizing antibodies to the tRA-treated cells further reduced cell survival and increased apoptosis.

Human adenoviruses are common human pathogens. Adenovirus early region 1A (E1A) proteins were originally described as immortalizing oncoproteins in rodent cells. Subsequent studies have shown that a '12 S' form of the E1A induces suscepitibilty to killer cell apoptosis. In a previous study, overexpression of E1A into an immortalized keratinocyte cell line PAM 212K has been shown to inhibit PTHrP expression via interaction with the the P3 promoter (Foley et al. Mol Cell Endocrino. 156:13-23, 1999). In the present study, we evaluated the effects of transient adenovirus type 5 early region 1A (E1A) gene transfection on PTHrP expression in PC-3 prostate cancer, a human breast carcinoma (MB 231), and a rat bladder carcinoma (NBT II) cell lines. Transfection with the '12 S' E1A gene resulted in a decrease in PTHrP mRNA levels in all three cell lines. We speculate that a part of the apoptosis-promoting effect of E1A may be mediated via repression of PTHrP expression. Further studies to evaluate the effects of E1A on cell apoptosis in these cell lines and the role of PTHrP in this process are warranted.

Influence of Chemotherapy(AC)on Bone Mineral Density (BMD) and Bone Ultrasonometry (QUS) in Women with Breast Cancer. M. Gottschalk*, P. Hadji*, C. Maskow*, V. Ziller*, C. Heitmann*, U. Wagner*. Endocrinology and Osteoporosis, Clinic of Gynokology and Obstretics of Philipps- University, Marburg, Germany.

Introduction: The aim of this prospective, case-control pilot study was to evaluate the influence of chemotherapy (Adriamycin/Cyclophosphamid) on BMD and QUS in premenopausal women with breast cancer.

Material and Methods: We included 53 premenopausal patients, mean age 47 ± 9,6 years with an incident diagnose of breast cancer who received a chemotherapy (4 cycles of AC) and 53 age- and BMI-matched controls. Women with metastases, a history of osteoporosis with or without fracture, diseases or treatments known to effect bone metabolism were excluded from the study. BMD was measured by DXA (DPX-L, GE/Lunar) at spine and hip. QUS was performed at the os calcaneus using the Achilles device (GE/Lunar) and at the phalanges using the Bone-Profiler (IGEA). Measurements were performed at baseline (before chemotherapy), after 6 and 12 months and were compared with measurement results of the age- and BMI-matched control group.

Results: DXA results of the spine and hip showed a significant decrease of T- and Z-score in patients with chemotherapy compared controls (p= 0,001). In accordance to QUS results, measurement at the os calcaneus as well as at the phalanges showed a similar significant, linear decrease of T- and Z-score (p= 0,001), with the largest difference between baseline and 12 months T-score (AD-SOS; p= 0,001).

Conclusion: The result of our prospective, case controlled pilot study confirms the deleterious influence of chemotherapy on BMD in women with breast cancer. This effect could equally be observed by DXA and QUS for the first time in this regard. Further, large scale longitudinal studies are needed to improve our understanding of the mechanism of bone changes during chemotherapy.

Disclosures: ***M. Gottschalk****, None.*

SU091

c-Src Inhibition as a Possible Therapy against Human Breast Cancer and Bone Metastases. D. Fortunati[1], C. Di Giacinto*[1], I. Recchia*[1], M. Susa*[2], D. Fabbro*[2], A. Teti[1], N. Rucci[1]. [1]Department of Experimental Medicine, University of L'Aquila, L'Aquila, Italy, [2]Novartis Pharma, Basel, Switzerland.

The proto-oncogene c-Src plays a role in breast tumors, which are prone to metastasize to bone. We investigated whether c-Src inhibition could affect survival and bone metastasis incidence in vivo. Intracardiac injection of human breast cancer cell line MDA-MB231 treated with c-Src inhibitor CGP76030 into Balb-c nu/nu mice resulted in a delayed cachexia and lethality, relative to mice injected with untreated cells. A delay was more prominent in mice injected with MDA-MB231 cells followed by in vivo oral gavage treatment with 100 mg/Kg/day of CGP76030. In untreated mice, osteolytic bone metastases progressively increased, reaching 12.5% incidence at day 31 and 40% at day 36 post-injection. In treated mice no bone metastases were detacted until day 36, while at day 45 bone lesions reached 40% incidence. When mouse bone marrow cells were cultured with conditioned media (CM) from MDA-MB231 cells, a significant increase of TRAP-positive multinucleated osteoclasts and resorption pits was measured, suggesting a stimulation of osteoclast activity by paracrine factors from breast cancer cells, such as IL-6 and IL-1beta, whose mRNAs were expressed in MDA-MB231 cells. Osteoblast cultures treatment with MDA-MB231 CM resulted in a up-regulation of IL-6, IL-1beta and RANKL mRNAs, suggesting an indirect stimulation of osteoclastogenesis and bone resorption via the osteoblast lineage. Similar results were observed using CM from a MDA-MB231 clone stably transfected with c-SrcWT construct (MDA-SrcWT), which also induced down-regulation of the osteoclastogenesis inhibitory cytokine IL-12 in osteoblasts. c-Src inhibitor caused a concentration- and time- dependent reduction of MDA-MB231 cell proliferation, adhesion, spreading and migration through gelatin. Consistently, MDA-SrcWT cells showed increased migration and invasion vs. parental cells. This increase was not observed in MDA-MB231 transfected with c-SrcK296R/Y528F kinase-dead and dominant negative construct (MDA-SrcK296R/Y528F). Treatment with CM from MDA-SrcWT cells significantly increased proliferation of the human endothelial cell line EAHy926, relative to treatment with CM from MDA-MB231 and MDA-SrcK296R/Y528F cells, while migration and invasion were unaffected by all types of CM. In conclusion, we demonstrated a role for c-Src in (i) development of in vivo bone metastases, (ii) breast cancer cell growth, motility and osteoclastogenesis ability, and (iii) paracrine stimulation of endothelial cell activity. We, therefore, identify c-Src as a pharmacological target for treatment of breast cancer-induced bone metastases.

Osteonecrosis of the Maxilla and Mandible in Patients with Metastatic Breast Cancer. C. H. Van Poznak[1], C. L. Estilo*[2], T. Williams*[2], N. Sauter[1], C. Hudis*[1], S. Tunick*[2], J. M. Huryn*[2], J. Halpern*[2]. [1]Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Dental Service, Memorial Sloan-Kettering Cancer Center, New York, NY, USA.

Background: Intravenous bisphosphonates (IVBP) are potent inhibitors of osteoclast activity, and have been shown to decrease skeletal morbidity rate in patients (pts) with metastatic bone disease by approximately one third. IVBPs have become standard therapy for pts with skeletal metastases from various solid tumors and multiple myeloma. Osteonecrosis (ON) of the jaw has been reported in pts treated with IVBPs. It is postulated that bisphophonates cause avascular necrosis of the jaw due to an antiangiogenic effect. To estimate the incidence and define the clinical sequelae of ON of the jaw in pts with metastatic breast cancer (MBC) receiving therapy with either pamidronate or zoledronic acid (IVBP), we preformed a retrospective chart review.

Patients and Methods: The medical and dental records of all pts with MBC who were treated in the Dental Service of Memorial Sloan-Kettering Cancer Center (MSKCC) between 1/1/00 and 9/14/03 were reviewed. Pts who presented with exposed bone or ON of the maxilla or mandible and were previously treated with IVBP were further evaluated for clinical and pathological characteristics of cancer, duration of IVBP therapy, dental history and symptomatology as well as dental intervention rendered.

Results: During the study period, 13,143 doses of IVBP were administered to 934 pts. 64 pts with MBC treated IVBP were evaluated by the MSKCC Dental Service and 6 pts (0.6%) were found to have ON of the maxilla or mandible. The median age of pts with ON was 53.5 years (range: 27-66), median duration of IVBP therapy was 52.5 months (range: 6-94). 4 of 6 pts presented with symptoms. ON was noted in the maxilla in 2 and mandible in 4. 4 pts had a history of dental extraction in the region of ON. 2 pts presented with spontaneous ON. All pts were prescribed chlorhexidine rinse & 4 pts received antibiotics. Conservative treatment consisting of local debridement and sequestrectomy was performed in 4 pts; resolution was achieved in 1 patient.

Conclusions: IVBPs are an important and effective treatment for many pts with MBC; however, it may be associated with ON, as a rare complication. Our retrospective review identified 6 cases among 943 pts. The true incidence may be greater and the specific causes may be multifactorial. Contributing factors may include advanced cancer, chemotherapy, IVBP and steroid use, as well as comorbid conditions and lifestyle behaviors. Clinicians involved in the care of pts with MBC treated with IVBPs should be aware of the possibility of ON. The etiology and optimal management of ON of the jaw in MBC pts warrants study.

Comparison of Bone-derived Osteonectin and Breast Cancer-secreted Osteonectin; Reducing and Non-reducing Conditions Reveal Distinct Differences. D. A. Campo*[1], D. Sosnoski*[2], C. V. Gay[2]. [1]Intercollege Graduate Degree in Physiology, Penn State University, University Park, PA, USA, [2]Biochemistry and Molecular Biology, Penn State University, University Park, PA, USA.

Osteonectin has been described as a chemoattractant directing breast cancer cell and prostate cancer cell migration toward bone. In order for a substance to act as a chemoattractant, a diffusible gradient must form, thus luring a responsive cell toward higher concentrations. A paradox exists in that not only do osteoblasts secrete osteonectin, but so do vascular endothelial cells and breast cancer cells which colonize bone, potentially negating the formation of a gradient of osteonectin to which breast cancer cells could respond. We hypothesize that there are tissue dependent configurations of osteonectin such that the bone-derived form can exist as a gradient. Osteonectin was initially isolated by collection of conditioned media from two breast cancer cell lines (MDA-MB-435 and MDA-MB-468), from an osteoblast cell line (hFOB1.1) and from a bone-derived vascular endothelial cell line (HBME-1). Osteonectin was removed from conditioned media by affinity column purification using an anti-human osteonectin mouse monoclonal IgG (Haematologic Technologies, Essex Junction, VT) and a Pierce Aminolink® Immobilization kit. Immunoblots were prepared under reducing and non-reducing conditions. Under non-reducing conditions, osteonectin from the cancer cell lines appeared as doublets, ~ 41 and 38 kDa from the MDA-MB-435 cells and ~41 and 36 kDa from the MDA-MB-468 cells whereas under reducing conditions only a single band (~57 or 54 kDa, respectively) was evident. This phenomenon was not observed in osteonectin from bone and endothelial cells both of which display a single band under both non-reducing (~38 kDa) and reducing conditions (~53 kDa). These results suggest that breast cancer cells secrete two forms of osteonectin with different configurations of disulfide linkages whereas bone and endothelial cells secrete osteonectin with a single arrangement of disulfide links. Because disulfide bonds influence protein folding, at least one of the breast cancer-secreted types of osteonectin will have a different three-dimensional structure from the bone or endothelial-derived osteonectin. We conclude that there is structural variation due to the arrangement of disulfide links between bone-derived and breast cancer-derived osteonectin. The structural variation between osteonectin from indigenous and foreign cells at the site of bone metastasis supports the hypothesis that bone-derived osteonectin could form an attraction gradient and act as a chemoattractant even in the presence of breast cancer-derived osteonectin.

Interleukin-1 Expression in Human Breast Cancer Bone Metastasis: A Newly Recognized Pathway in Breast Cancer-induced Osteolysis. A. G. Pantschenko*[1], R. Naujoks*[1], R. H. Quinn*[2], M. Sanders*[3], G. Gronowicz*[1]. [1]Dept. of Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA, [2]Combined Hartford Hospital and CT Children's Hospital Orthopaedic Oncology Service, Hartford, CT, USA, [3]Dept. of Pathology, University of Connecticut Health Center, Farmington, CT, USA.

Bone metastasis in human breast carcinoma (HBC) occurs in 83% of patients with advanced disease. The pathophysiology of human breast carcinoma-induced osteolysis (HBC-IO) involves an increase in the number and activity of osteoclasts within the HBC metastatic lesion. These observations strongly support the involvement of cell-to-cell interactions and cytokine networks. We have recently demonstrated that the expression of the pro-inflammatory IL-1 family of cytokines and receptors correlates with disease severity and induction of pro-angiogenic and mitogenic cytokines (*e.g.* IL-8) in HBC primary tumor. Furthermore, IL-8, a product of HBC IL-1 stimulation, has recently been shown to have a greater correlation with HBC bone metastatic potential than PTHrP in the nude mouse.

Since IL-1 expression has been correlated with HBC aggressiveness and IL-1 is a known activator of osteoclasts, we examined the expression of the IL-1 family of cytokines and receptors in HBC-IO using archival human samples and immunohistochemistry. Samples from pathological fracture resection or biopsy of HBC metastasis from 16 patients (mean age, 52yrs; age range, 34-83yrs; no prior radiation to site; 14 samples from proximal femur) were obtained from the Dept. of Pathology, Hartford Hospital, Hartford, CT. and analyzed using the following antibodies; IL-1α, IL-1β, IL-1R1, IL-1R2, IL-8, CXC-R2, PTHrP, and anti-osteoclast antigen.

Thirteen of sixteen samples (81%) showed positive IL-1β tumor cell staining. Among these samples, the majority of tumor cells stained (82%). These thirteen samples were also positive for tumor cell staining of IL1-R1. Fifteen out of sixteen samples (94%) showed osteoclasts IL-1R1 staining. 14/16 showed positive staining of more than 50% of osteoclasts. 1/16 showed staining in 20-50% of cells and 1/16 sample showed no evidence of IL-1R1 staining of osteoclasts. This study supports the hypothesis that HBC tumor cell-induced osteolysis can be mediated through the HBC expression of IL-1 and the subsequent activation of osteoclasts via IL-1R1.

	IL-1β			**IL-1R1**		
	Number of (+) Samples	**Percent (+) Cells**	**Staining Intensity (0-3)**	**Number of (+) Samples**	**Percent (+) Cells**	**Staining Intensity (0-3)**
Tumor Cells	13/16 (81%)	82%	2.3	13/16 (81%)	62%	2.0
Osteoclasts	0/16 (0%)	0%	0	15/16 (94%)	74%	2.8

SU095

Smad3 Interacts with JunB and Cbfa1/Runx2 for Transforming Growth Factor-beta1-Stimulated Collagenase-3 Expression in Human Breast Cancer Cells. N. Selvamurugan, S. Kwok*, N. C. Partridge. Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA.

The specific characteristics of breast cancer cells and the unique properties of the bone/bone marrow microenvironment are largely responsible for the observed high frequency of skeletal metastases from breast cancer. A series of recent studies have indicated that collagenase-3 (matrix metalloproteinase-13) is overexpressed in a variety of tumors from diverse sources. Collagenase-3 is characterized by its ability to degrade the extracellular matrix (ECM) and is stimulated by TGF-β1 (which is enriched in bone matrix) in the human breast cancer cell line, MDA-MB231. Collagenase-3-driven extracellular matrix proteolysis may support cancer cell growth by exposing the cells to growth factors and cytokines, resulting in bone degradation (osteolysis). A greater understanding of the regulatory mechanisms that control collagenase-3 expression may provide several new avenues for therapeutic intervention. To understand the molecular mechanisms responsible for TGF-β1 regulation of the collagenase-3 promoter, a functional analysis of the promoter region of the collagenase-3 gene was carried out and we identified the distal RD (runt domain) and proximal RD/AP-1 (activator protein-1) sites as necessary for full TGF-β1-stimulated collagenase-3 promoter activity. Gel shift, real time RT-PCR and Western blot analyses showed increased levels of c-Jun, JunB, and Cbfa1/Runx2 upon TGF-β1 treatment in MDA-MB231 cells. Co-immunoprecipitation *in vitro* studies identified no physical interaction between JunB and Cbfa1/Runx2; whereas Smad3 interacted with both. Chromatin immunoprecipitation experiments confirmed interaction of Smad3 with JunB and Cbfa1/Runx2. Under basal conditions, Cbfa1/Runx2 bound to both the proximal RD/AP-1 and distal RD sites. In response to TGF-β1, Cbfa1/Runx2 was seen only at the distal RD site; whereas JunB occupied the proximal RD/AP-1 site. An assemblage of Smad3, JunB, and Cbfa1/Runx2 at the distal RD site of the collagenase-3 promoter occurred in response to TGF-β1 in MDA-MB231 cells. Co-transfection of Smad3, JunB, and Cbfa1/Runx2 constructs along with a constitutively active TGF-β type I receptor construct identified functional interaction of these proteins and transcriptional activation of the collagenase-3 gene by TGF-β1. Taken together, our results suggest that TGF-β1 stimulated JunB and Cbfa1/Runx2 to bind to their respective DNA consensus sites and Smad3 is likely to stabilize their interaction to confer functional TGF-β1-stimulation of collagenase-3 expression in MDA-MB231 cells.

Role of VEGF in the Prostate Cancer Bone Microenvironment. C. Muir*[1], D. Carson[1], L. W. K. Chung*[2], M. C. Farach-Carson[1]. [1]Department of Biological Sciences, University of Delaware, Newark, DE, USA, [2]Department of Urology, Emory University, Atlanta, GA, USA.

Prostate cancer preferentially metastasizes to bone where it exhibits osteoblastic features. Angiogenesis is important for tumor growth, and vascular endothelial growth factor (VEGF) family members, including VEGF-A and VEGF-C, play an important role in this process. Hypoxia exists at tumor sites as a consequence of poorly organized or absent vasculature. Our purpose was to examine the effect of culturing bone-targeted, metastatic C4-2B prostate cancer cells and HS27a bone stromal cells in hypoxic conditions on expression of VEGF family members. A sealed growth chamber infused with 1% or 20% O_2 and 5% CO_2 was used to culture cells in hypoxic or normoxic conditions. RT-PCR and commercially available ELISA kits were used to determine growth factor and growth factor receptor expression at both mRNA and protein levels. The bone stromal cells and the prostate cancer cells both produced high endogenous levels of VEGF-A, but little to no detectable levels of HB-EGF and HGF were measured using ELISA. HS27a bone stromal cells expressed high amounts of VEGF-C, whereas the C42B cells made none, and no change was observed after hypoxic culture. Under hypoxic conditions, the cells upregulated secreted isoforms of VEGF-A ($VEGF_{121}$ and $VEGF_{165}$), but levels of heparin binding isoforms ($VEGF_{189}$) did not change. A greater than 2-fold change in secreted VEGF-A was observed in both the HS27a and C42B cells when cultured in 1% oxygen compared to 20% oxygen. Similar changes in VEGF-A were seen at the mRNA level detected by RT-PCR, though the change was more significant in the C42B cells. The mRNA was increased before day two during culture in 1% oxygen, but secreted protein began to change at day two and increased through day six. Treatment with 30ng/ml of $VEGF_{165}$ did not change mRNA levels of VEGF-A by C42B in either normoxic or hypoxic conditions, though C4-2B cells made low levels of VEGFR2, flk-1, and showed a moderate growth response to 30ng/ml of $VEGF_{165}$. Receptor expression levels were not changed during culture in 1% O_2. HBME, human bone marrow endothelial cells, express very high levels of flk-1 and are recruited for neovascularization of the hypoxic growing tumor within the bone environment. We conclude that culture in 1% O_2 causes a physiologically relevant increase in VEGF at mRNA and protein levels by prostate cancer and bone marrow stromal cells, and that this involves a paracrine loop that is likely to recruit bone marrow endothelial cells and support neovascularization.

Bisphosphonates Suppress the Mitogenic Effects of Bone-derived Growth Factors on Prostate Cancer Cells. N. Kheddoumi*[1], F. Journé*[1], L. Lagneaux*[2], J. C. Dumon*[1], J. J. Body[1]. [1]Laboratory of Endocrinology and Bone Diseases, Institut Jules Bordet, Brussels, Belgium, [2]Laboratory of Hematology, Institut Jules Bordet, Brussels, Belgium.

Insulin-like growth factor-1 (IGF-1) is a principal growth factor released from the bone matrix resulting from tumor-induced osteolysis, and IGF-1 is a powerful mitogen for prostate carcinoma cells. Bisphosphonates are potent inhibitors of osteoclast-induced osteolysis and are being evaluated as adjunctive therapy for the prevention of bone metastasis. Moreover, they were recently shown to induce prostate cancer cell apoptosis in vitro. In the present study, we have investigated the effects of bisphosphonates on the in vitro proliferation of PC-3 prostate cancer cells in the presence of IGF-1. PC-3 cells were cultured for 1 to 6 days in growth factor-free media with 1 to 100 µM zoledronic acid (Zol) or clodronate (Clod) with or without 100 ng/mL IGF-1. Cell growth was evaluated by crystal violet staining. Apoptotic cell death was assessed using annexin V / propidium iodide double staining. IGF-1 increased PC-3 cell growth by 23 ± 7% (mean ± SEM) at day 6 ($P < 0.001$). At 1 µM, Zol alone did not affect cell growth but completely abolished the mitogenic effects of IGF-1. At 10 µM, Zol inhibited cell proliferation whether IGF-1 was present or not, and 100 µM Zol induced a marked decrease in cell number (to 15% of baseline at day 6). Moreover, 100 µM Zol induced apoptosis in PC-3 cells whether IGF-1 was present or not. In contrast, 1 µM Clod did not inhibit cell growth nor abolish the stimulatory effects of IGF-1. At 10 µM, Clod did not affect cell growth alone but inhibited the mitogenic actions of IGF-1, and 100 µM Clod weakly inhibited cell proliferation with or without IGF-1. Clod did not induce apoptosis even at the highest concentrations. In conclusion, bisphosphonates inhibit the mitogenic effects of IGF-1 on prostate cancer cells, at 1 µM for Zol and 10 µM for Clod. At these concentrations, they had no effect on cell proliferation. At higher concentrations, bisphosphonates inhibit PC-3 cell growth in the presence or absence of IGF-1. Zol was more potent than Clod, and induced apoptosis of prostate cancer cells at the highest concentration. The growth inhibition achieved by Zol in the presence of IGF-1 may contribute to beneficial effects in the treatment of prostate cancer-induced bone disease. We are currently evaluating the effects of other bone-derived growth factors, such as basic Fibroblast Growth Factor, under similar conditions.

Inhibition of Growth of Breast Cancer Cells by Low-Dose Risedronate. F. H. Ebetino[1], L. Witters*[2], A. Lipton*[2]. [1]New Drug Development, Procter & Gamble Pharmaceuticals, Mason, OH, USA, [2]The Milton S. Hershey Medical Center, Pennsylvania State University, Hershey, PA, USA.

Risedronate (RIS) is a third generation nitrogen containing bisphosphonate (N-BP) used to prevent and treat postmenopausal and steroid-induced osteoporosis. Treatment of human breast cancer cell lines with RIS (1-20 µM) resulted in dose-dependent growth inhibition (MCF-7: IC50 = 6 µM; HER-2/neu transfected MCF-7: IC50 = 11 µM) These levels of RIS are not achievable in the plasma of patients receiving RIS. Bisphosphonates bind avidly to hydroxyapatite (HA), the major inorganic constituent of bone. The purpose of this study was to assess the effects of RIS bound to hydroxyapatite on the growth of breast cancer cells. MCF-7 cells were grown on HA wafers pretreated with 0.5 µM or 20 µM of RIS. Cells were also grown on HA wafers not pretreated with RIS but where RIS was added after attachment. Growth effects under these conditions were compared to the effects of RIS in culture media in 24 well plates. Cell number was determined by the colorimetric MTT tetrazolium dye assay after a 3 day exposure to RIS. MCF-7 cells grown in culture media were inhibited by 20 µM RIS (78%) or conditioned media from HA wafers pretreated with 20 µM RIS (71%). HA wafers pretreated with 20 µM RIS also inhibited cell growth but to a lesser extent (41%). MCF-7 cells were not inhibited by 0.5 µM RIS in culture media (7%) nor conditioned media from HA wafers pretreated with 0.5 µM RIS (4%). HA wafers pretreated with 0.5 µM RIS, however, inhibited MCF-7 cell growth by 29%. Also, when 0.5 µM RIS was added after cell attachment to the non pretreated HAP wafers, similar inhibition of proliferation was noted as with the pretreatment conditions. Thus, high doses (20 µM) of the N-BP, risedronate, produced antiproliferation of MCF-7 breast cancer cells in culture media, in conditioned media from HA wafers pretreated with 20 µM RIS, and to a lesser extent on the HA wafers pretreated with 20 µM RIS. Low doses (0.5 µM) of RIS caused negligible growth inhibition when added to culture media or in the conditioned media from HA wafers pretreated with 0.5 µM RIS. The 0.5 µM RIS pretreated HA wafers, however, had the ability to inhibit MCF-7 cells suggesting that interactions of tumor cells with bone may magnify the effectiveness of N-BPs beyond what may be expected from their serum concentrations.

Cell-surface Carbohydrate Expression Supports Breast Cancer Colonization of Bone. J. Stanley*, M. Bendre, J. Cárcel Trullols*, S. Shaaf,*, R. Saha*, T. Kieber-Emmons*, L. J. Suva. Orthopaedic Surgery, Pathology and Arkansas Cancer Research Center, UAMS, Little Rock, AR, USA.

It has been suggested that distinct tumor cell phenotypes are required for the establishment of metastatic lesions in different organs. These metastatic phenotypes include changes in carbohydrate expression profiles that have been postulated to improve survival of the tumor cell in the circulation, allow adhesion of tumor cells to target organs and facilitate positive interactions within the microenvironment of the target organ. The variability of carbohydrate sequences, which cell surfaces can present to endogenous lectins, adhesion molecules, and other receptors, creates a refined pattern of potential sites for interactions between a tumor cell and its surrounding microenvironment. In an effort to identify patterns of carbohydrate expression that correlate with bone-specific tumor growth, the cell surface carbohydrate profile displayed by osteotrophic MDA-MET cells was compared with parental MDA-231 cells. The differences in cell surface glycosylation between MDA-MET and parental MDA-231 cells were identified using 14 plant lectins and 4 carbohydrate specific mAb's by flow cytometry and lectin blots. By FACS, MDA-MET cells demonstrated increased binding of SNA, ECL and PHA lectins as well as 19-9 mAb, relative to MDA-231, demonstrating that MDA-MET cells display increased alpha 2,6 sialylation prodcucts. There was also an increase in unsubstituted terminal N-acetyllactosamine structures (ECL) and complex branched structures (PHA) in MDA-MET. FACS analyses were confirmed by Western blot. Microarray analysis (Affymetrix) indicated that the expression of several galactosyltransferase genes responsible for these carbohydrate modifications also correlated with lectin and antibody binding profiles. PCR amplification of human specific DNA from several tissues confirmed the bone-selective distribution of the MDA-MET cell micrometastasis in mice *in vivo*; MDA-MET "seed" but do not produce tumors within non-bone sites. The incubation of MDA-231 or MDA-MET cells with bone marrow-derived cells *in vitro* demonstrated a selective advantage for MDA-MET cell proliferation. This marrow-enhanced tumor cell proliferation was also seen *in vivo*, where unlike MDA-231 cells, MDA-MET form large tumors following tibial implantation. These data suggest that the differences observed in the carbohydrate signatures of MDA-MET cells play a role in the bone-specific colonization and growth in the marrow of this aggressive cell line. Further studies are ongoing to identify the roles of individual proteoglycans that may participate in the formation of secondary tumor growths of breast cancer in bone.

NF-kB and not p38 MAPK Is Essential for Bone Resorbing Factor Production by Breast Cancer Cells. C. Menaa, M. Corr*, C. Froelich*, S. Sprague. Medicine, Evanston Northwestern Healthcare Northwestern University, Evanston, IL, USA.

Bone metastases are a frequent complication in patients with advanced breast cancer (BC). This is related to the process by which tumor cells metastasize; that involves adhesion, migration, and induction of osteoclast (OC) formation. How tumor cells acquire these capacities and the mechanisms involved are not yet identified. However, it is known that tumor cells are the source for expression and secretion of factors involved in bone metastasis, such as MMP9, uPA, and more importantly bone resorbing factors (BF).

Previous studies have highlighted the role of NF-κB and p38 MAPK (p38) as potential signaling pathways critical for BC cell viability. Specifically, NF-κB has been reported to be responsible for cell transformation, death resistance, and motility. However, p38 has been linked to the expression of factors critical for cell invasiveness and PTHrP production. In addition, constitutive activity of both signaling pathways has been recorded in BC cells, and the degree of activation positively correlates with cell`s aggressiveness, suggesting that NF-κB and p38 could be responsible for induction and progression of BC. Since stimulation of OC formation is critical for bone metastasis, the role of NF-κB and p38 in BF production by BC cells was examined. Initially stable BC cell lines which over-express the inactive kinase (DN) p38 MAPK (T189/A-Y191/F) were established and demonstrated

that the DN suppresses p38 MAPK activation even following TNF-α stimulation. MDA-MB-231 or MCF-7 cells deficient in p38 activity are still able to support OC formation in RAW 264.7 cells and mouse bone marrow suggesting that p38 activity is not involved in BF production by BC cells. However, the inhibition of NF-κB activity following the over-expression of the super-repressor IκB (S32/A-S34/A) in BC cells totally blocks NF-κB and the capacity of these cells to support OC formation. Further analysis demonstrated that IκB-kinase (IkK) complex is critical for NF-κB activity and expression of BF as well. While the inhibition of IkK-α or β alone has no effect, the overexpression of the regulatory subunit, the IkKγ, totally abolishes NF-kB activity of BC cells, and subsequently their capacity to support OC formation. In summary, we found that while p38 might be critical for some fundamental aspects of BC cells, its constitutive activity is not responsible for BF production. In contrast, NF-κB signaling pathway, specifically the IκK complex, is essential for both constitutive activation of NF-κB and expression and secretion of BF in BC cells. In conclusion, these data establish the role of NF-κB in bone metastasis in BC. Thus, NF-κB could be a suitable therapeutic target for bone destruction in BC.

Bone Loss after Chemotherapy in Women with Early Breast Cancer. M. M. Pinheiro*[1], A. R. Siniscalchi*[2], S. M. T. Carvalho*[3], H. J. Rigon*[2], M. Mourao Netto*[3], V. L. Szejnfeld[1]. [1]Rheumatology, Unifesp, Escola Paulista de Medicina, Sao Paulo, Brazil, [2]Medicine Interne, Hospital do Cancer A C Camargo, Sao Paulo, Brazil, [3]Breast's surgery, Hospital do Cancer A C Camargo, Sao Paulo, Brazil.

Our aim was evaluate the impact of the chemotherapy (CT) on bone mineral density (BMD) and quantitative ultrasound (QUS) parameters in patients with early breast cancer (EBC). One-hundred sixty two women were enrolled in this study (62 with EBC and 100 healthy controls matched for age, body mass index and menopausal status). Patients with history of other cancers, previous CT or metastatic disease were excluded. Spine and femur BMD were performed using DXA (Lunar, DPX) and calcaneus QUS was done using Achilles plus (Lunar). Fifty-four (87.1%) EBC patients and 83 (83%) healthy controls completed a 10-month follow-up. Mean age, height, weight and BMI for EBC patients were 52.1 ± 10 years, 68.2 ± 14.3 kg, 1.57 ± 0.7 m and 27.6 ± 5.4 kg/ m2, respectively. Twenty (43.5%) EBC patients were pre-menopausal and six (13%) had previous atraumatic fracture. CT protocols used were [fluorouracil, doxorubicin, cyclophosphamide] (71.7%) or [cyclophosphamide, methotrexate, fluorouracil] (28.3%) with mean cycles of 5.8 ± 1.8 and 7.7 ± 2.1, respectively. At baseline, EBC patients had BMD and QUS measurements 5% higher than healthy controls. After CT (8.5 ± 2.7 months), EBC patients had significantly lower BMD (2%) and QUS (3.2%) measurements as compared to healthy controls. No new fractures were detected during the follow-up. In conclusion, CT affects negatively bone mass and can be a potential risk factor for fracture in EBC patients.

MRI Mapping of the Degree of Bone Mineralization. Y. Wu*[1], J. L. Ackerman*[2], L. Graham*[1], M. Glimcher[1]. [1]Orthopaedic Surgery, Children's Hospital, Boston, Boston, MA, USA, [2]Radiology Department, Massachusetts General Hospital, Boston, MA, USA.

The degree of bone mineralization (DM), is defined as the weight of bone mineral in a unit volume of bone matrix. It can be expressed as the ratio of bone mineral density (BMD) divided by the bone matrix fraction factor. DM is a crucial parameter for bone quality, because it modifies the elastic modulus of the matrix material.

The ^{31}P NMR signals of bone mineral and some fraction of the ^{1}H NMR signals of bone matrix can be imaged by solid state projection magnetic resonance imaging (SMRI). Our previous study has shown that ^{31}P solid state MRI (SMRI) measurement of BMD was feasible. In this current study, quantitative water and fat suppressed ^{1}H projection MRI (WASPI) measurement of bone matrix fraction factor was performed in a Bruker 4.7T scanner. Combined ^{31}P/^{1}H MRI was performed using a double tuned coil in the Bruker 4.7T scanner.

Table 1 shows the bone matrix fraction factor measured by ^{1}H WASPI and gravimetry. Comparing the data of MRI and gravimetry, these results look very promising.

Figure 1A and B show corresponding slices of ^{31}P SMRI and ^{1}H WASPI of a bovine cortical bone specimen. A preliminary mapping of the degree of bone mineralization is obtained by dividing the ^{31}P image intensity by the proton image intensity pixel by pixel (Figure 1C).

Our study results demonstrate that measurement of matched ^{31}P SMRI and ^{1}H WASPI images of bone specimens is feasible, which would lead to the measurement of bone mineralization if ^{31}P and ^{1}H intensity are converted to BMD and bone matrix fractor respectively.

Table 1 Bone matrix fraction factor determined by ^{1}H WASPI and gravimetry (*all specimens were from the same bone)

	Bovine trabecular 1*	Bovine trabecular 2*	Bovine trabecular 3*	Bovine trabecular 4*

Comparison of Radiographic Absorptiometry (RA) and DXA in a Postmenopausal Middle Eastern Population. A. Ghasemzadeh*[1], N. Bayat*[2], G. Ali Shiri*[3], S. Hosseini M.*[4], E. P. Boling[5]. [1]Medical Physics, Research Center for Sciences and Technology in Medicine, Tehran, Iran (Islamic Republic of), [2]Rheumatology Dept, Baghayatallah Hosp.Baghayatallah Medical scineces University, Tehran, Iran (Islamic Republic of), [3]Rhumatolgy Dept., Baghiaitallah Hospital,Baghiaitallah Medical Science university, Tehran, Iran (Islamic Republic of), [4]Baghayatallah Medical scineces University, Baghayatallah Hosp., Tehran, Iran (Islamic Republic of), [5]Loma Linda University, Loma Linda, CA, USA.

Limited availability of DXA can delay or prevent diagnosis of osteoporosis in Middle Eastern women. A correlation study was therefore conducted in post-menopausal Middle Eastern females comparing peripheral bone mineral density (BMD) measured by RA to axial BMD measured by DXA. Data analysis showed good correlation between peripheral and axial BMD measurements.

33 postmenopausal Iranian women aged 45 to 74 years were seen at the BMD center of Baghayatallah Hospital, Tehran, Iran from November 2003 to January 2004 and were considered for this study. Those with secondary causes of osteoporosis were excluded. The mean age of the study participant was 57.9 + 7.7 years.

Peripheral BMD was measured by automated Osteogram (CompuMed, Inc; Los Angeles, CA) using radiographic absorptiometry (RA), a technique which measures BMD of 3 middle phalanges using 2 view, non-dominant hand X-rays taken with an adjacent aluminum reference wedge. Axial BMD of hip and L2-L4 spine was performed using a Norland XR-36 densitometer (Fort Atkinson, WI).

Pearson correlation coefficients between RA BMD of the middle phalanges and DXA BMD of the spine and femoral neck were 0.77 and 0.80 respectively. In comparison, Pearson between DXA BMD of the spine and DXA BMD of the femoral neck was 0.84. The correlation between RA BMD and the two DXA BMD assessments is considered statistically significant per kappa score definitions. In addition, it is comparable to the correlation between the two DXA BMD assessments at 0.84.

Osteogram measured BMD may be a cost effective and more readily available alternative to axial BMD for the diagnosis of osteoporosis in postmenopausal Middle Eastern women.

SU104

Effect of Urbanization on Bone Mineral Density; A Comparative Study. C. Pongchaiyakul*[1], T. V. Nguyen[2], V. Kosulwat*[3], R. Rajatanavin*[4]. [1]Department of Medicine, Division of Endocrinology, Khon Kaen, Thailand, [2]Department of Medicine, Garvan Institute of Medical Research, Sydney, Australia, [3]Institute of Nutrition, Salaya campus, Division of Endocrinology, Nakonprathom, Thailand, [4]Department of Medicine, Division of Endocrinology, Bangkok, Thailand.

A cross-sectional study was designed to examine the difference in bone mineral density (BMD) between urban and rural Thai populations. Femoral neck and lumbar spine BMD was measured by DXA in 411 urban and 436 rural subjects (340 men and 507 women), age between 20 and 84 years. After adjusting for age and body weight, femoral neck BMD in rural men and women was significantly higher than those in urban men and women ($P <$ 0.001), but the difference was not observed at the lumbar spine. In the entire sample, rural subjects had a higher cross-sectional "rate of bone loss" than urban subjects, particularly at the femoral neck. As a result, among those aged 50^{+} years, BMD in rural subjects tended to be lower than (or converged to) BMD in urban subjects. After stratified by sex, age group, and BMI category, the urban-rural difference in femoral neck BMD became more pronounced in the younger age group (< 50 years old) and higher BMI (≥ 25 kg/m^2) in both men and women. This data suggest that femoral neck BMD in rural men and women was higher than their counterparts in urban areas. This difference could potentially explain the urban-rural difference in fracture incidence.

Contribution of Lean Tissue Mass to the Urban-Rural Difference in Bone Mineral Density. C. Pongchaiyakul*[1], T. V. Nguyen[2], J. A. Eisman[2], R. Rajatanavin[3]. [1]Division of Endocrinology, Department of Medicine, Faculty of Medicine, Khon Kaen University, Thailand, [2]Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, [3]Division of Endocrinology, Department of Medicine, Mahidol University, Thailand.

While the urban-rural difference in bone mineral density (BMD) has been well established, the reason for the difference is largely unknown, particularly in developing countries. This cross-sectional, epidemiologic study was designed to examine the hypothesis that measures of body composition such as lean mass (LM) and fat mass (FM) contribute to the urban-rural difference in BMD. The setting was in Bangkok city and Khon Kaen province. Lumbar spine and femoral neck BMD, LM and FM were measured by dual-energy X-ray absorptiometry in 411 urban and 436 rural Thai subjects, aged 20-84 years. The results showed that rural subjects had significantly higher BMD, higher LM and lower FM than urban subjects. In multiple linear regression analysis, LM, but not FM, was an independent predictor of BMD in both men and women. When the two groups were matched for FM, rural subjects with higher LM were associated with a 4.4percent to 7.2percent higher BMD than urban subjects. However, when the two groups were matched for LM, rural subjects with higher FM did not have higher BMD than those in urban areas. In match-pair regression analysis, the urban-rural difference in LM explained approximately 23percent and 5percent of the urban-rural difference in femoral neck BMD in men and women, respectively. These data are consistent with the hypothesis that the association between BMD and body composition is mediated mainly through lean mass, and that the urban-rural difference in BMD could be explained in part by the urban-rural difference in lean mass.

Assessment of Cortical Bone Mineral Density by Peripheral Quantitative Computed Tomography in Children: Impact of Partial Volume Effects. L. W. Kibe*, B. S. Zemel, M. B. Leonard. Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, USA.

DXA measures of areal-bone mineral density (aBMD) are confounded by bone size. Peripheral quantitative computed tomography (pQCT) is purported to estimate volumetric BMD (vBMD) independent of bone size. However, as a consequence of incomplete filling of voxels at the bone edges (partial volume effects), cortical vBMD is underestimated in thinner bones, potentially confounding results in children with poor growth or thin bones. The objective of this study was to evaluate pQCT estimates of cortical vBMD as a function of bone thickness in healthy children and adolescents.

Methods: PQCT (Stratec XCT-2000; voxel size 0.4 mm) scans of the left tibia were obtained at the 38% site in 140 subjects, at the 20% site in 147 subjects and at both sites in 15 subjects, ages 5 to 19 yr. Cortical bone was identified at a threshold of 710 mg/cm^3, and cortical vBMD (CORT-vBMD) was determined as the mean vBMD over the entire cortical bone in the slice. In order to isolate a region of cortex with completely filled voxels, a 2 x 2 voxel region of interest (ROI) was manually centered between the endosteal and periosteal envelope at the thickest region of the cortex, and vBMD was measured (ROI-vBMD). Test-retest precision for ROI-vBMD was performed in 30 subjects: the CV was 2.6%.

Results: The mean ($\pm$ SD) cortical thicknesses (mm) at the 38% and 20% sites were 5.1 $\pm$ 0.9 (range 3.1 - 7.8) and 3.1 $\pm$ 0.7 (range 1.6 - 5.4), respectively. In the 15 subjects with both 20% and 38% scans, CORT-vBMD was significantly greater at the 38% compared with 20% site (1098 $\pm$ 52 vs. 1075 $\pm$ 63 mg/cm^2, p=0.001) but ROI-vBMD did not differ between sites (1176 $\pm$ 60 vs. 1180 $\pm$ 70, p=0.79). In the 140 subjects with 38% scans, CORT-BMD was significantly less than ROI-vBMD (1097 $\pm$ 54 vs. 1176 $\pm$ 81, p< 0.0001), consistent with partial volume effects. The difference between CORT-vBMD and ROI-vBMD did not vary as a function of cortical thickness. In contrast, in the 147 subjects with scans at the 20% site, the differences between CORT-vBMD and ROI-vBMD were more pronounced (1065 $\pm$ 55 vs. 1180 $\pm$ 59, p< 0.0001), and the difference (ROI-vBMD - CORT-vBMD) was negatively correlated with cortical thickness (p< 0.0001). That is, CORT-vBMD underestimated vBMD to an even greater degree in thinner bones.

Conclusion: pQCT measures of vBMD are subject to greater partial volume effects at the thinner 20% site. The partial volume effects are minimized through application of a discrete ROI which provides a measure of vBMD comparable to values obtained at the thicker 38% site. These effects are likely even greater in the thinner radius, another site commonly studied in pediatric pQCT applications.

An Evaluation of DXL Calscan Reproducibility. L. I. M. Toft[1], T. B. Brismar*[2]. [1]Merck, Sollentuna, Sweden, [2]Center for Surgical Sciences, Division of Radiology, Karolinska Institutet, Stockholm, Sweden.

The standard technique to measure spine and hip is rather expensive and requires skilled staff to provide accurate measurements. Techniques cheaper and easier to use have therefore been developed. Such a technique is dual X-ray and laser of calcaneus (DXL). The method combines DXA with laser technology. Theoretically the technique will obtain a more accurate BMD value as the laser enables a measurement of heel thickness making it possible to base the calculations on a three-compartment-model (fat, lean and bone).

We have evaluated short and long term reproducibility of DXL Calscan as well as the agreement between 4 individual units. The variation in BMD and T-score between the right and the left foot in a clinical material has also been studied retrospectively.

Short term reproducibility and agreement between individual units;

19 individuals aged 46 +/- 12 years were scanned twice on each of four DXL Calscan (Demetech, Stockholm, Sweden) units. All individuals were measured 8 times resulting in a total of 152 measurements. The difference between all 4 scanners was significant. The short term CV% for all measurements on all scanners was 2.1% and the average CV% per scanner ranged from 1.1% to 1.8%.

Long term reproducibility

The left foot was measured in one female volunteer aged 32 years at 13 occasions during 13 months. The average BMD was 400 mg/cm^2 with a CV% of 1.3%.

Variation in BMD and T-score between the right and left foot:

The right and left calcaneus was measured in 334 individuals (18 males and 316 females) under clinical suspicion of osteoporosis. There was no statistical difference in average BMD of the right and left foot (309 mg/cm^2 and 313 mg/cm^2 respectively). The squared correlation coefficient (r^2) between the right and left side was 0.92.

Conclusion

The observed difference between the units emphasis the importance of always using the same unit for follow-up studies. The observed average difference between individual units was however small (equivalent to 0.13 T-score) and should only be of minor importance in the epidemiological perspective. Both short and long term reproducibility of the equipment was good. We conclude that the Demetech DXL Calscan has a good potential for epidemiological studies.

Osteoporosis in Chinese American Women: Development of a Bone Densitometry Database. M. A. Donovan[1], A. Opotowsky*[1], R. Babbar*[2], F. Nabizadeh*[2], M. Della Badia*[1], D. McMahon*[1], G. Liu*[2], J. P. Bilezikian[1]. [1]Medicine, College of Physicians and Surgeons, Columbia University, New York, NY, USA, [2]Medicine, NYU Downtown Hospital, New York, NY, USA.

Asian women have been shown to have lower bone mineral density (BMD) than Caucasian women. Despite this, studies in Asia and the USA suggest that Chinese women have a lower hip fracture rate than Caucasian women. The relationship between BMD and fracture risk, therefore, may differ for Caucasian and Asian women, an observation that may have implications for diagnosis and treatment of osteoporosis. The purpose of this study is threefold: (1) to develop a referent BMD database among Chinese American women; (2) to establish a relationship between BMD and fracture risk in this population; (3) and to compare these data to information for Caucasian women in the USA and Chinese women in China. Four hundred Chinese American women, living in New York City, ages 20 to 90, are being recruited. Along with DXA of the total hip (TH) and lumbar spine (LS), demographic, familial, nutritional, behavioral, and attitudinal features are being obtained using a bilingual questionnaire. The project also includes a case-control comparison of patients who will have sustained a hip fracture. To date, 356 women have been recruited. Preliminary data in this Chinese American population suggest that mean BMD values are lower at the TH for the decades beginning at ages 20 (.899±.109 *vs* .942± .122g/cm^2, p=.02), 30 (.897±.103 *vs* .939±.122g/cm^2, p=.06), 40 (.906±.129 *vs* .922±.122 g/cm^2, p=.02) and 50 (.809±.120 *vs* .886±.122 g/cm^2, p=.02), but not for those at 60, 70, or 80 compared to NHANES III values for Caucasian women. Similar findings are apparent for mean LS BMD values compared to the Hologic Caucasian female BMD database. In addition, peak BMD in Chinese American women is lower at the TH (.906±.129 *vs* .942±.122g/cm^2, p<.0001) and LS (1.013±.126 *vs* 1.047±.11g/cm^2, p<.0001) compared to Caucasian women and was not achieved until the fifth decade (ages 40-49). When we used this newly established Chinese American database, the osteoporosis detection rate in our Chinese American cohort ≥ age 50 was 51% lower than when we used the Hologic Caucasian database (p<.001). If fracture risk is considered in relation to peak BMD for a specific population, and not BMD in absolute terms (g/cm^2), then use of a Caucasian reference for diagnosis of osteoporosis would lead to an overestimate of fracture risk among Chinese Americans. These observations may explain apparent discrepancies between T-scores and fracture incidence among Chinese Americans. This study provides, for the first time, a race and geographically-specific BMD database that has direct clinical relevance to a Chinese American population.

DXA Bone Mineral Density (BMD) Measurements of the Proximal Femur: Clinical Value of Bilateral Hip Determinations and in the Location of the Region of Interest of the Femoral Neck. M. T. DiMuzio. The North Shore Osteoporosis Center, Deerfield, IL, USA.

Hip fracture is the most critical skeletal site in which to monitor fracture risk. DXA, is the gold standard for determining BMD and its sensitivity and accuracy have long been established as the principal risk factor for ranking a patient's skeletal health. However, the differences in skeletal structure and organization as well as location leads to differences in a given patients BMD values throughout the skeleton. This skeletal discordance must be taken into account when evaluating a patient for fracture risk and osteoporosis.

This study uses DXA to measure the BMD of the hip and shows: 1) the BMD of the femoral neck region is critically sensitive to location, and 2) the bilateral measurement of hip BMD is essential in determining a patients risk for hip fracture.

Patients were referred for a bone density test. Of the 350 subjects in the study, no preference for age, weight or WHO category of fracture risk was used to select patients for inclusion. 95% of the group were caucasian women, 5% were caucasian men. Each bone density test was performed using a Hologic QDR4500A.

Regions of Interest (ROI): BMD measurements of the femoral neck ROI were made along the neck beginning at greater trochanter and moving toward the head of the femur. BMD was determined at equal increments along the neck and showed a consistent increase for all patients. For the 350 patients examined, the average change in BMD from the edge of the greater trochanter to the central neck region was a 7.6% increase in BMD.

Bilateral Hip BMD: There were no patients found with identical BMD measurements of the right and left femur. The differences between right and left hips and the Total Hip and Femoral Neck BMD measurements were between 0.5% and 12% and 1% and 8%, respectively.

CONCLUSIONS: In all patients examined, the BMD increased as one moved from the edge of the greater trochanter toward the head of the femur. Since fracture risk increases with decreasing BMD, it is critical to measure to where the BMD is lowest in the femoral neck: along the edge of the greater trochanter. The use of handedness or other patient specific factors to assume hip dominance proved to be an insensitive means to monitor BMD of the hip. It is suggested and apparent from these results that both hips should be monitored and that the lowest valued hip (the hip at highest fracture risk) be used to follow future changes in BMD.

An Evaluation of the Revised United Kingdom National Osteoporosis Society Position Statement on the use of Peripheral X-ray Absorptiometry. R. Patel, E. Panayiotou*, G. Blake, I. Fogelman. Osteoporosis Research Unit, Guy's King's and St Thomas' School of Medicine, London, United Kingdom.

In a recent revision of its position statement on the clinical use of peripheral X-ray absorptiometry (pDXA), the United Kingdom National Osteoporosis Society (NOS) recommended a triage approach to the interpretation of peripheral measurements based on setting device specific upper and lower thresholds with 90% sensitivity and 90% specificity for identifying patients with osteoporosis at the hip or spine. For patients with a pDXA measurement either below the lower threshold or above the upper threshold, the decision whether or not to offer treatment is made without reference to an axial DXA examination. However, patients with a pDXA result between the two thresholds are recommended to have an axial DXA measurement to obtain a definitive diagnosis of osteoporosis. In this study we examined the practical implications of the NOS triage algorithm based on theoretical calculations using a bivariant Gaussian model. The predictions were compared with data from clinical studies using the Osteometer DTX200 and Schick AccuDEXA devices. The calculations predict that for a population of white women with a mean age of 60 y and for peripheral versus axial BMD correlation coefficients of $r = 0.2$, 0.4, 0.6 and 0.8 the percentages of patients requiring an axial DXA examination are 72%, 60%, 41% and 17% respectively. These predictions were compared with data from a study of 393 white women aged 55 to 70 y (mean age 62.5 y) who had spine and hip DXA followed by a forearm pDXA measurement on the DTX200. The device specific upper and lower thresholds were DTX200 T-scores of -1.4 and -2.6 respectively. Application of the NOS pDXA triage algorithm would result in 39% of women being sent for axial DXA, while for the observed correlation coefficient between hip and forearm BMD ($r = 0.65$) the model predicted 36%. In the second clinical study 300 white women aged 55 to 70 y (mean age 62.6 y) had spine and hip DXA followed by a finger pDXA measurement on AccuDEXA. The device specific upper and lower thresholds were AccuDEXA T-scores of +0.1 and -1.6 respectively. Application of the NOS pDXA triage algorithm would result in 44% of women being sent for axial DXA, while for the observed correlation coefficient between hip and finger BMD ($r = 0.58$) the model predicted 43%. We conclude that in practice for correlation coefficients around $r \approx 0.6$, the NOS pDXA triage algorithm requires sending about 40% of patients for hip and spine DXA.

Gender Differences in Areal Bone Mineral Density (aBMD) Represents the Difference in Bone Size rather than in True Volumetric Bone Mineral Density (vBMD). B. Kim[1], J. Son*[2], G. Kim*[1], S. Kim*[3], D. Lee*[3]. [1]Family medicine and Community health, Ajou University College of Medicine, Suwon, Republic of Korea, [2]Family medicine, Eulji hospital, Seoul, Republic of Korea, [3]Family medicine, Samsung cheil hospital, Seoul, Republic of Korea.

We investigated how bone structure influences gender difference in aBMD in Korean adults. 183 men and 183 women, who attended periodic health examination program at the health promotion center at Ajou university hospital from Jan. 2001 to Dec. 2002, were enrolled for this study. We measured bone width, height, bone mineral content (BMC) and aBMD by dual energy absorptiometry (DEXA) and calculated bone volume and vBMD by Carter's method at the third lumbar vertebra. Height, width and volume of L3 vertebra were larger in men than in women, respectively (3.62±0.202cm vs 3.39±0.176cm, 5.02±0.336cm vs 4.42±0.271cm, 77.67±11.009cm^3 vs 58.34±7.733cm^3, all $p<0.001$). BMC and aBMD of the vertebra were also larger in men than in women, respectively (20.50±3.822g vs 15.68±3.178g, 1.13±0.173g/m^2 vs 1.05±0.197g/m^2, all $p<0.001$). However, BMC adjusted by bone volume, true BMD (vBMD) shows no difference between both genders (men; 0.27±0.042cm^3/g, women; 0.27±0.054cm^3/g, P=0.31). Bone mass and Bone size are larger in men than in women while true BMD in men is in consistency with that in women. Higher aBMD in men accounts for bigger bone size in men rather than true BMD.

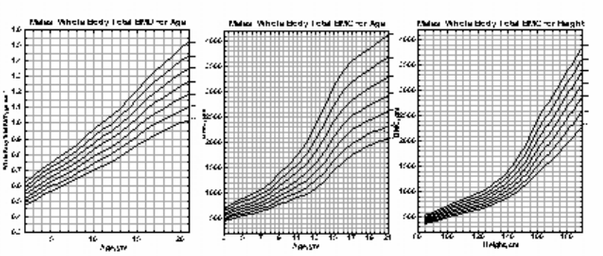
Reference Data for the Whole Body, Lumbar Spine and Proximal Femur for American Children Relative to Age, Gender and Body Size. B. S. Zemel[1], M. B. Leonard[2], H. J. Kalkwarf[3], B. L. Specker[4], L. J. Moyer-Mileur[5], J. A. Shepherd[6], T. J. Cole*[7], H. Pan*[7], T. L. Kelly[8]. [1]GI and Nutrition, Children's Hospital of Philadelphia, Philadelphia, PA, USA, [2]Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA, USA, [3]General and Community Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA, [4]Nutrition Center, South Dakota State University, Brookings, SD, USA, [5]Center for Pediatric Nutrition Research, University of Utah, Salt Lake City, UT, USA, [6]Radiology, University of San Francisco, San Francisco, CA, USA, [7]Institute of Child Health, University College London, London, United Kingdom, [8]Research and Development, Hologic, Inc, Bedford, MA, USA.

Assessment of bone mineral accrual abnormalities in children is dependent on reference data that capture the range of variability in healthy children relative to age, gender and body size. Childhood bone mineral disorders are often associated with growth abnormalities, so assessment relative to body size is essential. We report age and gender-specific reference data for bone mineral content (BMC) and density (BMD) of the whole body (WB), spine and proximal femur, and size-specific spine and WB BMC reference values in White children from a large U.S. multi-center sample.

Healthy children were evaluated at five centers in numerous IRB approved research protocols. DXA spine (n=1444), hip (n=1047) and whole body (n=1948) exams were acquired on Hologic, Inc. QDR 4500 fan beam systems and analyzed with the automatic low density analysis methods using the latest generation of software (version 12.1). Scan images were analyzed centrally by a single operator (TLK) to assure consistency. Gender-specific reference curves were generated using the LMS Pro software relative to age (WB, spine and proximal femur) and size (WB BMC-for-ht and spine BMC-for-bone area).

Children ages 5 to 20 years were evaluated for the spine and proximal femur; WB reference data extend from age 3 to 20 years. Several reference curves are shown.



These reference curves are based on a large multi-center convenience sample of healthy children using state-of-the-art scan analysis and statistical approaches for reference curve generation. They allow for age, gender and size-specific comparisons with healthy children for the detection of abnormal bone mineral values in children in both research and clinical care.

Precision of Peripheral Quantitative Computed Tomography Measures of the Tibia in Children. B. S. Zemel[1], D. Paulhamus*[1], C. Dilzer*[1], V. A. Stallings*[1], M. Shabbout*[2], M. B. Leonard[3]. [1]GI and Nutrition, Children's Hospital of Philadelphia, Philadelphia, PA, USA, [2]Biostatistics, Children's Hospital of Philadelphia, Philadelphia, PA, USA, [3]Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Peripheral quantitative computed tomography (pQCT) is increasingly available as a research tool in studies of pediatric bone disorders. In adults, the radius is the usual measurement site. For children, the tibia is a more optimal site because it has a larger diameter, greater thickness, and is a weight bearing site. Because of modeling of the tibia during growth, and maturational changes in the epiphysis, use of pQCT in children presents unique challenges. Here, we report the precision of pQCT measures of the tibia in children to aid in the interpretation of these measures.

Healthy children, ages 6 to 18 yrs were recruited from pediatric practices and the general community. Subjects were free of chronic disease and medication use that would affect growth or dietary intake. Tibia length was measured anthropometrically. pQCT measurements of the distal left tibia were obtained at the 3%, 8mm and 38% sites using a Stratec XCT 2000 (Orthometrix, White Plains, NY) 12-detector unit. The proximal edge of the medial physis was used as the reference point (voxel size = 0.4mm, scan speed = 25mm/sec). Duplicate measurements were obtained with repositioning, and repeated scout view scans. Within-subject coefficient of variation (CV) was estimated using the method of Bland and Altman (BMJ, 1996;313:106).

Sixty children enrolled in the study. Paired usable scans were available for 56, 51 and 55 children at the 3%, 8mm and 38% sites, respectively. Subjects were approximately evenly divided between younger (6 to 10 yrs) and older (11 to 18 yrs) children. The CVs of selected measures are shown in the table. Values for younger children are slightly higher than for older children. Trabecular density at the 3% site has a lower CV than at the 8mm site suggesting that a relative distance is more reproducible than a fixed distance.

Site	Measure	All Ages	6 to 10 yrs	11 to 18 yrs
3 Percent	Trabecular Density	1.4	1.5	1.3
8 mm	Trabecular Density	2.6	2.7	2.4
38 Percent	Cortical Density	0.7	0.9	0.5
38 Percent	Cortical Thickness	1.4	1.4	1.5
38 Percent	Endosteal Circumference	1.7	1.8	1.5
38 Percent	Periosteal Circumference	0.4	0.5	0.3
38 Percent	Strain Strength Index	2.1	2.2	2.0

In sum, measures of trabecular and cortical density, and cortical geometry of the tibia can be obtained with excellent precision in children. Reproducible measures can be obtained in both younger and older children. Use of a fixed distance at the distal site is not quite as reproducible as at a percentage distance from the reference point.

Total Lymphocyte Count and Lumbar Bone Mineral Density in Korean Postmenopausal Women. Y. Moon*, Y. K. Kim*. Family Medicine, Hallym University College of Medicine, Chunchon, Republic of Korea.

In vitro and vivo studies showed that several hormones and cytokines produced by immune system can affect in bone metabolism. Our aim was to evaluate the association between total lymphocyte count (TLC) and lumbar bone mineral density (BMD) in Korean postmenopausal women. We included 143 healthy women out of 423, who were after at least 2 years of menopause and not being diagnosed and treated for any chronic diseases including osteoporosis. Lumbar BMD was measured by dual-energy X-ray absorptiometry at lumbar (L)1-4. A positive correlation was observed in lumbar BMD (L1, r=0.294, P < 0.01; L2, r=0.249, P < 0.001; L3, r=0.260, P < 0.001; L4, r=0.222, P < 0.001; total r=0.286, P < 0.001) after adjusting for age and body mass index (BMI). Our data showed a positive association between TLC and lumbar BMD in a sample of apparently healthy, postmenopausal women, suggesting possible connection between the immune system and bone metabolism.

Determinants of Bone Mineral Density in Asian Men. J. Gu*[1], K. K. Lee*[1], E. Y. N. Cheung*[1], K. F. Lam*[2], A. Y. Y. Ho[1], S. Tam*[3], A. W. C. Kung[1]. [1]Medicine, The University of HongKong, HongKong, Hong Kong Special Administrative Region of China, [2]Statistics & Actuarial Science, The University of HongKong, HongKong, Hong Kong Special Administrative Region of China, [3]Clinical Biochemistry Unit, Queen Mary Hospital, HongKong, Hong Kong Special Administrative Region of China.

Osteoporotic fractures are increasing among Asian populations in both sex but the risk factors for low bone mineral density (BMD) in Asian men is unknown. To determine the hormonal and lifestyle risk factors for low BMD in Asian men, 407 community dwelling southern Chinese men aged 50 years and above were studied. Medical history and lifestyle habits were obtained using a structured questionnaire. Dietary calcium and phytoestrogen intake was assessed by a semi-quantitative questionnaire. BMD at the spine and hip were measured by DXA. Fasting blood was analyzed for 25(OH)D, PTH, total and bioavailable estradiol (bio-E) and testosterone (bio-T). The mean age of the cohort was 68.42±10.4 (50-96) yrs. In the linear regression model, weight, age, bio-E, cigarette smoking and weight bearing exercise were significant determinants of total hip BMD. Together they explained 46.4% of the total variance of hip BMD with body weight being the most important determining factor (r^2=0.39). With age and weight adjustment, height, bio-T and flavonoid intake were identified as additional determinants of total hip BMD. Strategy to prevent bone loss and osteoporosis in Asian men should include lifestyle modification and maintenance of hormonal sufficiency.

Total Skeleton Is a Useful Tool to Study Bone Mineral Density and Body Composition in Healthy Postmenopausal Women. A. Bagur[1], S. Mastaglia*[1], M. Royer*[2], B. Oliveri[1]. [1]Sección Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina, [2]Sección Climaterio, Divisiòn Ginecologìa, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina.

Total skeleton (TS) is a useful tool to study simultaneously bone mineral density (BMD) and body composition (BC) in different diseases. Endogenous estradiol (EE2) over 10 pg/ml may play a role in the protection of BMD in healthy postmenopausal women (PMPW). The aim of this study was to evaluate the usefulness of TS to distinguish the effect of different EE2 levels on BMD in healthy PMPW, and to analyze its relationship with BC. Ninety-seven PMPW aged 55 to 75 years were studied. TS was measured by DXA (Lunar Prodigy). Serum calcium, bone alkaline phosphatase (BAP), serum crosslaps (sCTX), E2 (a sensitive assay that detects up to 5 pg/ml), estrone and urine calcium were measured. The general characteristics of the population were (mean ± DS): weight 65 ± 11 kg, height 1.55 ± 0.05 m, BMI 27 ± 4, TS BMD 0.985 ± 0.18 g/cm2, % fat 40.4 ± 6.3, fat mass 26.5 ± 7.3 kg, lean 37.6 ± 4.5 kg, EE2 10.1 ± 4.9 pg/ml, estrone 20.7 ± 10.2 pg/ml, SHBG 42.5 ± 17 nmol/l, scalcium 9.3 ± 0.5 mg/dl, phosphate 3.6 ± 0.5 mg/dl, BAP 74.7 ± 18.1 UI/L, sCTX 542 ± 254 ng/ml and urine calcium 157 ± 78.3 mg/24 hs. The population was divided according to EE2 levels: <10 and ≥10 pg/ml. Women with EE2 ≥10 pg/ml had higher BMD and BC values compared with women with EE2 <10 pg/ml: fat mass 28.2 ± 7.3 vs 25.1 ± 7.1 kg (p<0.04), lean 38.6 ± 4.8 vs 36.8 ± 4.1 kg (p<0.05), weight 68.4 ± 11.3 vs 63.8 ± 9.8 kg (p<0.03), TS BMD 1.028 ± 0.09 vs 0996 ± 0.08 g/cm2 (pns, 0.09) and EE2 14.3 ± 4.5 vs 6.8 ± 1.8 pg/ml (p<0.0001). Obese women with BMI values over 30 (n=17) were compared with women with BMI between 20 and 30 (n=78). Only two women had BMI values below 20. As expected, obese women had higher weight, fat, lean, and BMI values as well as higher EE2 (12.2 ± 6.3 vs 9.7 ± 4.5 pg/ml, p<0.05) and TS BMD (1.030 ± 0.11 vs 1.007 ± 0.09 g/cm2, p<0.02) and lower BAP values (72.8 ± 18.8 vs 83.2 ± 17.5, p<0.04) than PMPW with normal weight. No significant data were found with estrone. The following significant correlations were found: EE2 correlated with weight (r=0.2, p<0.05), fat mass (r=0.2, p<0.03 and estrone (r=0.4, p<0.0001); fat mass correlated with weight (r=0.9, p<0.0001), lean (r=0.5, p<0.001), TS BMD (r=0.4, p<0.0001), calcium (r=-0.2, p<0.03) and SHBG (r=-0.3, p<0.001). No correlations were found with estrone.

In conclusion, TS is a useful tool to evaluate the relation between levels of EE2 and BMD as well as to study differences in BC in healthy PMPW. Obese women had higher EE2 levels and TS BMD than PMPW with normal BMI.

Bone Mineral Density Reference Values in Males and Females 10 to 21 Years of Age in Venezuelan Subjects. G. S. Riera, R. Carvajal*, G. Velasquez*, M. Naressi*, J. Ramos*. Medicine, UNILIME.Universidad de Carabobo, Valencia, Venezuela.

Bone Mineral Density reference values for Latin American populations are scarce. However, comparison for diagnosis of low bone mineral density in adults requires normal reference values of 20 - 40 years-old control population. In contrast, in young individuals, matched by sex and age. The aim of this study is to show BMD values in normal young Venezuelan males and females subjects between ages 10 and 21.

191 healthy subjects with at least one Venezuelan progenitor, ages between 10 and 21, without any systemic disease of drug use which affects bone metabolism were recruited for Bone Mineral Density assessment. None of the subjects were under heavy physical therapy or training nor had previous fracture. BMD was measured by DEXA (LUNAR DPX. Variation Coefficient: 1.5%) at femoral neck and lumbar spine (L1-L4),

Subjects were divided into two groups: 89 males and 102 females. BMD results are presented in the 2 tables as follow.

Males. Age	Mean value (SD) Troch Femoral Neck	Mean value (SD) L1 - L4	Mean value (SD)
10 - 11	0.867 ± 0.13	0.755 ± 0.09	0.779 ± 0.11
12 - 13	0.956 ± 0.11	0.830 ± 0.08	0.846 ± 0.11
14 - 15	1.032 ± 0.18	0.911 ± 0.16	0.986 ± 0.16
16 - 17	1.086 ± 0.10	0.913 ± 0.10	1.103 ± 0.16
18 - 19	1.135 ± 0.10	0.845 ± 0.04	1.243 ± 0.05
20 - 21	0.956 ± 0.11	0.752 ± 0.12	1.092 ± 0.03

Females. Age	Mean value (SD) Troch	Mean value (SD)	Mean value (SD)
Femoral Neck		L1 - L4	
10 - 11	0.754 ± 0.15	0.655 ± 0.11	0.815 ± 0.10
12 - 13	0.913 ± 0.11	0.782 ± 0.11	0.981 ± 0.14
14 - 15	0.965 ± 0.12	0.775 ± 0.10	1.037 ± 0.13
16 - 17	0.995 ± 0.07	0.816 ± 0.07	1.094 ± 0.11
18 - 19	1.001 ± 0.11	0.759 ± 0.08	1.116 ± 0.07
20 - 21	0.959 ± 0.11	0.785 ± 0.11	1.156 ± 0.13

This study presents normal reference BMD values for young Venezuelan males and females subjects, 10-21 years of age, obtained with Lunar densitometer

Recalculation of the NHANES Database Standard Deviation Improves T-score Agreement and Reduces Osteoporosis Prevalence. N. Binkley[1], M. K. Drezner[1], D. Krueger[1], E. M. Lewiecki[2], P. D. Miller[3], J. A. Shepherd[4], G. M. Kiebzak[5]. [1]University of Wisconsin, Madison, WI, USA, [2]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA, [3]Colorado Center for Bone Research, Lakewood, CO, USA, [4]University of California, San Francisco, CA, USA, [5]St. Luke's Episcopal Hospital, Houston, TX, USA.

The International Committee for Standards in Bone Measurement recommended the NHANES database for femur T-score derivation. Acquired on Hologic (Hol) instruments, this database requires conversion equations for application to other DXA systems. Total femur (TF) conversions have previously been available, femur neck (FN) and trochanter (TR) equations were reported recently. Appropriately, GE Lunar (GE) incorporated NHANES values into their female database. This should produce T-score and diagnostic agreement between Hol and GE instruments, however, this has not been evaluated. Thus, we compared T-scores from femur scans using GE Prodigy and Hol Delphi densitometers in 89 postmenopausal women.

The TF GE Hol T-score difference ($p < 0.01$) was < 0.1 with equal diagnoses of osteoporosis. FN and TR differences were larger, with mean GE T-scores lower than Hol ($p < 0.001$) by 0.17 and 0.50 respectively, thereby introducing osteoporosis diagnostic disagreement (13 [GE] vs 9 [Hol]). Our evaluation suggested that this disparity resulted from direct application of Hol standard deviations (SD) at the FN and TR. As such, we applied the conversion formulae to the NHANES young-normal female raw data and found the FN and TR SDs were greater than assumed by GE (0.138 vs 0.120 and 0.114 vs 0.099). Using these calculated SDs to derive new T-scores reduced the mean GE/Hol T-score difference to .03 at the FN and .34 at the TR and resolved osteoporosis diagnostic disagreement (n = 9). To validate utility of our calculated SDs, we compared GE femur scans in 115 additional postmenopausal women analyzed with software prior to and after the NHANES update. A FN and TR T-score difference ($p < 0.001$) was present with lower values found using post NHANES software, leading to increased osteoporosis prevalence from 7.8% to 18.3%. Using our calculated SDs to derive T-scores reduced osteoporosis prevalence to 9.6%.

These data reveal that the GE NHANES database update leads to lower FN and TR T-scores than obtained with Hol or prior GE software. An updated SD reduces this difference, but TR discrepancy remains raising questions regarding conversion equation accuracy at this site. Use of updated SD values at the femur subregions for GE densitometers is recommended. Difficulties with the T-score based diagnostic system, such as noted here, should further prompt development of diagnostic criteria that include absolute fracture risk estimates.

Vertebral Fracture: A Difficult Diagnosis? The Act'os Study. J. Fechtenbaum[1], F. Bugnard*[2], S. Kolta[1], R. Said*[1], O. Madi*[3], P. Orcel[4], C. Roux[1]. [1]Rheumatology, Cochin hospital, Paris, France, [2]MAPI - CRO, Lyon, France, [3]Aventis, Paris, France, [4]Rheumatology, Lariboisière hospital, Paris, France.

Introduction: osteoporotic vertebral fractures are responsible of chronic back pain, impaired function and alteration of quality of life. Their secondary prevention is possible through several effective treatments. Their diagnosis is therefore necessary for an optimal management of osteoporosis.

Aim of the study: to evaluate the concordance in the diagnosis of radiologic vertebral fractures between rheumatologists.

Patients and methods: we have evaluated X-rays of dorsal and lumbar spines as well as the thoraco-lumbar junction of 629 menopausal patients taken in standardized conditions. The inclusion criterion was the presence of at least one vertebral fracture according to the investigator. The X-rays have been analyzed by a central reader, blind to the diagnosis of the investigator, according to a semi-quantitative method (grades 0 to 3). The concordance has been evaluated on the patient and on the vertebral levels.

Results: in the centralized reading, a diagnosis of the presence or absence of fracture could be done in 588 patients (in 41 cases, the diagnosis was not possible due to the presence of some non legible or missing vertebrae with the remaining vertebrae being non fractured). Diagnosis was confirmed in 548 cases (6.8% false positive). At the vertebral level (from T4 to L5, 7 878 vertebras), the kappa score varied from 0.20 to 0.77. It increased linearly from T4 to be greater than 0.6 for the 9 vertebrae from T8 to L4.

According to the centralized analysis, 1 536 vertebrae were fractured. Among these, 396 were considered as non fractured by the investigator (25.8% false negative). Fractures concerned all the vertebrae and 268 were grade 1, 74 grade 2 and 54 grade 3.

Among the 6 342 non fractured vertebrae according to the centralized analysis, 397 were considered as fractured by the investigator (6.3% false positive). The majority of these discrepancies was situated from T4 to T6. Among the 588 evaluable patients, 51.3% had at least one false negative and 52.4% one false positive vertebra.

Conclusion: the concordance of the diagnosis of vertebral fracture between specialists is not optimal. Some of these discrepancies could be explained by the difference in labeling of the vertebrae, others by the differences in the evaluation of the deformations of the vertebral bodies.

Bone Mineral Density In Pre- and Postmenopausal Women on L-thyroxine Suppressive Therapy. J. Payer*, L. Baqi*, Z. Killinger*, P. Hruzikova*, E. Stenova*. 1st Internal Clinic, Comenius Universtity Hospital, Bratislava, Slovakia.

Patients with long- term L-thyroxine suppressive therapy have high bone turnover, which could be associated with bone loss. The aim of our investigation was to examine effect of long- term L-thyroxine suppressive therapy on bone in relation to menopausal status. METHODS: 30 (aged 37±7yrs) premenopausal (PrSUPP) and 32 (aged 60±6yrs)postmenopausal (PoSUPP)with T4 suppresive therapy, 40 (aged 32±5yrs)premenopausal (PrEUTH), and 39 (aged 59±7yrs) postmenopausal control euthyroid (PrEUTH) women were studied. Bone mineral density (BMD) was assessed by dual X-rays absorptimetry (DXA) at lumbar spine(LS), and at the proximal femur (PF). BMD was expressed as g/cm2. Bone markers used were serum osteocalcin (S-OC) and serum NTx (S-NTx). RESULTS: At all sites, BMD findings were significantly lower ($p<0,05$) in PrSUPP and PoSUPP as compared to both EUTH controls groups. In comparing (PrSUPP) and (PoSUPP) BMD was significantly lower ($p<0,05$}only in LS region. There was no correlation between BMD and TSH and fT4 levels. S-OC, S-NTx and duration of L-thyroxine suppressive therapy negatively correlated with BMD. CONCLUSION: Women who are using L-thyroxine suppressive therapy are regardless to the age at higher risk of osteoporosis. This study suggests that L-thyroxine suppressive therapy affects bone mineralization and that is common with high bone turnover in pre- and postmenopausal women at the cortical and trabecular bone.

Long-term Bone Loss in Men and Women: Effects of Quadriceps Strength and Body Weight. T. V. Nguyen, N. D. Nguyen, J. R. Center, J. A. Eisman. Bone and Mineral Program, Garvan Institute of Medical Research, Sydney, Australia.

Although femoral neck bone mineral density (FNBMD) is known to progressively decline with advancing age, the rate of loss in past longitudinal studies was based on a relatively short duration of follow-up with mostly two measurements per subject. Also, little is known about the underlying factors for the decline. This study was designed to estimate the rate of change in FNBMD and risk factors for the change in the elderly population.

Femoral neck BMD (g/cm^2) was measred in 866 female and 516 male participants in the Dubbo Osteoporosis Epidemiology Study, who had had at least 3 visits since 1989 at intervals of approximately 2 years between any two consecutive visits. The average number of BMD measurements was 4 for each subject. At each visit, quadriceps strength (maximum isometric contraction) (QS, kg), body weight and lifestyle factors, such as dietary calcium intake, smoking and alcohol intake, were also obtained. The relationships between FNBMD, weight and quadriceps strength across visits were analyzed for *each* individual in a mixed-effects model with the assumption that the change in BMD and the magnitude of association between a risk factor and BMD varied randomly among subjects.

On average FNBMD decreased by 0.57±1.28% and 0.30±1.05% (mean±SD) per year for women and men, respectively. However, the rate of decline increased with advancing age in women such that by the age of 80 yr, their rate of loss was equivalent to that in men (0.69±1.18%). The rate of change in BMD for *a given individual* was negatively correlated with both change in weight and change in quadriceps strength, such that increasing weight and quadriceps strength was associated with lesser bone loss. These two factors accounted for 13% and 12% of the variance of bone loss in men and women, respectively. There was no significant association between dietary calcium intake, smoking or alcohol use and the loss in FNBMD. These results indicate that the rate of loss in FNBMD is lower than previously reported (which was about 1% per year) and that change in quadriceps strength and change in body weight were significant determinants. Enhancement of physical fitness may have a protective effect against bone loss in the elderly.

Precision of Spine BMD Measurement with and without Leg Elevation. S. Yang, T. Jeon*. Radiology, Eulji University Hospital, Daejeon, Republic of Korea.

There are some report that BMD measurement with the legs down shows no significant change on spine BMD accuracy and precision. We also studied to see the impact of leg elevation from DXA in our country.

Forty volunteers were scanned four times at the lumbar spine using Hologic QDR 4500A. Two scans were done with the leg elevated (E scan) by the spine positioning device supplied by manufacture. The other two scans were done with the legs lying flat (F scan) neutrally without femur positioner. Subjects were repositioned between all four scans. The precision error and linear regression were determined for the BMD obtained in each position.

Mean age of the subjects was 52 (range; 40 ~ 71). BMD was higher in the F scan (mean: 0.922 g/cm^2) compared with E scan (0.907 g/cm^2) except in two volunteers. T-scores at L1-4 were 0.13 higher for F scan. Only two volunteers had different diagnosis using T-scores from normal to osteopenia and vice versa from the two methods. Precisions (%CV) of the E scan were 1.50, 1.52, 1.96, 1.50, and 0.97% for the L1, L2, L3, L4, and L1-4 respectively. Precisions of the F scan were 1.46, 1.88, 1.63, 1.83, and 1.09% for the L1, L2, L3, L4, and L1-4 respectively. Correlation between two scans was high (r=0.99).Diagnostic differences from E and F scan are very small (0.13 T scores).

There is no significant statistical difference in spine BMD between with the legs elevated and with the legs flat on the scan table. One step scan with the leg flat with the dual femur positioner can expedite the examination without jeopardizing diagnostic value.

SU123

Bone Mineral Density in Male Osteoporotics with Vertebral Fractures. P. Ryan[1], D. Doyle*[2], V. Thompson*[2], J. Griffin*[3], J. Day*[4], C. Kelsey*[5], G. Cambell*[6], G. Cambell*[6], N. Saunders*[7]. [1]Osteoporosis Unit, Medway Maritime Hospital, Gillingham, Kent, United Kingdom, [2]Chingford Osteoporosis Unit, Chingford, Essex, United Kingdom, [3]Rheumatology, Chase Fram Hospital, London, United Kingdom, [4]Elderly Care Unit, Luton and Dunstable Hospital, Luton, Herts, United Kingdom, [5]Rheumatology, Oldchurch Hospital, Romford, Essex, United Kingdom, [6]Elderly Care, Addenbrookes Hospital, Cambridge, United Kingdom, [7]Procter and Gamble plc, Staines, Middx, United Kingdom.

Interpretation of Bone Mineral Densitometry (BMD) in male vertebral fracture is complex. The same relationship between bone density and fracture occurs in males as in females and absolute fracture risk is similar at the same BMD. However, because BMD levels are higher and BMD changes with age differently the same T and Z scores imply different fracture risks in the 2 genders. In clinical practice there is sometimes difficulty in attributing vertebral fractures to osteoporosis or whether to infer other causes. This study retrospectively examined BMD data on 76 male vertebral fracture patients (average age 67 years) selected from clinical databases from 6 centres, which were matched by a randomly selected group of 104 females (average age 71 years) with vertebral fractures. For inclusion patients had to have a BMD and spinal x-rays within 1 year of the scan. Patient data was collected on BMD at the spine and hip, numbers and severity of vertebral fracture (Genant scale) and clinical risk factors. A single investigator read all the x-rays blinded to other results. 23 patients had BMD measurements on Lunar and 157 on Hologic devices. There were 190 male and 202 female fractures, (Wedge male 161, female 170, Mid male 29, female 32). Average T scores were similar in the spine (Male -2.55, Female -2.70) and slightly lower in females at the femoral neck and total hip (Male Total Hip -2.08, Female Total Hip -2.71). Average Z scores were markedly lower in males at spine (Male -1.86, Female -0.58) but similar at the femoral neck and total hip (Male Total Hip -1.19, Female -0.94) In the Hologic subgroup Male BMD was higher at all sites, more obviously at the hip (Male BMD Spine 0.794 g/cm2, Total Hip 0.758 g/cm2, Female BMD Spine 0.761 g/cm2, Total hip 0.644 g/cm2). Fracture thresholds derived from Hologic data suggest greater differences in hip compared to spine BMD (90 % threshold Male Spine 1.028 g/cm2, Total Hip 0.957 g/cm2, Female Spine 1.006 g/cm2, 0.796 g/cm2). Study findings suggest that when considering male vertebral fractures T scores in the spine can be used in a similar way to females, whereas Z scores in men are much lower, but the converse applies for the hip. Absolute BMD thresholds for vertebral fracture are higher in men than in women, particularly at the hip.

Pediatric DXA Precision Varies with Age. J. A. Shepherd[1], B. Fan[1], M. Sherman*[1], V. Gilsanz[2], M. Horlick[3], H. Kalkwarf[4], J. Lappe*[5], S. Mahboubi*[6], B. Zemel[7], M. Fredrick*[8], K. Winer[9]. [1]Radiology, University of California at San Francisco, San Francisco, CA, USA, [2]Radiology, Children's Hospital of Los Angeles, Los Angeles, CA, USA, [3]Pediatric, Columbia University, New York, NY, USA, [4]Pediatrics, Children's Hospital of Cincinnati, Cincinnati , OH, USA, [5]Pediatrics, Creighton University, Omaha, NE, USA, [6]Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, USA, [7]GI and Nutrition, Children's Hospital of Philidelphia, Philadelphia, PA, USA, [8]Clinical Trials, Clinical Trials & Surveys Corp, Baltimore, MD, USA, [9]Center for Research for Mothers and Children, National Institute of Child Health and Human Development, Bethesda, MD, USA.

When assessing the suitability of a technique for follow up purposes, one of the most important parameters is precision. Constant adult precision values are commonly applied to pediatric patients or populations with little evidence that they are valid. The purpose of our study was to access the repeatability of four bone densitometry regions of interest (ROIs) in children as a function of age. We recruited 155 children of mixed sex and ethnicity, 30 children each from 5 clinical sites across the country. The subjects were recruited in three age groups of 10 children (Group C (6 to 9), B (10 to 13), and A (14 to 16 years)). These participants were all part of the larger reference data study, the NICHD BMD in Children Study. Each participant had duplicate scans with repositioning of the following DXA ROIs: PA spine, proximal femur, whole body, and forearm. Each clinical site used the same densitometer (Hologic Delphi, Hologic, Inc. Bedford, MA) and all scans were centrally analyzed by one trained research assistant using the Discovery software (version 12.1). The coefficient of variation (CV) is shown for each group and ROI in the graph. The Discovery analysis algorithms identified bone well for all age groups and measurement sites. Age-related changes were evident for the spine, hip, and whole body, but less so for the radius. Adolescent CVs were in general similar to adult values from the literature. We conclude that precision in DXA scans of children varies with age. These unique precision measures should be taken into account when determining if actual change has occurred between baseline and follow-up examinations.

Dual Energy X-ray Absorptiometry (DXA) of the Forearm in Men: Radius versus Total. V. I. Petkov*[1], M. I. Williams*[2], P. S. Via*[3], T. Hodson*[3], R. A. Adler[1]. [1]Endocrinology, McGuire Veterans Affairs Medical Center/Virginia Commonwealth University School of Medicine, Richmond, VA, USA, [2]Endocrinology, McGuire Veterans Affairs Medical Center/Virginia Commonwealth University School of Pharmacy, Richmond, VA, USA, [3]Endocrinology, McGuire Veterans Affairs Medical Center, Richmond, VA, USA.

The role of the dual energy X-ray absorptiometry (DXA) of the forearm for the diagnosis of osteoporosis (OP) is not well defined, especially in men. ISCD recommends using only 1/3 radius (Lunar densitometers default) when DXA of the spine is not acceptable. However, Hologic densitometers report total distal forearm by default. From observational cohort studies of fractures in men, central DXA predicts fractures modestly, at best. Adding forearm (FA) to spine and hip DXA, especially in older men, may improve the predictability of fractures. We decided to test if the addition of FA to spine and hip BMD will increase significantly the proportion of men identified to have OP. Additionally, we explored the sensitivity of different FA sites for diagnosis of OP.

Veteran men who had a BMD test as a result of an interventional study for improving diagnosis and treatment of OP in primary care clinics were included in the analysis. All patients had DXA of the spine, hip and forearm (Hologic Delphi). OP was defined as a T-score $\leq$ -2.5. The proportions of male patients with OP identified by spine plus hip and spine, hip plus various distal forearm regions were compared using the McNemar test for paired categorical data.

The mean age of the study group (N=355) was 71.5 (9.3) years and the mean weight was 75.9 (10.7) kg. Using ISCD recommendations for the diagnosis of OP (the lowest of T-scores at L1-L4 spine, femoral neck, trochanter or total hip) 25.9 % had osteoporosis and 53.5% osteopenia. Adding total distal forearm (or total radius) significantly increased the number of men with OP to 36.1% (36.9%). Replacing total FA/radius with 1/3 radius decreased the number of osteoporotic men to 32.7%, while adding ultradistal radius to 1/3 radius significantly increased the proportion of osteoporotic men (41.4%). Currently we are evaluating fracture data on the study patients.

Adding FA DXA in the diagnosis of OP in older men would identify a greater number of men with osteoporosis, in whom treatment should decrease fracture incidence.

SU126

Precision of Fan-Beam Densitometers in Clinical Practice. L. S. Weynand*, H. S. Barden, K. G. Faulkner. GE Healthcare, Madison, WI, USA.

Precision error determines the ability of a DXA system to detect small changes in patient bone mineral density (BMD). Factors affecting precision include the scan region, consistency of scan acquisition and analysis, operator training, densitometry equipment and software, and short- and long-term variations in densitometer performance. Recently, several studies have reported BMD precision at leading centers considered experts in the field of densitometry research and clinical osteoporosis (1). We evaluated precision errors at non-research centers to compare with precision obtained by densitometry experts.

Twenty clinics with fan-beam densitometers participated in the study; 10 Lunar Prodigy systems, and 10 Hologic 4500 or Delphi systems. Each center determined their precision error using clinic patients. Each clinic measured either 30 subjects twice or 15 subjects three times, with repositioning between scans. Standard 30-second scan mode was used for all systems. Acquisition and analysis was performed by trained technologists at each center. BMD precision error was calculated as the root-mean-square standard deviation (RMS-SD) and coefficient of variation (RMS-%CV) for the repeated measurements using a standardized spreadsheet program.

Average precision error at the non-research centers was approximately 50% higher than published precision values from research centers (1) at all scan regions. Hologic precision errors were 50% to 120% higher than Prodigy precision errors, depending on the region. Precision errors at individual centers ranged from a low of 1.0% at the spine to a high of 9.7% at the femur neck for the Hologic systems, and from a low of 0.6 % for total femur to a high of 8.2 % for femur neck for the Prodigy.

We conclude that non-expert densitometry providers had, on average, a 50% higher precision error than expert centers. These results, coupled with the wide range of precision errors found in the study, emphasize the need for every densitometry center to conduct their own precision study and understand the effect their precision has on patient care. Centers with precision errors grossly out of line with established standards should attempt to eliminate possible errors due to malfunctioning equipment, outdated software, inconsistent operator intervention, or insufficient operator training.

SU127

Use of Anthropomorphic Phantoms to Cross-Calibrate DXA Scanners. L. Cole*, N. C. Grinnell*, T. M. DeFrancisco*, S. M. Strot*, E. A. Mossman, M. R. McClung. Oregon Osteoporosis Center, Portland, OR, USA.

Dual-energy X-ray absorptiometry (DXA) is widely used for the assessment of skeletal status in clinical or research settings. Differences in BMD measurement between DXA scanners from different manufacturers have been well established. Because of differences in calibration standards, even DXA scanners from the same manufacturer sometimes produce clinically significant differences in BMD. With equipment upgrades or when comparing clinical results from different laboratories, it is often desirable to cross-calibrate two or more DXA scanners. Because it is often not practical to use subjects for the cross-calibration, anthropomorphic phantoms are frequently used instead. The purpose of this study was to determine how well cross-calibration with phantoms predicts in vivo performance.

Two GE-Lunar Prodigy densitometers were cross-calibrated using both subjects and three anthropomorphic phantoms (GE Lunar Aluminum Step Wedge [LUN], Bona Fide Anthropomorphic Spine Phantom [BF], and Hologic Anthropomorphic Hip Phantom [HOLH]). The total hip (TH) and lumbar spine 1-4 (LS) regions were measured on each of 20 subjects on both DXA machines. Each phantom was measured 20 times on both scanners. Mean BMD values and regression equations were calculated to standardize the table results for the patients and for each phantom.

Table 1. Regression slopes and intercepts for phantom and patient cross-calibration data.

Phantom/ROI	Mean BMD Scanner1	Mean BMD Scanner 2	Slope	Slope p	Intercept	Intercept p
LUN	1.182	1.195	1.0261	<0.0001	-0.0179	0.0005
BF	1.074	1.082	1.0222	<0.0001	-0.0157	0.0077
Patient LS	1.099	1.090	1.0057	<0.0001	-0.0158	0.5773
HOLH	0.810	0.814	0.9318	0.0006	0.0594	0.3156
Patient TH	0.920	0.907	0.9573	<0.0001	0.0264	0.2109

The LUN and BF anthropomorphic phantoms, which simulate the spine region, both match the patient regression equation at LS fairly well, but neither matches well with the patient TH equation. In contrast, the HOLH hip phantom is similar to the patient TH equation, but does not correspond well with the LS equation.

These data suggest that the use of site-specific anthropomorphic phantoms is required for cross-calibrating densitometers where in vivo cross-calibration is impractical.

Utility of Measuring Both Hips in Patients with Discordant Hip and Spine DXA Measurements. T. M. DeFrancisco*, S. M. Strot*, L. Cole*, N. C. Grinnell*, E. A. Mossman, M. R. McClung. Oregon Osteoporosis Center, Portland, OR, USA.

Dual energy x-ray absorptiometry (DXA) is generally agreed to be the best method for measuring bone mineral density (BMD) in order to diagnose osteoporosis, establish fracture risk, and monitor the effects of therapy, with the spine and hip the most commonly measured regions. When measuring the spine and one hip there can often be discordance between the two sites, where one site has BMD values consistent with osteoporosis (OP) and the other does not. In these cases, due to the potential for measurement artifact and/or disparity between the two hips, the opposing hip is often measured. However, it is unclear if there is a diagnostic advantage to measuring the second hip when a discordance exists between the spine and initial hip measurement.

The purpose of this study was to determine if there is a significant difference between DXA measurements of opposite hips in patients with discordance at the spine and the first measured hip, and to determine if such a difference would systematically affect diagnostic categorization in these patients.

We examined data from the electronic medical records of patients referred to the Oregon Osteoporosis Center for DXA testing from January 2000 through March 2004. 1374 patients had record of a DXA measurement at the spine and both hips on a single Lunar Prodigy densitometer (GE Lunar, Madison, WI). 206 of these had discordant first total hip (TH) and L1-4 lumbar spine (LS) measurements, with LS higher (T > -2.5) in 113 of these records.

Paired samples T-testing showed no significant difference in opposite hip TH BMDs among these patients, with a mean difference of only -0.004 g/cm^2 from first to second hip scanned (95% CI, -0.023 to 0.015, p=0.66). 113 patients (55%) of discordant records had a first measured TH value consistent with OP, while 126 (61%) had values consistent with OP at either TH. These percentages were identical using the femoral neck (FN) region instead of TH, and FN BMDs were not significantly different in the 228 patients discordant at LS and first measured FN (p=0.19). We conclude that there is not sufficient diagnostic or clinical advantage in including the second hip to justify its measurement when a discordance exists between the spine and initial hip measurement.

Structure Analysis of High Resolution MRI of the Proximal Femur Using a 3D Anisotropic Method for the Prediction of Mechanical Strength In Vitro. R. A. Monetti*[1], H. Boehm*[2], D. Mueller*[2], E. Rummeny*[2], G. Morfill*[1], S. Majumdar[3], D. Newitt[3], T. Link[3], C. Raeth*[1]. [1]Cips, Max-Planck-Institut fuer extraterrestrische Physik, Garching, Germany, [2]Department of Radiology, TU-Munich, Munich, Germany, [3]Department of Radiology, UCSF, San Francisco, CA, USA.

In this study the so called scaling vector method (SVM) was applied to analyze the trabecular bone structure of high resolution magnetic resonance (HR-MR) images of the proximal femur. Using the SVM a 3D non-linear texture measure which takes into account the anisotropic nature of the trabeculae was extracted. The performance of this new structure analysis technique for the prediction of the biomechanical properties of the bone was compared with BMD and the standard 2D histomorphometric parameters.

25 human proximal femur specimens from 10 female and 15 male donors aged 39 to 91 years were obtained 1 to 2 days postmortem. Coronal HR MR images of the proximal femur were obtained using a 1.5 T MR scanner equipped with 22 mT/m gradients and a prototype 2 element phased array coil. A 3D-spin-echo sequence with an echo time (TE) of 13.0 ms, repetition time (TR) of 50 ms, and 3 acquisitions was used. A matrix of 384 x 512 was applied with a field of view (FOV) of 75 x 100 mm, yielding a pixel size of 0.195 × 0.195 mm^2. Sections with a slice thickness of 0.9 mm were obtained. The acquisition time was 27:19 min. Nineteen 0.9 mm thick sections were acquired. DXA of the proximal femur was performed using a DPX-L scanner and areal BMD (g/cm^2) of the femoral neck was determined.

The maximum compressive strength (MCS) was obtained in an electro-mechanical materials testing machine. Compressive force on the femur head was increased stepwise (0.5 kN). MCS was calculated from the first local maximum of the stress-strain curve. MCS ranged from 3.20 to 16.95 kN. After selecting the region of interest (ROI) and normalization of the images the structure analysis was performed using algorithms able to account for the orientation of the mineralized trabeculae of the proximal femur, i.e. the new anisotropic SVM.

In order to predict the mechanical strength of the bone, we performed a correlation analysis. The correlation coefficient obtained using the SVM versus MCS was 0.83 ($p < 0.001$) which should be compared with 0.74 and 0.68 obtained for BMD-neck and Apparent Bone volume versus MCS, respectively.

We conclude that local 3D non-linear structural anisotropic texture measures extracted from HRMRI applying the scaling vector method can successfully predict the mechanical properties of femoral specimens.This suggests that anisotropic texture measures have a superior performance in cases where directional properties play a relevant role.

Map of Heel BUA Values May Provide New Information on Skeletal Integrity. R. K. Bhattacharya[1], J. H. Goll*[2], D. L. Medich[1], K. T. Vujevich*[1], M. E. Shoup*[1], J. M. Wagner[1], S. M. Sereika*[3], S. L. Greenspan[1]. [1]Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [2]Quidel Corp., Mountainview, CA, USA, [3]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA.

Bone mineral density (BMD) explains 50-70% of the variance of fracture risk, but other factors, such as bone geometry, bone turnover and fall biomechanics, contribute to fracture risk. Traditionally calcaneal ultrasound measures bone strength by broadband ultrasound attenuation (BUA). We have examined graphical presentations, which we call maps, of the BUA values measured over areas of 10 cm^2 of the calcaneus. These maps show substantial heterogeneity and biological diversity. We have assigned the maps to 4 groups, based on certain topological features or shapes observed. Our objective was to explore correlations between shapes and BUA, BMD, bone markers (osteocalcin, NTx), height, weight, and body mass index (BMI).

We enrolled 67 newly postmenopausal women from a study on osteoporosis prevention. At screening, women taking hormone replacement therapy, other antiresorptive agents, or anabolic therapies were excluded. We assessed BMD of the hip and spine (QDR-4500A; Hologic, Inc.), heel ultrasound by broadband ultrasound attenuation ([BUA] QUS-2; Quidel Corp.), height, weight, BMI, and markers of bone turnover. The BUA maps were separated into four distinct shapes by a blinded reviewer. (See table; *p<0.05, **p<0.01)

As expected, BUA was associated with hip and spine BMD, weight, and BMI, but not with markers of bone turnover. Furthermore, the topographical maps were associated with hip BMD, weight, BMI, and BUA. Using univariate multinomial logistic regression, we observed significant univariate effects on shape for BUA; BMI; weight; and total hip, trochanter, and intertrochanter BMD (all p<0.05). When multivariate multinomial logistic regression was done, the only statistically significant relationship we found was between BUA and the maps.

We conclude that ultrasound-derived topographical maps of the heel are associated with hip BMD, standard ultrasound, and weight, a relationship that may prove useful in the assessment of skeletal integrity. Future studies are needed to examine how maps may change with time or treatment and whether they can be used to enhance fracture prediction using quantitative ultrasound.

Measures of Association

	BUA (r)	Shapes (r^2)
Total hip	.47**	.14*
Femoral neck	.29*	.09
Trochanter	.47**	.16
Spine	.38**	.07
Weight	.48**	.16*
BMI	.45**	.14
BUA	--	.32*

Side-to-Side Differences in Bone Strength in a Chronic Stoke Population: a pQCT Study. P. C. Fehling[1], M. C. Ashe[1], J. J. Eng*[2], H. A. McKay[1]. [1]Departments of Orthopaedics/ Family Practice; Division of Orthopaedic. Engineering Research, University of British Columbia, Vancouver, BC, Canada, [2]School of Rehabilitation Sciences, University of British Columbia, Vancouver, BC, Canada.

Following a stroke individuals have increased risk of fracture. Previous studies of this population have shown that BMD, measured by DXA, is significantly reduced in the affected limb compared with the nonaffected limb. There have however, been few pQCT studies of this population. Thus, we investigated the side-to-side difference in bone mass and structure by DXA and pQCT in ambulating chronic stroke patients. We recruited 42 participants (mean age 67.8 ± 7.3) who were at least 12 months post stroke (mean 45.0 ± 22.3 mo) and independently ambulating with or without an assistive device. Based on the American Heart Association Functional Classification (range from 1= complete independence to 5 = complete dependence) subjects had an average score of 2.4 ± 0.9 (mode = 3). We used dual energy X-ray absorptiometry (DXA: Hologic 4500W, software version 11.2) to assess total body and bilateral proximal femoral BMC (g) and aBMD (g/cm^2). We used peripheral quantitative tomography (pQCT:Stratec XCT 2000; 2.5 mm slice, scan speed 25 mm/second, 0.5 mm voxel) to assess cross sectional area (CSA, cm^2),vBMD (g/cm^3), and polar moment of inertia (Ipolar) for bilateral tibiae at 5 and 30% of bone length. Scans were analyzed with BonAlyse 1.3 software (BonAlyse Oy, Jyväskylä, Finland). Participants were 80.4 ± 16.5 kg, 169.2 ± 9.5 cm. Fifty per cent of subjects met the criteria of osteopenia and 10% met the criteria of osteoporosis. At the total proximal femur aBMD was 5.2% lower and BMC was 6.6% lower in the affected vs. non-affected side (P=0.001). Results were similar for all proximal femur subregions of interest. There were no statistically significant bilateral differences in any bone structural parameter (by pQCT) at either the 5 or 30% sites of the tibia. At 30%, CSA was 452.6 ± 80.1 vs. 449.3 ± 86.2, vBMD (g/cm^3) was 720.2 ± 106.6 vs. 716.9 ± 104.8, and Ipolar was 2951.8 ± 1121.0 versus 2908.5 ± 1181.9 (affected limb vs. non-affected limb, respectively). This is one of the first studies to use pQCT technology in stroke patients - a population at increased risk of fracture. Our novel data do not reveal any bilateral differences in measures of bone material or geometric properties using pQCT. These findings are not consistent with past studies that used DXA measurement alone in this population. Further studies are needed to determine if the discrepancy observed in this study between technologies (DXA vs. pQCT) are the result of measurement site limitations (hip vs. tibia), technology or represent true regional bone biology differences.

SU132

3D-Evaluation of Bone Microarchitecture in Humans using High Resolution pQCT; A New in vivo, Non Invasive and Time Saving Procedure. M. Neff[1], M. Dambacher[2], S. Haemmerle*[3], R. Rizzoli[4], P. Delmas[5], R. Kissling*[6]. [1]Center for Osteoporosis, Zürich, Switzerland, [2]University Clinik Balgrist, Zürich, Switzerland, [3]Federal Institute of Technology ETH, Zürich, Switzerland, [4]University Hospital Geneva, Geneva, Switzerland, [5]Hopital E. Herriot Lyon, Lyon, France, [6]University Clinic Balgrist, Zürich, Switzerland.

In contrast to animals (e.g. mice, rats) the in vivo, non invasive and quantitative evaluation of 3D-bone microarchitecture, which play an important role in the fracture risk prediction of the skeleton, was not directly possible in humans. But lately the quantitative and non-invasive 3D structure analysis in vivo became also available in humans with the help of high resolution pQCT (Densiscan-3D/XtremeCT, Scanco Medical Ltd).

The new high resolution pQCT has a 2-dimensional detector array combined with a 100µm focus x-ray tube (effective energy 42keV), enabling the simultaneous acquisition of a stack of 100 tomograms perpendicular to the bone axis with a maximal diameter of 126mm. The isotropic resolution is 120µm (10% MTF, isotropic voxel size 82µm). The tomograms are taken 7mm proximal from the endplate of the distal radius and/or 20mm from the endplate of the distal tibia respectively delivering a coverage of a region of about 8mm. The data acquisition time is about 3 minutes and the effective radiation dose for a standard examination (scout view included) below 3µSv (CTDIw = 6.1mSv). With automatic repositioning the reproducibility is <±1% (for structure elements) in mixed collectives.

In praxi it is now routinely possible (see graph) to quantify in vivo in humans the microarchitectural features as number of trabeculae, trabecular and cortical thickness, trabecular spacing and endosteal surface in addition to the volumetric BMD of trabecular and cortical bone.

Such quantitative characterizations will give better insight in pathogenesis, prevention and in treatment of primary and secondary osteoporosis. It also improves the individual skeletal fracture risk prediction; e.g. with the help of finite element analysis.

A Novel Approach For Monitoring and Predicting Bone Microstructure in Osteoporosis. S. K. Boyd[1], C. Mattmann*[1], A. Kuhn*[1], R. Müller[2], J. A. Gasser*[3]. [1]Calgary Centre for Innovative Technology, University of Calgary, Calgary, AB, Canada, [2]Institute for Biomedical Engineering, ETH and University Zürich, Zürich, Switzerland, [3]Novartis Institutes for Biomedical Research, Basel, Switzerland.

In vivo measurements of bone microstructure allow novel insight into the process of bone loss in diseases such as osteoporosis. Currently, histomorphologic information can be extracted from these temporal series of 3D data using standard techniques developed for micro-computed tomography (micro-CT) data. However, to fully realize the potential of newly available in vivo data, temporal trends at a trabecular level need to be identified, and these data may allow projection of future bone architectures.

The purpose of this research is to establish a new method to track temporal changes of bone micro-architecture based on in vivo measurements, and to use that information to extrapolate future bone architecture in a disease process.

The method was developed using data from simulated atrophy of canine femoral trabecular bone, and then applied to in vivo measurements in a rat model of osteoporosis (Novartis, Switzerland). A group of 10 ovariectomized (OVX) virgin, 8 mo old Wistar rats were in vivo micro-CT scanned (Scanco Medical, Switzerland) at 0, 4, 8 and 12 wk post-OVX in the proximal tibia. A second group of 10 sham-operated rats served as controls. In each rat, temporal data series were registered to superimpose 3D architecture from different time points. Deformable registration between each time point provided a 3D deformation field, and the trend of these fields between times 0, 4 and 8 wk was linearly extrapolated to predict the 3D micro-architecture at 12 wk. The prediction was directly compared to measured architecture at 12 wk.

The OVX rats, as expected, had decreased bone volume ratio (N=5, 40% decrease), and the sham-operated rats exhibited a minimal decrease (N=7, <2% decrease). The extrapolated 3D architecture from the canine data resulted in maximum local errors of 5 um (relative to

34 um isotropic resolution). Predicted 12 wk OVX rat bone architecture matched well with structural parameters (BV/TV, Tb.Th) of the measured 12 wk post-OVX data, and captured the dominant changes in architecture at the individual trabecular level. Complete resorption of trabeculae was problematic to predict, however the four week time interval may have been too large considering the significant architectural changes in the OVX rat.
In conclusion, this method based on measured trajectories of in vivo data provides novel insight into changes in 3D bone microstructure in the OVX model for osteoporosis, and introduces the ability to track individual trabeculae and predict future micro-architecture in a disease process.

The Spinal Curvature Irregularity Index (SCII) for the Thoracolumbar Spine Identifies Vertebral Fractures. G. Maalouf[1], R. Zezabe[2], N. Maalouf*[3], J. Wehbe*[1], E. Seeman[2]. [1]Orthopaedic Dept, St. Georgia Hospital, Beirut, Lebanon, [2]Austin & Repatriation MC University of Melbourne, Melbourne, Australia, [3]Southwestern MC, University of Texas, Dallas, TX, USA.

Differences in anterior and posterior vertebral heights (VHs) form the thoracolumbar curvature needed for stability in bipedal gait. Modest differences in VHs within and between adjacent vertebrae allow the spinal curve to change its trajectory gently. Large differences in VHs, as occurs following a fracture, produce abrupt changes in the curve direction producing a departure from regularity (i.e. irregularity). In this study we wished to determine if irregularity in the spinal curvature, quantified as the Spinal Curvature Irregularity Index (SCII), was correlated with the number of fractures and could identify women with vertebral fractures.
VHs and bone mineral density (BMD) were measured using DXA (Lunar Prodigy, GE Healthcare) in 470 Lebanese women aged 20-88 yrs. Vertebral heights (T4-L4) were obtained from a lateral spine scan while the BMD (L1-L4) was obtained from an AP-spine scan. Regularity of the curvature of the spine was measured by comparing the ratio of the anterior to the posterior vertebral height of one vertebra to that of the adjacent one (calculated in caudocephalic direction). The SCII in % for adjacent vertebrae *i* and *i+1* is given by

$$SCII_{i,i+1} = [(1 - I_{i,i+1})^2]^{1/2}$$

with

$$I_{i,i+1} = Ha_i/Hp_i * Hp_{i+1}/Ha_{i+1}$$

(Ha_i , Hp_i anterior and posterior heights of vertebra *i*; Ha_{i+1}, Hp_{i+1} anterior and posterior heights of vertebra *i+1*). Irregularity was measured at each pair of adjacent vertebrae and expressed as the SCII for the entire thoracolumbar spine. The average SCII in an individual is given by the sum of all $SCII_{i,i+1}$ devided by the number of adjacent vertebrae in the individual. Vertebral fractures were classified as wedge and as crush deformities using cutoffs of 3 SD (moderate) or 4 SD (severe).
A total of 74 deformities (43 moderate, 31 severe) were identified in the lateral scans of 56 of the 470 women. In all women younger than 50 mean SCII was 6.1% while for all women older than 50 mean SCII was 7.1%. To obtain a normal distribution of the SCII, the SCII was transformed ($SCII^{0.25}$). There were statistically significant differences between mean values for subjects with and without deformities for SCII (transformed) and age- and weight-adjusted BMD, but not age-adjusted height. Binary logistic regression calculations show that SCII is a good predictor of the presence of deformities, while age-adjusted height and age & weight-adjusted BMD are not. The probability of having a deformity increases about 1.75 times for every SD increase in transformed SCII.
We conclude that SCII provides a valuable measure to identify women with vertebral fractures.

Treatment with Tibolone Partially Protects 3-D Microarchitecture of Lumbar Vertebral Bone Tissues and Prevents Ovariectomy-induced Reduction in Mechanical Properties. M. Ding*[1], M. Dalstra*[1], H. Weinans[2], A. G. Ederveen[3], I. Hvid*[1]. [1]Orthopaedic Research Laboratory, Aarhus University Hospital, Aarhuc C, Denmark, [2]Orthopaedic Research Lab, Erasmus University Rotterdam, Rotterdam, Netherlands, [3]Dept of Pharmacology, N.V. Organon, Oss, Netherlands.

Tibolone (Org OD14) is a tissue selective steroid with estrogenic effects on the brain, bone and vagina, without stimulating the breast and endometrium. A previous study has shown that long-term treatment with tibolone prevents ovariectomy (OVX) induced bone loss in rats. The aim of this study was to investigate the effects of tibolone on three-dimensional (3-D) microarchitecture and mechanical properties of rat lumbar vertebra. We hypothesized that tibolone might have significant effects on 3-D microarchitecture of vertebra, thus to preserve OVX-induced reduction in mechanical properties.
One hundred and sixty-six female 10-month-old rats were randomly allocated into one of the 13 groups. These groups included a baseline control group at experiment start-up and three groups (SHAM, OVX and OVX+tibolone) at each termination point - 4, 14, 34, or 54 weeks. The treated groups received tibolone 2 mg/kg/day, orally. After sacrifice, rat third lumbar vertebrae were removed and micro-CT scanned. Microarchitectural properties of the cancellous and cortical bones were quantified and the mechanical properties of the lumbar cancellous and cortical bones were determined separately.
Our data demonstrated that OVX lead to pronounced reduction in mechanical properties and bone mass. Treatment with tibolone increased mechanical properties and improved 3-D microarchitecture of both cancellous and cortical bone as compared to placebo treatment. Long-term treatment with tibolone for 54 weeks prevented OVX-induced reduction in the mechanical properties of both cancellous and cortical bone. Tibolone was shown to have relatively stronger microarchitectural compensation effect on trabecular bone than on cortical bone. Tibolone treatment did not prevent OVX-induced microarchitectural deterioration over the entire experimental period; there was only a statistically significant difference in microarchitectural parameters between OVX and tibolone groups after 34 weeks of tibolone treatment. This partially improved microarchitecture resulted in full recovery of mechanical properties to normal level, suggesting increased bone quality after long-term tibolone treatment. We concluded that long-term tibolone treatment completely preserved bone's mechanical properties and partially protects OVX-induced microarchitectural deterioration.

SU136

Fluid Flow-induced ATP Release Occurs by a Vesicular Mechanism and Mediates Prostaglandin Release. D. C. Genetos[1], H. J. Donahue[2], R. L. Duncan[3]. [1]Cellular and Molecular Physiology, Pennsylvania State University College of Medicine, Hershey, PA, USA, [2]Orthopaedics and Rehabilitation, Pennsylvania State University College of Medicine, Hershey, PA, USA, [3]Orthopaedic Surgery, Indiana University College of Medicine, Indianapolis, IN, USA.

Emerging data suggests an important role for ATP-activated purinergic (P2) receptors in osteoblast and osteoclast function. In this study, we examined the mechanisms mediating fluid flow-induced ATP release. We found that fluid flow induced a rapid yet transient increase in ATP release compared to static MC3T3-E1 cells (59.8±15.7nM vs. 6.2±1.8nM), peaking within 1 minute of flow onset. While other authors have found a role for gap junctional communication and hemichannels in ATP release in astrocytes and chondrocytes, we found that inhibition of gap junctional communication with 18α-glycyrrhetinic acid had no effect on ATP release in the static or flowed state. We next examined what role vesicle formation and function played had in flow-induced ATP release. Inhibition of vesicle formation with monensin and, brefeldin A significantly attenuated flow-induced ATP release without affecting static ATP release. Inhibition of vesicle fusion at the plasmalemma in the presence of *N*-ethylmaleimide also significantly attenuated ATP release from flowed cells, suggesting that flow-induced ATP release was mediated through vesicular fusion and was dependent on Ca^{2+} entry into the cell via L-type voltage-sensitive Ca^{2+} channels. Activation of P2 receptors with the addition of exogenous ATP to static cells significantly increased prostaglandin E_2 (PGE_2) and I_2 (PGI_2) release, while hydrolysis of secreted ATP with apyrase prevented flow-induced increases in PGE_2 and PGI_2 release. These data suggest a time line of mechanotransduction where fluid shear results in Ca^{2+} entry through activation of L-VSCC's that, in turn, stimulates vesicular ATP release. Further, these data suggest that P2 receptors must be activated to complete the anabolic response of bone to mechanical load.

Normal Bone Geometry but Reduced Bone Mineral at the Femoral Neck with Cystic Fibrosis. J. H. Cole*[1], K. Kent*[2], G. S. Bhudhikanok*[3], L. K. Bachrach[3], M. C. van der Meulen[1]. [1]Sibley School of Mechanical and Aerospace Engineering, Cornell University, Ithaca, NY, USA, [2]Department of Medicine, Stanford University, Stanford, CA, USA, [3]Department of Pediatrics, Stanford University, Stanford, CA, USA.

Low bone mineral density at various anatomic sites is common among patients with cystic fibrosis (CF) (Bhudhikanok *et al.* 1996). Normal bone geometry and reduced bone mineral were reported previously in the femoral cortex of CF patients (Cole *et al.* 2003). The purpose of this study was to examine a primarily cancellous bone site in a population of CF patients and to correlate a bone strength indicator with measures of bone mineral. Bone mineral was assessed for 42 CF patients (15 male, 27 female, ages 8-48) using pencil-beam dual energy X-ray absorptiometry (QDR 1000W, Hologic Corp). Bone mineral content (BMC, g) and areal bone mineral density (BMD, g/cm^2) at the left femoral neck (FN) were recorded at baseline and at a 1.5-year follow-up visit. Bone mineral apparent density (BMAD, g/cm^3) was used as an estimate of volumetric bone density (Katzman *et al.* 1991). Geometric strength at the FN was assessed using the section modulus (Z, cm^3), an indicator of cross-sectional bone strength calculated from the cross-sectional moment of inertia (I, cm^4) and the bone diameter (D, cm). Both I and D were computed directly using the X-ray absorption curve from a single scan line at the mid-neck (Myers *et al.* 1993), requiring no geometric assumptions. Linear regressions were used to assess the correlation of Z with bone mineral measures (BMC, BMD, BMAD). Z increased linearly with BMC ($p<0.0001$, r^2=0.84-0.86) and BMD ($p<0.0001$, r^2=0.52-0.60) but not with BMAD at both baseline and follow-up. Similarly, changes in Z increased linearly with changes in BMC ($p<0.0001$, r^2=0.72) and BMD ($p<0.0001$, r^2=0.49) but not BMAD. As expected, Z was linearly related to body mass at baseline and follow-up ($p<0.0001$, r^2=0.68-0.72). Surprisingly, however, this relationship was identical between CF patients and a normal Caucasian population (48 male, 53 female, ages 9-26). Therefore, as was seen in the analysis at the mid-diaphysis, the geometry of the FN for CF patients is comparable to that of normal subjects for a given body size. This, along with a reduced BMAD, suggests that their skeleton does not compensate in size for the reduction in bone mineral density. This lack of adaptation is present for both cortical and cancellous bone sites. For CF patients, the cancellous bone of the FN is not more responsive to its mechanical environment than the femoral cortex, and this may account for the high incidence of fragility fractures across all sites.

Radiographic Image Resolution of Fan-Beam Bone Densitometers Performing Vertebral Fracture Assessment. L. G. Jankowski*[1], G. Avery*[2], S. B. Broy[1]. [1]Center for Arthritis and Osteoporosis, Illinois Bone and Joint Institute, Morton Grove, IL, USA, [2]Nuclear Medicine, Methodist Hospital, Indianapolis, IN, USA.

We measure the radiographic resolution of the vertebral fracture assessment imaging modes on two different bone densitometers.

Bone densitometers have been approved for radiographic imaging of the lumbar and thoracic spine for vertebral fracture assessment (VFA), to identify vertebral deformities and measuring vertebral heights. One limitation often cited for these devices is their inherently poorer resolution compared to conventional radiographs. We acquired images of a standard radiographic line pair phantom (Nuclear Associates Part No. 07-538) using the recommended acquisition and image processing modes for VFA, on a GE-Lunar Prodigy Advance system with ClearView software, and a Hologic QDR 4500 SL, with Image-Pro software. We determined the inherent system resolution in units of line-pairs per millimeter (lp/mm).

The phantom was orientated with the lines in the transverse plane (horizontal lines on screen), as well as in the sagittal plane. The Prodigy scanner exhibited detector saturation when the phantom was scanned in air, so the phantom was placed between acrylic plates, each 4 cm thick, and maintained this configuration on the 4500SL. Two readers, using all available imaging tools provided by the respective manufacturers, obtained the best possible image resolution of the phantom line sets on the image display. The resolution was recorded as the highest grouping of lines that can be clearly resolved as three separate lines. When the readers disagreed, the average of their readings were used.

The best resolution on the QDR4500 was 0.9 lp/mm in the transverse plane, and 0.6 lp/mm in the sagittal plane. The best resolution on the Prodigy in the transverse plane was less than 0.6 lp/mm, the coarsest line spacing in the phantom, as only one of the two readers was able to visualize this grouping. Neither reader could visualize the line sets of the phantom in the sagittal plane on the Prodigy. The ability to identify compression deformities using a bone densitometer is limited by the inherent imaging resolution. The Hologic systems provided consistently better resolution than the Prodigy system in both the transverse and sagittal planes. The radiographic phantom used did not have sufficiently coarse gradations to accurately quantify the resolution on the Prodigy. A resolution phantom of suitable design may have value in assessing and monitoring system performance, or in selecting systems suitable for VFA.

Assessment of Femoral Neck Torsional Strength Indices. M. Sode*[1], J. Keyak*[2], M. Bouxsein*[3], T. Lang[1]. [1]Radiology, University of California, San Francisco, CA, USA, [2]Orthopaedic Surgery, University of California, Irvine, CA, USA, [3]Orthopedic Research Laboratories, Beth Israel Deaconess Medical Center, Boston, MA, USA.

Torsional strength indices (TSI), computed from QCT scan data may be predictive of bone strength. The goal of our study was to evaluate three TSI at femoral neck for their repeatability and correlations with femoral neck strength by a 3D finite element model (FEM).

To evaluate repeatability, nine subjects (60±10 years) underwent QCT imaging of the hip (GE 9800Q, 3mm slices) twice with repositioning between scans. Polar moment of inertia (CSMI) in a 4-mm thick transverse section at minimum cross-sectional area (CSA) of the left femoral neck was calculated. TSI were derived by dividing CSMI by a calculated bone width derived from CSA. Three TSI were computed: 1) TSI_E in which the image voxels were mapped to elastic modulus prior to CSMI calculation, 2) TSD in which the images had units of bone density and 3) TSC in which only voxels inside the cortex were included. Precision of TSI was computed from the nine repeat scans as the root-mean square coefficient of variation in %.

We obtained QCT scans of the left hip in 30 women (74±4 years) and computed TSI_E, TSD and TSC. The FEM of the left hip of each subject was generated and loaded simulating single-limb stance, giving failure load (FL) in kN. Agreement between TSI and FL was determined using linear regression and root mean square error (RMSE) was computed for the regression equation. The effects of trabecular BMD (tBMD), cortical BMD (cBMD), cortical volume (cVOL), and CSA on TSI were determined by multi-linear regression and given as standardized β, which represented the effect in units of SD on TSI of a 1SD change in each predictor variable.

Precisions for TSI_E, TSD and TSC were 6%, 5% and 3% respectively. Correlations of TSI with FL and β values for tBMD, cBMD and CSA are tabulated below.

Modest agreement of TSI with FL may be due to the fact that only torsion is taken into account and that they represent (unlike FEM) a thin section of the femoral neck. Also, FEM tends to predict fractures near the femoral head rather than at the minimum CSA. Because the cortical elements have high density and are situated at the bone periphery, TSI_E and TSD measures were strong functions of cBMD and CSA.

Only the TSI were addressed here; strength indices in other loading conditions will be explored.

Calcium Absorption in Hip Fracture Subjects. A. G. Need*[1], M. Metz*[1], P. D. O'Loughlin*[1], M. Horowitz*[2], B. E. C. Nordin*[1]. [1]Clinical Biochemistry, Institute of Medical and Veterinary Science, Adelaide, Australia, [2]Department of Medicine, Royal Adelaide Hospital, Adelaide, Australia.

Impaired intestinal calcium absorption has been reported in hip fracture cases [1] and claimed to increase the risk of hip fractures prospectively [2] but the relation between this impairment and circulating vitamin D metabolites has not been examined. We have measured fractional radiocalcium absorption (α)[3] and serum 25 hydroxyvitamin D (25D) and 1,25 dihydroxyvitamin D (1,25D) in 56 ambulant outpatients (48 female, 8 male) of mean age 67(SD11) yr with prevalent hip fracture, and in the same number of age and sex matched controls.

Mean α was significantly lower in the fracture subjects (0.46(0.18) vs 0.63(0.22):P<0.001) as was serum 1,25D (89(46) vs 106(36) pmol/L:P=0.036), but 25D did not differ significantly between the groups (54(27) vs 61(23) nmol/L:P=0.17). α was significantly related to 1,25D in both groups but not related to 25D in either group. Using the relation between α and 1,25D in the controls (α=0.36+0.0026x1,25D: r=0.41,P=0.002) as the reference line we calculated that the lower 1,25D in the fracture cases (17 pmol/L) could only account for 20% of their calcium absorption deficit.

The results suggest that the calcium absorption deficit in cases of hip fracture is largely due to a diminished intestinal response to circulating 1,25D.

Quantitative Analysis of Messenger RNA Expression of Lysyl Hydroxylases in Mandibular and Femoral Bone Marrows of Senescence-Accelerated Mice. T. Matsuura, K. Yamamoto*, Y. Nagashima*, Y. Daigo*, M. Katafuchi*, H. Sato*. Oral Rehabilitation, Fukuoka Dental College, Fukuoka, Japan.

Messenger RNA analysis of bone marrow is a potential examination to diagnose the quality of maxillofacial bone. Lysyl hydroxylases (LHs) are responsible for collagen cross-linking, determining bone quality. To investigate mRNA expression patterns of LHs in bone marrows with potentially different bone quality, we quantified the mRNA expression of LH isoforms (LH1, LH2, and LH3), type I collagen (COLI), and alkaline phosphatase (ALP) in the mandibular and femoral bone marrows of three senescence-accelerated mouse (SAM) strains; osteoporosis model SAMP6, mandibular osteoarthritis model SAMP8, and their control SAMR1. Total RNAs directly isolated from the bone marrow were used for reverse transcription and the products were then used to quantify mRNA expressions of the molecules using a real-time PCR assay. The experimental protocol was approved by the Ethical Committee for Animal Experiments in our institute. The expression levels of any molecule were varied in the mandibular and femoral bone marrows. The expression levels of COLI, ALP, and LH2 were higher in the mandibular than in the femoral bone marrows. In the mandibular bone marrow, the expression levels of COLI of 3 SAM strains was significantly different from one another. In both the bone marrows, the expressions between COLI and LH1 and between ALP and LH2 were associated with each other. This study indicates that gene expression patterns of LH1 and LH2 in bone marrows are associated with those of developmental bone markers and those of LH2 and the bone markers are differential between mandible and femur. Quantitative mRNA analysis of LHs in combination with developmental bone markers in bone marrows may be useful to investigate their relationship with quality of maxillofacial bone.

Markers of Bone Remodeling Predict Rate of Bone Loss in Multiple Sclerosis Patients Treated with Low Dose Glucocorticoids. J. J. Stepan[1], E. Havrdova*[2], M. Tyblova*[2], D. Horakova*[2], V. Ticha*[2], V. Zikan*[1], I. Novakova*[2]. [1]3rd Dept. of Internal Medicine, Charles University Faculty of Medicine, Prague, Czech Republic, [2]Dept. of Neurology, Charles University Faculty of Medicine, Prague, Czech Republic.

The contribution of the underlying disease, for which glucocorticoids are used, confounds the assessment of glucocorticoid effects on bone. Multiple sclerosis (MS) is a gait disorder characterized by acute episodes of neurological defect leading to progressive immobilization. Long-term glucocorticoid use and progressive immobilization, along with vitamin D deficiency, are likely to be determinants for osteoporosis and skeletal muscle atrophy, and the increased risk of fracture in patients with multiple sclerosis. The aim of this study was to evaluate the clinical value of markers of bone remodeling in assessment of rate of bone loss in patients with MS long term treated with low dose glucocorticoids. The study involved 70 patients with MS. Thirty one women were premenopausal (mean age, 35.1 ± 8.1 yrs), 16 postmenopausal women (mean age, 50.3 ± 5.0 yrs) were on regular hormone replacement therapy. Mean age of men was 42.4 ± 12.1 yrs. The patients received the daily recommended dose of calcium (500 mg) and vitamin D (400 IU). Motor function of the patients was evaluated using the Kurtzke Expanded Disability Status Scale (KEDSS). Bone mineral density (Hologic QDR 4500) was determined at the lumbar spine and proximal femur at baseline and after 1.8 ± 0.8 years. Bone remodeling was assessed using circulating concentrations of type 1 collagen cross-linked C-telopeptide (beta CTX), aminoterminal propeptide of type I procollagen, and N-MID osteocalcin (OC). A control group of 140 age-matched healthy subjects was used to compare bone-turnover markers. The plasma CTX concentration was the most significant parameter of bone remodeling which correlated with the rate of bone loss and with the KEDSS. After adjustment for BMI, the plasma CTX concentration remained the most significant predictor of the rate of bone loss ($p<0.05$). The rate of bone loss at the proximal femur was not significantly different between tertiles of plasma OC concentrations. In physically disabled patients, plasma OC was not significantly increased despite evidence of increased bone resorption, indicating an impaired coupling between bone resorption and bone formation in GC treated patients. In conclusion, in physically active patients with MS treated with low-dose GC, the bone-turnover markers were not different from controls. Patients having plasma CTX but markers of bone formation higher as compared to controls were confirmed 2 years later as bone losers.

SU143

Urine Osteocalcin as a Marker of Bone Metabolism. K. K. Ivaska*[1], S. Käkönen*[1], P. Gerdhem[2], K. Akesson[2], K. J. Obrant[2], A. Nenonen*[3], A. Heinonen[3], P. Kannus*[3], K. Uusi-Rasi[3], H. K. Väänänen*[1]. [1]Institute of Biomedicine, Department of Anatomy, University of Turku, Turku, Finland, [2]Department of Orthopaedics, Malmö University Hospital, Malmö, Sweden, [3]UKK Institute for Health Promotion Research, Tampere, Finland.

Osteocalcin (OC) is produced by osteoblasts and although most of OC is adsorbed to bone hydroxyapatite, some OC leaks into blood stream where it can be detected. Part of OC found in blood is also thought to originate from degradation of bone matrix during bone resorption. Levels of circulating OC have been widely used in clinical investigations as a marker of bone turnover. In addition to circulation, OC can be found in urine as mid-molecule fragments and these fragments (U-OC) can be classified into two main categories according to their size.

We developed three immunoassays for the detection of various molecular forms of U-OC. Competitive U-TotalOC assay recognized OC fragments from both U-OC categories whereas two-site assays U-MidOC and U-LongOC were unable to detect more truncated fragments in the second category. U-OC was studied in healthy premenopausal women (n=58) and postmenopausal women with or without hormone replacement therapy (HRT) (n=13 and n=20, respectively). The association of U-OC and bone mineral density (BMD) was evaluated in 1040 randomly recruited 75-year-old women. Furthermore, U-OC was studied in a one-year double-blinded placebo-controlled alendronate intervention trial (n=76 for both placebo and alendronate) in which U-OC levels were measured at baseline and after 3, 6 and 12 months. All U-OC values were corrected for urine creatinine.

U-OC measured with any of the three assays had a significant correlation to BMD measured at various body sites ($p<0.0001$, Spearman's correlation coefficients from -0.15 to -0.29). Total concentration of U-OC (U-TotalOC) was significantly higher in postmenopausal women compared to premenopausals ($p<0.05$) and U-MidOC and U-TotalOC assays were also able to distinguish between postmenopausal women with and without HRT ($p<0.05$ and $p<0.01$). Furthermore, all U-OCs were significantly reduced after three months treatment with alendronate ($p<0.001$) and did not alter during the remaining follow-up period. Previously we have also demonstrated that U-MidOC and U-LongOC were able to predict fractures, particularly fractures engaging trabecular bone.

In conclusion, urine osteocalcin offers an alternative method for monitoring bone metabolism and may have potential applications in diagnostics related to disorders of bone metabolism.

Differences in Baseline NTX Levels in Treatment-Naïve Patients and Patients Previously Treated with Alendronate, Etidronate, or Hormone Replacement Therapy. W. G. Bensen*[1], W. P. Olszynski[2], A. Jovaisas*[3], S. Morin[4], J. Stewart*[5], C. Crowley[6], K. S. Davison[1]. [1]Med., McMaster Univ., Hamilton, ON, Canada, [2]Med., Univ. of Saskatchewan, Saskatoon, SK, Canada, [3]Med., Univ. of Ottawa, Ottawa, ON, Canada, [4]Int. Med., McGill Univ. Health Centre, Montreal, PQ, Canada, [5]Aventis Pharma Inc., Laval, PQ, Canada, [6]P&G Pharmaceuticals, Toronto, ON, Canada.

Anti-resorptive therapies differ in the rate and extent of bone turnover suppression, as well as the rate and extent of resolution of bone turnover after their discontinuation. The Point-of-Care device and Actonel® Once-a-Week Dosing Satisfaction Trial (POWER) is a 24-week, multi-centre, prospective, open-label, randomized, controlled community practice-based study designed to determine whether feedback on response to therapy, assessed by bone turnover, will improve subject satisfaction with therapy. Eligible patients included postmenopausal women diagnosed with osteoporosis who were untreated or previously treated for osteoporosis, but discontinued prior to enrolment due to lack of effect or intolerance. All patients were assigned Actonel® 35 mg Once-a-Week treatment. The levels of urinary cross-linked N-telopeptides of type I collagen (NTX) were measured at baseline in half the cohort using the Osteomark® NTX Point-of-Care device.

Baseline Characteristics of Bone Turnover Marker Group (mean±SD)

Characteristic	Treatment naïve	Previously treated		
		Hormone	Etidronate	Alendronate
Sample size	641	66	269	74
Age in years (y)	67±11	66±10	71±10	68±11
Uncorrected NTX (nM BCE/ mM creatinine)	71±45	67±44	58±38	39±25
Time on therapy (mo)	NA	49±73	34±27	22±30
Time since therapy discontinued (mo)	NA	4.5±8.3	2.9±6.4	4.0±5.6

Baseline NTX (95% CI), corrected for time on and time since discontinuation of therapy, was 41 (32-50) for the alendronate group, 59 (54-63) for the etidronate group and 64 (55-73) for the hormone replacement therapy group. Baseline NTX was significantly lower in the alendronate group compared to either the etidronate ($p=0.0004$) or hormone replacement therapy ($p<0.001$) groups. The untreated group had significantly ($p<0.0001$) higher baseline NTX than both bisphosphonate groups. No significant NTX differences existed between etidronate and hormone replacement therapy groups. Baseline NTX levels with previous alendronate therapy were the lowest of all therapies investigated, independent of time on and time since discontinuation of therapy. These results may have important implications for individuals who discontinue anti-resorptive therapy and plan to begin anabolic therapy, as decreased levels of bone turnover may attenuate the anabolic effects.

Pharmacokinetics of ^{41}Ca Distribution in Mice. D. W. Burton[1], D. J. Hillegonds*[2], R. L. Fitzgerald*[3], D. A. Herold*[3], L. J. Deftos[1]. [1]Medicine, University of California and SDVAMC, San Diego, CA, USA, [2]Center for Accelerator Mass Spectrometry, Lawrence Livermore National Laboratory, Livermore, CA, USA, [3]Pathology, University of California and SDVAMC, San Diego, CA, USA.

Previous studies have shown the value of ^{41}Ca, a rare isotope with a half-life of 10^5 years, in tracking bone health, primarily related to osteoporosis. Accelerator mass spectrometric quantitation of ^{41}Ca offers advantages over ^{45}Ca decay counting because of the elimination of radiation hazards in both handling and waste disposal, while retaining the advantages of high tracer selectivity and sensitivity. This novel ^{41}Ca tracer technique promises to provide a direct measure of net bone calcium balance in both humans and in animal models. Our goal is to use ^{41}Ca technology to develop a minimally invasive method to detect the transition from the primary cancer site of prostate, breast or lung cancers to the skeleton and to assess the efficacy of treatments on the bone lesions. To demonstrate the feasibility of using the ^{41}Ca assay in mouse models for lytic and/or osteoblastic bone cancer lesions, we established a baseline for the pharmacokinetic distribution of the ^{41}Ca material in mice. In this study, normal, immunocompromised SCID mice were injected IP with 0.55 nCi ^{41}Ca / 0. 5 ml PBS. After 4 weeks, to allow the mice to equilibrate with a stable pool of ^{41}Ca, they were exanguinated and various organs harvested. The tissues were weighted, and microwave digested with nitric acid. Carrier ^{40}Ca was added to the samples and they were analyzed for ^{41}Ca/Ca ratios by accelerator mass spectrometry (AMS). The ^{41}Ca dosed mice specimens had ^{41}Ca/Ca ratios >100-fold above non-^{41}Ca dosed tissue controls. As expected, the majority of the ^{41}Ca that was retained by the mice was in the skeleton. The tibiae and femurs demonstrated >5000-fold higher levels of ^{41}Ca/^{40}Ca /g wet weight compared to the other soft tissues specimens evaluated (heart, kidney, muscle, spleen, liver, and RBCs). The serum ^{41}Ca/Ca ratios were also readily measurable above background. Ongoing studies using the ^{41}Ca assay in a SCID mouse model for prostate cancer that produces lytic bone lesions are currently underway. If the ^{41}Ca assay demonstrates an excess loss of ^{41}Ca in the sera or feces from mice that have overall lytic bone lesions compared to control mice, this ^{41}Ca method could be applied clinically to patients for monitoring skeletal changes.

Urinary Gamma-glutamyl Transpeptidase (GGT) Activity Measurement Is Useful as a Novel Biochemical Marker for Bone Metabolism. I. Kodama[1], M. Sanada*[1], M. Tsuda*[1], K. Ohama*[2]. [1]Obstetrics and Gynecology, Hiroshima University, Hiroshima City, Japan, [2]Hiroshima Prefectural Hospital, Hiroshima City, Japan.

The purpose of this study is to investigate the measurement of urinary gamma-glutamyl transpeptidase (GGT) activity is useful as a biochemical marker for bone metabolism in postmenopausal women.

A total of 80 postmenopausal Japanese women, aged 48 to 74 years, were admitted to study. Each subject had experienced natural menopause for at least 1 year but not longer than 5 years. All participants were followed up without any lifestyle modification. A total of 30 women (mean age 52.5±1.3) received conjugated equine estrogen, 0.625 mg daily each morning for 12 months (HRT group). A total of 25 women (mean age 64.2±1.6) received alendronate sodium 35mg daily each morning for three months (ALN group). Urinary cross-linked N-telopeptides (NTX), GGT activity and serum GGT activity were measured on all HRT group subjects before the start of therapy and for 3, 6 and 12 months after therapy. Urinary NTX and GGT activity were measured on all ALN group subjects before the start of therapy and three months after therapy. Lumber spine (L2-L4) bone mineral density (BMD) and femoral neck BMD were measured using a dual X-ray absorptiometer (DPX-alpha, Lunar Co). These parameters were measured on all HRT group subjects before the start of therapy and for 6 and 12 months after therapy.

Correlation between urinary GGT activity and NTX were significant at before the start of therapy, and those relations were being maintained within the period of therapy (HRT group and ALN group) .

L2-L4 BMD was increased after the start of the HRT, averaging +3.24% and +5.91%, at the 6 months and 12 months, respectively.

Femoral neck BMD was slightly increased compared with baseline value, averaging +0.97% and +1.97 %, at the 6 months and 12 months after HRT.

In conclusion, we now report that urinary GGT activity measurement is useful as a novel biochemical marker for bone metabolism.

Disclosures: ***I. Kodama****, None.*

Technical and Clinical Evaluation of a Point of Care Device for Measurement of N-Telopeptide Fragment of Type I Collagen in Urine. R. A. Hannon, J. V. Boreham*, J. A. Porter*, K. Karnik*, A. C. Eagleton*, R. Eastell, A. Blumsohn. Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom.

Assessment of bone turnover using point-of-care technology may facilitate therapeutic monitoring in osteoporosis. We examined the detailed technical and clinical performance of a point of care device (POCD) for measurement of NTX and creatinine (Cr) in urine (OSTEOMARK® NTX Point-of-Care) in comparison with laboratory methods (automated chemiluminescent immunoassay, Ortho ECI NTX; manual immunoassay, Osteomark ELISA NTX; enzymatic Cr).

Between device analytical imprecision was 20.4% (CV) over 12 weeks at 17.5nmolBCE/mmol. The effect of in-vivo dilution on Cr correction was assessed by measuring NTX/Cr in fasting second morning void urine on two occasions in 19 healthy adults with a) fluid restriction, b) 500ml oral water at first morning void. POCD NTX/Cr was not significantly affected by fluid intake (ratio hydrated/dehydrated 1.22±0.12) despite a 3-fold difference in urine concentration. Within-subject imprecision of POCD NTX/Cr was 26.7% (CVa+i) at an interval of 1 day, and 41.7% at an interval of 1 week. The circadian rhythm of POCD NTX/Cr was similar to that for ECI NTX/Cr. POCD NTX/Cr was 37.4±4% higher for samples collected at 07h30 vs 13h30 in 15 healthy volunteers. In healthy adults POCD NTX/Cr decreased by 20.0±3.8% following milk supplementation (n=20, 500mL bd x 1wk) and by 24.6±4.8% following calcium supplementation (n=25, 500mg bd x 1wk). In postmenopausal women with osteoporosis POCD NTX/Cr decreased by 60.9±7.4% following alendronate (n=15, 10mg + 500mg Ca x 24wks), and by 50.0±4.8% following risedronate (n=14, 5mg x 13wks). All based on SMV urine collection. The apparent response to risedronate depended on the timing of sample collection (24.3±6.9% at 13h13, vs 50.0±4.8% at 07h30 P<0.01). Responses were similar in all respects to ECI NTXC/Cr and ELISA NTX/Cr. Calibration was similar to ECI NTX/Cr (slope of Deming comparison 1.14, r=78, n=60 over the reference range). POCD NTX/Cr was higher in postmenopausal women (geometric mean 55.3nmol/mmol [95% CL 46.4-65.8] n=30) vs premenopausal women (35.6nmol/mmol [30.9-41.0] n=30, P<0.01), and the estimated premenopausal reference interval (95% limits 16.6-76.5nmol/mmol) was similar to ECI NTX/Cr.

Data were obtained under controlled laboratory conditions. POCD may perform differently under other conditions. Although the technical imprecision of POCD NTX/Cr may be greater than laboratory NTX/Cr, data obtained by the POCD is clinically plausible, unaffected by urine flow rate, comparable to that obtained using ELISA NTX and ECI NTX, and is likely to be useful for therapeutic monitoring.

Serum Osteocalcin Assay by the Elecsys 2010 Is Robust and Suitable for Monitoring Bone Turnover. E. T. Leary, T. K. Aggoune*, T. H. Carlson*. Pacific Biometrics, Inc., Seattle, WA, USA.

Serum osteocalcin (OC) has demonstrated clinical utility as a biomarker of bone formation. However, OC is commonly believed to be unstable and to require special sample handling. OC fragments especially produced in some disease states may interfere with many existing assays. Therefore, we evaluated the long-term performance of the N-MID Osteocalcin assay on the automated Elecsys 2010 analyzer (Roche Diagnostics) and the stability of different sample types under a variety of conditions. The Elecsys OC is specific for intact OC (amino acids 1-49) and the main N-terminal fragment (amino acids 1-43) resulting from proteolytic cleavage after blood collection.

OC assay precision was evaluated by commercial and in-house quality control samples. To evaluate the stability of OC by Elecsys, matched serum, K_3 EDTA plasma (EDTA) and Li heparin plasma (Heparin) were collected from volunteers. Sample stability was evaluated at room temperature, at 4 ° C for 7 days and at -70°C for 2 yr. To measure OC in a specimen matrix likely to accumulate fragments, matched serum, EDTA, and Heparin samples were collected from 44 subjects on kidney hemodialysis. OC analyzed within one month of collection and again after 4 yr of storage at -70°C were compared. To demonstrate that samples stored long-term were suitable for monitoring clinical response, OC was measured in 103 osteoporotic postmenopausal women on antiresorptive therapy, at baseline and after 12 weeks of treatment. Values determined immediately after the treatment period were compared with those after 3 yr of storage at -70°C.

Within-run precision of OC was 1.4 -3.6 % CV at 72 - 7.9 ng/mL. Among-run precision was 3.7-5.9% CV at 21.3 - 110 ng/mL. OC concentrations in serum, EDTA and Heparin did not differ significantly. EDTA was a more stable matrix at room temperature and at 4 deg C than either serum or Heparin (3-4 days versus 24 hr or less). Change in OC at 24 mo at -70°C was less than 10% for all three sample types, with no trend. Assays of samples from subjects on renal dialysis with greatly elevated values (17-1133 ng/mL, SD = 300 ng/mL) recovered well in dilution studies. OC values agreed after 4 yr of storage in serum, EDTA, and Heparin and correlated well with the initial results (all r > 0.99, slopes 0.92 - 1.01 and intercepts -7.2 - +1.3 ng/mL). Initial OC results for 103 osteoporotic women on antiresorptive therapy exhibited a mean decrease of 20.2% from baseline (baseline mean = 30.4 ng/ml) compared to -21.1 % (baseline mean = 32.2 ng/mL) measured in samples following 3 yr of storage.

We conclude the N-MID Osteocalcin assay on the Elecsys 2010 is stable and robust, and may be included in clinical trials with usual precautions.

Unexplained Increase in Parathyroidectomies in the U.S. T. Cantor. President, Scantibodies Laboratory, Inc., Santee, CA, USA.

With the increased use of vitamin D analogs for "medical parathyroidectomy" for ESRD (end stage renal disease) patients it was expected that the number of parathyroidectomies would decrease. Therefore, the USRDS (US Renal Data Services) database on parathyroidectomies was examined to see if this expectation was, indeed, realized. From 1995 through 1998 the number of parathyroidectomies declined steadily among the Medicare ESRD patients in the US as expected. However, in 1999 the trend changed, with an increasing number of parathyroidectomies. This trend has persisted through 2001 (the latest data available). From 1999 to 2000 there was a 17% increase in parathyroidectomies and from 2000 to 2001 there was a 29% increase in parathyroidectomies. K/DOQI (National Kidney Foundation's Kidney Disease Outcome Quality Inititative) guideline 14 states that "parathyroidectomy should be recommended in patients with severe hyperparathyroidism (serum levels of intact PTH >800 pgm/ml)." Therefore, the predominant intact PTH assay used should be examined for any changes that might explain this increase in parathyroidectomies. Meanwhile, this data indicates a reason for caution before prescribing a parathyroidectomy.

Microarray Study of Circulating Monocytes in Search for Functional Genes for Osteoporosis. Y. Z. Liu*, V. Dvornyk*, Y. Lu*, H. Shen*, J. Wilde*, T. Conway*, R. R. Recker, H. W. Deng. Osteoprosis Research Ctr. and Dept. of Biomedical Sciences, Creighton Univ., Omaha, NE, USA.

Circulating monocytes are major target cells for hormones in bone metabolism and actively participate in osteoclastogenesis by either serving as the early precursors of osteo-

clasts or producing cytokines important to osteoclast differentiation, activation, and apoptosis.
Gene expression studies of blood monocytes in high vs. low BMD subjects may identify genes functionally relevant to osteoclastogenesis and thus to bone mass variation and pathogenesis of osteoporosis.
In this study, we analyzed gene expression of blood monocytes using Affymetrix HG-U133A GeneChip®, containing probes for 14,500 genes. The monocytes came from 14 perimenopausal women aged 47-55. The subject distribution and BMD Z score for the L1-4 (mean±SD) are listed in Table 1A.
Comparison of low vs. high BMD women has identified 42 differentially expressed genes (p<0.001). Since menopause has dramatic effects on bone loss, we also compared 4 postmenopausal low vs. 4 postmenopausal high BMD women in order to identify genes relevant to postmenopausal BMD variation. This revealed 69 differentially expressed genes (p<0.001). Their biological functions are listed in Table 1B (↑,↓: up or downregulated).

Table 1A	Pre-		Post-menopausal	
	N	Z_{BMD}	*N*	Z_{BMD}
High BMD	4	2.74±1.04	4	2.03±0.95
Low BMD	2	-0.83±0.21	4	-1.67±0.17

Table 1B	Low vs. high BMD		Post-M low vs. high BMD	
	↑	↓	↑	↓
Cell signaling	6	1	4	2
Transcription regulation	2	-	3	2
Proteolysis	1	1	1	3
Apoptosis	1	1	2	1
Other (e.g., immune response)	21	8	35	16
Total	31	11	45	24

Among the genes differentially expressed, several ones are of potential importance. The FOLR2 gene is upregulated in low BMD subjects and its upregulation has been associated with monocyte activation in inflammatory conditions. JAK2, GPR44, and GPS1 are members of two important pathways for monocyte differentiation and proliferation, i.e., JAK/STAT and MAPK. The first two genes are up- and the last downregulated in low BMD subjects. Two genes related to bone metabolism, caldecrin and P2RX5, are down and upregulated respectively in postmenopausal low vs. high BMD subjects. The caldecrin gene can inhibit PTH's bone resorption and the P2RX5 gene is involved in interleukin processing and release as well as activation of NF-κB and p38 MAP kinase. Importantly, the chromosome regions of these two genes have also been found linked to BMD.
This is the first *in vivo* gene-expression profiling study of osteoporosis in humans. By confirming important genes relevant to bone metabolism and identifying novel genes for further study, it demonstrates the power and prospect of microarray in genetic dissection of osteoporosis.

Genetic Liability to Fracture in Elderly. K. Michaëlsson[1], H. Melhus[2], H. Ferm*[1], A. Ahlbom*[3], N. Pedersen*[4]. [1]Dept. of Orthopaedics, University Hospital, Uppsala, Sweden, [2]Dept. of Clin. Pharmacol, University Hospital, Uppsala, Sweden, [3]IMM, Karolinska Institutet, Stockholm, Sweden, [4]Dept. of Epidemiol. and Biostat, Karolinska Institutet, Stockholm, Sweden.

The extent of genetic influence on fracture risk is unclear. Twins offer a natural study population for evaluating genetic risk. The authors of the only previous fracture twin study concluded that the heritability of osteoporotic fracture risk was low. On the contrary, genetic influence on variation in BMD has been determined as substantial and a low BMD has become the most established risk factor for osteoporotic fractures. The extent to which BMD is the primary risk factor for osteoporotic fractures ought to be reflected in genetic liability to these fractures. On the other hand, if concomitant diseases, balance disorders or lifestyle habits not directly related to BMD but to fracture risk have a low genetic impact, these may modulate and counterbalance the strong genetic impact of BMD when estimating the influence of genetic propensity to fractures. A low genetic impact on fracture risk should encourage life style intervention approaches but a high genetic influence should focus research and primary prevention efforts to families with high risk of fractures.
In order to evaluate the genetic liability of fractures in the elderly we used a cohort, within the Swedish Twin Registry, of all 33,432 twins born 1896-1944 who were alive in 1972. The Swedish Inpatient Registry and computer assisted telephone interviews enabled us to identify twins with fractures. There was 6,520 twins with any fracture, 3,681 with any osteoporotic fracture and 1,097 with a hip fracture after the age of 50 years.
Genetic variation in liability to fracture differed considerably by type of fracture and age. Less than 20% of the overall age-adjusted fracture variance was explained by genetic variation. The age-adjusted heritability of any osteoporotic fracture was, however, somewhat greater (0.27, 95% CI 0.09-0.28), and for hip fracture alone, 0.48 (95% CI 0.28-0.57). The genetic influence was not attenuated after further adjustment for several known osteoporotic covariates. Genetic influences were considerably greater for first hip fractures before the age of 69 years (0.68, 95% CI 0.41-0.78) and between 69-79 years (0.47, 95% CI 0.04-0.62) than for hip fractures after 79 years of age (0.03, 95% CI 0.00-0.26).
These findings can be important to effectively target interventions and research efforts to prevent fractures. The search for susceptibility genes and environmental factors that may modulate expression of these genes in young patients with hip fracture should be encouraged. Prevention of fractures in the oldest can be focused on life-style interventions.

Variability in Bone Status among Inbred Strains of Mice. S. Syberg*, S. D. Ohlendorff*, Z. Henriksen*, J. Teilmann*, N. R. Jørgensen. Dep. of Endocrinology and Clinical Biochemistry, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark.

More than 70% of the variability in human bone density has been attributed to genetic factors. For experimentally defining the genetic influence on bone status, animal models are important. The purinergic P2X7 receptor mediates intercellular signaling between osteoblasts and osteoclasts, and it is involved in the regulation of osteoclast activity. Knockout models for this receptor have been established, but conflicting results have been reported for the different models. However, the knockouts are based on inbred strains of mice housing a natural mutation in the P2X7 gene, which may account for some of the conflicting results. The purpose of this study was to compare adult peak bone density with bone strength measurements in 5 inbred strains of mice and to relate them to the P451L mutation in P2X7.
Fifteen females from each strains were DEXA scanned to determine bone mineral density (BMD) and bone mineral content (BMC). The ability of the femurs to resist mechanical forces was quantified, by a three-point bending test ex vivo (Maxload/N). Finally, the distribution of the P451L mutation in the strains was determined by sequencing exon 13 of P2X7.
BMD and BMC varied significantly among the strains (see table below). AKR had the higher BMD and BMC, whereas C57BL and BALB had the lower. In bone strength measurements femurs from the C57BL strain were significantly weaker than from the other strains, while femurs from C3H were significantly stronger that the others. The P451L mutation is very frequent in the inbred strains. Between BALB and C57BL, where the latter is housing the P451L mutation of P2X7, there was no significant difference in BMC or BMD, however there was a significant difference in bone strength. BALB mice had significantly stronger femurs than C57BL. However between 129X1 and C3H there was no difference in BMC or BMD, and again a significant difference in bone strength, but in this case the P451L mutation is in the mice with the strongest femur.
In conclusion the P451L mutation in P2X7 is not associated with the difference in bone density of different strains. Thus no correlation between the mutation in P2X7 and bone strength have been found at the age of 4 months. When choosing a strain as background for an animal model of osteoporosis it is important to be aware of the differences in bone status between the strains.

Strain	Mean ± SD			
	BMD (g/cm2)*	BMC (g)*	Maxload (N)*	P451L mutation
AKR/J	0,0576 ± 0,0021	0,599 ± 0,04	30,2 ± 2,4	+
C3H/HeJ	0,0563 ± 0,0018	0,558 ± 0,04	34,2 ± 3,0	+
129X1/SvJ	0,0561 ± 0,0020	0,535 ± 0.05	31,5 ± 3,2	-
BALB/cJ	0,0512 ± 0,0017	0,471 ± 0,03	24,6 ± 1,6	-

Bone Vasculature as a New Marker for Bone Quality Varies within the Femoral Diaphysis of Two Genetically Distinct Mouse Strains. P. Schneider*[1], M. Stampanoni*[2], L. R. Donahue[3], R. Müller[1]. [1]Institute for Biomedical Engineering, ETH and University Zürich, Zürich, Switzerland, [2]Swiss Light Source (SLS), Paul Scherrer Institute (PSI), Villigen, Switzerland, [3]The Jackson Laboratory, Bar Harbor, ME, USA.

In clinical orthopaedics fractures often occur in bones exposed to chronic overload. On the microstructural level bone density and architecture are the dominant parameters determining bone strength. However, to determine tissue strength, cellular effects such as tissue mineralization or cell lacunae variations must be investigated. More recently, it was found that bone vasculature is a major contributor to local tissue porosity and therefore is linked directly to the mechanical tissue properties. With the advent of synchrotron radiation sources, micro-computed tomography (SRμCT) with resolution on the order of 1 μm becomes feasible. Moreover, new features such as bone vasculature and even single osteocytes inside the bone tissue are now detectable in a fully nondestructive and three-dimensional fashion. In this study, inbred strains of growth hormone deficient mice B6-*lit/lit* (B6*lit*) and C3.B6-*lit/lit* (C3*lit*) were used to quantify ultrastructural bone tissue properties. Here we report of vascular alterations in the two strains as assessed from SRμCT. Measurement of the mid-diaphyses of ten B6*lit* and C3*lit* femoral specimens was performed (1 mm section, 1.75 μm voxel size). Morphometric indices for vasculature and bone were determined including cortical thickness (Ct.Th), vessel thickness (Vs.Th), number (Vs.N), and orientation. Results showed that local Vs.N was higher in C3*lit* where Ct.Th was larger along the cortical circumference. This feature was less pronounced in B6*lit* where Ct.Th varied only mildly in the different regions. Additionally, vessel orientation was mainly radial for all B6*lit* specimens as well as for those regions in C3*lit* bones with low Ct.Th. This behavior changed when Ct.Th increased locally such that vessels started to be oriented along the longitudinal axis. This was not the case in B6*lit* with a more uniform, rather thin cortex. In this study, for the first time, we described a method to assess 3D bone vasculature in a fully non-destructive way and with micrometer resolution. First results indicate that vasculature varies in different genetic backgrounds. From this we hypothesize that better understanding of bone vasculature will provide new insight in the assessment of bone quality and its contribution to bone strength and fracture risk.

A New Recurrent Mutation for Paget's Disease of Bone. L. Michou*[1], C. Collet*[2], S. Varin*[3], Y. Maugars*[3], J. Laplanche*[2], P. Orcel[4], F. Cornélis*[1]. [1]Unité de génétique clinique, Hôpital Lariboisière, Paris cedex 10, France, [2]Service de Biochimie, Hôpital Lariboisière, Paris cedex 10, France, [3]Service de rhumatologie, Hôpital Hôtel Dieu, Nantes, France, [4]Fédération de rhumatologie, Hôpital Lariboisière, Paris cedex 10, France.

Purpose : Paget's disease of bone (PDB) has often an autosomal dominant pattern of inheritance, with high penetrance. Genetic heterogeneity has been demonstrated and a first PDB gene was discovered, Sequestosome 1 (5q35). All mutations reported were located at exon 7 and 8, which encode the ubiquitin protein-binding domain. The P392L mutation was the only mutation reported in France, with a frequency of 11% in the French population affected by PDB. The aim of this study was to search for other recurrent mutations in the French population.

Methods: DNA sequencing of Sequestosome 1 gene, exons 7 and 8 (with adjacent intron sequences), was performed in 52 patients without P392L mutation.

Results: The IVS7+1 G-A mutation affecting the splice donor site in intron 7, previously described only in one Australian family, was found in a patient of French Caucasian origin.

Conclusions : The discovery of this new recurrent mutation in PDB supports the hypothesis of its direct pathophysiological involvement and validates the DNA test strategy, for patients who do not carry the P392L mutation, of exon 7 and 8 sequencing.

Functional Networks of Structure-Function Interactions Determined for Bone Using Multigenic Perturbations in Recombinant Inbred Mice. K. J. Jepsen[1], J. H. Nadeau*[2]. [1]Mt Sinai School of Medicine, New York, NY, USA, [2]Case Western Reserve University, Cleveland, OH, USA.

Correlation metrics have proven successful in defining functional relationships among cardiovascular traits [1]. This approach used Recombinant Inbred (RI) mouse strains to test multiple genetic perturbations that occur in a natural, non-pathological manner. The analytical method measures the tendency of traits to correlate after genetic randomization of the parental genomes in the RI panel. In this study, we tested whether this network analysis would correctly identify known structure-function relationships for bone [2].

Femurs from 20 AXB/BXA RI mouse strains (16 wks, n=1-6/strain) were phenotyped for mechanical properties [stiffness, max load, post-yield deflection (PYD), work-to-failure] and physical traits [area, moment of inertia (J), mineral content]. Using the mean values of each RI strain, a correlation matrix was established that related each physical trait with each mechanical property. Correlations exceeding a threshold of 0.66 were considered significant ($p<0.05$).

Genetic randomization was associated with significant variation in all physical traits and mechanical properties among the RI panel, as expected. The correlation matrix, which revealed significant and non-significant correlations, identified the physical traits and mechanical properties that cosegregated (i.e., remained functionally related) after randomization of AJ and B6 genes in the RI panel. To visualize these interactions, a hierarchical network was constructed by linking the physical traits and mechanical properties that correlated significantly (Fig 1). This preliminary network correctly identified the functional interactions among the physical traits and the mechanical properties that were determined by independent means [2]. Thus, this network method is a powerful, multivariate approach for identifying physical traits that are deterministic of genetic variation in adult bone strength and fragility. Further, this approach can be extended to the next hierarchical level to identify the cellular processes that define adult bone size, shape, and quality. [1] Nadeau et al, 2003 Genome Res 13. [2] Jepsen et al, 2003 Mamm Genome 14.

Gene Expression in Femoral Bone from Two Divergent Chicken Populations, Differing Markedly in Bone Phenotypes. C. Rubin*[1], R. Fredriksson*[2], P. Savolainen*[3], U. Gunnarsson*[2], J. Lundeberg*[3], L. Andersson*[2], A. Kindmark[1]. [1]Dep. Medical Sciences, Uppsala University, Sweden, [2]Dep. of Animal Breeding and Genetics, Swedish Univ. of Agricultural Sciences, Uppsala, Sweden, [3]Dep. of Biotechnology, Royal Institute of Technology (RIT), Stockholm, Sweden.

Domestic animals are excellent models for evolution by natural selection since the selection for growth traits over a long period of time has introduced a multitude of genetic changes. The domestic White Leghorn (WL) chicken and the wild ancestor, the Red Junglefowl (RJF) are separated by several thousand years of evolution. The selection in the WL for growth traits and egg production has resulted in profound differences in bone phenotypes between the populations, with bone mineral content (BMC) differing as much as 40%. As a part of a large-scale functional genomics project (FunChick) aimed at elucidating the genetic explanations of several multifactorial traits, we have previously performed a Quantitative Trait Loci- (QTL) analysis of a WL and RJF intercross. Results reveal five regions with significant QTLs affecting BMC and/or bone biomechanical strength (manuscript in preparation).

To identify candidate genes responsible for the phenotypic heterogeneity of the two founder populations, we analysed gene expression in femoral bones from 20 WL and RJF founders using cDNA microarrays developed at RIT, comprising 13000 putatively unique chicken clones.

Twenty individuals, (5 male and 5 female from each population) were sacrificed at 250 days of age (approved by local ethics committee). Femoral bones were snap frozen in liquid nitrogen and stored at -70°C. 20 µg of purified RNA from each individual and 20 µg reference RNA were subjected to cDNA synthesis and were labelled with either Cy3 or Cy5 in a dye swap manner, and were then hybridised onto the microarray. The raw fluorescence data was subjected to filtration, normalization and statistical tests in the software R, where all individuals representing the same sex and population were treated as biological replicates.

In total, 2753 transcripts displayed differential expression, as measured by an empirical Bayesian approach, the B-test. Fifty genes showed significant ($P < 0.05$) differential expression between (1.3-2.4 fold change), but not within populations.

Altogether, the expression data, the results from our QTL-analysis and the newly released chicken genome assembly will greatly facilitate the future identification of genes affecting bone metabolism and bone biomechanical strength. The human orthologues of candidate genes thus identified in chicken will be characterized and screened for association to bone metabolic phenotypes in our population based human cohorts.

Association of Peak Bone Mineral Density and Related Factors with Osteoporosis in Chinese Women: A Case Control Study for Daughter to Mother. Y. Qin*, Z. Zhang, Q. Huang*, J. He*, Y. Hu*, Q. Zhou*, M. Li*, Y. Liu*. Center for preventing and treating osteoporosis, affiliated sixth people`s hospital,Shanghai Jiaotong university, Shanghai, China.

To determine whether premenopausal daughters of women with postmenopausal osteoporosis have lower bone mineral density (BMD) than other women of the same age, and to analyses the related risk factors affecting BMD variation. We recruited aged 20 ~ 40 healthy Han nationality premenopausal women and their healthy parents. The lumber spine (L_{1-4}) and proximal femur (femoral neck, trochanter, ward's striangle) were measured by dual-energy X-ray aborptionmetry in each subject. The study subjects were 126 mothers with osteoporosis,126 of their premenopausal daughters, 136 normal postmenopausal mothers and 149 their premenopausal daughters(in which 123 and 13 families have 1 and 2children, respectively). In the study, daughters were excluded if their fathers were osteoporosis or osteopenia. All subjects completed a questionnaire to obtain information on lifestyle. The VDR *Apa* I genotype and ER-α *Pvu* II, *Xba* I genotype were determined by PCR-restriction fragment length polymorphism. As compared with daughters of normal mothers, daughters of mothers with osteoporosis were weight less ($P<0.05$). The daughters of the mothers with osteoporosis did not differ in age, height, menarche age, milk consumption, activity and occupation. The daughters of mothers with osteoporosis had lower BMD in L_{1-4} ,femoral neck, trochanter and Ward's triangle than the daughters of normal mothers, by 6.2%, 7.9%, 7.1% and 9.6% , respectively ($P<0.001$). Multivariate regression analysis demonstrated that weight was most highly associated with BMD at all measurement sites, which contributed to 14.7%, 18.3%, 16.2% and 8.0% of BMD variation at L_{1-4} ,femoral neck, trochanter and Ward's triangle, respectively. Secondly is a family history, which explained 3.2%, 2.9%, 1.8% and 2.2% of BMD variation, respectively. Age of menarche was less to weight and family history in contributing BMD variation. When weight was excluded in the analysis, family history became the most important factors affect BMD variation and contributed to 5.1%,5.3%,4.2% and 4.1% of BMD variation , respectively. We did not detected age, height, milk consumption, activity, occupation, VDR *Apa* I genotype and ER-α *Pvu* II, *Xba* I genotype contributed to BMD variation in the study. We conclude that daughters of women with osteoporosis have reduced bone in the lumber spine and proximal femur. Weight was the most important factor affecting BMD variation. Secondly was family history.

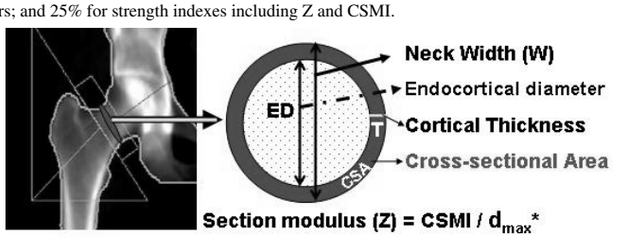
Novel DEXA-based Osteoporosis Phenotypes for Genetic Studies. F. Rivadeneira[1], M. C. Zillikens*[1], J. J. Houwing-Duistermaat*[2], T. J. Beck[3], Y. Aulchenko*[4], B. Oostra*[4], A. G. Uitterlinden[1], C. M. van Duijn*[4], H. A. P. Pols[1]. [1]Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands, [2]Medical Statistics & Bioinformatics, Leiden University Medical Center, Leiden, Netherlands, [3]Radiology, Johns Hopkins University, Baltimore, MD, USA, [4]Genetic Epidemiology, Erasmus Medical Center, Rotterdam, Netherlands.

BMD is a highly heritable surrogate phenotype for fracture. Its use in genetic linkage and association studies is complicated by its ambiguous relation to mechanical properties and its dependence on size and age. This study explored alternative bone phenotypes based on DEXA and hip geometry measured with the *Hip Structural Analysis* (HSA) software.

We estimated heritabilities ($\mathbf{h^2}$) and genetic correlations (**GC**) in 374 men and 545 women (age 18-85 years) from the ERF study, an extended-pedigree study designed to map disease-related QTL. Age and sex adjusted traits included BMD of the hip, spine and total body (including composition) and HSA measurements. Statistically independent phenotypes were identified using principal components analysis (**PCA**). An index of mechanosensitivity (**IM**) was estimated as the ratio of section modulus (Z)/moment arm to lean mass.

Total body, hip and spine BMD $\mathbf{h^2}$ ranged from 50-70%. Height, fat and lean mass indexes (FMI, LMI) $\mathbf{h^2}$ were 60, 31 and 28%. **GC** between BMD sites ranged from 70 to 99% (same regions) and was 20%, 15% and 30% with height, FMI, and LMI. Bone geometry $\mathbf{h^2}$ was 40% for BMD, buckling ratio (BR, index of cortical instability) and cortical thickness (T); 30% for cross-sectional area (CSA); 50% for inner (ED) and outer (W) bone diameters; and 25% for strength indexes including Z and CSMI.



*$\mathbf{d_{max}}$: maximum distance from center of mass to medial or lateral cortex

Table. Genetic correlations narrow neck (NN) phenotypes

	NN-BMD	NN-Z	NN-BR
LUNAR-BMD	0.83 (0.05)	0.56 (0.12)	-0.76 (0.06)
W	-0.26 (0.14)	0.55 (0.12)	0.54 (0.11)
CSA	0.88 (0.03)	0.94 (0.03)	-0.67 (0.09)
ED	-0.46 (0.12)	0.36 (0.15)	0.71 (0.07)
T	1.00 (0.00)	0.67 (0.10)	-0.96 (0.02)
Z	0.69 (0.09)	-	-0.41 (0.15)
CSMI	0.39 (0.14)	0.91 (0.03)	-0.09 (0.17)
BR	-0.95 (0.03)	-0.41 (0.15)	-
Height	0.07 (0.11)	0.48 (0.13)	0.12 (0.11)
FMI	-0.15 (0.16)	-0.17 (0.20)	0.23 (0.17)
LMI	0.03 (0.17)	0.04 (0.20)	0.08 (0.19)

Data are correlations (SE) adjusted for sex and age

Table shows **GC** of the HSA. **PCA** of HSA measurements identified two independent components explaining 95% of the variance in all traits: a component highly correlated with BMD, BR, and T (stability) with $\mathbf{h^2}$ of 45% and a component highly correlated with W, ED, CSMI and Z (dimensions and strength) with $\mathbf{h^2}$ of 39%. **IM** had an $\mathbf{h^2}$ of 27% and a higher **GC** with the stability component (42%) than with the strength-related component (3.5%).

We identified two heritable and genetically independent components of hip bone geometry. A conceptually biomechanical trait like **IM**, reflects genetically-determined predisposition to weak bones that reach instability faster with age. Gene identification studies should be targeted on these phenotypes.

Disclosures: ***F. Rivadeneira****, None.*

Test of Linkage and/or Association of Genes and Bone Mineral Density in Chinese. A. W. C. Kung[1], H. H. L. Lau[1], A. D. Paterson*[2], W. M. W. Cheung*[1], K. D. K. Luk*[3], V. Chan*[1]. [1]Medicine, The University Of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [2]Program in Genetics and Genome Biology, The University of Toronto, Toronto, ON, Canada, [3]Orthopaedic Surgery, The University Of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

Bone mineral density (BMD), one of the major determinants of osteoporosis and fracture risk, is a complex trait with a heritability estimate that ranges from 50% to 90%. Linkage and/or association of 14 loci of 8 candidate genes were evaluated in 177 southern Chinese pedigrees with 674 subjects (each pedigree was identified through a proband having BMD Z score $\leq$-1.28 at the hip or spine) by the quantitative trait locus transmission disequilibrium test (QTDT). The candidate genes studied include estrogen receptor alpha (ERα) and beta (ERβ), calcium sensing receptor (CASR), vitamin D receptor (VDR), collagen type Iα1 (COLIA1), LDL receptor-related protein 5 (LRP5), transforming growth factor β1 (TGFβ1) and parathyroid hormone receptor (PTHR). Nucleotide (nt) Ivs1-397T/C (Pvu II genotype) and Ivs1-351G/A (Xba I genotype) of ERα; 1082A/G (Rsa I genotype), 1730G/A (Alu I genotype) and CA repeat polymorphism (D14s1026) of ERβ; CA repeat polymorphism of CASR; 2T/C (Fok I genotype) of VDR; -1363 C/G and -1997 T/G of COLIA1; 266 A/G, 2220 C/T and 3989 C/T of LRP5; 29 T/C of TGFβ1 and D3S1289 (which is closely related to the PTHR gene) were analyzed. BMD values were adjusted for sex, age, height and weight. For the total association, D14s1026 genotypes of ERβ were associated with femoral neck and total hip BMD (both $p<0.05$); D3S1289 (which is closely related to the PTHR gene) was associated with trochanter BMD ($p<0.02$) and total hip BMD ($p<0.03$). For within-family association, D14s1026 genotypes of ERβ were associated with femoral neck and total hip BMD (both $p<0.05$); D3S1289 was associated with trochanter BMD ($p<0.02$) and total hip BMD ($p<0.03$). For linkage analysis of all pedigree, Ivs1-351G/A genotype of ERα was in linkage with L1-4 BMD ($p<0.05$); 1082A/G, 1730G/A and D14s1026 genotypes of ERβ were linkage with L1-4 ($p<0.05$) and femoral neck BMD ($p<0.03$); ERβ 1082A/G and D14s1026 genotypes of ERβ were linkage with total hip BMD ($p<0.05$). These data suggested that ERα and ER beta gene might play a modulatory role in determining bone mineral density in our population. Further mapping studies are required to determine the genetic association of D3S1289 with BMD.

Disclosures: ***A.W.C. Kung****, None.*

SU160

Familial Aggregation of BMD and Osteoporosis. Y. Feng*[1], X. Xu*[1], Y. H. Hsu*[1], H. Terwedow*[1], T. Zang*[2], Z. Li*[2], X. Hong*[2], B. Wang*[1], M. L. Bouxsein[3], J. Brain*[1], S. R. Cummings[4], C. Rosen[5], X. Xu*[1]. [1]Program for Population Genetics, Harvard School of Public Health, Boston, MA, USA, [2]Institute of Biomedicine, Anhui Medical University, Hefei, China, [3]Beth Israel Deaconess Medical Center, Boston, MA, USA, [4]San Francisco Coordinating Center, UCSF, San Francisco, CA, USA, [5]Maine Center for Osteoporosis Research and Education, St. Joseph Hospital, Bangor, ME, USA.

Data from a cross-sectional study in Anhui, China were used to examine the familiar aggregation of BMD and osteoporosis. A total of 6760 subjects aged 25-65 years from 1843 families were available for the analysis. Whole body and hip BMD was assessed for each subject by DXA. Pearson's correlation coefficients of BMD were calculated for each sibling pair and multiple regression models were used to test the family aggregation with adjustment for potential confounders. The correlation coefficients of BMD varied among different skeletal sites and between men and women and their ranges were from 0.17 to 0.57. The estimated regression coefficients were 0.313 (SE=0.027) and 0.207 (SE=0.025), respectively for total body BMD and total hip BMD, in men; 0.230 (SE=0.032) and 0.298 (SE=0.037) in premenopause women; and 0.319 (SE=0.059) and 0.193 (SE=0.063) in postmenopause women. If the first sibling had osteoporosis, defined as BMD <-2.5 using young individuals from a population as a reference database, then his/her same sex siblings had a significantly higher chance of being diagnosed as having osteoporosis. Specificlly, the OR for osteoporosis in the younger sibling when the older sibling had osteoporosis was 10.1 (95% CI: 3.5-29.4) in males and 3.8 (95% CI: 1.8-8.1) in females.

This analysis demonstrated a significant familiar aggression for both BMD and osteoporosis in our population.

Supported by NIAMS grant R01 AR045651.

Chromosomal Regions Influencing Femoral Shaft Failure Load in Laboratory Mice: Concordance with Regions Associated with Intrinsic Strength, Density, and Geometry. R. F. Klein[1], J. N. Kansagor*[1], W. J. Wagoner*[1], A. S. Carlos*[1], J. K. Belknap*[2], M. Shea[3], E. S. Orwoll[1]. [1]Bone and Mineral Unit, Oregon Health & Science University, Portland, OR, USA, [2]Department of Behavioral Neuroscience, Oregon Health & Science University, Portland, OR, USA, [3]Department of Orthopaedics, Oregon Health & Science University, Portland, OR, USA.

Bone strength and thus, the likelihood of fracture, is a complex trait likely influenced by a number of different genes. The number, locations and effects of the individual genes contributing to natural variation in skeletal fragility are all unknowns. To complement previous genetic analyses of bone density and bone geometry (determinants of skeletal fragility) in laboratory mice, we examined femoral shaft failure load (FL) in a genetically heterogeneous F_2 population of mice (N=994) derived from C57BL/6 (B6) and DBA/2 (D2) inbred mouse strains. Femora were harvested from 16-week-old mice and bone mineral density (BMD) was measured by DEXA, femoral geometry (cortical area, CtAr; cortical thickness, CtTh) was measured by microCT and FL was determined by 3-point bending. Femoral bending strength (FBS) was calculated from the load deflection curve and the cross-sectional areal measurements. FL values were normally distributed, suggesting polygenic control of this trait. Analysis of 18 RI strains derived from the same progenitors (B6 & D2) provided a narrow-sense heritability estimate of 0.53 for FL. To identify genetic loci influencing FL, a whole genome scan was carried out using 154 polymorphic microsatellite markers distributed across 19 autosomes and X chromosome. Quantitative trait locus (QTL) analysis of the B6D2F_2 population revealed 8 chromosomal regions (QTLs 1-8; see table) that were very strongly linked to FL (peak logarithm of the likelihood for linkage (LOD) score ≥ 3.6). Interestingly, no unique FL QTLs were identified. Instead, all of the FL QTLs were concordant with femoral bone density, bone geometry and/or intrinsic bone strength loci. Thus, a substantial genetic contribution to femoral breaking strength appears to be exerted by effects on multiple skeletal traits (pleiotropism) to coordinately regulate overall skeletal integrity. These results suggest that the genetic determinants of the complex phenotype of skeletal fracture can be effectively studied by analysis of primary skeletal characteristics.

	QTL 1	QTL 2	QTL 3	QTL 4	QTL 5	QTL 6	QTL 7	QTL 8

The Muscle-Bone Relationship in The Lower Skeleton Is Gender- Specific: The Age, Gene/Environment Susceptibility Study. T. F. Lang[1], G. Sigurdsson[2], B. Jonsdottir[2], K. Siggeirsdottir*[2], G. Eiriksdottir*[2], S. Sigurdsson*[2], M. Garcia*[3], M. Meta[1], T. Harris*[3]. [1]Radiology, University of California, San Francisco, San Francisco, CA, USA, [2]Icelandic Heart Association, Reykjavik, Iceland, [3]Epidemiology and Biometry, National Institute of Aging, Bethesda, MD, USA.

Muscles exert among the strongest mechanical loads on bone, and studies have found a relationship between bone density and muscle mass. Because of sex differences in muscle size, muscle strength, and body habitus, we hypothesized that the relationship between muscle mass, muscle strength and bone density would differ between genders. Thus, we have performed analyses of 1,146 subjects (466 male and 680 female) enrolled in the Age, Gene/Environment Susceptibility-Reykjavik Study (AGERS) cohort, a group aged 67 years or older participating in an ongoing research study in Iceland. To assess muscle mass and attenuation, we used computed tomography to measure the area (QAR) and mean hounsfield unit (QHU) of the quadriceps muscle group at the mid-thigh (a measure of fat infiltration into muscle). We also measured the quadriceps strength (QSTR). Trabecular bone mineral density (BMD) was measured in g/cm^3 at the femoral neck (ftBMD) and trochanteric (trtBMD) regions using quantitative computed tomography. We performed gender-specific multivariate linear regressions relating BMD to QAR, QHU and QSTR, adjusting for body mass index (BMI) and age. To determine the statistical significance of gender differences in muscle-BMD relationships, data from men and women were pooled in another regression model incldluing interactions for muscle parameters and gender.

	Men	Women
Variable	Mean (SD)	Mean(SD)
ftBMD (g/cm^3)	0.042 (0.055)	0.021 (0.040)
trtBMD (g/cm^3)	0.081 (0.042)	0.057 (0.032)
QHU (HU)	47.6 (3.9)	46.7 (3.47)
QAR (cm^2)	64.1 (15.4)	43.4 (7.1)
QSTR (newton)	404.2 (101.7)	254.1 (71.2)
BMI	26.4 (3.7)	27.0 (4.9)
Age	75.9 (5.6)	75.6 (5.7)

Age- and BMI-adjusted means for the key variables are shown below. Age was inversely correlated with BMD and BMI was positively correlated with BMD in both genders. In gender-specific models, QSTR, but not QAR or QHU, was significantly associated with ftBMD ($p<0.01$) and trtBMD ($p<0.05$) in men, but only QHU was associated with trtBMD ($p<0.05$) in women. In the pooled model, there was a statistically significant interaction term ($p<0.05$) between gender and QHU only, indicating a sex difference in the effect of QHU on bone density.

Our data support sex differences in the bone-muscle relationship in the lower skeleton. We conclude that strategies aimed at modifying bone density by changing muscle mass or strength should take gender into account.

Effects of Gender on Genetic Regulation of Trabecular and Cortical Bone in Congenic Strains of Mice. W. G. Beamer, K. L. Shultz, K. M. Delahunty*, L. R. Donahue, C. J. Rosen. The Jackson Laboratory, Bar Harbor, ME, USA.

Genetic analyses of crosses among inbred strains of mice have defined heritability, enumerated major and minor effect loci, and established chromosomal locations for genes underlying many bone properties. Further genetic manipulations (congenic and consomic strains, chemical mutagenesis, spontaneous mutations) have confirmed genome wide screen data for quantitative trait loci (QTL), as well as facilitated functional and molecular studies aimed at gene identification. A critical theme that needs further experimental attention is the role of gender in relation to understanding and interpreting QTL effects on bone. Orwoll and Klein (2001) first reported differences in QTL between females and males associated with areal BMD observed in BXD Recombinant Inbred strains and in (B6xDBA/2)F2 progeny. Both shared and unique QTL were indicated as participants in sex specific pathways regulating peak bone mass.

To further examine sex specific effects, we tested isolated 4 mo old femurs by pQCT from 11congenic strains carrying individual QTL for strong or weak effects on total bone volumetric (v)BMD. Each congenic strain was made by introgressing chromosomal segments carrying QTL from C3H/HeJ (high vBMD; C3H) into C57BL/6J (low vBMD; B6) background strain by repeated backcrossing. Data were gathered on trabecular bone (metaphyseal mineral, volume) and on mid-diapyseal cortical bone (mineral, volume, cortical thickness, periosteal circumference). The resultant data yielded clues about which bone compartment and gender showed effects associated with each of the QTL on bone. QTL on Chrs 1, 4 and 9 markedly influenced male trabecular bone, while having little if any effect on female trabecular bone. Chrs 10 and 11 QTL did not affect trabecular bone in either gender. Six remaining QTL (Chrs 6, 8, 13, 15, 17, and 18) significantly affected trabecular bone in both males and females. None of the 11 congenics significantly changed only female trabecular bone. All 11 QTL affected cortical bone. QTL on Chrs 4, 9, and 10 primarily affected male cortical bone, with little if any effect in females. Conversely, QTLs on Chrs 13, 15, and 18 primarily affected female cortical bone with little or no effect on male cortical bone. Five remaining QTLs (Chrs 1, 6, 8, 11, and 17) significantly affected cortical bone in both sexes. Surprisingly, the majority of QTL from C3H reduced bone in the congenic strains. These data confirm sex specific pathways for acquisition of peak bone mass, reveal compartment specific effects, and imply caution is warranted when generalizing findings across gender.

Unique and Common Genetic Effects between Bone Mineral Density and Calcaneal Quantitative Ultrasound Measures among Healthy Adults: The Fels Longitudinal Study. M. Lee, S. A. Czerwinski*, A. C. Choh*, E. W. Demerath*, W. C. Chumlea*, S. S. Sun*, R. M. Siervogel, B. Towne*. Lifespan Health Research Center, Wright State University School of Medicine, Dayton, OH, USA.

Areal bone mineral density (BMD) measures and calcaneal quantitative ultrasound (QUS) measures are correlated, and both traits predict the osteoporotic fracture risk independently. However, few studies have examined the common genetic effects (i.e., pleiotropy) between these traits in extended families. In this study, we estimate the additive genetic correlation (ρ_G) and random environmental correlation (ρ_E) between BMD measured at various skeletal sites and calcaneal QUS measures in a sample of healthy adults. The study population includes 537 adults (251 men and 286 women) aged 18 to 91 years (mean ± SD: 45 ± 16 yrs) who belong to 110 nuclear and extended families participating in the Fels Longitudinal Study. Total body, lumbar spine (L1-L4), and femoral neck BMD were measured using dual energy X-ray absorptiometry (DXA: QDR4500, Hologic, Inc., Waltham, MA). Three measures of calcaneal structure, speed of sound (SOS), broadband ultrasound attenuation (BUA), and quantitative ultrasound index (QUI) were collected from the non-dominant heel using the Sahara ® bone sonometer (Hologic, Inc., Waltham, MA). Using a variance components-based maximum likelihood method (SOLAR), we estimated the heritability of the different BMD and QUS measures while simulateously adjusting for age, sex, age^2, age-by-sex, age^2-by-sex, physical activty, smoking, alcohol use and menopausal status. Genetic and enviromental correlations between the different BMD and QUS measures were also estimated.

Heritability estimates were significant for all traits ($p < 0.000001$), and ranged from 0.64 to 0.68 for the BMD measures, and from 0.55 to 0.78 for the QUS measures. Significant nonzero genetic correlations were found between the different BMD and QUS measures. For total body BMD, $\rho_G \pm$ SE was 0.53 ± 0.11 with BUA, 0.52 ± 0.10 with SOS, and 0.53 ± 0.10 with QUI. For lumbar spine BMD, $\rho_G \pm$ SE was 0.37 ± 0.12 with BUA, 0.34 ± 0.10 with SOS, and 0.35 ± 0.11 with QUI. For femoral neck BMD, $\rho_G \pm$ SE was 0.60 ± 0.11 with BUA, 0.40 ± 0.11 with SOS, and 0.48 ± 0.10 with QUI. Tests for complete pleiotropy (i.e., $\rho_G = 1$) revealed incomplete pleiotropy between the different BMD and QUS measures ($p < 0.00001$). All random environmental correlations were not significantly different from zero.

This study demonstrates that BMD and calcaneal QUS measures among healthy men and

women are heritable, and are, in part, jointly influenced by a common set of underlying genes. Additionally, this study also shows evidence for a different set of genes independently influencing each trait.

Relationship between Vitamin D Receptor Gene Polymorphism and Trabecular Bone Pattern of the Mandible in Japanese Postmenopausal Women. A. Taguchi[1], S. C. White*[2], J. Kobayashi*[3], S. K. Survice*[4], T. Nakamoto*[1], M. Ohtsuka*[3], M. Sanada*[5], M. Tsuda*[5], K. Ohama*[5], Y. Suei*[1], K. Tanimoto*[3]. [1]Oral & Maxillofacial Radiology, Hiroshima University Hospital, Hiroshima, Japan, [2]Oral & Maxillofacial Radiology, UCLA School of Dentistry, Los Angels, CA, USA, [3]Oral & Maxillofacial Radiology, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan, [4]Biomathematics, The David Geffen School of Medicine at UCLA, Los Angels, CA, USA, [5]Obstetrics and Gynecology, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan.

Tooth loss and oral bone loss may be partly influenced by genetic factors in postmenopausal women (JAMA, 2001; Menopause, 2003); however, little is known about whether mandibular trabecular bone pattern is also influenced by genetic factors. In this study, we investigated the associations between vitamin D receptor (VDR) gene polymorphism and several parameters that characterize trabecular bone pattern of the mandible in 96 Japanese postmenopausal women (mean age [SD], 54.3 [6.9] years). Strut analyses and run-length analysis were used to evaluate trabecular bone pattern of the mandibular ramus on digitized dental panoramic radiographs scanned at 600 dpi. Patients' DNA was amplified with the polymerase chain reaction and Bsm I restriction enzyme was used to analyze VDR gene allele. Patients who were homozygous for the presence of this restriction site were designated as genotype bb. BMD of the femoral neck was measured by dual energy x-ray absorptiometry. Bsm I polymorphism was in Hardy-Weinberg equilibrium. There was no significant association between VDR gene polymorphism and any 30 parameters obtained by strut analyses. However, subjects with bb allele had significantly smaller run-length analysis parameters (gray level non-uniformity, run length non-uniformity and run percentage measured both horizontally and vertically) than did those with B allele. After adjustment of age, years since menopause and body mass index, significant differences still remained in horizontal run percentage (P=0.035), vertical gray level non-uniformity (P=0.025) and vertical run percentage (P=0.016) between subjects with and without B allele. There was no significant difference in low BMD status at the femoral neck between them. These results suggest that VDR gene polymorphism may be associated with mandibular trabecular bone pattern in postmenopausal women.

Relationship among Calcium Sensing Receptor Gene (CA) Polymorphism, Bone Mineral Density and Bone Responsiveness to Hormone Replacement Therapy in Postmenopausal Korean Women. J. Kim, S. Ku*, C. Suh*, S. Kim*, Y. Choi*, S. Moon*. Obstetrics & Gynecology, Seoul National University Hospital, Seoul, Republic of Korea.

Genetic factors are known to play an important role in the regulation of bone mineral density (BMD), and the inheritability of BMD has been estimated to lie between 50 - 85%, and to have a strong effect in the axial skeleton. However, the genes responsible for the regulation of bone mass have not yet been defined. The aims of the present study were to evaluate the relationship among the cytosine adenine (CA) polymorphism in calcium sensing receptor (Casr) gene, BMD, and bone responsiveness to hormone replacement therapy (HRT). Casr (CA) polymorphism was analyzed by polyacrylamide-urea gel electrophoretic patterns, genescan and direct DNA sequencing in 502 postmenopausal Korean women. Among these women, 352 women received sequential HRT for 1 year. Serum bone alkaline phosphatase, CrossLaps, osteocalcin, calcitonin, and parathyroid hormone levels were measured by enzyme-linked immunosorbent assay, immunoassay and serum calcium and phosphorus levels by atomic absorptiometry. BMD at the lumbar spine and proximal femur was determined by dual energy X-ray absorptiometry before and after HRT of 1 year. Nine Casr alleles were observed with product sizes ranging between 176-196 base pair (bp), and their distributions were as follows: 188bp 26.2%, 194bp 19.8%, 186bp 18.2 %, 190bp 15.5%.192bp 14.3% etc. No significant differences in basal BMD and annual percentage changes of BMD after HRT were noted among Casr (CA) genotypes. There were no significant differences in the levels of bone turnover markers and their 6 month percentage changes after HRT among Casr (CA) genotypes. The Casr (CA) genotypes were not distributed differently between HRT-responders and HRT-nonresponders (women who lost more than 3 % of bone mass per year) or between women with normal BMD and women with low bone mass. In conclusion, Casr (CA) polymorphism is not associated with BMD and bone responsiveness to HRT in Korean women.

Interactions of Calcium Intake with FokI and Androgen Receptor Genotypes in Men. E. A. Krall[1], J. C. Fleet[2], P. S. Vokonas*[3], D. R. Miller*[4], S. E. Rich*[1]. [1]Boston University, Boston, MA, USA, [2]Purdue University, West Lafayette, IN, USA, [3]VA Boston Healthcare System, Boston, MA, USA, [4]VA Center for Health Quality, Outcomes, and Economic Research, Bedford, MA, USA.

Previous studies suggest the associations between bone mineral density (BMD) and polymorphisms of the vitamin D receptor (VDR) are modified by calcium intake, but the results are inconsistent. We examined interactions of calcium intake with the FokI polymorphism and the androgen receptor (AR) in the VALOR study, an observational study of men. Mean age at enrollment was 70 years and 96% of subjects were white. Total body, hip and radius BMD was measured up to 3 times over a mean follow-up of 2 years. Consent for genetic analyses was obtained from 546 men. DNA was isolated from packed red blood and buffy coat cells and analyzed using PCR amplification followed by enzymatic digestion (FokI) or electrophoresis (AR). Dietary and supplemental calcium intakes were assessed by food frequency questionnaire. Total calcium intake was dichotomized at the median (807 mg/day). Distributions of FokI and AR were: 218 FF (41%), 235 Ff (44%), and 81 ff (15%); and 112 (21%) with ≥25 CAG repeats in the AR, 424 (79%) with ≤24 repeats. BMD was analyzed with repeated measures analysis of covariance, controlling for age, body mass index and years of follow-up. Before interactions were examined, only femoral neck BMD was associated with the FokI genotype (p=0.04), and no sites were associated with AR. Significant genotype/calcium interactions were found for both genotypes at all sites. BMD at the femoral neck (p for interaction =0.04) and total radius (p=0.03) was lower in men with ff or Ff genotypes vs. FF if calcium intake was below the median, but comparable if calcium was above the median (table). This trend was also observed at the total body (n=515, p=0.02). Similarly, BMD at the femoral neck (p=0.02), total radius (p=0.04) and total body (p<0.01) was lower in men with ≥25 CAG repeats in the AR vs. ≤24 repeats if calcium intake was low but comparable if calcium was high. These results indicate that environmental factors such as diet influence the attainment of BMD in men and failure to account for environment may attenuate associations of BMD with genotype.

BMD (g/cm^2): mean ± se

Transmission Disequilibrium Analysis of Polymorphisms of Candidate Genes from Chromosome 1p36 and Bone Mineral Density in Osteoporosis Families. M. Devoto*[1], K. Sol-Church*[1], D. Stabley*[1], C. McKay[1], A. Tenenhouse[2], L. D. Spotila[3]. [1]Nemours Children's Clinic, Wilmington, DE, USA, [2]Montreal General Hospital, Montreal, PQ, Canada, [3]Drexel University, Philadelphia, PA, USA.

Low bone mineral density (BMD) is one of the major risk factors for osteoporosis. Epidemiological studies support the hypothesis that a large part of the variation in BMD is caused by genetic susceptibility factors. In an attempt to identify the specific genes that might influence BMD, and thus osteoporosis, we have performed a whole genome scan for linkage in a total of 40 Caucasian families recruited through a proband with low BMD. After fine mapping, a region on 1p36 near marker D1S214 received support as a candidate locus for femoral neck BMD from both linkage (max lod = 3.53) and linkage disequilibrium analysis ($p < 0.01$). In the present study, we have selected a number of genes based on their location in 1p36 and available information about function and pattern of expression to evaluate as possible candidate genes for femoral neck BMD.

Genotyping of single nucleotide polymorphisms (SNPs) of the selected candidate genes is being performed by either Pyrosequencing using SNPs selected from publicly available databases or on the ABI 7900HT Sequence Detection System using commercially available Applied Biosystems Assays-on-Demand™. Linkage disequilibrium analysis in the sample of 40 families is being carried out using the QTDT software including sex, age and BMI as covariates. Results of this analysis for nine SNPs tested in the guanine nucleotide binding protein (G protein), beta polypeptide 1 gene (GNB1) did not show any significant results (all p-values > 0.1). A second gene, WD repeat-containing protein 8 (WDR8) was selected because experiments in mouse had shown expression in bone and cartilage and in bone forming cells including osteoblasts and chondrocytes during ossification. Among six SNPs tested in this gene, one yielded a nominal p-value of p = 0.006 for association with femoral neck BMD. Additional tests are in progress to confirm this finding and exclude other genes as possible candidates.

Interaction between Vitamin D Receptor and Estrogen Receptor Genotypes does not Influence BMD, Rate of Bone Loss and the Response to Treatment with Calcitriol or Estrogen in Elderly Women. P. B. Rapuri, J. C. Gallagher, V. Haynatzka*. Bone Metabolism Unit, Creighton University, Omaha, NE, USA.

The possibility of an interaction between vitamin D receptor (VDR) and estrogen receptor (ER) polymorphims with bone mass has been investigated with inconsistent results. In the present study, we evaluated the interaction between ER and VDR polymorphisms in relation to bone mineral density (BMD), rate of bone loss and response to treatment with calcitriol, estrogen and combination of both. In a double blind placebo controlled study, 489 elderly women were randomized to 4 treatment groups, calcitriol (0.5 mcg/d), estrogen (CEE 0.625mg/MPA2.5 mg), calcitriol+estrogen and placebo. In this population, we examined whether the interaction between ER and VDR genotypes is related to BMD at baseline (n=489), rate of bone loss in women receiving the placebo treatment (n=96) and response to treatment with calcitriol (n=86) estrogen (n=79) and combination of both (n=76). The women were genotyped for VDR TaqI and ER PvuII and XbaI restriction fragment length polymorphisms. BMD (spine, proximal femur, total body and radius) at baseline and at the end of the study (36 months) was determined by DEXA. The BMD at baseline and the percent change in BMD in various treatment groups was compared between the women with various combinations of VDR and ER genotypes. Statistical analysis was performed by procedure Mixed (SAS) after adjusting for significant covariates like age, weight, calcium intake etc. There were no significant differences in BMD at baseline and rate of change in BMD in treatment groups between the various combinations of VDR and ER genotypes. In conclusion, our results suggest no significant gene X gene interaction effect for the VDR TaqI and ER PvuII or VDR TaqI and ER XbaI polymorphisms, which influenced BMD, rate of bone loss or response to treatment to calcitriol, estrogen or combination of both.

Poly Adenosine Repeat in the Human Vitamin D Receptor Gene Is Associated with Increased Bone Loss in Elderly Women. P. B. Rapuri, J. C. Gallagher, V. Haynatzka*. Bone Metabolism Unit, Creighton University, Omaha, NE, USA.

Polymorphisms at the 3' -end of vitamin D receptor (VDR) gene, ApaI, TaqI and BsmI are in strong linkage disequilibrium with a poly adenosine (A) microsatellite at the VDR 3'UTR, which has been shown to be associated with altered transcriptional activity of endogenous human VDR proteins. However there is no information on whether polymorphism in the poly A microsatellite is associated with bone mineral density (BMD) and rate of bone loss in elderly postmenopausal women. In the present study, we examined the association of VDR polymorphism, the poly A microsatellie with rate of bone loss in a cohort of 78 Caucasian elderly women aged 65-77 years recruited for an osteoporosis intervention trial and receiving placebo treatment for 3 years. The VDR poly A microsatellite localized in the 3' untranslated region from these women was amplified by PCR and the DNA sequence was determined. Based on the length of the A repeat, when the alleles of poly(A) were classified into biallelic system, long (L: A18-22) and short (S: A12-17), the prevalence of SS was 13%, LS 40% and LL was 41% which followed the Hardy-Weinberg equilibrium. These women had previously been genotyped for TaqI and BsmI polymorphism. We observed a strong linkage between S and t/B alleles in this population (SS genotype is equivalent to tt/BB genotypes). BMD (spine, proximal femur, total body and radius) at baseline and end of the study (36 months) was determined by DEXA. Biochemical measurements were made by standard procedures. The percent change in BMD and biochemical variables were compared between the VDR genotypes by procedure Mixed (SAS) after adjusting for significant covariates like age weight etc. Our results suggest that women with SS genotype lost significantly more bone over 3 years at femoral neck compared to women with LL genotype. Even at spine and radius, a similar trend was observed. However, the rate of change in biochemical variables was not different between the three genotypes.

In conclusion, our results demonstrate higher rate of bone loss in elderly women with SS genotype which has been shown to be associated with decreased transcriptional activity of endogenous VDR proteins. Thus variation at this polymorphic site may play a role in VDR functional activity thereby influencing bone.

Rate of change in BMD in relation to VDR poly (A) polymorphism

Association of Estrogen Receptor-alpha and Vitamin D Receptor Genotypes With Therapeutic Response to Calcium in Postmenopausal Chinese Women. Z. Zhang, Y. Qin*, Q. Huang*, J. He*, M. Li*, Q. Zhou*, Y. Liu*, H. Hu*. Center for preventing and treating osteoporosis, affiliated sixth people`s hospital,Shanghai Jiaotong university, Shanghai, China.

To investigate the correlation between calcium treatment in postmenopausal women and estrogen receptor-alpha (ER-alpha) *Xba* I and *Pvu* II genotype and vitamin D receptor (VDR) *Apa* I genotype. One hundred fifteen postmenopausal Chinese women of Han population were enrolled and treated with Calcichew-D_3 (1000 mg daily as calcium and 400 U daily as vitamin D_3) for 1 year. At entry and after 1 year treatment, the bone mineral density (BMD) at lumbar spine 1-4 (L1-4) and left proximal femur including femoral neck (Neck), trochanter (Troch), serum alkaline phosphatase (ALP), osteocalcin (OC), parathyroid hormone (PTH), 25-hydroxy[25-(OH)] vitamin D, urinary calcium and urinary creatinine-corrected free pyridinoline (PYD) levels were evaluated. DNA was extracted from blood and analyzed with PCR-restriction fragment length polymorphism for *Xba* I and *Pvu* II ER-alpha genotype and *Apa* I VDR genotype. After 1 year of calcium supplementation, a significant increase of BMD in L1-4, Neck and Troch, and a marked reduction in serum ALP and PTH levels, and a significant increase of serum 25-(OH) vitamin D level were observed (P<0.01 or P<0.05). At baseline and after 1 year of treatment, no significant association was found between *Xba* I, *Pvu* II and *Apa* I genotypes and BMD in L1-4, Neck and Troch, and all bone turnover marker levels. However, the percentage of change (median, Q_R) in Neck BMD was significantly different in homozygous XX [-4.1394, (-6.5359 ~ -1.3678)] in comparison with Xx [1.7212, (-1.1198 ~ 3.2039)] (P<0.001) or xx [1.2195, (-1.7408 ~ 3.0560)] *Xba* I ER-alpha genotype (P=0.001). Women with ER-α XX genotype may have a higher risk of relatively fast bone mass loss in femoral neck after menopause than those with the Xx and xx genotype and that they may have a poor responsiveness to calcium supplementation. The changes in BMD are not associated with ER-alpha *Pvu* II genotype and VDR *Apa* I genotype after 1 year of calcium supplementation.

Association Study and Haplotype Analysis of Twelve Prominent Candidate Genes for BMD Variation in Chinese. S. F. Lei*, M. X. Li*, F. Y. Deng*, D. K. Jiang*, M. Y. Liu*, X. D. Chen*, W. X. Jian*, J. J. Guo*, H. Xu*, Y. B. Wang*, H. W. Deng. College of Life Sciences, Hunan Normal University, Changsha, China.

To evaluate the importance of twelve prominent candidate genes (i.e., the ER-α, VDR, BGP, COL1A1, COL1A2, IL-6, PTH, CASR, IGF-I, TNFR2, PTHR1, and AHSG) on BMD at different skeletal sites in Chinese, we simultaneously tested linkage and/or association of the genes with BMD variation in 401 Chinese nuclear families containing 1,260 subjects.

Each of the nuclear families includes both parents and at least one healthy female offspring aged 19-45with the average 31.4. The mean family size is 3.14 and 349, 50, 2, and 1 families have 1, 2, 3, and 4 children, respectively. Exclusion criteria were adopted to minimize any known potential confounding effects on the study phenotypes of the female offspring. Sixteen markers were genotyped, which are ER-αs *Xba*I, *Pvu*II, and (TA)n, VDR's *Apa*I, BGP's *Hind*III, COL1A1's 1997G/T, COL1A2's *Msp*I and (GT)n, IL-6's *BsrB*I and (CA)n, PTH's *BstB*I, CASR's (AT)n, IGF-I's (CA)n, TNFR2's (CA)n, PTHR1's (AAAG)n, and AHSG's *Sac*I. Hologic QDR 2000+ DEXA scanner was used to measure BMD at the total hip and the L1-4 spine regions. Using QTDT, we tested stratification, within-family association, and total-family association of the above markers and their haplotypes with the hip and spine BMD measured with Hologic.

Table 1 summarizes the most significant results (p values) of the QTDT analysis. Within- or total-family association analyses suggest that the markers or haplotypes of the ER-α, COL1A2, TNFR2, and IL-6 genes are associated with BMD at the hip or spine in our Chinese subjects.

Table 1	**Within-Family Association**		**Total-Family Association**	
	Spine	**Hip**	**Spine**	**Hip**
ER-α: *Xba* I	0.054	-	-	-
ER-α: $(TA)_{21}$	-	-	0.013	0.001
ER-α: *P-x-*$(TA)_{21}$	-	-	0.0007	0.0006
COL1A2: *Msp* I	0.013	0.053	-	-
COL1A2: $(GT)_{17}$	0.0120	0.0108	0.0704	-
COL1A2: *m-*$(GT)_{17}$	0.0040	0.0056	0.0297	0.0789
TNFR2: $(CA)_4$	-	0.015	0.095	0.041
IL-6: *b-*$(CA)_{15}$	-	-	-	0.0262

Our results suggest that the ER-α, TNFR2, COL1A2, and IL-6 genes may play an important role in BMD determination in Chinese, whereas the VDR, BGP, COL1A1, PTH, CASR, IGF-I, PTHR1, and AHSG genes may not contain the QTLs for BMD variation in Chinese. Testing candidate genes for BMD variation in different populations may reveal ethnic peculiarity in BMD determination and confirm genes commonly important to osteoporosis for various ethnic groups.

Association of Single Nucleotide Polymorphisms in The Low Density Lipoprotein Receptor-related Protein 5 Gene (*LRP5*) with Bone Mineral Density of Adult Women. Y. Ezura[1], T. Urano[2], T. Nakajima*[1], Y. Sudo*[1], H. Yoshida*[3], T. Suzuki[3], T. Hosoi[4], S. Inoue[2], M. Shiraki[5], M. Emi*[1]. [1]Department of Molecular Biology, Institute of Gerontology, Nippon Medical School, Kawasaki, Japan, [2]Dept. Geriatric Medicine, Faculty of Medicine, University of Tokyo, Tokyo, Japan, [3]Department of Epidemiology, Tokyo Metropolitan Institute of Gerontology and Geriatric Hospital, Tokyo, Japan, [4]Department of Internal Medicine, Tokyo Metropolitan Institute of Gerontology and Geriatric Hospital, Tokyo, Japan, [5]Research Institute and Practice for Involutional Diseases, Nagano, Japan.

Low-density lipoprotein receptor related protein 5 (LRP5), a Wnt co-receptor, is an important regulator of the bone development and its maintenance. Recently we identified a correlation between the intronic single nucleotide polymorphism (SNP) and vertebral bone mineral density (BMD) (JBMM 2004, in press), which encouraged us to investigate further the causative genetic ground in this locus for BMD determination. Mutation searches for the selected subjects, as well as scanning searches for functional SNPs correlating with the adjusted BMD were conducted on two independent subject groups of adult Japanese women. The subject group from the initial study was expanded to 387 individuals recruited from the same institute (Group H), and the causative mutation was searched among 12 subjects who had prominently high bone mass (Z-score >3.0). Entire 23 exons and flanking regions were investigated by direct sequencing. Linkage disequilibrium (LD) was analyzed for independently recruited 384 adult Japanese women (Group G) by estimating haplotype frequencies and statistical indices D' and r^2. Genotypic association of 37 SNPs was investigated for adjusted BMD levels among Group G subjects (n=384). Reproducible association was tested for spinal BMD Z-score among the Group H subjects (n=387). Combined effects of the variations were examined by multiple regression analysis. As a result of the mutation search, no rare mutation was detected among the selected 12 individuals. LD analysis on Group G subjects indicated linkage disequilibrium within the entire 132kb region of the LRP5 gene, however a transitional gap around the 7th intron was indicated. The genotypes of two coding-SNPs A1330V (c.3989C>T) and c.2220C>T significantly correlated with radial BMD (Group G: p = 0.019 and 0.021). Multiple regression analyses implied a combined effect of another missense coding-SNP Q89R (c.266A>G). However, reproducible correlation was detected only for A1330V (Group H: p=0.03). Our results indicate the important function of the common genetic variations in LRP5 affecting BMD in adult women, which may contribute to susceptibility of osteoporosis.

Non-replication in Genetic Studies of Complex Diseases-Lessons Learned from Osteoporosis. H. W. Deng, H. Shen*, Y. J. Liu*, P. Y. Liu*, R. R. Recker. Osteoporosis Research Ctr. and Dept. of Biomedical Sciences, Creighton Univ., Omaha, NE, USA.

Over the past decades, numerous linkage and association studies have been performed to search for genes predisposing to complex human diseases. However, little success has been achieved and inconsistent or controversial results have been accumulated. The 'frustrating' results have led to pessimism about these approaches in gene mapping of complex diseases in general. Reviewers are reluctant to publish or fund such studies. We argue that those non-replication results are not unexpected, given the complicated nature of complex diseases and a number of confounding factors, such as limited statistical power, population stratification, heterogeneity of linkage disequilibrium between marker and QTL, etc. Based on our experience in genetic studies of osteoporosis, we briefly address major potential factors for this inconsistency and provide suggestive remedies. We also point out that with low statistical power, even a 'replicated' finding is still likely to be a false positive. Despite various factors could result in the lack of reproducibility seen in genetic studies of complex diseases, however, this situation does not condemn the approach as being futile, but rather indicate that caution should be take when designing the studies and interpreting the results. We believe that, with rigorous control of study design and interpretation of different outcomes, inconsistency might be largely reduced and the chances of successfully revealing genetic components of complex diseases could be greatly improved.

Mutation Analysis of the LRP5 Gene in Men with Idiopathic Osteoporosis. P. Crabbe*[1], A. Willaert*[2], I. Van Pottelbergh*[1], P. Coucke*[2], S. Goemaere[1], A. De Paepe*[2], J. Kaufman[1]. [1]Dep. of Endocrinology, Ghent University Hospital, Ghent, Belgium, [2]Dep. of Medical Genetics, Ghent University Hospital, Ghent, Belgium.

The aim of this study was to investigate the role of the low-density lipoprotein receptor-related protein 5 (*LRP5*) gene in male idiopathic osteoporosis (IO). Various mutations in the *LRP5* gene have been associated with different bone phenotypes and a quantitative trait locus for bone mineral density was mapped to the *LRP5* region of chromosome 11. These findings underscore the importance of LRP5 in skeletal regulation and make it a plausible candidate gene for IO.

For this study sixty-six male IO probands were selected on the basis of a BMD Z-score ≤ -2.0 at the lumbar spine (Z_L) or at the proximal femur (Z_{TH}) (Van Pottelbergh et al. 2003, JBMR 18:303-311). All 23 exons and relevant exon-intron boundaries of the *LRP5* gene were amplified by polymerase chain reaction with exon-specific primers. Mutation screening was performed by means of denaturing high performance liquid chromatography and conformation sensitive gel electrophoresis in combination with direct sequencing, restriction enzyme analysis or SNaPshot analysis. Genetic analysis revealed 23 sequence variants, of which 12 had not been reported before. Because of a possible functional aspect, we focused our analysis on the five missense mutations that were detected in the male IO probands. Two of them (1999G>A and 3989C>T) had been reported either as polymorphisms or in association with BMD, the other three (1067C>T, 1364C>T and 4609G>A) were newly detected in this study. These three new missense mutations are all located in highly conserved regions of LRP5. Modeling data showed that mutations 1067C>T and 1364C>T are both located at the surface of the second YWTD-EGF like domain of LRP5 and therefore may disrupt a protein-binding site. None of the three new mutations was found in a control panel and segregation analysis in the respective families could not exclude their possible causality.

Overall, we conclude that for 1999G>A and 3989C>T our results are in agreement with those reported by others and we can assume these are general polymorphisms in the population, while mutations 1067C>T, 1364C>T and 4609G>A are putative disease-causing mutations for male IO. These findings, indicating a possible role of mutations in the *LRP5* gene in a minority of men with IO, warrant further research addressing their prevalence in additional patient populations and efforts to assess their functional role.

Relation of the XbaI and PvuII Polymorphisms of the Estrogen Receptor Gene and the CAG Repeat Polymorphism of the Androgen Receptor Gene to Peak Bone Mass and Bone Turnover Rate Among Young Healthy Men. V. V. Välimäki*[1], K. Piippo*[2], S. Välimäki*[1], E. Löyttyniemi*[3], K. Kontula*[4], M. J. Välimäki[1]. [1]Division of Endocrinology, Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland, [2]Dept. of Medicine, Helsinki University Central Hospital and Research Program in Molecular Medicine, University of Helsinki, Helsinki, Finland, [3]Department of Statistics, University of Turku, Turku, Finland, [4]Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland.

The genes coding for estrogen receptor-α (ER-α) and androgen receptors (AR) are potential candidates for regulation of bone mass and turnover, which may contribute to both achievement of peak bone mass and bone loss after completion of growth. The present study was aimed at elucidating the role of two restriction fragment length (XbaI and PvuII) polymorphisms of the ER gene and the CAG repeat polymorphism of the AR gene as determinants of peak bone mass in men.

A cross-sectional study, with data on lifestyle factors collected retrospectively, was performed in 234 young men, aged 18.3 to 20.6 years. 184 men were recruits of the Finnish Army, and 50 were men of similar age, who had postponed their military service for reasons not related to health. Bone mineral content (BMC), density (BMD), and scan area were measured in lumbar spine and upper femur by dual-energy X-ray absorptiometry (DXA). Bone turnover rate was assessed by measuring serum procollagen type I N propeptide (PINP) and tartrate-resistant acid phosphatase 5b (TRACP5b) as well as urinary excretion of N-terminal cross-linking telopeptide of type I collagen (NTX-I). After adjusting for age, height, weight, exercise, smoking, calcium and alcohol intake BMC, scan area, and BMD at all measurement sites were similar for the different XbaI and PvuII genotypes of the ER and independent of the number of the CAG repeats of the AR gene. Except for urinary NTX-I which showed a tendency to higher values for the xx (P=0.084) and pp (P=0.10) genotypes of the ER, bone turnover markers were not related to the genotypes studied. The XbaI and PvuII polymorphisms of the ER gene and the CAG polymorphism of the AR gene are not determinants of peak bone mass and bone turnover rate among young Finnish men.

Allelic Imbalance in Human Trabecular Bone Cells: An Approach to Identify SNPs Regulating Gene Expression. E. Grundberg*[1], T. Pastinen*[2], O. Nilsson*[3], T. J. Hudson*[2], H. Brändström*[1]. [1]Department of Medical Sciences, Uppsala University, Uppsala, Sweden, [2]McGill University and Genome Quebec Innovation Centre, Montreal, PQ, Canada, [3]Department of Surgical Sciences, Uppsala University, Uppsala, Sweden.

Osteoporosis is a complex disease characterized by reduced bone mineral density (BMD) and development of fractures of e.g. the spine, hip and wrist. Moreover, BMD is under strong genetic control, demonstrated in numerous family and twin studies.

Several approaches are currently being used to identify the genes underlying the disease, such as genome-wide linkage studies and association studies, using single nucleotide polymorphisms (SNPs) in candidate genes. However, most of the SNPs studied have no functional validation.

We report an approach for investigations of polymorphisms that regulate gene expression in human trabecular bone cells. The detection of a regulatory SNP or allelic imbalance is based on quantitative genotyping of polymorphisms in RNA transcripts derived from heterozygous individuals and comparing the observed allele ratios in corresponding genomic DNA samples, which are assumed to represent 50:50 allele ratios. Genotyping is performed using Fluorescence polarization-single base extension (FP-SBE) to provide quantitative detection of allele-specific transcripts.

To validate the method described herein we examined an imprinted gene, *MEST*, and a gene previously reported to have allelic imbalance in lymphoblastoid cell lines, *BTN3A2*. Human trabecular bone cells from 50 individuals were cultured until confluency and RNA and DNA from each sample were isolated. The polymorphisms were amplified by polymerase chain reaction (PCR) and the relative expression of the two alleles in a heterozygous sample was examined by genotyping of both genomic DNA and cDNA from the same cellular sample by FP-SBE. The study was approved by the local ethic committee.

For *MEST*, 43 % of the samples were heterozygous for the coding SNP and all of them showed mono-allelic expression in the trabecular bone cells. In a total of 13 heterozygous individuals (27 %) for *BTN3A2*, five of them showed allelic imbalance, which are in agreement with previously findings in lymphoblastoid cell lines.

In conclusion, the method offers tools for efficient identification and characterization of allelic variation or imbalance of gene expression in human trabecular bone cells. This promotes identification of regulatory sequence variants in candidate genes for osteoporosis.

Low DXA and CT Bone Measures in Young Adults with a Simple Sequence Repeat in IGF-I Gene. X. Liu*[1], C. Rosen[2], S. Mora[1], D. Dong*[1], P. Pitukcheewanont[1], V. Gilsanz[1]. [1]Childrens Hospital Los Angeles, Los Angeles, CA, USA, [2]Maine Center for Osteoporosis Research and Education, Bangor, ME, USA.

Several studies have suggested that a polymorphism in a microsatellite within the IGF-I gene is related to decreased bone mass in elderly subjects, although other investigations in premenopausal women have found no such evidence. In the current study, we assessed the possible association between IGF-I genotypes and bone density in 235 healthy white young adults (102 females and 133 males) ages 15 to 20 years, who had achieved sexual and skeletal maturity. Skeletal maturity was assessed by hand and wrist radiographs and sexual maturity by physical examination (attainment of Tanner 5). Areal bone mineral density (BMD) in the spine, hip and total body were obtained by DXA and CT was used to determine volumetric bone density (BD) in the spine and cortical bone area (CBA) and cross-sectional area (CSA) in the femur. Subjects with the 192/192 genotype had lower values for all DXA BMD measurements and lower CT values for BD in the spine and CBA in the femur than subjects with any other IGF-I genotype. Values for CSA were non-significantly lower. These results indicate a relationship between IGF-I genotype and bone mass at sexual and skeletal maturity. This information may contribute to the identification of a subset of the population of normal young adults who may be at risk for developing vertebral fractures later in life, and may ultimately be of value in the planning of early preventive strategies for osteoporosis.

				DXA				CT

A Functional $(AAAG)_n$ Polymorphism in the PTHR1 Promoter Is Associated with Height but not with BMD in a Large Cohort of Young Caucasian Women. A. Scillitani*[1], C. Jang*[2], B. Wong*[2], L. Rubin[2], G. Hendy[3], D. Cole[2]. [1]CasaSollievo Sofferenza, San Giovanni Rotondo, Italy, [2]University of Toronto, Toronto, ON, Canada, [3]McGill University, Montreal, PQ, Canada.

The PTHR1 receptor mediates the action of parathyroid hormone and the parathyroid hormone related peptide (PTHrP). Interacting with this receptor, PTHrP contributes to skeletal development through the regulation of chondrocyte proliferation and differentiation, and the P3 promoter of the *PTHR1* gene is the major one in human bone and kidney. Recently, a tetranucleotide repeat - $(AAAG)_n$ - in the P3 promoter has been shown to have functional activity related to size, and homozygosity for $(AAAG)_6$, or the 6/6 genotype, has been associated with greater adult height compared to the 5/5 genotype (J Clin Endocrinol Metab 2002;87:1791). The aim of this study was to evaluate the association of the $(AAAG)_n$ polymorphism with height and bone mineral density (BMD) measured at lumbar spine (LS) and femoral neck (FN) in 565 young Caucasian women aged 18-35 yr recruited from the metropolitan Toronto area. With informed consent, genomic DNA was extracted from whole blood, amplified for the P3 promoter flanking the polymorphism, and genotyped by comparison with sequenced controls following electrophoretic separation on high-resolution polyacrylamide gels. Allele frequencies for $(AAAG)_n$ were: 76.8% (n=5); 20.9% (n=6); 1.8% (n=7); 0.18% (n=8); 0.27% (n=9); 0.08% (n=2), and there was no evidence for Hardy-Weinberg disequilibrium. Univariate analysis of variance showed that subjects bearing one or two of the n=6 allele (6/x & 6/6) had significantly greater mean height (1.656 ± 0.004 m) than all others (x/x, 1.644 ± 0.003 m; p = 0.034). This association was significant after adjusting for multiple covariates - current age, age at menarche, physical activity, smoking status, and intakes of caffeine and calcium. In this multiple regression analysis, the model accounts for 5.5% of the total variance in height, and the *PTHR1* promotor polymorphism for 13.6% of explained variance. Comparison of genotype groups for BMD at LS and FN was not significant (LS: 6/6 & 6/x *vs* x/x, 1.196 ± 0.009 *vs* 1.187 ± 0.007 g/cm^2 p = 0.4 - FN: 1.016 ± 0.008 *vs* 1.002 ± 0.006 g/cm^2, p = 0.2). In conclusion, our data show that the $(AAAG)_5$ allele is the most common allele in our panmictic North American cohort and confirm matching results on smaller Caucasian and Asian populations already described. Moreover subjects bearing one or two $(AAAG)_6$ alleles are taller than subjects without, confirming published results and re-inforcing the notion that *in vivo* variation in promoter activity of the *PTHR1* gene may be a relevant genetic influence on final adult height.

Disclosures: ***A. Scillitani****, None.*

SU180

Effect of the $P2X_7$ Glu496Ala Polymorphism in Osteoclasts and Association to Bone Mass. S. D. Ohlendorff*, S. Petersen*, C. L. Tofteng*, N. R. Jørgensen. 545, Osteoporosis Research Unit, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark.

P2X7 is a ligand-gated cation channel present in many different cells of the immune and hemopoietic system. It is present on the surface of osteoclasts, and is supposedly involved in osteoclast apoptosis and cell death. A Glu496Ala polymorphism has been identified in the human gene coding for the P2X7 receptor. In cells from individuals carrying the CC genotype of this polymorphism, receptor function is partly disrupted. The aim of this study was to determine the association between the presence of the Glu496Ala polymorphism and osteoclast survival *in vitro*. Osteoclasts were cultured from peripheral blood obtained from women (aged 54-69) participating in the Danish Osteoporosis Prevention Study (DOPS), previously genotyped for the Glu496Ala polymorphism. Mature osteoclasts were stimulated with 2 mM adenosine 5'-triphosphate (ATP) for 30 minutes, 1 hour, 4 hours or 24 hours. After incubation supernatant was removed and lactate dehydrogenase (LDH) released from the osteoclasts was measured, as evidence for cell death. Amount of LDH released is calculated as % LDH released by experimental samples in relation to maximum LDH release of controls. Mean percent elevation of LDH release after 24 hours of ATP stimulation in osteoclasts from individuals with the AA genotype was 53,16 % (n=4), compared to 20,84 % (n=4) for the AC and 5,45 % for CC (n=2) genotype. Thus, the cytotoxic effect of ATP on the osteoclasts was dramatically decreased in cells with the CC genotype as compared to AA and AC genotypes. Moreover, osteoclasts from AA individuals were morphologically affected by ATP stimulation after 4 hours. Cells with the AA genotype were granulated and shrinking, signs of beginning cell death. After 24 hours these cells were completely lysed and apoptotic. The osteoclasts from AC individuals showed a delayed apoptosis process compared to osteoclasts from AA individuals, although shrinkage was observed after 4 hours of ATP stimulation. Granulation and lysis was evident after 24 hours of ATP stimulation, though quite a few cells had still survived 24 hours stimulation with ATP. In contrast, osteoclasts from CC individuals were not showing any signs of apoptosis, even after 24 hours of stimulation with 2mM ATP. In conclusion, presence of the C allele of the P2X7 Glu496Ala polymorphism is clearly associated with an increased osteoclast survival *in vitro*, after stimulation with ATP. The lack of apoptosis seen in osteoclasts from individuals with the CC genotype might indicate that the presence of the C allele of the Glu496Ala polymorphism could be associated with increased osteoclast activity and bone resorption *in vivo* leading to bone loss and osteoporosis.

Aromatase and Estrogen Receptor Alpha Gene Polymorphisms: Response of the Bone Mineral Density in Post-menopausal Women to HRT. L. Masi, S. Ottanelli*, F. Del Monte*, S. Carbonell*, L. Guazzini*, N. Fossi*, A. Gozzini*, C. Mavilia*, A. Falchetti*, R. Imbriaco*, A. Amedei*, A. Tanini, M. L. Brandi. Internal Medicine, University of Florence, Florence, Italy.

Genetic factors regulate bone mineral density (BMD) and possibly development of osteoporosis. Sex steroids play a pivotal role in maintaining bone. The formation of estrogens from C19 steroids is catalyzed by aromatase in post-menopausal women and men. It is known that polymorphism at the human ERα and at the aromatase genes are associated with low BMD in postmenopausal women. In the present study we evaluated the possibility of interaction between aromatase and ERα genotypes with bone mass and we assessed the response in BMD to HRT in a cohort of postmenopausal women. Subjects consisted of 240 Italian postmenopausal women with a range of age 36-76 years (mean 61.3±8.6). Subjects under HRT received 17β-Estradiol (TTS 50μg/day) and nomegestrol acetate 5mg/day (12 days/month). Vertebral BMD was measured at the baseline and after 1 year. Genomic DNA was isolated from EDTA blood samples by a standard procedure. Pvu II and Xba I

polymorphism of the ERα was determined by PCR and TTTA repeats for the aromatase gene were evaluated by sequence analysis. The capital *P* and *X* and the lower-case *p* and *x* represent respectively the absence and the presence of the restriction site for the ERα. For the TTTA repeats polymorphism the subjects were divided on the basis of the mean TTTA repeats: low (<8) medium (8-10) and high (>10). The genotype distribution for ERα was as follow: XX 41.3%; Xx 44.9%; xx:13.7% (χ2 analysis: p=0.3) and PP: 34.3%; Pp:46.05%; pp: 19.53% (χ2 analysis: p=0.07). For the aromatase TTTA repeats the distribution was as follow: low: 40%; medium 42% and high:18%. The genotype with a low number TTTA repeats was more frequent in osteoporotic and osteopenic subjects in comparison with normal (42.8 and 39.2% vs.17.86%). Ancova analysis did not show any statistical differences in the LS-BMD of various ER alpha genotypes (p=0.6), although LS-BMD tended to be lower in subjects with pp and xx genotypes. During HRT an increase of the LS-BMD was present in all the genotypes suggesting a feeble influence of the polymorphism on the hormone response. The same results were observed for the aromatase gene polymorphism. The absence of difference in the LS-BMD in subjects with or without HRT suggests a low influence of the aromatase gene on the HRT response. In conclusion, ER-alpha and aromatase gene polymorphism do not seem to influence the response to HRT.

COL1A1, but not ESR1 or VDR Polymorphisms are Associated with BMD in a Cohort of Spanish Postmenopausal Women. S. Balcells*[1], M. Bustamante*[1], A. Enjuanes*[2], N. Garcia-Giralt*[1], I. Aymar*[2], X. Nogués[2], L. Mellibovsky*[2], A. Díez-Pérez[2], D. Grinberg*[1]. [1]Genetics, Universitat de Barcelona, Barcelona, Spain, [2]Urfoa, IMIM-Hospital del Mar-Universitat Autònoma de Barcelona, Barcelona, Spain.

We have previously identified two polymorphisms in the upstream regulatory region of COL1A1 (-1663indelT and -1997G>T) and showed that they were associated with lumbar spine BMD in Spanish postmenopausal women. We also showed that the sites containing these polymorphisms (PCOL1 and PCOL2) were binding sites for osteoblast nuclear proteins, and that there were affinity differences between the two alleles of each polymorphsim (JBMR 17:384-93;2002). The aim of the present study was to compare the effect of these two polymorphisms on BMD with the effects of polymorphisms of the VDR and ESR1 genes in an enlarged cohort of postmenopausal women.

We have genotyped the following polymorphisms: -1663indelT, -1997G>T and Sp1 of COL1A1; BsmI, ApaI,TaqI and FokI of VDR; and XbaI, PvuII and the promoter (TA)n of ESR1 in a total of 544 DNA samples. The methods employed included SNaPshot, Genescan, RFLP and automatic sequencing. All polymorphisms were found to be in Hardy-Weinberg equilibrium. Haplotypes were obtained using PHASE. BMD was measured by dual-energy X-ray densitometry. Statistical tests (performed with SPSS v. 11.5) were the Chi-square, ANOVA and ANCOVA. Age, body weight, height, and years since menopause were used as covariables for statistic analyses, when appropriate.

None of the polymorphisms was significantly associated with osteoporosis, according to the Chi-square test. A significant association with lumbar spine BMD (LS-BMD) was found only for -1997G>T of COL1A1, when using ANCOVA (p=0.044). We also observed an association (p=0.001) between LS-BMD and the interaction of the two COL1A1 promoter polymorphisms. No other polymorphism gave significant results (or even a hint of association) with BMD in our cohort. Overall, osteoporosis was present in 33.3% of the cases. However, in homozygotes for the T allele of -1997G>T the presence of this condition was almost doubled (62%) and in the group of women carrying two copies of the [-1997T/-1663 8T/Sp1 G] haplotype of COL1A1 the cases with osteoporosis were 75%.

In conclusion, by enlarging the cohort we have found that the association observed previously still holds true, while none of the VDR or ESR1 polymorphisms gave any significant results. Most probably the relatively modest size of this cohort precludes the detection of moderate effects. In this respect, the -1997G>T polymorphism, as well as its interaction with other COL1A1 polymorphisms, may be considered an important genetic factor for BMD determination.

(TAAA)n-Alu Element Polymorphism in Vitamin D Binding Protein Gene and Its Association with Bone Density and Osteoporosis in Men. Z. H. Aloanzi*[1], S. P. Tuck*[2], S. S. Varanasi[1], N. Raj*[3], J. S. Harrop*[4], G. D. Summers*[5], D. B. Cook*[1], R. M. Francis[2], H. K. Datta[1]. [1]School of Clinical & Laboratory Sciences, University of Newcastle, Newcastle upon Tyne, United Kingdom, [2]School of Clinical Medical Sciences, University of Newcastle, Newcastle upon Tyne, United Kingdom, [3]Rheumatology, Derbyshire Royal Infirmary, Derby, United Kingdom, [4]Biochemistry, Derbyshire Royal Infirmary, Derby, United Kingdom, [5]Rheumatology, Derbyshire Royal InfirmarY, Derby, United Kingdom.

In an earlier pilot study in men we found a significant association of BMD with tandem tetranucleotide (TAAA) repeats downstream of intron 8 of vitamin D-binding protein (DBP) gene. Here we present a larger study in men to examine the possible association of DBP gene (TAAA)n polymorphism with plasma DBP concentration and BMD. The subjects were all age-matched English Caucasian, comprising 56 men with idiopathic osteoporosis and 114 male control subjects. The osteoporotic men all had a BMD T score of < -2.5 at either the femoral neck or lumbar spine. The commonest genotype in men with osteoporosis was 8/10, which had a frequency of 30.4%, compared with 13.2% in the control subjects. The predominant DBP-*Alu* genotype in the control subjects was 10/10 (42.1%), whereas the frequency of this genotype in men with osteoporosis was 8.9%. The odds ratio calculated for the commonest genotype in men with osteoporosis compared with control subjects was 10.8 (95% confidence interval 3.4-35.5). In control subjects, the commonest allele *10 was found with a significantly higher frequency than allele *8 (Fisher's exact two-tailed p<0.005). In view of the relative preponderance of 8/10 and 10/10, and relative low frequency and absolute number of the remaining DBP-*Alu* genotypes, the effect of only the main genotypes was studied. The anthropometric indices of the 8/10 and 10/10 DBP-*Alu* genotypes, comprising data from both control subjects and osteoporotic patients, were compared, and no significant differences were seen in age, height, weight and BMI. However, the two genotypes demonstrated a significant difference in BMD; the total femur, femoral neck and lumbar spine BMD being lower for the 8/10 compared with 10/10 DBP-*Alu* genotype. The magnitude of the differences in BMD between the two genotypes was similar at all sites. Higher plasma DBP concentrations were found in men with the 8/10 genotype than the 10/10 genotype (p<0.01). In conclusion, our results suggest that (TAAA)n-Alu polymorphism has an important effect on bone density in men, which may be mediated via an effect on circulating DBP. The observed variation in BMD in different DBP-*Alu* genotypes may also be explained by linkage disequilibrium with other genes located near the DBP locus.

Polymorphisms in the Estrogen Receptor β (*ESR2*) Gene are Associated with Peak Bone Mineral Density in Caucasian Men and Women. S. Ichikawa*[1], D. L. Koller[2], M. L. Johnson*[1], D. Lai*[2], T. M. Fishburn*[1], M. Peacok[1], C. C. Johnston[1], S. L. Hui[1], T. M. Foroud[2], M. J. Econs[1]. [1]Medicine, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA.

Peak bone mineral density (BMD) is a major determinant of osteoporotic fracture and is a highly heritable trait. Recently, we reported several quantitative trait loci (QTLs) for peak BMD identified by 9-cM genome scan. Significant linkage for trochanter BMD in Caucasian and African American sister pairs was found at chromosome 14q (LOD score = 3.5). Follow-up analysis with markers spaced at 5-cM interval confirmed the linkage to 14q in women, where the estrogen receptor β (*ESR2*) gene is located. Analysis of this region including a microsatellite marker with the *ESR2* gene (D14S1026) further confirmed the linkage finding, with a LOD score of 2.0 at the intragenic marker position. Estrogens are necessary for the acquisition of optimal peak bone mass, and functional sequence variations in *ESR2* are likely to influence acquisition of peak bone mass. A recent study in the Framingham cohort suggests that genetic variations in *ESR2* account for up to 4% difference in femoral BMD. To determine whether *ESR2* polymorphisms are associated with peak BMD in our population, we tested ten single nucleotide polymorphisms (SNPs) encompassing the entire *ESR2* gene. Peak BMD at femur and lumbar spine was measured in 190 men (age 20-61) and 588 women (age 21-52) from Indiana. SNP genotyping was performed using matrix-assisted laser disorption/ionization time-of-flight (MALDI-TOF) mass spectrometry of allele-specific primer extension products. We found statistically significant association between *ESR2* alleles and spinal BMD in both men and women. Five of the ten genetic variations reached significance in men, whereas only two reached significance in women (p-value < 0.05). The strongest association in both sexes was found with the allelic variation present in the 5' flanking region of *ESR2* (p-value = 0.004). The alleles may account for up to 2.8% and 0.9% of the spinal BMD variation in healthy men and women, respectively. Further, these results suggest that *ESR2* polymorphisms may be more important in development of bone mass in men than in women.

Polymorphisms in the Bone Morphogenetic Protein 2 (*BMP2*) Gene Do Not Affect Peak Bone Mineral Density in Men and Women. S. Ichikawa*[1], D. L. Koller[2], M. L. Johnson*[1], D. Lai*[2], C. C. Johnston[1], S. L. Hui[1], T. M. Foroud[2], M. Peacock[1], M. J. Econs[1]. [1]Medicine, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA.

Peak bone mineral density (BMD) obtained during young adulthood is a major determinant of osteoporotic fracture in later life. Although peak BMD certainly has an environmental component, it is a highly heritable trait. Recently, bone morphogenetic protein 2 (*BMP2*) located at human chromosome 20p12.3 was reported as a susceptibility gene for osteoporosis and BMD variation in Icelandic and Danish populations. To determine whether the *BMP2* gene contributes to peak BMD variation in our Caucasian population, we tested five single nucleotide polymorphisms (SNPs), four of which were determined to be associated with osteoporotic phenotypes in the previous study. SNP genotyping was performed using matrix-assisted laser disorption/ionization time-of-flight (MALDI-TOF) mass spectrometry of allele-specific primer extension products. Peak BMD measurements were taken at the femur and the lumbar spine (L_2-L_4) in 190 men (age 20-61 years) and 588 women from Indiana (age 20-46 years). We observed marginal association with a missense polymorphism in exon 2 (Ser37Ala), which was highly associated with osteoporosis in the Icelandic patients. However, this polymorphism did not reach statistical significance (p-value > 0.1) at the femur neck or spine in either sex. We were also unable to find any association with haplotypes constructed with the five tested SNPs that span the entire *BMP2* gene. Therefore, we conclude that genetic variations in *BMP2* do not substantially contribute to peak BMD variation in our population.

Tumor Necrosis Factor Alpha Polymorphism, Bone Strength Phenotypes, and the Risk of Fracture in Older Women. S. P. Moffett*[1], J. M. Zmuda[1], J. I. Oakley[1], T. J. Beck[2], J. A. Cauley[1], K. L. Stone[3], L. Lui[3], K. E. Ensrud[4], T. A. Hillier*[5], M. C. Hochberg*[6], P. Morin*[7], D. Green*[8], G. Peltz*[8]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Radiology, Johns Hopkins University, Baltimore, CA, USA, [3]Medicine, University of California, San Francisco, CA, USA, [4]General Internal Medicine, Veterans Affairs Medical Center, Minneapolis, MN, USA, [5]Kaiser Permanente Center for Health Research, Portland, OR, USA, [6]School of Medicine, University of Maryland, Pittsburgh, PA, USA, [7]Axys Pharmaceuticals, La Jolla, CA, USA, [8]Roche Molecular Systems, Alameda, CA, USA.

Tumor necrosis factor alpha (TNFα) is a proinflammatory cytokine that promotes osteoclastic bone resorption. Several potentially functional polymorphisms have been identified in the regulatory region of the TNFα gene including a G-308A polymorphism (rs1800629). We evaluated the association between the G-308A polymorphism at the *TNFA* locus and bone mineral density (BMD), bone structural geometry and the risk of fracture in 4402 women aged 65 years and older participating in the Study of Osteoporotic Fractures (SOF). Femoral neck BMD and structural geometry were measured using dual-energy X-ray absorptiometry (Hologic QDR 1000). Incident fractures were confirmed by physician adjudication of radiology reports. Despite similar femoral neck BMD, women with the A/A genotype had greater subperiosteal width (A/A=3.30cm vs G/G=3.21cm, p=0.01) and endocortical diameter (A/A=3.03cm vs G/G=2.95cm, p=0.03) than those with the G/G genotype. The net result of these structural differences was that there was a greater distribution of bone mass away from the neutral axis of the femoral neck in women with the A/A genotype, resulting in greater indices of bone bending strength (cross-sectional moment of inertia: A/A=1.97, G/A=1.90, G/G=1.82, p=0.004; section modulus: A/A=1.18, G/A=1.16, G/G=1.12, p=0.003). There were 376 incident hip fractures during 12.1 years of follow-up. There was a 22% decrease in the risk of hip fracture per copy of the A allele (RR: 0.78; 95% C.I.: 0.63, 0.96). Adjustments for potential confounding factors and adjustments for BMD or bone strength indices had little effect on this association. The G-308A polymorphism was not associated with other fractures (non-spine RR: 0.95; 95% C.I.: 0.86, 1.05). The G-308A substitution in the *TNFA* promoter region may be a novel genetic marker of bone strength and hip fracture susceptibility among older women. These results require confirmation, but suggest a potential role of altered TNFα production and/or signaling in the etiology of osteoporosis.

Genetic Polymorphisms of OPG, RANK and ESR1 in Bone Mineral Density in Korean Postmenopausal Women. J. Choi*[1], A. Shin*[1], S. Park*[2], H. Chung[3], S. Cho*[4], C. Shin[4], Y. Chung[5], K. Lee*[1], K. Lee*[1], C. Kang*[6], C. Kang*[6], D. Cho*[7], D. Kang*[1]. [1]Dept. of Preventive Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea, [2]Konkuk University, Chungju, Republic of Korea, [3]Ewha Womans University, Seoul, Republic of Korea, [4]Seoul National University, Seoul, Republic of Korea, [5]Ajou University, Suwon, Republic of Korea, [6]KAIST, Daejeon, Republic of Korea, [7]Clinical Research Institute, Labgenomics Co.,Ltd, Yong-In, Republic of Korea.

To evaluate the association between genetic polymorphisms of OPG, RANK and ESR1 which regulate the osteoclastogenesis and low bone mineral density (BMD), a cross-sectional study was conducted in 752 Korean postmenopausal women. The differences of calcaneus and distal radius BMDs between each genotypes (OPG 163 A>G, 1181 G>C, RANK 421 C>T, 575 T>C, and ESR1 1335 C>T, 2142 G>A) were tested by the analysis of covariance (ANCOVA) adjusted for age, BMI, and years since menopause. In OPG 1181 G>C locus, women with CC genotype have higher BMD at calcaneus and distal radius compared to those with GG genotype; those differences were statistically significant (p=0.003 at calcaneus; p=0.020 at distal radius). No significant association was observed between BMDs and the polymorphisms of RANK and ESR1. The OPG haplotype constructed with 163 A and 1181 G allele was the significant independent predictor of BMD (p=0.037 at calcaneus; p=0.008 at distal radius) in the multiple linear regression model that included other possible predictors of BMD. The association between OPG haplotype and BMD was noted in the subjects carrying RANK 575 TT or ESR1 2142 GG genotypes but this was not significant in those without these genotypes. These results suggested that OPG genetic polymorphisms were related to low BMD in postmenopausal women in Korean.

Haplotype Analysis of SNPs of Bone Morphogenetic Proteins (BMPs) and Bone Mineral Density (BMD) in Young Korean Men and Women. J. Choi*[1], H. Chung[2], S. Cho*[1], D. Kim*[3], C. Shin[1], Y. Chung[4], A. Shin*[1], I. Choi*[1], D. Kang*[1]. [1]Seoul National University, Seoul, Republic of Korea, [2]Ewha Womans University, Seoul, Republic of Korea, [3]Kangbuk Samsung Hospital, Seoul, Republic of Korea, [4]Ajou University, Suwon, Republic of Korea.

Bone morphogenetic proteins (BMPs) play critical roles in osteoblast differentiation and were also associated with bone mineral density (BMD). To investigate the association between the single nucleotide polymorphisms (SNPs) of BMPs and BMD, a cross-sectional study was conducted in healthy 270 men and 299 women aged 20-39 in Korea. SNPs of BMP2, BMP4, BMP6, and BMP9 were selected of which allele frequencies were reported more than 10% from NCBI dbSNP and JSNP; BMP2 -1103 C>A, c.584 G>A, IVS1-2744 A>G, c.893 T>A, BMP4 c.712 T>C, IVS1-160 C>T, BMP6 c.1283 G>C, IVS4-6838 A>G, IVS5+24 C>T and BMP9 -305 C>T. All SNPs were determined by the 5'-nuclease assay. Individual haplotypes were estimated by a Bayesian method. The differences of calcaneus and distal radius BMDs between each SNP and haplotype were tested by ANCOVA adjusted for age and BMI. SNPs of BMP2 c.584 G>A and c.893 T>A were significantly associated with BMD of female radius and male calcaneus, respectively. Four SNPs of BMP2 were found to be in strong linkage disequilibrium (LD) (D'0.95), thus four common haplotypes accounted for more than 95%. BMD at distal radius in women significantly decreased with the number of BMP2 A-A-G-A haplotype reconstructed with all variant alleles increased (p=0.030). SNPs of BMP4 c.712 T>C, IVS1-160 C>T were also significantly associated with female radius and male calcaneus BMD. Indicating strong LD between two SNPs of BMP4 (D' ≥0.99), BMD at distal radius in women significantly increased with the number of BMP4 C-C haplotype increased (p=0.042). SNP of BMP6 c.1283 G>C were associated with female calcaneus BMD, however, there was no significant relation between BMP6 haplotypes and BMD. These results suggested that SNPs and haplotypes of BMP2 and BMP4 were associated with BMD in women.

The Polymorphisms of the VDR cdx-2 Influence Bone Mineral Density (BMD) in Postmenopausal Women. J. M. Quesada-Gomez[1], A. Casado*[2], R. Cuenca-Acevedo*[1], L. Barrios*[1], C. Diaz-Molina*[1], G. Dorado*[3]. [1]Unidad Metabolismo Mineral, Hospital Reina Sofia, Cordoba, Spain, [2]Sanyres (Grupo PRASA, I+D+I), Cordoba, Spain, [3]Bioquimica y Biologia Molecular, Universidad de Cordoba, Cordoba, Spain.

Genetic factors play an important role in pathogenesis of osteoporosis. The vitamin D endocrine system regulates the bone, mineral metabolism and other physiological processes through the vitamin D receptor protein (VDR). The caudal-related homeodomain protein (*cdx-2*) VDR binding element polymorphism has been recently described in relation to osteoporosis. We have studied the relationship of such polymorphism with bone mineral density in a Spanish cohort of 225 postmenopausal women. We have applied and optimized a DNA pooling approach for large-scale genotyping. Concentration of each individual DNA sample was measured at 260 nm. Samples were diluted to 10 ng/µl and 30 ng of each sample were "pooled". Two different pools were constructed, according to the BMD T score (cutoff at -2,5). Such DNA pools were used to determine the frequencies of the alleles "*A*" and "*G*" by Quantitative Real-Time PCR (QRT-PCR; kinetic PCR). The BMD values obtained for *A* and *G* alleles were significantly different. The A allele showed a protective effect on BMD. A novel allele-specific analysis was performed on an individual scale confirming the DNA pooling. These results were further confirmed by DNA sequencing. The allele-specific genotyping method used involved a quantitative real-time PCR (QRT-PCR). Reactions were carried out as follows: 1 cycle denaturing and *AmpliTaq* Gold (Applied Biosystems) activation at 94 ºC for 7 min; 3 cycles denaturing at 94 ºC for 25 sec, hybridization at 57 ºC for 25 sec and extension at 72 ºC for 20 sec; 3 cycles denaturing at 94 ºC for 25 sec, hybridization at 59 ºC for 25 sec and extension at 72 ºC for 20 sec; and 31 cycles denaturing at 94 ºC for 25 sec, hybridization at 60 ºC for 25 sec and extension at 72 ºC for 20 sec. We have found the following genotypic frequencies: 8% AA (adenine at position -3,731 relative to transcription start site of human *vdr* gene 5-ATAAAAACTTAT-3'), 58% GG (guanine at position -3731 5'-GTAAAAACTTAT-3') and 34% AG. The bone mineral density in this cohort of Spanish postmenopausal women is associated with *cdx-2* polymorphisms at *vdr* gene ($p<0.01$ for GA heterozygotes) and confirms previously reported data. Furthermore, the polymorphism detected could affect the expression of the *vdr* in the small intestine, modulating the bone mineral density response to vitamin D availability.

Regulation of mRNA Expression of MEPE/OF45 by FGF2 in Cultures of Rat Bone Marrow-Derived Osteoblastic Cells. G. X. Zhang*, M. Mizuno*, K. Tsuji*, M. Tamura. Department of Biochemistry and Molecular Biology, Graduate School of Dental Medicine, Hokkaido University, Sapporo, Japan.

Matrix extracellular phosphoglycoprotein (MEPE)/ osteoblast/osteocyte factor 45 (OF45) is a factor of osteoblastic phosphatonin and minhibin. It is recently isolated RGD-containing matrix protein that acts as the tumor-derived phosphaturic factor in oncogenic hypophosphatemic osteomalacia. It is also highly expressed by osteoblasts and osteocytes and markedly increased during differentiation and mineralization. The regulation and mechanisms of regulation for MEPE/OF45 gene is unknown in osteoblasts. We examined the regulation of MEPE/OF45 mRNA expression in osteoblastic cells derived from high-density cultures of primary rat bone marrow stromal cells incubated with dexamethasone, ß-glycerophosphate and ascorbic acid.

The level of MEPE/OF45 mRNA in these cells was down-regulated by the addition of fibroblast growth factor 2 (FGF2) for 48 h. These effects were observed in a dose-dependent manner between 2 and 10 ng/ml. To study the mechanism of MEPE/OF45 mRNA was reduced by FGF2, we examined transcription factor Runx2 or osterix mRNA expression and cell proliferation by the addition of FGF2. Runx2 or osterix mRNA expression and cell proliferation were not affected by the addition of FGF2 in these high-density cultures, indicating that regulation by FGF2 may not be dependent on these transcription factors or on the proliferation of cells. Additionally, experiments using actinomycin D indicated that FGF2 decreased the stability of the MEPE/OF45 mRNA. We also added FGF2 with cycloheximide to the cells indicated that down-regulation of MEPE/OF45 mRNA by FGF2 was

independent on de novo protein synthesis. Moreover, inhibition of a specific mitogen-activated protein kinase (MAPK) /extracellular signal-regulated kinase kinase (MEK) by PD98059 blocked FGF2-regulated MEPE/OF45 expressions, indicating that this regulation requires the MAPK pathway. These results suggest that MEPE/OF45 gene is one of the targets of FGF2 and may play an important role during bone formation and calcification.

Intraarticular Injection of Basic Fibroblast Growth Factor with Hyaluronic Acid Enhances Osteochondral Repair of the Knee in Rabbits. N. Miyakoshi, M. Kobayashi*, K. Nozaka*, Y. Shimada*, K. Okada*, E. Itoi*. Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

Growth factors including basic fibroblast growth factor (bFGF) are expected to be the useful tools for enhancing bone and cartilage repair. However, suitable carriers are required to deliver a growth factor to the injury site. This study was to investigate osteochondral repair and potential carrier role of hyaluronic acid (HA) after the intraarticular injection of bFGF with HA. Osteochondral defect was created on the medial femoral condyle of the Japanese white rabbits and received weekly intraarticular injection of bFGF (1 or 10 μg) either alone or combination with HA. Prior to the administration, bFGF was incubated with HA or vehicle-saline for 24 hours at 4 °C. Four weeks after the initial injection, the animals were killed and the defect was evaluated grossly (12-point scale) and histologically (16-point scale). The effect of single intraarticular injection of bFGF (1 μg) with HA was also compared to that of the carrier known as gelatin microspheres (GM) incorporating bFGF. Weekly administration of bFGF alone induced undesirable side effects such as inflammatory responses and osteophyte formation, while administration of HA alone showed moderate osteochondral repair comparing to the vehicle treated control defect but it was still insufficient. On the other hand, weekly administration of 1 μg of bFGF with HA yielded significantly better osteochondral repair than each treatment alone in grossly and histologically with minimal side effects ($p<0.05$). Single administration of 1 μg bFGF with HA but not GM incorporating bFGF showed significantly better osteochondral repair comparing to the vehicle treated control defect ($p<0.05$). Our study showed that low-dose bFGF with HA was effective for osteochondral repair in rabbits. The significant osteochondral repair role of bFGF with HA comparing to GM incorporating bFGF might be explained by the potential carrier role of HA and possible synergistic acts between these two agents during the osteochondral repair. The combination of HA with bFGF significantly reversed the side effects resulted from single use of bFGF.

Stage-Dependent Modulation of MC3T3-E1 Osteoblasts Differentiation by FGF2/FGFR2 Signaling. R. Shozui*, Y. Tanimoto*, K. Moriyama. Department of Orthodontics and Dentofacial Orthopedics, Institute of Health Biosciences, The University of Tokushima Graduate School, Tokushima, Japan.

Fibroblast growth factors (FGFs)/Fibroblast Growth Factor receptors (FGFRs) signaling has been reported to play critical roles in bone formation and resorption. We previously reported the abnormal enhancement of osteoblast differentiation and mineralization in the cells derived from Apert syndrome patients associated by S252W mutation of FGFR2 as well as in MG63 human osteosarcoma cells overexpressing FGFR2 with S252W mutation. Furthermore, we have also shown that a soluble form of FGFR2 with S252W mutation acts as a potent negative regulator for osteoblast differentiation and mineralization induced by the abnormal FGFR2 signaling. In the current study, in order to further elucidate the role of FGF2/FGFR2 signaling in osteoblasts differentiation and mineralization, we examined the expression of osteoblastic marker genes in MC3T3-E1 cells with or without FGF2 (5 ng/ml) administration by Northern blotting. FGF2 transiently inhibited RUNX2 mRNA expression at 24 hours, and it was recovered to the basal level at 48 hours. On the other hand, a stimulation of osteopontin (OPN) mRNA expression was observed after 48 hours of the FGF2 treatment in the subconfluent MC3T3-E1 culture, while a drastic elevation was observed as early as 12 hours of the treatment in the confluent culture. In order to evaluate the effect of FGF2 on matrix mineralization, MC3T3-E1 cells were cultured in a-MEM supplemented with 10-8 M dexamethasone, 10 mM b-glycerophosphate, and 50 mg/ml ascorbic acid with or without FGF2 (5 ng/ml), and the mineralized nodule formation was visualized by alizarin red-S staining. Although there was no difference in mineralized nodule formation with or without FGF2 at the early stage of the culture, FGF2 intensified the nodule formation at the later stage. For better understanding the role of FGF2 in osteoblast, we established three stable clones of MC3T3-E1 cells overexpressing the soluble FGFR2 with S252W mutation (sFGFR2-Ap). All the clones which were confirmed to express sFGFR2-Ap in the conditioned medium by Western blotting showed lower expression of OPN mRNA and significantly higher expression of osteoprotegerin (OPG) mRNA. These results suggested that FGF2/FGFR2 signaling might have not only the stage-specific effect on osteoblast differentiation but also indirect effect on osteoclast differentiation.

Dietary Phosphorus Regulates Serum FGF-23 Concentrations and 1,25(OH)$_2$D Metabolism in Mice. F. Perwad*[1], N. Azam*[2], M. Y. H. Zhang[1], T. Yamashita*[3], H. S. Tenenhouse*[4], A. A. Portale*[1]. [1]Pediatrics, University of California San Francisco, San Francisco, CA, USA, [2]Pediatrics, University of Texas Medical Branch, Galveston, TX, USA, [3]Pharmaceutical Research Laboratories, Kirin Brewery Co. Ltd., Takasaki, Japan, [4]Pediatrics and Human Genetics,, McGill University, Montreal, PQ, Canada.

Fibroblast growth factor-23 (FGF-23) is a novel secreted peptide involved in the regulation of phosphate (Pi) homeostasis and vitamin D metabolism. Excess circulating FGF-23 contributes to hypophosphatemia, renal Pi wasting, and suppression of serum 1,25(OH)$_2$D concentrations in humans and mice. Conversely, FGF-23 gene ablation in mice induces the opposite effects on Pi and vitamin D metabolism. Dietary Pi is known to regulate serum Pi, renal tubular transport of Pi, and synthesis of 1,25(OH)$_2$D independently of PTH, although the mechanisms are unknown. To determine whether serum FGF-23 concentration is regulated by dietary Pi intake, we fed intact C57Bl/6 mice diets containing varying Pi content (0.02, 0.6, 1.0, and 1.65%) for 5 days, and measured serum intact FGF-23 and Pi concentrations, renal mitochondrial 1α-hydroxylase (P450c1α) activity, and P450c1α mRNA abundance. Changes in dietary Pi intake from 0.02% to 1.65% induced significant increases in serum FGF-23 concentrations over a 7-fold range, from 9.8 ± 3.3 to 65.4 ± 15.9 pg/ml, and in serum Pi over a 3-fold range, from 1.2 ± 0.2 to 3.4 ± 0.3 mM. Across the range of dietary Pi, serum FGF-23 concentrations varied directly with those of serum Pi ($r = 0.80$, $p<0.001$). Diet-induced changes in serum FGF-23 concentrations were rapid, occurring as early as 4 hours after the change in dietary Pi. With the low Pi (0.02 and 0.6%) diets, renal 1α-hydroxylase activity and P450c1α mRNA abundance were significantly increased relative to values on the higher Pi (1.0 and 1.65%) diets. The concentrations of FGF-23 correlated inversely with 1α-hydroxylase activity and P450c1α mRNA ($r = -0.6$, $p<0.01$) across all diet groups. To determine whether FGF-23 is regulated by dietary Pi per se or by serum Pi concentration, *Npt2* gene-ablated (*Npt2-/-*) and wild-type (WT) mice were fed the above diets. Under each dietary condition except 0.02% Pi, serum FGF-23 concentrations were significantly lower in *Npt2-/-* mice than in WT mice, but these changes were accounted for entirely by the lower serum Pi levels in *Npt2-/-* mice. The present data demonstrate that dietary Pi intake regulates serum FGF-23 levels in mice and suggest that this effect is mediated by changes in serum Pi concentration. Furthermore, the data support the hypothesis that regulation of renal P450c1α gene expression by dietary Pi is mediated by the direct action of FGF-23 on the kidney.

FGF23: The Counter Regulatory Phosphaturic Hormone For Vitamin D-Mediated Hyperphosphatemia. S. Liu, L. D. Quarles. Internal Medicine/The Kidney Institute, University of Kansas Medical Center, Kansas City, KS, USA.

FGF23 is a pathologic phosphaturic factor in several hypophosphatemic disorders, such as TIO, XLH, ADHR, and McCune Albright disease. The regulation and physiological function of FGF23 have not been defined. Vitamin D increases gastrointestinal absorption of calcium and phosphorus. Calcium balance is restored by suppression of the calcemic hormone PTH, which also reduces renal phosphate excretion. Positive phosphate balance would occur in response to Vitamin D without other mechanisms to enhance renal phosphate excretion. In this study we investigated whether FGF23 is a counter-regulatory hormone for Vitamin D. To assess regulation of FGF23 transcription, we isolated a 3550 base pair of 5' flanking region containing the mouse *fgf23* promoter. The mouse *fgf23* promoter contained a transcription start site, a consensus TATA-box, multiple putative cis-acting regulator elements, and had 67% homology with the human promoter over the first 800 base pairs. We subcloned the 3550 base pair mouse promoter region into pGL3-Basic vector to generate a *fgf23* promoter-luciferase reporter construct, p3.5*fgf23*-luc. We transfected the p3.5*fgf23*-luc construct into ROS17/2.8 osteoblasts and evaluated promoter activity in response to 1,25(OH)$_2$-vitamin D$_3$, calcium and phosphorus. We observed a 6-fold increase of promoter activity of p3.5*fgf23*-luc vs. pGL3-Basic in ROS17/2.8 cells. In addition, we found a dose dependent stimulation of *fgf23* promoter activity in response to 1,25(OH)$_2$-vitamin D$_3$. The maximal increase was 2.1 fold at 10^{-8} M 1,25(OH)$_2$-vitamin D$_3$. In contrast, addition calcium or phosphorus to the media had no effect on *fgf23* promoter activity in Ros 17/2.8 osteoblasts. To evaluate the biological significance of vitamin D regulation of *fgf23* promoter activity *in vivo*, we administrated 1,25(OH)$_2$-vitamin D$_3$ at a dosage of 100 pg/gram body weight to 8-week old C57BLK/6J mice by IP injection. We collected serum samples at 24 hours after injection and measured circulating FGF23 levels by ELISA assay. Serum *fgf23* concentrations increased from a basal level 90.0±8.9 pg/ml to 136.4±8.7pg/ml (Mean±SEM) at 24 hours after a single inject of 1,25(OH)$_2$-vitamin D$_3$ ($p<0.01$). Concomitant changes in serum calcium and phosphorus concentrations were not observed. Our data suggests that FGF23 is a counter-regulatory phosphaturic hormone that maintains phosphate homeostasis in the setting of Vitamin D administration.

FGF23 Expression during Osteoblast Development and Matrix Mineralization *In Vitro* and *Vivo* Suggest that FGF23 may be a Local Regulator of Bone Formation. C. Ijuin*[1], H. Wang*[2], K. Tanne*[3], J. E. Audin[4], N. Maeda*[2], Y. Yoshiko[2]. [1]Orthodontics Department, Hiroshima University Hospital, Hiroshima, Japan, [2]Oral Growth and Developmental Biology, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, [3]Orthodontics and Craniofacial Developmental Biology, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, [4]Molecular and Medical Genetics, University of Toronto, Toronto, ON, Canada.

FGF23 is thought to play important pathophysiological roles in such diseases as autosomal dominant hypophosphatemic rickets, tumor-induced osteomalacia and possibly X-linked hypophosphatemic rickets (XLH). Consistent with this, data from Hyp (the homologue of XLH) mice, from treatment with recombinant FGF23, from transgenic mice over-expressing FGF23 in bone and from FGF23-deficient mice all implicate FGF23 in maintenance of serum phosphate levels and $1,25(OH)_2D$ metabolism. Notably, FGF23-deficient mice also show mineralization defects in bone. Together the data led us to hypothesize that FGF23 may have a direct action on bone metabolism. In northern blotting and semiquantitative PCR, FGF23 mRNA was detected in a wide variety of adult and fetal rat tissues including brain, heart, thyroid, femur and calvaria. Interestingly, FGF23 mRNA levels were higher in young adults compared to fetal femur and calvaria. Immunohistochemistry revealed that FGF23 is localized to mature osteoblasts in both trabecular and membranous bones in young adults. No significant labeling was detected in osteoprogenitors, osteocytes or osteoclasts. However, proliferative and prehypertrophic chondrocytes were labeled. We further assessed FGF23 expression during osteoblast development and bone formation in fetal rat calvaria (RC) cell cultures. FGF23 mRNA and protein (by immunocytochemistry) levels significantly increased during osteoblast differentiation and bone nodule formation. Strikingly, however, FGF23 mRNA levels decreased when β-glycerophosphate was added to mature nodule-containing RC cell cultures to induce mineralization. Our results suggest that FGF23 expression is developmentally regulated during osteoblast differentiation and matrix mineralization. Taken together with the results of cartilage immunohistochemistry, our findings strongly suggest that FGF23 may be involved in both endochondral and intramembranous bone formation independently of its systemic actions.

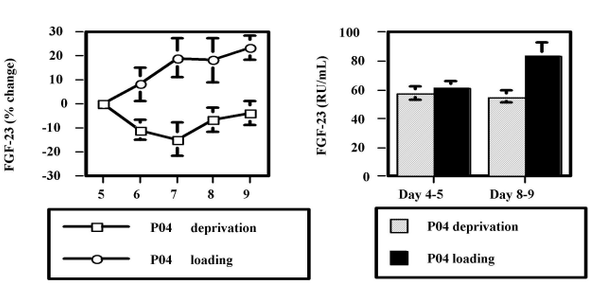
The Effects of Dietary Phosphate on the Regulation of FGF-23 in Humans. S. M. Burnett, S. Gunawardene*, F. R. Bringhurst, H. Jueppner, J. S. Finkelstein. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

Serum fibroblast growth factor 23 (FGF-23) levels are elevated in phosphate (PO_4) wasting disorders and are detectable in healthy individuals. Knockout of the FGF-23 gene in mice increases serum $P0_4$ levels suggesting that FGF-23 plays a physiologic role in $P0_4$ regulation. To examine the effects of dietary $P0_4$ on FGF-23 in humans, we randomly assigned 60 healthy males and females, age 18-45, to either a low or a high PO_4 diet intervention for 4 days (days 5-8), after a 4 day control diet. During PO_4 deprivation, the dietary PO_4 was 500mg/day and subjects consumed 2.2g of aluminum and magnesium hydroxide QID. During PO_4 loading, dietary PO_4 was 500 mg/day and subjects consumed an additional 2000mg daily of PO_4 supplements. Calcium, sodium, and caloric intakes were kept constant. Fasting blood and urine samples were collected on days 1, 4, 5, 6, 7, 8, and 9 for PO_4, Ca, FGF-23 and other measures, including the fractional excretion of PO_4 ($FePO_4$). FGF-23 was measured using an immunometric assay detecting intact and C-terminal FGF-23 (Immutopics). 24 hour urine samples were collected on days 4-5 and 8-9 for PO_4, creatinine, Na and Ca. We present data (mean ±SE) from the first 45 of 60 subjects. PO_4 loading increased 24 hour urine PO_4 excretion from 442 ±31 to 1140 ±63 mg/day ($p<0.001$); increased $FePO_4$ from 9 ±0.7 to 17 ±0.8% ($p<0.001$); and decreased urinary Ca excretion from 182 ±24 to 91 ±13 mg/day ($p<0.001$). PO_4 deprivation decreased 24 hour urine PO_4 excretion from 500 ±40 to 69 ±14 mg/day ($p<0.001$); decreased $FePO_4$ from 9 ±0.6 to 2 ±0.4% ($p<0.001$); and increased urinary Ca excretion from 177 ±13 to 216 ±18 mg/day ($p<0.01$). Changes in serum FGF-23 are shown in the figure.



PO_4 loading increased FGF-23 from 61 ±5 to 83 ±10 RU/mL , with an overall 23% increase, ($p<0.02$). PO_4 deprivation had minimal effects on FGF-23 (58 ±4 vs 55 ±4 RU/mL, $p=0.3$). There was, however, a 15% decrease in FGF-23 levels on the 3rd day of PO_4 deprivation. Serum FGF-23 levels and $FePO_4$ correlated weakly ($r = 0.13$). Based on these preliminary data, FGF-23 appears to increase with PO_4 loading, and may promote increased PO_4 excretion. Changes in FGF-23 with PO_4 deprivation are less dramatic and return to baseline over 4 days. FGF-23 may have a greater role in the normal physiologic response to increased dietary PO_4 than the physiologic response to decreased dietary PO_4 .

Extra-Skeletal Effects of Systemic Treatment with Basic Fibroblast Growth Factor in Ovariectomized Rats. H. L. Wamsley*, U. T. Iwaniec, T. J. Wronski. Physiological Sciences, University of Florida, Gainesville, FL, USA.

Basic fibroblast growth factor (bFGF) is a pleiotropic mitogen, which, as a potent bone anabolic agent, shows promise as a therapy for osteoporosis. The purpose of this study was to determine systemic side-effects induced by subcutaneous (sc) injection of bFGF. Female Sprague Dawley rats were ovariectomized (ovx) at 3 months of age and left untreated for 2 months to develop osteopenia. The rats were then injected sc for 3 weeks with vehicle (n=9) or with bFGF (n=10) at 1 mg/kg daily. Blood and urine samples were collected for hematologic and biochemical analyses. Kidneys, livers, and proximal tibiae were collected for histology. Data were analyzed using a t-test and expressed as mean ± SD.

SC treatment of ovx rats with bFGF for 3 weeks resulted in a 4-fold increase in osteoblast surface ($P<0.002$) and a 6-fold increase in osteoid surface ($P<0.0004$) compared to vehicle-treated rats. There was no significant difference in body weight between groups, but extra-skeletal effects were detected in bFGF-treated rats. These animals became anemic with a 2.5-fold decrease in packed erythrocyte volume compared to vehicle-treated rats ($P<0.0001$). The bone marrow myeloid:erythroid ratio was higher in bFGF-treated (3.17±1.08) than vehicle-treated rats (1.71±0.23) ($P=0.001$), although there was no significant difference between groups in hematopoietic area of tibial marrow. Hepatic extramedullary hematopoiesis (EMH) that was predominantly myeloid occurred in bFGF-treated rats. There was a 19-fold increase in the number of EMH foci ($P=0.0001$) within the livers of these animals. Glomerular hypertrophy was also found in bFGF-treated rats. The parietal layer of Bowman's capsule was thicker in bFGF-treated (3.42±0.38 μm) than vehicle-treated rats (2.53±0.18 μm) ($P=<0.0001$), and the glomerular diameter was greater in bFGF-treated (114.38±6.28 μm) than vehicle-treated rats (104.24±6.07 μm) ($P<0.003$). However, serum biochemical evidence for renal dysfunction was weak, and there were no urine biochemical signs of dysfunction. There was a small (0.06 mg/dL), but significant ($P<0.05$) increase in serum creatinine in bFGF-treated rats compared to vehicle-treated rats. There were no significant differences between groups in serum albumin, calcium, and phosphorus, nor in urine protein:creatinine ratio. In summary, bFGF-treated ovx rats develop anemia due to a relative increase in myelopoiesis in the bone marrow and liver. The mild glomerular hypertrophy linked with bFGF treatment is not accompanied by strong biochemical evidence for renal dysfunction nor a decrement in general health status. These observations indicate that rats tolerate short-term treatment with bFGF relatively well.

Effect of FGFR3 Anti-sense Oligonucleotides on Bone Growth in an Ex-vivo Long Bone Model and in FGFR3 Mutant Dwarf Mice. M. Liu*[1], Y. Wang*[1], K. Hull*[1], L. Wenrich*[2], C. Reed*[2], S. Davis*[2], J. Siu*[2], H. U. Bryant[1], G. Krishnan[1]. [1]Bone and Inflammation, Eli Lilly and Co, Indianapolis, IN, USA, [2]ISIS Pharmaceutical Inc, Carlsbad, CA, USA.

Achondroplasia (ACH) is the most common form of short-limbed dwarfism in humans. A single gain-of-function point mutation in the FGFR3 (G380R) gene is responsible for 98% of its etiology. Results from various targeting mutations in mice showed that there is a correlation between the mutant FGFR3 expression level and the severity of the dwarfism phenotype. We investigated the bone growth effect of anti-FGFR3 oligonucleotides (ASO) in metatarsal culture, an endochondral ossification model for long bone growth. We are also examining the FGFR3 ASO in a dwarf mouse strain with a mutation in FGFR3. The ASO uptake in metatarsal organ culture was examined using a FITC-labeled ASO. Neonatal rat (P0) metatarsals were cultured with 5 μM of FITC-ASO for 72 hr before processing the image using a fluorescent microscope. Whole-mount imaging indicated there is good cellular uptake of ASO in this metatarsal culture system and the uptake was sustained up to5 days after removal. ASO A is a modified 20-mer targeting rat FGFR3, and ASO B is a control. In vitro assay with ASO A showed dose-dependent target reduction of FGFR3 RNA level with IC50= 20 nM. Pre-natal rat (E20) metatarsals were collected and the mineral deposited on the putative diaphyseal region was measured at the beginning and the end of the treatment. FGFR3 ASO and the control ASO were added to the organs and cultured for 7 days with daily change in media containing treatment agents (n=8). The results indicate that FGFR3 ASO was able to promote mineralization at 10 μM and it is 50% more effective compared to the BMP-4 positive control (25 mg/ml). The FGFR3 ASO also dose-dependently reverses the inhibitory effect of FGF2, a ligand for the FGFR3 signal pathway. In order to examine the growth promoting effect by inhibiting FGFR3 in a genetically altered environment, two 20-mer modified ASOs specific for mouse FGFR3 were designed and characterized. In vitro, they showed a dose-dependent target reduction of FGFR3 RNA with IC50=25 nM. To explore the correlation of bone growth efficacy of ASOs between the ex-vivo model and an in vivo model, studies are designed using a dwarf mouse strain with a FGFR3 point mutation (G369C)**. ** This mouse strain is licensed from Dr. Chu-Xia Deng's laboratory of NIH.

Physiological levels of mechanical stress induce *FGF-2* gene and protein expression in MC3T3-E1 osteoblasts. M. Hughes-Fulford[1], C. Li*[2]. [1]Medicine, USCF/ VAMC, San Francisco, CA, USA, [2]Lab of Cell Growth, NCIRE, San Francisco, CA, USA.

Although it is clear that FGF-2 is an important modulator of osteoblast function and bone growth, it's response to normal exercise and it's role in induction of proliferation is not well characterized. In these studies we used short-term physiological g-loading, which results in ERK 1/2 phosphorylation in a dose-dependent manner, with maximum phosphorylation saturating at mechanical loading levels of 120 μstrain (12.g; p< 0.001). We found that a 15-minute pulse of 120 μstrai*n* significantly induced *egr-1, cox-2,* and *fgf-2* over 2-5 fold within 30 minutes with no change in *18S, EP-1* or *TGFβ.* MAPK inhibitors did not affect induction of *fgf-2*, however the induction of *cox-2* and *egr-1* was inhibited by MEK1/2 inhibitor U0126 (p<0.001) but was not affected by MEK1 or p38 MAPK specific inhibitors. We also found that FGF-2 protein and the FGF-2 receptor were significantly increased in osteoblasts after g-loading. Syntheses of all three isoforms of FGF-2 (24kD, 22kD and 18kD) were significantly increased in a 12-g gravity vector (p<0.001). Using immunoflorescence we found that much of the FGF-2 protein was translocated to the nucleus within an hour. The long-term consequence of a single 15-minute gravity pulse was a 200% increase in cell growth (p<0.001) where addition of 2ng of recombinant FGF-2 caused an 80% increase (p<0.01) in proliferation when compared to quiescent cells. These studies suggest that physiological levels of mechanical stress induce immediate-early gene expression and growth in MC3T3-E1 osteoblasts. Induction of *egr-1, cox-2* was primarily mediated through an ERK1/2 mediated pathway, however induction of *fgf-2* was independent of the MAPK signal transduction.

TGF-*B* Stimulates Secretion of Cytokines Involved in Bone Destruction from Metastatic Renal Cell Carcinoma. S. Kominsky*, M. Doucet*, K. Weber. Orthopaedic Surgery, Johns Hopkins University School of Medicine, Baltimore, MD, USA.

The TGF-*B* signaling cascade has been implicated in bone metastasis. A vicious cycle of tumor growth and bone destruction has been described in metastatic breast cancer where factors produced by tumor cells enhance osteoclast-mediated bone lysis which, in turn, releases factors that stimulate tumor cell growth. We hypothesized that the TGF-*B* signaling cascade was also important in tumor growth and resultant bone destruction in metastatic renal cell carcinoma (RCC).

Eighteen human samples of RCC bone metastasis were evaluated for the expression of TGF-*B*, TGF-*B*RI, and TGF-*B*RII by immunohistochemistry. Human bone-derived RCC lines, RBM1-IT4, RBM23, and RBM17, were used for western blotting, proliferation studies, and ELISA. For western blotting, cells were probed with antibodies to ERK, phospho-ERK, p38, phospho-p38, Smad2, and phospho-Smad2 with and without the addition of 5 ng/ml of TGF-*B*.

The results revealed that all human tissue samples expressed TGF-*B*, TGF-*B*RI and TGF-*B*RII. There was no significant change in tumor cell proliferation with the addition of 5ng/ml TGF-*B* on MTT studies. Western blotting revealed high constitutive phosphorylation of ERK and p38 that was not affected by TGF-*B*. However, there was a 17- to 62-fold increase in Smad2 phosphorylation that varied by cell line with the addition of 5 ng/ml of TGF-*B*. ELISA revealed very high secreted levels of PDGF-AA (276 pg/10^5 cells) and VEGF (328 pg/10^5 cells) in the RBM1-IT4 cell line that was increased 1.3 to 2-fold with the addition of 2.5 ng/ml of TGF-*B*. Lower levels of IL-6 (1 pg/10^5 cells) were present in two cell lines but could be stimulated 2.3 to 4.6-fold by TGF-*B*. Neutralizing antibodies diminished the effect of TGF-*B*. No TNF-*a* or IL-1*B* secretion was observed.

Based on this preliminary data, we conclude that the TGF-*B* signaling pathway is active in both bone-derived human tissue and cell lines from metastatic RCC. The TGF-*B* dependent stimulation of cytokines known to be involved in angiogenesis and osteoclast-mediated bone destruction may provide targets for future therapy.

Inhibition of Endogenous TGF-b Signaling Accelerates Maturation of Osteoblast Differentiation from Mesenchymal Progenitors. S. Maeda[1], M. Hayashi*[1], K. Shirakawa*[1], S. Komiya[2], T. Imamura*[1], K. Miyazono*[1]. [1]Department of Biochemistry, The JFCR Cancer Institute, Tokyo, Japan, [2]Department of Orthopaedic Surgery, Graduate School of Medicine and Dentistry, Kagoshima University, Kagoshima, Japan.

Transforming growth factor-b (TGF-b), one of the most abundant cytokines in bone matrix, has positive and negative effects on bone formation, although the molecular mechanisms of these effects are not fully understood. Bone morphogenetic proteins (BMPs), members of the TGF-b superfamily, induce bone formation in vitro and in vivo. Here, we show that osteoblastic differentiation of mouse C2C12 cells was greatly enhanced by the TGF-b type I receptor kinase inhibitor SB431542. This promotive effect of the compound was prominent after 48 hours of induction. Endogenous TGF-b was found to be highly active and induce expression of inhibitory Smads(Smad6/7) during the maturation phase of osteoblastic differentiation induced by BMP-4. SB431542 suppressed endogenous TGF-b signaling and repressed the expression of inhibitory Smads during this period, while the acceleration of BMP signaling was observed only in SB431542-treated cells. The inhibition of TGF-b signaling and Smad6 by SB431542 seemed to be responsible for the enhancement of BMP signaling, because siRNA of Smad3 and Smad6 mimicked the effect of SB431542. SB431542 also induced production of alkaline phosphatase and bone sialoprotein, and matrix mineralization of human mesenchymal stem cells. Moreover, SB431542 accelerated bone growth in organ culture of mouse embryo metatarsal bones. Thus, signaling cross-talk between BMP and TGF-b pathways plays a crucial role in regulation of osteobtastic differentiation, and TGF-b inhibitors may be invaluable for treatment of various bone diseases by accelerating BMP-induced osteogenesis.

TGFß-induced Osteoblastic Cell Proliferation Is mediated by Prostaglandin-dependent Activation of Extracellular-signal-Regulated Kinase. C. Ghayor*, A. Rey*, J. Caverzasio. Rehabilitation and Geriatrics, Service of Bone Diseases, University Hospital of Geneva, Switzerland.

TGFß is a major coupling factor between bone formation and bone resorption and is known to stimulate osteoblastic proliferation and matrix deposition. The cellular and molecular mechanisms involved in these effects are incompletely understood. Activation of Smad and of mitogen-activated protein (MAP) kinase pathways have been shown to be involved in mediating TGFß effects on osteoblasts but the precise function of each pathway remains unclear.

In the present study, we investigated the role of MAP kinases in mediating cell proliferation induced by TGFß in MC3T3-E1 cells and calvaria-derived primary cultured osteoblasts.

TGFß (2.5 ng/ml) induced activation of the three MAP kinases ERK (extracellular-signal-regulated kinase), p38 and JNK (c-Jun-NH2-terminal kinase) in MC3T3-E1 cells. Surprisingly, whereas activation of Smad2 was rapid and maximal after 15 min incubation, activation of MAP kinases was delayed. p38 stimulation was detected after 1 h exposure whereas activation of ERK and JNK was only detected after 3 h suggesting indirect activation of MAP kinases by TGFß. Associated with this effect, TGFß enhanced cell proliferation by about two fold in both MC3T3-E1 and calvaria-derived osteoblastic cells. Since prostaglandins (PGs) have been reported to mediate some of the TGFß effects on osteoblatic cells, we investigated the influence of indomethacin (indo), a specific PGs synthesis inhibitor, on cell proliferation and signaling induced by TGFß. Indo (10 μM) completely blunted cell proliferation induced by TGFß and markedly reduced activation of MAP kinases without influencing Smad2 phosphorylation. EP4A (5-10 μM), a specific PGE2 receptor antagonist also blunted TGFß-induced osteoblastic proliferation. In addition to these effects, PGE2 (1 μM) rapidly activated MAP kinases in MC3T3-E1 cells (< 15 min) and increased cell proliferation by about 2 fold. The role of each MAP kinases in mediating TGFß- and PGE2-induced cell proliferation was investigated using selective inhibitors. U0126 (10 μM), a specific inhibitor of the ERK pathway, completely blocked both TGFß- and PGE2-induced cell proliferation whereas SB203580 (10 μM) and SP600125 (20μM), which are selective inhibitors of respectively p38 and JNK pathways had no effect.

In conclusion, data presented in this study strongly suggest that activation of the ERK pathway by prostaglandins mediates cell proliferation induced by TGFß in osteoblastic cells.

The Role of Smad3 in TGF-ß Inhibition of Adipocyte Differentiation of Marrow Stromal Cells. S. Zhou[1], S. Cao*[2], J. Greenberger[2], M. Epperly*[2], S. Lechpammer[1], J. Glowacki[1]. [1]Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, USA.

Marrow stromal cells (MSCs) have the potential to differentiate to lineages of several mesenchymal tissues, including fat, cartilage, bone, tendon, and muscle. Here, we identified pathways involved in TGF-B inhibition of adipocyte differentiation of MSCs.

Testing different adipocytogenic supplements showed that hMSCs express Smads 2,3,5, and 9; they differentiate to adipocytes; and they express PPARγ2 and lipoprotein lipase (LPL) when cultured in MEM-a, 1% FBS-HI, 1 μM dexamethasone, 0.5 mM 1-methyl-3-isobutylxanthine, ± 10 μg/ml insulin (DM±I). Murine MSCs express PPARγ2 in DMEM, 1% FBS-HI with DM+I. Oil red-O staining, RT-PCR, Western blot, and macroarrays were used to assess TGF-ß effects on adipocytogenesis.

In human MSCs, TGF-ß1 downregulated adipocyte genes (PPARγ2, adipsin, LPL, PI3K, etc) and upregulated TGFß/Smad target genes (PAI-1) and Wnt genes (Wnt2, 4, 5a, 7a, 10a, LRP5). Western blot showed that TGF-ß1 increased the stability of Wnt signal molecule ß-catenin. TGF-ß1 and theWnt-mimetic LiCl synergistically inhibited adipocyte differentiation.

Because of the importance of Smad signaling in TGF-ß's effects, we studied both long-term bone marrow cultures (LTBMC) and MSCs from $Smad3^{+/+}$ and $^{-/-}$ mice. LTBMCs from both achieved confluence of the adherent compartment after 8 w in McCoy's 5A medium (25% FBS). After 22 w, the average number of non-adherent cells in $Smad3^{-/-}$ (2.6 ± 0.5 x 10^6 cells) was 288% greater (p = 0.0316) than in $Smad3^{+/+}$ (0.9 ± 0.3 x 10^6 cells) LTBMCs. The number of hematopoietic CFU-GEMM colonies (d 14) in $Smad3^{-/-}$ cultures (188 ± 8.7) was 1250% greater (p<0.0001) than in $Smad3^{+/+}$ cultures (15.3 ± 2.3). Microscopic inspection at 27 weeks showed that more (16.5%, p<0.001) $Smad3^{-/-}$ adherent cells contained lipid droplets (6.6 ± 0.7%), compared with $Smad3^{+/+}$ adherent cells (0.4 ± 0.2%). Because these findings indicate differences in hematopoiesis between $Smad3^{+/+}$ and $^{-/-}$ LTBMCs, we measured adipocyte differentiation in $Smad3^{+/+}$ and $^{-/-}$ MSCs. There were two notable differences in adipocyte development in isolated MSCs. First, there was more extensive (37-fold) adipocyte differentiation in $Smad3^{-/-}$ than $Smad3^{+/+}$ MSCs; this indicates that Smad3 is a critical inhibitor of adipocyte differentiation. Second, there was a 7-fold attenuation of TGF-ß's inhibition of adipogenesis in cells lacking Smad3

In conclusion, Smad and ß-catenin are involved in the inhibitory effects of TGF-ß on adipocyte differentiation in human and murine marrow stromal cells. Use of $Smad3^{-/-}$ murine MSCs shows a key role of that mediator in TGF-ß inhibition of adipocyte differentiation.

Regulation of MEIS2 Transcription Factors during Estrogen Deficiency, a Potential Mechanism for Regulation of CIITA. N. Kirma, M. N. Weitzmann, K. Dark*, W. Qian, R. Pacifici. Division of Endocrinology, Metabolism and Lipids, Emory University, Atlanta, GA, USA.

We have recently demonstrated that a central event in the initiation of bone destruction during estrogen deficiency is the upregulation of the key regulator of MHCII expression, CIITA. CIITA induction leads to enhanced antigen presentation and expansion of the pool of TNF producing T cells. This enhanced pool of TNF synergizes with amplifies RANKL induced osteoclast formation and activity. The upregulation of CIITA is mediated in part by a decrease in the level of TGF-beta. New lines of evidence suggest that TGF-beta may both stimulate and suppress gene transcription by the recruitment of co-repressors and co-activators to TGF-beta responsive promoters. One such co-repressor is TGIF, while MEIS2 is a transcriptional co-activator that apposes TGIF mediated repression by competing with it for the same DNA binding site. Western blot analyses confirmed the expression of TGIF proteins in bone marrow monocytes (BMM), a population in which CIITA is upregulated in the bone marrow by ovariectomy (ovx). Likewise, DNA-binding isoforms of MEIS2 (c and d) and MEIS2e, an endogenous dominant negative isoform, were detected in BMM by western blotting. To test the effect of estrogen deficiency on the expression of TGIF and MEIS2 isoforms we performed ovx or sham operations on C57BL6/J mice and isolated BMM after 2 week. The data showed a decrease in MEIS2e levels in ovx BMM, suggesting that estrogen deficiency may upregulate the DNA binding activity of stimulatory MEIS2 isoforms by downregulating the levels of inhibitory MEIS2e. No differences in the concentrations of TGIF or MEIS2 c and d isoforms were observed. To test the balance of DNA binding activities between TGIF and MEIS2 in ovx BMM, we performed EMSA and antibody supershift studies using a commercial consensus sequence containing a binding site for TGIF/MEIS2. The data revealed an increased level of MEIS2 complex bound to the consensus probes in ovx relative to sham BMM. No binding of TGIF to the probe was observed under either sham or ovx conditions. Together, the data suggest that in ovx BMM gene transactivation through TGIF/MEIS2 consensus sequences may be stimulated via the enhanced binding of stimulatory MEIS2 species, a consequence of downregulation of the inhibitory isoform MEIS2e.

Role of TGF-b in the Early Steps of Chondrogenesis. S. S. Dong*, H. Seo*, R. Serra. Cell Biology, University of Alabama at Birmingham, Birmingham, AL, USA.

The differentiation of mesenchymal cells into chondrocytes takes place along a multi-step pathway and multiple cytokines are known to influence discrete steps in the pathway. A number of studies suggest that TGFb plays a critical role in the regulation of the cartilage differentiation. To investigate the role of TGFb in regulating chondrogenesis, we generated a recombinant adenovirus containing a truncated TGFb type II receptor (DNIIR) that acts as a dominant negative to block TGFb signaling. Limb bud micromass cultures isolated from E11.5 mouse embryos were infected with DNIIR and rapidly lost their responsiveness to TGFb. DNIIR infection of limb micromass cells caused decreased alcian blue staining and reduced nodule formation in vitro, suggesting that condensation and chondrogenesis require TGFb signaling. Treatment with TGF-b resulted in increased alcian blue staining early and inhibition of alkaline phosphatase activity in later cultures. In addition, we examined whether TGFb modulates Sox9 expression. Sox9 is well known as a potent transcription factor in activating the expression of chondrocyte marker genes. We demonstrate that there are no changes in Sox9 expression or activation in response to TGFb, as measured by RT-PCR and IP/Western analysis. In summary, we conclude that TGFb signaling is an important regulator of chondrogenesis, however, TGFb does not regulate Sox9 expression or activation. The mechanism by which TGFb promotes chondrogenesis is currently unclear. Understanding the early steps of cartilage development should provide valuable insights into mechanisms for regenerating cartilage.

Connective Tissue Growth Factor (CTGF) Mediates Condensation of Mesenchymal Stem Cells Induced by TGF-β1. J. J. Song*[1], R. A. Kanaan[2], F. F. Safadi[1], S. N. Popoff[1]. [1]Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, [2]Orthopaedics, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

Cellular condensation is a stage of skeletogenesis involving the congregation of mesenchymal stem cells and is considered to be a critical step in this process. CTGF is a matricellular protein that has been shown to be highly expressed in cellular condensations by *in situ* hybridization studies during embryonic development. Interestingly, CTGF-deficient mice demonstrated a misshapen skeleton attributed to endoskeletal abnormalities and abnormal cartilage development. CTGF has been found to be highly up-regulated with TGF-β stimulation, and CTGF has also been found to enhance receptor binding of TGF-β. We propose that CTGF may promote condensation through the TGF-β pathway, a known regulator of cellular condensation. In this study, we established high-density micromass cultures using the C3H10T1/2 murine mesenchymal stem cell-line. These cells have been shown to form prechondrocytic nodules following TGF-β1 treatment. C3H10T1/2 cells were micromass cultured in HamF12 media with 10% fetal bovine serum and with 1 ng/ml TGF-β1 treatment. Under these conditions, cellular condensations (nodules) were formed within 72 hours. Next, we down-regulated CTGF expression using an antisense CTGF oligonucleotide, confirming expression levels by RT-PCR and Western blot analyses. Attenuation of CTGF expression was sufficient to inhibit nodule formation induced by TGF-β1 treatment. These results were confirmed using CTGF siRNA, an even more effective method to silence CTGF expression. Knock down of CTGF protein expression was decreased from 40-50% using the antisense oligonucleotide up to 80-90% using siRNA compared to TGF-β1-treated controls. Micromass cultures transfected with CTGF siRNA also showed significant inhibition of cellular condensation induced by TGF-β1. In addition, the levels of fibronectin, an extracellular matrix protein known to play a role in cellular condensation, was down-regulated by CTGF siRNA treatment in micromass cultures. In conclusion, these results demonstrate that CTGF is an important mediator of TGF-β-induced cellular condensation *in vitro*, and supports a role for CTGF in proper skeletal development. The precise nature of the mechanism of action of CTGF in promoting cellular condensation will be elucidated with further experimentation.

Alpha V Beta 3 Integrin Ligands Enhance Volume-sensitive Calcium Influx in Mechanically Stretched Osteocytes. A. Miyauchi[1], M. Gotoh[2], K. Notoya[2], H. Sekiya[3], Y. Takagi[1], K. Jinnai*[1], Y. Yoshimoto[1], T. Sugimoto[4], K. Chihara[4], T. Fujita[5], Y. Mikuni-Takagaki[6]. [1]National Hyogo-Chuo Hospital, Sanda, Japan, [2]Pharmaceutical Research, Takeda Chemical Industries, Osaka, Japan, [3]School of Dental Medicine, Tsurumi University, Yokohama, Japan, [4]Endocrinology/Metabolism, Kobe University Graduate School of Medicine, Kobe, Japan, [5]Ca Research Institute, Kishiwada, Japan, [6]Oral Biochemistry, Kanagawa Dental College, Yokosuka, Japan.

Osteocytes transmit load-induced signals, which result in bone formation. Our previous report illustrated that mechanosensing in rat osteocytes depends on a volume-sensitive calcium influx pathways that is regulated by activation of stretch activated cation channels (SA-Cat), further suggesting that osteocytes utilize contact with the bone matrix upon stretching. $\alpha_V \beta_3$ integrin (vitronectin receptor), highly expressed in osteocytes (Bennett JH et al., 2001), is also reported being upregurated by mechanical strain in osteoblasts (Cavalcant-Adam EA et al., 2002). Therefore, we examined whether specific cell-matrix interaction regulates volume-sensitive calcium influx pathways in osteocytes. Rat osteocytes adhered to the substrates, type I collagen (COL I), fibronectin (FN), osteopontin (OPN), vitronectin (VN), laminin (LN), and thrombospondin (TSP). The cells fully spread on FN, COL I, VN and OPN,and the adhesion to OPN and VN was almost completely inhibited by a GRGDS peptide. Stretch loading by swelling rat osteocytes in hypoosmotic solution (182 mosm, normal 363mosm) induced rapid and progressive increase (100±15nM above basal (n=16)) of cytosolic calcium concentration, $[Ca^{2+}]i$, which was detected by using video-image analysis with fura-2. Cells on FN, LN, TSP-coated coverslips responded less to the hypotonic stimuli (76, 50, and 43% $[Ca^{2+}]i$ increase, respectively) compared to the control cells on Matrigel (MG). In contrast, the cells on OPN, VN, and COL I responded more or equally well (250, 150, and 100% $[Ca^{2+}]i$ increase, respectively) to the hypotonic stimuli. Addition of a soluble GRGDS peptide, not a GRGES peptide at 200 μg/ml prior to the hypotonic stimulation of the cells, enhanced the hypotonic stimulation of $[Ca^{2+}]i$ by 230%. Similarly, specific soluble $\alpha_V \beta_3$ ligand echistatin (10^{-9}M to 10^{-7}M) enhanced hypotonic stimulation of $[Ca^{2+}]i$ by as much as 240%. Perturbation of actin filament by cytochalasin D treatment inhbited hypotonic stimulation of $[Ca^{2+}]i$ by 70%. These data support the notion that the integrin signaling interact with that of mechanosensing to regulate SA function in osteocytes. $\alpha_V \beta_3$ integrin was suggested to play a key role in this process.

Cyclooxygenase-2 Inhibitor Suppresses Cancellous Bone Restoration in Tibia in Association with Restriction of Osterix Expression in Reloading Period after Hindlimb Elevation of Mice. K. Nakai*, S. Tanaka*, A. Sakai, M. Tanaka*, H. Otomo*, M. Nagashima*, S. Akahoshi*, T. Mori, T. Takeda*, Y. Katae*, H. Hirasawa*, T. Nakamura. Orthopaedic Surgery, School of Medicine, University of Occupational and Environmental Health, Kitakyusyu, Japan.

To clarify the role of cyclooxygenase-2 (COX-2) in acute recovery of trabecular bone mass during the reloading state after unloading, 108 male C57BL/6J mice, at 8 weeks of age, were divided into two weight-matched groups; ground control (GC) and reloading (RL). The hindlimbs of GC were normal loaded through the experimental period and those of RL were reloaded after 7-day tail-suspension. At the 8th experimental day, GC was divided into three groups; GC baseline, GC+vehicle administration (Veh), and GC+Celecoxib (selective COX-2 inhibitor) administration (Cel). RL was also divided into RL baseline, RL+Veh and RL+Cel. Tibias of GC and RL baseline were harvested at the 8th experimental day, and tibias of other groups were harvested at the15th and 22nd days, and 24 and 48 hours after reloading. Celecoxib was given 30 mg/kg body weight twice a day, and started 3 hours before reloading. At the 8th day, bone volume (BV/TV) of the proximal tibia in RL baseline significantly decreased compared with that in GC baseline. At the 22nd day, BV/TV in RL+Veh was restored to the same level of that in GC+Veh, but that in RL+Cel was not restored. At the 15th day, bone formation rate (BFR/BS) in RL+Veh and RL+Cel increased compared with that in GC+Veh. Even though, there was significant difference in BFR/BS between RL+Cel and RL+Veh. There were no differences in the respective values of the osteoclast surface (Oc.S/BS) and the osteoclast number (Oc.N/BS) among these four groups at the 15th and 22nd days. Quantitative RT-PCR was performed using bone marrow cells of tibias after 24 and 48 hours from reloading. After 24 hours, osterix mRNA expression in RL+Veh showed 2-fold increase compared with GC that in baseline but the expression in RL+Cel did not increased. c-fos expression in RL+Veh showed 8- and 10-fold increase after 24 and 48 hours, respectively, but the expression in RL+Cel did not increased. The expressions of bmp2 and dlx5 in RL+Veh did not change at 24 and 48 hours, and those expressions in RL+Cel increased at 48 hour. These results suggest that COX-2 inhibitor suppresses cancellous bone restoration in tibia in association with restriction of osterix expression and enhances bmp2 and dlx5 expressions.

The Reduced Osteogenic Potential after Skeletal Unloading Relates to the Decreased Expression of PECAM-1 in Bone Marrow Cells in Mice. M. Sakuma-Zenke*[1], A. Sakai[1], S. Nakayamada*[2], N. Kunugita*[3], S. Uchida[1], S. Tanaka*[1], T. Mori[1], Y. Tanaka[2], T. Nakamura[1]. [1]Department of Orthopaedic Surgery, University of Occupational and Environmental Health, Kitakyushu, Japan, [2]First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, [3]Department of Health Information Science, University of Occupational and Environmental Health, Kitakyushu, Japan.

Appropriate vascularization is emerging as a prerequisite for bone development and regeneration. We tested the hypothesis that skeletal unloading reduces osteogenic potential by inhibiting angiogenesis and/or vasculogenesis in bone marrow cells. Eight-week-old male mice were assigned to three groups as follows, after acclimatization for one week: ground control (GC), tail-suspension (TS) and reloading after 7-day TS (RL). Bilateral tibial and humeral samples were used for analyses. MC3T3-E1, mouse osteoblastic cell line, and EOMA and ISOS-1, mouse endothelial cell lines, were also used. The flow cytometric analysis revealed that one-week of TS significantly decreased the expression of platelet endothelial cell adhesion molecule-1 (PECAM-1, CD31) in tibial bone marrow cells, but did not those of angiopoietin-1, angiopoietin-2, Flk-1 (vascular endothelial growth factor receptor), and VE-cadherin. The expression of PECAM-1 in tibial marrow cells was significantly reduced at day 3 of TS and thereafter still showed lower level to day 7 of TS, compared to that at day 7 of GC. This decreased expression of PECAM-1 recovered to the GC level by 5-day reloading after 7-day TS. However, the expression of PECAM-1 in humeral marrow cells after TS and RL constantly kept the same level as that of GC. In bone marrow cell culture, the formation of alkaline phosphatase (ALP)-positive colony forming units-fibroblastic was significantly reduced under the medium condition of the supplementation of anti-PECAM-1 antibody, compared under that of immunoglobulin G. ALP production of cultured MC3T3-E1 was enhanced in combination with EOMA, expressing PECAM-1, but not in combination with ISOS-1, unexpressing PECAM-1. The anti-PECAM-1 antibody inhibited the increase in ALP production under the coculture with EOMA. In conclusion, our data demonstrate that the reduced osteogenic potential after skeletal unloading closely relates to the decreased expression of PECAM-1 in bone marrow cells. We speculate that the loss of ostegenic potential due to skeletal unloading may be related to the suppression of PECAM-1 signaling on endothelial cellular surface.

Bio-imaging of Intracellular Nitric Oxide in Single Cells after Mechanical Loading. A. Vatsa*[1], D. Mizuno*[2], T. H. Smit*[3], C. F. Schmidt*[2], F. C. MacKintosh*[4], J. Klein-Nulend[1]. [1]Oral Cell Biology, ACTA-Vrije Universiteit, Amsterdam, Netherlands, [2]Biophysics and Complex Systems, Vrije Universiteit, Amsterdam, Netherlands, [3]Physics and Medical Technology, Vrije Universiteit Medical Centre, Vrije Universiteit, Amsterdam, Netherlands, [4]Theoretical Physics, Vrije Universiteit, Amsterdam, Netherlands.

Osteocytes are the professional mechanosensors of bone. The strain-derived interstitial fluid flow through the lacuno-canalicular porosity seems to mechanically activate them, which may be related to mechanical adaptation of bone. After mechanical loading they produce nitric oxide (NO) that likely affects osteoblasts and osteoclasts. Since the mechanosensitive part of the osteocytes (protrusions or cell body), is unknown, information is needed on the single osteocyte's response to localized mechanical loading. Here we studied intracellular NO production in single MC3T3-E1 osteoblasts after mechanical loading using DAR 4M AM rhodamine.

DAR 4M AM rhodamine loaded, surface-attached MC3T3-E1 cells were subjected to oscillatory mechanical loading (144-560 pN, 0.5-3 Hz, 1 min) through cell-attached colloid particles using optical tweezers. DAR 4M AM is membrane-permeable and traps NO forming a stable, fluorescent compound intracellularly, visible with a rhodamine filter.

Non-loaded cells showed detectable basal NO levels. Mechanical loading increased fluorescence by +21% as compared to the non-loaded fluorescence levels (Fig. 1). Loosely surface-attached cells showed higher deformation and increased fluorescence +25% with lower force (144pN) as compared to firmly-attached cells, which required larger forces (310-560 pN) for deformation showing +18% increase.

NO is essential for loading-induced bone formation, and is a meaningful parameter for measuring bone cell activation after mechanical loading. Its short half-life (0.1-5 s) makes its online detection difficult. Here we show that the NO upregulation in a single bone cell after a localised and quantified mechanical stimulus can be determined using DAR 4M AM rhodamine. This model allows further study on the mechanosensitivity of different parts of a single osteocyte.

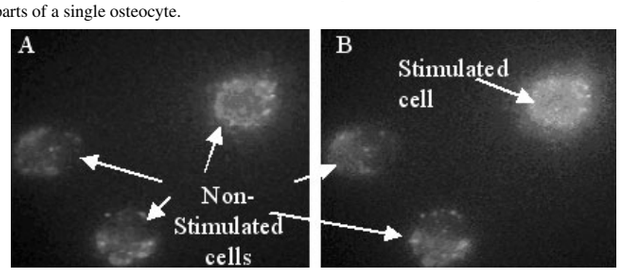

Fig.1. Intracellular NO detection by fluorescence in a single cell, A, before, B, 20 min after mechanical loading

Agent Based Model of Real-Time Signaling in Osteocytic Networks-Implications for Downstream Mechanotransduction Events. B. J. Ausk*, T. S. Gross, S. Srinivasan. Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, USA.

Recently, we observed that insertion of 10-s rest (unloaded intervals) between each load cycle lowered the threshold strain-magnitude (by 30%) and load cycle numbers (5-fold) required to initiate bone formation. Using approaches uniquely suited for analysis of complex adaptive systems, we explored the cell level basis for our counterintuitive observations. Specifically, we developed agent based models of real-time signaling induced in osteocytic networks by mechanical stimuli. The behavior of osteocytic cells were modeled as follows: 1) a threshold level of stimulus magnitude was required to initiate cell activity, 2) cell-cell signaling initiated cell activity if signals exceeded a threshold, 3) cell activity was modulated based on 'metabolic' stores and the rate at which stores were recovered. In the context of these functions, the response of an osteocytic network to cyclic and rest-inserted (10-s) stimuli was simulated. Network response (average of cell responses) was monitored across time, and over a range of load cycles and stimuli magnitudes. As one reporter of the network signaling, the real-time response was integrated over a specified number of load cycles ('network power'). Real-time network response to cyclic stimuli consisted of a large magnitude transient followed by low-level steady state fluctuations. In contrast, enhanced and sustained responses were elicited by rest-inserted loading (multiple peaks). To relate these distinct real-time signaling events (sec) to *in vivo* bone formation (wks), we assumed that network power in response to 50 cycles of cyclic stimuli would represent the 'threshold' level of signaling required before bone formation events were initiated downstream. Interestingly, and paralleling *in vivo* observations, network power in response to 10 cycles of rest-inserted stimuli was similar (~ 5% increase) to that induced by 50 cycles of cyclic stimuli (i.e., similar response despite 5-fold decrease in load cycles). As well, network power in response to 50 cycles of rest-inserted loading was dramatically enhanced compared with cyclic stimuli (~ 500%). This model observation also mirrored the ability of rest-inserted loading to substantially enhance bone formation *in vivo* (nearly 3-fold compared with identical magnitude/load cycles of cyclic stimuli). Given these relations, and the influence of real-time signaling events (e.g., Ca^{2+} fluctuations) in controlling down-stream gene transcription events, we speculate that the enhanced and sustained real-time signaling induced in osteocytic networks may underlie the osteogenic potency of rest-inserted loading regimens.

Evidence That BMD Response To Mechanical Loading (ML) In Vivo Is Caused By Acute Up-Regulation Of Both Bone Formation (BF) Genes And Down Regulation Of Bone Resorption (BR) Genes. C. Kesavan*, S. Mohan, S. Oberholtzer*, D. J. Baylink. JLP VAMC, Loma Linda, CA, USA.

Increase in bone mass in response to skeletal loading is an important adaptive response. It is likely that regulation of both osteoblast (OB) and osteoclast cell functions are involved in producing an optimal response to a given skeletal load. To evaluate the OB and osteoclast cell response to mechanical input, we tested the hypothesis that in vivo ML by 4-point bending leads to acute reduction in the expression of BR genes and a progressive increase in the expression of BF marker genes. We measured expression changes by real time PCR in 12 genes that relate to BF and BR at d2, 4, 8 and 12 of training in 10-wk old C57Bl/6J mice. A 9N load at 2Hz (36cycles) was applied on the right tibia by a 4 point bending device and the left tibia was used as an internal control. 12 days of loading caused a highly significant ($p<0.001$) increase in BMC (33%), volumetric BMD (14%) and total area (26%) as measured by pQCT in the loaded bone compared to corresponding unloaded bone. Measurement of gene expression changes by real time PCR at d2 showed significant ($p<0.01$) change in the down-regulation of BR makers MMP and TRAP by 2 and 4-fold with no change in the expression of BF genes compared to control. 4-days of loading caused down regulation of BR genes MMP-9, TRAP and Sodium-potassium pump by 3, 5, and 2-fold respectively ($p<0.0001$). In contrast, the expression of type-I collagen (Col 1) and bone sialoprotein (BSP) was increased by 2-fold as expected. After 8 days of loading, the expression of TRAP was decreased by 3-fold while expression of Col 1, ALP, BSP, and osteocalcin (OC) was increased by 3-fold. Surprisingly, the expression level of BR marker genes were increased after 12 days of loading (MMP-9 by 12 fold and TRAP by 7.5 fold) which may reflect loading induced increase in remodeling. In contrast, expression of Col 1, BSP, ALP and OC increased by 4.2, 8, 6 and 4 fold respectively ($p<0.001$). In order to determine if gene expression change can be used as a surrogate for bone anabolic response, we determined the correlation between expression levels and BMD changes and found total BMD measured by pQCT showed significant correlation with BSP ($r=0.54$, $p<0.01$) and OC ($r=0.66$, $p<0.01$) expression. Conclusions: 1) ML by 4-point bending increased both size and volumetric BMD after 12 days; 2) The expression levels of BF genes were increased throughout the loading period; 3) This is the first report to demonstrate acute reduction in BR marker genes in response to loading. 4) The increase in expression of BR genes at day 12 may indicate loading induced remodeling of bone. 5) Our findings demonstrate the usefulness of gene expression changes as surrogate marker for bone anabolic response to ML.

SU213

Bone Anabolic Response To A Mechanical Load Is A Complex Trait And Involves Bone Size, Material Bone Density (mBMD) And Volumetric Bone Density (vBMD) Phenotypes. C. Kesavan*, S. Mohan, J. Wergedal, D. J. Baylink. JLP VAMC / LLU, Loma Linda, CA, USA.

Different mouse strains show large variations in BMD in response to the same mechanical load, suggesting that bone response to mechanical loading is genetically regulated. To test the hypothesis that the mechanical load response is a complex trait, we applied 4-point bending to the tibia to evaluate response in six different strains of mice in order to select the two strains with the most different respnse. These were C3H/HeJ (C3), the poor responder, and C57BL/6J (B6), the good responder. These two parents were used to produce 300 F2 mice. The 4-point bending method utilized a 9N load (3500 ue, upper limit of physiological strain) at 2Hz for 36 cycles and was applied for 12 days. Two days after the last load, skeletal changes were evaluated by pQCT. In these F2 mice, all three phenotypes (change in bone size, mBMD and vBMD) showed Gaussian distributions, consistent with complex traits. Heredity indexes ranged from 86-70%. The vBMD data demonstrate that some F2 mice had decreased bone density in response to the load whereas other mice gained as much as 20% in vBMD of the tibia. The other phenotypes ranged from -5 to +5% for mBMD, and -10 to +30% for bone size in the F2 mice. Cortical BMD reflects material bone mineral density (mBMD) since vascular canal volume in our sampling site is too low to alter cortical BMD (less than 1% of the bone volume). Our data on mBMD of bone formed prior to loading indicates for the first time that mechanical loading increases mBMD. We next determined if the magnitude of bone anabolic response to 4-point bending is dependent on body size. None of the three phenotypes were positively correlated with body weight. Furthermore, there was no significant difference betweem the bone size (unloaded bones) and the degree of change in vBMD in response to loading. These data demonstrate that a differential anabolic response cannot be explained by differences of applied mechanical strain in the F2 mice or to differences in body size. Summary: 1) Anabolic response to a standard mechanical load can be divided into at least three different phenotypes (change in bone size, vBMD and mBMD). 2) These three phenotypes show a Gaussian curve in the B6/C3H F2 mice consistent with a complex trait controlled by several genes. 3) Bone size and vBMD changes are dependent upon new bone formation, found to be exceedingly variable in our F2 mice. However, the mBMD phenotype, a measurement of mineral density in preexisting bone, implies that there is a mechanism to increase mBMDmaterial density i.e. the bone quality can adapt to a large mechanical load. Conclusion: This study shows genetic-environmental adaptive interactions in bone of a remarkable magnitude.

Mechanosensitivity of Human Mesenchymal Stem Cells. R. C. Riddle*, A. F. Taylor*, D. C. Genetos, H. J. Donahue. Department of Orthopaedics and Rehabilitation, Pennsylvania State University College of Medicine, Hershey, PA, USA.

Mechanical signals are clearly important to the maintenance of skeletal homeostasis as both the addition and removal of load are followed by alterations in bone mass. Load-induced oscillatory fluid flow has previously been shown to induce a number of well-defined biochemical responses that are thought to link mechanical signals with cellular responses. However, little is known about the mechanisms by which mesenchymal stem cells respond to mechanical signals and oscillatory fluid flow in particular. The purpose of this study was to determine whether oscillatory fluid flow regulates the behavior of human bone marrow-derived mesenchymal stem cells (hMSCs) in a manner similar to osteoblasts. Exposing hMSCs to physiologic levels of fluid flow that induce shear stresses of 5, 10, and 20 dynes/cm^2 induced a rapid increase in intracellular calcium concentration in 56 ± 2.4%, 87 ± 7.9%, and 89 ± 10.4% (mean ± SD) of cells, respectively. Absolute increases in intracellular calcium in response to these three shear stresses were on the order of 60 ± 20.4, 95 ± 12.5, and 189 ± 30.4nM. Subsequent experiments designed to elucidate the mechanism involved in intracellular calcium increase were performed with a shear stress of 20 dynes/cm^2, as the greatest calcium response was observed in this condition. Treatment with 5μM verapamil and 10μM gadolinum chloride, which antagonize the L-type calcium channel and mechanosensitive cation channel, respectively, did not have a significant effect on either the percentage of cells responding or absolute calcium increase. Treatment with 1μM thapsigargin, which empties intracellular calcium stores, and 10μM U73122, which antagonizes phospholipase C, markedly decreased both the percentage of cells responding and absolute calcium increase suggesting that these responses result from IP_3-mediated calcium release. On a longer time-scale, exposing cells to 20 dynes/cm^2 of fluid shear induced a robust increase in the phosphorylation of the extracellular signal-regulated kinase (ERK), an important regulator of osteoblastic differentiation, at 15, 30, and 60 minutes of flow. Following 120 minutes of flow ERK phosphorylation returned to basal levels. Downstream targets of these responses are currently under investigation. These data suggest that fluid flow not only regulates osteoblastic behavior but also that of hMSCs and imply that a common pathway exists by which mechanical signals are translated to cellular responses.

Correlations between DMP1/ MEPE Gene Expression in osteocytes and Axial Strains in an *In-vivo* Model of Overload. S. P. Kotha*[1], J. Gluhak-Heinrich[2], M. Schaffler[3], S. Harris[1], L. F. Bonewald[1]. [1]Oral Biology, University of Missouri, Kansas City, MO, USA, [2]Orthodontics, U of Texas Health Science Center, San Antonio, TX, USA, [3]Mount Sinai School of Medicine, New York, NY, USA.

Alterations of strain in bone are related to different biological responses, with bone loss at low strains, tissue homeostasis at normal strains, modeling at higher strains and the overload response at even higher strains. The osteocyte is believed to play a critical role as mechanotranducer, translating strain magnitude into an appropriate biological response. Using an overload model, where there is both bone formation and resorption, we studied the expression of molecules that are highly expressed in osteocytes, namely, Dentin Matrix Protein 1 (DMP1) and Matrix Extracellular Phosphoglycoprotein (MEPE) and correlated them to axial strains determined from finite element analysis. These molecules may have opposing effects on mineralization, with DMP1 acting as a modulator and MEPE acting as an inhibitor. The right ulna was loaded at 4 Hz with a maximum force of 20N until there was a 30% loss in whole bone stiffness. The left ulna served as contralateral controls and was not subjected to loading. Gene expression of DMP1 and MEPE mRNA was assayed at 2 days by quantitative *in situ* hybridization using P^{32} labeled RNA probes in control and loaded ulnae. Finally, gene expression in all osteocytes that fell along lines with a particular axial strain value were averaged and correlated to local strains as determined from our computational model. The results indicate that loaded ulnae expressed ~2 and 4 times more DMP1 and MEPE gene expression, respectively. The in-plane pattern of gene expression per osteocyte was highly correlated to axial strain magnitude in loaded (DMP1: $r^2= 0.71$; $p< 0.03$; MEPE: $r^2= 0.82$; $p< 0.02$) and control (DMP1: $r^2= 0.64$; $p< 0.05$; MEPE: $r^2= 0.83$; $p< 0.01$) ulnae. The magnitude of expression was similar when considering tensile or compressive strains. At the same strain level, DMP1 to MEPE expression ratios were higher in control bone (~4 times) than in loaded bone (~2 times). The longitudinal pattern of DMP1 and MEPE gene expression, i.e. expression along the length of the ulna, was also highly correlated to peak axial compressive strain at seven cross-sections in both the loaded (DMP1: $r^2= 0.68$; $p< 0.03$; MEPE: $r^2= 61$; $p<0.03$) and control (DMP1: $r^2= 0.65$; $p< 0.05$; MEPE: $r^2= 0.57$; $p<0.05$) ulnae. These findings indicate that DMP1 and MEPE gene expression is higher in regions with higher axial strains within control bone and that gene expression increases when strains are further increased in the loaded bones. This suggests that both molecules may have to be simultaneously expressed in order to regulate the mineralization process.

A Novel Mechanical Stress-induced Signaling Pathway Leading to Protein Kinase C Delta-dependent Smad1 Activation in Osteoblasts. S. Kido[1], D. Inoue[1], T. Imamura*[2], K. Miyazono*[3], T. Matsumoto[1]. [1]Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medicine, Tokushima, Japan, [2]The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Japan, [3]Department of Molecular Pathology, Graduate School of Medicine University of Tokyo, Tokyo, Japan.

Although mechanical stress to bone plays an important role in maintaining bone mass and strength, the molecular mechanisms by which mechanical loading stimulates bone formation are not fully understood. We have already reported that fluid shear stress (FSS) to primary mouse calvarial osteoblasts (POB) activates Smad1, a critical factor for osteoblast differentiation that mediates BMP actions. In the present study, we further determined the upstream signaling event causing Smad1 activation. Fluid shear stress (FSS) induced Smad1 phosphorylation at S463/S465 in the C-terminal SSXS motif and nuclear translocation with Smad4. Functional and biological significance of these events was confirmed by our observations that FSS induced promoter activity of Smad6, a known target of Smad1, and that FSS increased alkaline phosphatase activity of C3H10T1/2 and C2C12 cells overexpressing Smad1. We found that FSS activation of Smad1 was almost completely inhibited by PKC inhibitors or depletion by long-term treatment with TPA. All the other chemical inhibitors including those for PI-3K, ERK, p38MAPK and PKA had little effect on FSS-induced Smad1 phosphorylation. Surprisingly, PKC inhibition did not affect Smad1 activation by BMP-2, an authentic ligand of ALK3 and 6 receptors known to directly phosphorylate and activate Smad1. Further analysis revealed a critical role for PKCδ, one of the novel PKC isoenzymes, because FSS-induced Smad1 phosphorylation was almost completely inhibited by either selective PKCδ inhibitor (rottrelin) or PKCδ siRNA. We also confirmed that FSS as well as TPA treatment resulted in PKCδ activation. We then tested a hypothesis that Smad1 is a substrate of PKCδ. Consistently, we were able to show direct physical interactions of PKCδ with GST-Smad1 in vitro. Moreover, in vitro kinase assays and LC-mass spectrometry demonstrated that recombinant PKCδ was indeed able to phosphorylate Smad1 by itself. In summary, we have demonstrated that mechanical stress activates Smad1 via a novel PKCδ -dependent signaling pathway distinct from that induced by BMP-2. Further delineation of this pathway will form a molecular basis to better understand the mechanism of mechanical stress-induced bone formation and to identify novel molecular targets for the treatment of immobilization osteoporosis.

Differentiation Affects MC3T3-E1 Mechanoresponsiveness and P2Y2 Expression. C. A. Strohbach*[1], D. C. Genetos[2], A. F. Taylor*[1], H. J. Donahue[1]. [1]Orthopaedics and Rehabilitation, Pennsylvania State University College of Medicine, Hershey, PA, USA, [2]Cellular and Molecular Physiology, Pennsylvania State University College of Medicine, Hershey, PA, USA.

Osteoblasts respond to a variety of mechanical stimuli, including strain-induced fluid flow. We, and others, have previously demonstrated that exposure of MC3T3-E1 osteoblasts to oscillatory fluid flow (OFF) induces a rapid and transient increase in cytosolic calcium levels ($[Ca^{2+}]_i$). To our knowledge, all previous studies used the MC3T3-E1 cell line in its undifferentiated state. The aim of this study was to determine the effects of differentiation on OFF-induced Ca^{2+} transients. Cells were grown in αMEM+10%FBS+1%PS for 2 days or 21 days. Alizarin Red staining for calcium incorporation into the matrix, as well as von Kossa staining for phosphate content, confirmed the differentiated phenotype of the cells cultured for 21 days compared to 2 days. MC3T3-E1 cells grown in monolayer for 2 days or 21 days were subcultured onto quartz slides 2 days before Ca^{2+} imaging experiments. On the day of experimentation, cells were loaded with 10μM Fura2/AM and placed in a parallel plate flow chamber. Following a 3min no-flow period, cells were exposed to OFF (20dynes/cm^2, 1Hz) for 3min Cells were considered responsive if the maximum $[Ca^{2+}]_i$ during flow was greater than or equal to the no-flow $[Ca^{2+}]_i$ average plus 4 standard deviations of no-flow $[Ca^{2+}]_i$. There was no significant difference between undifferentiated and differentiated cells in the percentage of cells responding to flow (87% vs 82%, respectively). However, differentiated cells demonstrated a significantly higher resting $[Ca^{2+}]_i$ compared to undifferentiated cells (366nM vs 127nM; $p < 0.0001$). In addition, the maximum Ca^{2+} amplitude during OFF was significantly higher in differentiated cells compared to undifferentiated cells (380nM vs. 100nM; $p < 0.0001$). Because it has previously been demonstrated that activation of the ATP-activated P2Y2 purinergic receptor is required for OFF-induced increases in $[Ca^{2+}]_i$, we examined whether increased P2Y2 expression could be responsible for the increased Ca^{2+} response in differentiated cells. We found higher P2Y2 expression in the differentiated cells compared to undifferentiated cells. These data demonstrate that differentation state affects MC3T3 responsiveness to OFF, perhaps through increased P2Y2 receptor expression.

Effects of Treadmill Exercise on Bone Mass and Bone Metabolism in Ovariectomized Rats. N. Nakamichi*[1], S. Ichimura[2], Y. Aoki*[1], J. Iwamoto[3], Y. Toyama*[4], K. Nemoto*[1]. [1]Orthopaedics surgery, National Defense Medical College, Saitama, Japan, [2]Orthopaedics surgery, Kyorin University, Tokyo, Japan, [3]Sports Clinic of Medicine, Keio University, Tokyo, Japan, [4]Orthopaedics surgery, Keio University, Tokyo, Japan.

Introduction: There are numerous reports on the positive effects of exercise on bone mass in postmenopausal women. In adult animals with estrogen deficiency, there are conflicting reports of a positive effect or no significant effect.Several experimental studies have shown the effect of exercise on bone mass in mature rats, and it has been confirmed that exercise increases bone mass in mature rats. However, a few studies have reported the effect of exercise on bone markers and calciotropic hormones in mature rats. In the present study, we examined the effects of treadmill exercise on bone mass, bone markers, and calciotropic hormones.

Methods: 23 week-old female Wistar rats were divided into 4 groups of 8 animals each; ovariectomy (O), ovariectomy and exercise (OE), sham-operated (S), and sham-operated and exercise (SE). The exercise regimen consisted of treadmill running at 12 m/min, 5°incline, 1hr per day a week, for 12 weeks. Left tibia was used for histomorphometric analysis. Left femur was used for structural analysis by micro-computed tomography. Serum calcium (Ca), inorganic phosphorus (Pi), total alkaline phosphatase (ALP), osteocalcin (OC), PTH and 1,25(OH)2VitD3 were also analysed.

Results: Serum Ca and Pi levels in O and OE groups were significantly lower than S and SE groups. Serum total ALP and OC levels in OE and SE groups were significantly higher than that of O and S groups respectively.12-week exercise increased BV/TV in S (4%) and O (6%) groups and Tb.Th. in the S (6%) and O (11%) groups, and decreased TBPf in S (31%) and O (7.6%), and SMI in S (13%) and O (9%). Therefore, these results suggest that 12-week treadmill exercise protects against the deterioration of microarchitecture in the osteoporotic rat model induced by ovariectomy.

Discussion: It is accepted that exercise promotes a positive calcium balance and increases skeletal mass, largely as a result of an increase in 1,25(OH)2VitD3 and enhancement of intestinal calcium absorption in rats. In the present study, treadmill exercise increased the serum 1,25(OH)2VitD3 level in the OVX rats. It is speculated that treadmill exercise stimulated bone formation and suppressed bone resorption, resulting in an increased demand for minerals that was satisfied by an increase in serum 1,25(OH)2VitD3 level and increased intestinal absorption of calcium.

Long-Term Voluntary Exercise Increases Cortical Bone Mass in Male Rats. S. L. Doody*[1], S. Judge*[2], R. R. Arzaga*[1], U. T. Iwaniec[1], T. J. Wronski[1], J. E. Sellman*[2], D. S. Criswell*[2], C. Leeuwenburgh*[2]. [1]Physiological Sciences, University of Florida, Gainesville, FL, USA, [2]Applied Physiology, University of Florida, Gainesville, FL, USA.

Long-term, voluntary mechanical loading in wheel-running animals may provide a sufficient stimulus to prevent osteopenia associated with aging and inactivity. Therefore, the aim of this experiment was to determine the effects of 24 months of voluntary wheel-running exercise on cortical and cancellous bone morphometry of the tibia in Fisher-344 rats. Two-month-old rats were randomly assigned into a wheel-running group (WR; n = 20) and a sedentary control group (S; n = 20). Both groups were 8% calorically restricted throughout the 24 months. WR ran voluntarily within a wheel approximately 1400 m/day during this time. Eleven WR and 12 S rats completed the study. The tibiae were harvested and processed undecalcified for quantitative bone histomorphometry. The cortical bone measurements were performed on the distal tibial diaphyses 1-2 mm proximal to the tibio-fibular junction and the cancellous measurements were performed on the proximal tibial metaphyses using standard methods. Data were analyzed with an independent samples t-test (2-tailed) and reported as mean ± SD.

WR had significantly greater cortical area (4.02 ± 0.20 vs. 3.80 ± 0.20 mm², $p < 0.01$) than S. WR had a significantly smaller endocortical perimeter (3.77 ± 0.21 vs. 3.95 ± 0.20 mm, $p = 0.0514$) and also a smaller medullary area (1.06 ± 0.12 vs. 1.17 ± 0.12 mm², $p < 0.03$) compared to S. In addition, cortical thickness was 7% greater in WR than S ($p < 0.001$). Significant differences between the two groups were not detected in either cortical cross-sectional bone tissue area (cortical area + marrow area; WR = 5.09 ± 0.21 vs. S = 4.97 ± 0.25 mm², $p < 0.2$) or periosteal perimeter (WR = 8.70 ± 0.21 vs. S = 8.61 ± 0.23 mm, $p < 0.36$). There were also no differences between the two groups for cancellous bone volume (WR = 10.84 ± 2.92 vs. S = 9.48 ± 3.52%, $p < 0.32$) or node to terminus ratio, a measure of trabecular connectivity (WR = 0.24 ± 0.15 vs. S = 0.40 ± 0.34), $p < 0.19$). There was a trend for increased trabecular number (2.19 ± 0.56 vs. 1.72 ± 0.54 /mm, $p = 0.0578$) and decreased trabecular separation (436.79 ± 127.34 vs. 590.37 ± 235.63 μm, $p = 0.0688$) in WR compared to S. The results demonstrate that long-term voluntary wheel-running increases cortical bone area and thickness, but not cancellous bone volume or connectivity. Therefore, this experiment provides evidence that bone responds to long-term mechanical loading in a site-specific manner.

Are Bone Mineral Gains Maintained in Boys One Year following the Cessation of an Intervention? S. L. Manske[1], K. J. MacKelvie[2], A. D. G. Baxter-Jones[3], H. A. McKay[1]. [1]Department of Orthopaedics, University of British Columbia, Vancouver, BC, Canada, [2]Endocrinology and Diabetes Unit, British Columbia Children's Hospital, Vancouver, BC, Canada, [3]College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada.

We recently reported a greater increase in bone mineral content at the femoral neck (4.3%) following a 20-month jumping intervention (10 min, 3x/week) in intervention boys compared with controls. The present study served to determine whether the bone mineral accrual advantage was maintained one year after the cessation of the exercise program. We re-assessed a subset of boys (12.74 ± 0.48 years at 1-year follow-up) who had been assigned to intervention (n = 14) or control (n = 21) groups in the original Healthy Bones II Study (n = 64 at the end of 20 months). All boys performed regular activities and PE following cessation of the program. We evaluated proximal femur (PF) and femoral neck (FN) bone mineral content (BMC, g) with DXA (Hologic QDR 4500). We assessed height (cm), weight (kg) and maturity (self-assessed Tanner staging) with standard techniques. Physical activity and calcium intake were assessed by questionnaire. The primary outcome measures were adjusted percent change in BMC at the PF and FN at 1-year follow-up. Data were analyzed using ANCOVA, adjusted for end of intervention (20-month) BMC, change in height and final Tanner stage. In this subset of boys, the 20-month change during the intervention period for the intervention group at the femoral neck was slightly smaller (2.2% greater than control, 95%CI = -4.5% to 8.9%, $p > 0.05$) than the 20-month change reported for the larger cohort (4.3% greater than control, $p < 0.01$). At 1-year follow-up, there was no difference between intervention and control groups for adjusted PF BMC (-1.0%, 95%CI = -6.5% to 4.5%) or FN BMC (-0.2%, 95%CI = -3.2 to 3.7). Results indicate that in boys, bone accrual advantages obtained in an intervention may not be sustained after the cessation of the intervention. Ongoing high-impact activity may be required. Further research should support development of minimal, sustainable interventions.

High-Frequency Vibrations, in the Absence of Strain, Can Increase Cortical Bone Volume. R. A. Garman[1], L. R. Donahue[2], C. T. Rubin[1], S. Judex[1]. [1]Biomedical Engineering, State University of New York at Stony Brook, Stony Brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA.

Bone's adaptive response to changes in its mechanical loading environment can be used for developing an effective countermeasure of osteopenia. Interestingly, even very small mechanical signals can be anabolic such as low-level vibrations inducing high-frequency (45Hz) but low-magnitude (0.3g) stimuli. We have shown that this stimulus can promote bone formation and increase bone quantity and quality, although the physical basis by which skeletal tissues sense these signals is not well understood. While this specific loading regimen introduces deformations between 5 and 20 microstrain, preliminary data suggest that deformations less than 5 microstrain may also be anabolic. Here, we applied vibratory signals to bone that primarily accelerate the bone and further minimize matrix deformations.

The left hindlimbs of eight female C57BL/6J mice were subjected to high-frequency (45Hz) vibrations at accelerations of either 0.3g or 0.6g for 10min/d. The right hindlimbs served as contralateral controls. After 3 weeks, micro-computed tomography was used to analyze changes in cortical bone of the diaphyseal, metaphyseal, and epiphyseal regions.

Vibratory loading at 0.3g and 0.6g did not alter cortical bone morphology in the diaphysis or metaphysis of the tibia. In contrast, epiphyseal cortical bone displayed greater bone area in the limb vibrated at 0.3g than in the control (+3.2%, p=0.06). Furthermore, loading at 0.6g also induced greater bone area in the vibrated limb (+10%, $p<0.05$) as compared to control. Pooling both vibrated limbs (0.3g and 0.6g) and control limbs revealed a significant difference in bone area between the groups - vibrated limbs were 8.4% greater ($p<0.01$) than the controls.

Although previous low-frequency mechanical loading regimens imply that bone deformations are critical for initiating an anabolic response, this study suggests that bone mass may be increased at strain levels below those typically associated with disuse. This change in bone mass was isolated to the epiphysis, perhaps due to the different anatomical features (spatially more confined, different tissue attachments) found at the proximal tibia as compared to distal regions. Interestingly, vibratory loading at a greater acceleration induced a more pronounced change in bone area than at the lower acceleration, related possibly to differences in shear stress magnitudes on the bone surfaces. In short, this study suggests that acceleration-based vibratory stimuli can increase cortical bone mass and introduces a loading regimen that, with continued development, may lead to a treatment for bedrest and disuse-induced osteopenia.

Aging Does Not Reduce the Skeletal Sensitivity to Loading. O. Leppanen*, J. Jokihaara*, I. Pajamaki*, H. Sievanen*, P. Kannus*, T. L. N. Jarvinen. Department of Orthopaedics and Traumatology, University of Tampere, Tampere, Finland.

Aging has been shown to decrease the sensitivity of mechanosensory cells of bones to loading-induced stimuli. According to prevailing understanding, this deterioration of the cellular function reduces the capacity of the aged skeleton to adapt to changes in the incident loading, and consequently, results in age-related loss of bone.

To explore the possible modulatory effect of aging on the mechanosensitivity of bones, 100 male Sprague-Dawley rats were randomized into 4 loading (15 animals / group) and 4 control (10 animals / group) groups. The rats in the loading groups were subjected to 14-weeks of progressively intensifying treadmill training at the age of 5-weeks (young), 33-weeks (adult), 43-weeks (old), and 75-weeks (senescent). At the end of the training, the femoral necks were analyzed using peripheral quantitative computed tomography (pQCT) scanning and mechanical testing.

A significant response was observed in the young and senescent rats in the bone cross-sectional area (tCSA) and in the bone mineral content (tBMC), whereas no response was observed in the adult and old rats (A and B, figure below). However, a completely inverse response was observed in the volumetric density (tBMD). Finally, in the structural strength (F_{max}) of the femoral neck, the pattern of response between the different age-groups was virtually identical to the changes seen in tCSA and tBMC, although reaching borderline significance only (p=0.055 and 0.087 in the young and senescent, respectively). In conclusion, the aged bones seem to maintain their capacity to respond to increased loading.

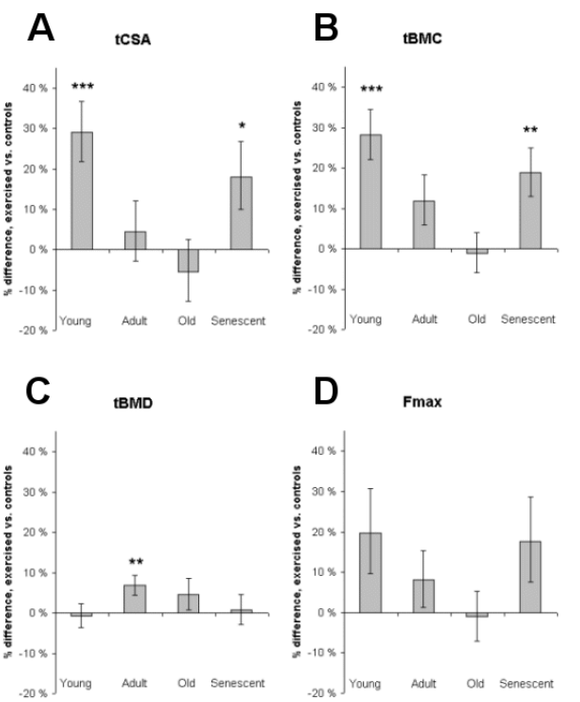

Figure. Effect of exercise on the characteristics of femoral neck in young, adult, old and senescent rats. (A) Total cross-sectional area (tCSA), (B) total bone mineral content (tBMC), (C) total bone mineral density (tBMD), and (D) biomechanical strength (Fmax). Bars represent percent (%) improvements ± the standard errors of the means (SEM) of the loading group compared with corresponding control group at the end of the 14-week exercise period. Significant differences between exercised and controls are indicated: *$p < 0.05$; **$p < 0.01$; ***$p < 0.001$.

The Correlation between Different Parameters of Physical Fitness and Bone Mineral Content in Hong Kong Adolescents (Preliminary Baseline Results) - The HKABC Study (Adolescent Bone Health Cohort). D. T. K. Choy[1], E. M. C. Lau[1], D. Lo*[1], D. Chan*[1], P. C. Leung*[2]. [1]Jockey Club Centre for Osteoporosis Care and Control, School of Public Health, Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [2]Department of Orthopaedics and Traumatology, Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

Little is known about the determinants for bone growth in Asian adolescents. The HKABC study is a large scale longitudinal study of Hong Kong adolescents and the objective of this cohort study is to find out the different determinants that will affect bone growth in adolescents e.g., in-utero factors, physical characteristics, nutritional factors and different types of physical activities. We plan to follow up 1000 subjects for 3 years and each subject will have an annual assessment involving a face-to-face interview using a standardized, structured questionnaire. The subjects aged 10 to 13 years old were recruited from different primary schools situated in different areas in Hong Kong. Bone mineral density (BMD) was measured by DEXA (Hologic, Inc). Physical fitness were assessed by standardized methods including 1) Step test, 2) Hand grip and leg strength, 3) one minute sit-up, 4) Sit and reach test. We have analyzed the results of the first 200 subjects. We found that there is a strong positive correlation (Pearson Partial Correlation Coefficients 0.3-0.71, $p<0.0001$) between both the upper and lower limb strength with the bone mineral content at all sites (total hip, spine and whole body) in both sexes. The trunk flexibility of the boys as demonstrated by the sit and reach test also have positive correlations with the BMC at all sites. The VO2 max that is derived from the sub-maximal step test have a

strong inverse correlation (p<0.0001) with the percent body fat in both sexes but there are no correlation with BMC at the different sites. All results were adjusted for pubertal stage. In conclusion, muscle strength is a major determinant of BMC in adolescents but cardiovascular fitness as measured by VO2 max may not have a positive correlation with BMC in adolescents. These preliminary results suggest that different types of physical activities will have different impacts on the bone growth of adolescents.

Genetic Regulation of Mechanotransduction in Mice. A. G. Robling*[1], S. J. Warden[1], K. L. Shultz*[2], W. G. Beamer*[2], C. H. Turner[1]. [1]Indiana University, Indianapolis, IN, USA, [2]Jackson Laboratory, Bar Harbor, ME, USA.

Adequate bone mass and strength are key factors in the prevention of osteoporotic fracture. It is clear that peak bone mass and mineral density are highly heritable traits, with an estimated 50-70% of the variability explainable by genetic composition. However, it is unclear how these genes exert their influence on bone mass. An emerging explanation proposes that a collection of genes modulates bone tissue's sensitivity to routine mechanical loading events, thereby augmenting bone mass through mechanotransduction pathways. The purpose of this study was to assess the contribution of two different genetic loci_one on mouse Chromosome 1 and the other on mouse Chromosome 13_to mechanically stimulated bone formation. Two congenic mouse strains were created in which a region (~40-80 cM) of mouse Chrs. 1 or 13 were moved from C3H/HeJ (C3H) strain to a C57BL/6J (B6) background strain through selective breeding over 9 generations. The regions moved to the B6 background corresponded to two of several quantitative trait loci (QTL) identified for bone size. The resulting congenics were 99% B6 with the remaining genomic DNA comprising the Chr. 1 or 13 QTL of interest. Male and female congenic (1T and 13B) and B6 control mice were subjected to in vivo loading of the right ulna at one of three different load magnitudes. A separate set of animals from each group were strain gauged at the ulnar midshaft to estimate strain at each loading level. Loading was conducted once per day for 3 days (60 cycles/day; 2 Hz). Fluorochrome labels were injected IP 5 and 12 days after loading began. After sacrifice, bone formation rates were measured in loaded (right) and control (left) ulnae. 1T male congenics exhibited significantly lower BFR/BS per unit mechanical strain compared to male B6 controls, but the same comparison among females yielded the opposite result (greater sensitivity in female 1T vs. B6 mice). These results correspond to a sex-specific effect on polar moment of inertia in the femur. The 13B female congenics exhibited a similar bone formation response to loading as the female B6 controls, but the male 13B mice exhibited lower BFR/BS per unit strain than the male B6 controls. Our results indicate that the genetic regulation of mechanotransduction is a real but complex process that involves a number of genes and interactions. Our data might explain why different individuals can engage in similar exercise protocols yet experience different results in terms of bone mass accrual.

Non-invasive Axial Loading of the Murine Tibia Induces Increases in Cortical Bone Formation Accompanied by Modification in Trabecular Bone Architecture: A Novel Model for in vivo Loading Studies. R. L. de Souza*[1], M. Matsuura*[2], F. Eckstein[3], S. C. F. Rawlinson[1], L. E. Lanyon[1], A. A. Pitsillides[1]. [1]Veterinary Basic Science, Royal Veterinary College, London, United Kingdom, [2]Institute of Anatomy, Ludwig-Maximilians-Universitä, Munchen, Germany, [3]Institute of Anatomy, Paracelsus Medizinische Privatuniversität, Salzburg, Austria.

Systematic study of bones' adaptive responses to loading requires a simple non-invasive model in an appropriate experimental animal where bones' loading may be controlled and the modelling and remodelling of their cortical and cancellous regions quantified. For many purposes the experimental animal of choice is the mouse.

Here we describe validation of a model for in vivo axial loading of the tibia in 14 week old female C57Bl/J6 mice. The peak strains at the tibial midshaft during walking (<300μ) and jumping (<600μ) were measured with longitudinally oriented strain gauges attached to the bone's lateral and medial surfaces. These gauges were also used to determine the strains engendered by external compressive loading between the flexed knee and ankle *ex vivo*. Applied loads between 7 and 12N produced strains of 1200-2000μ, and repetitions of these loads on alternate days for 3 weeks produced significant load magnitude-related increases in periosteal bone formation throughout the one third of the tibia length along which measurements were made. In contrast, increases in endocortical apposition from the tibial midshaft, extending only distally. Micro-CT scans showed significant increases in trabecular bone volume and thickness that contrasted with the decreases in bone volume, trabecular thickness and number, and greater separation of trabeculae following sciatic neurectomy-induced unloading. This model has several advantages over other approaches, including the scope to study the effects of loading in cancellous as well as cortical bone, against a background of disuse or of treatment with osteotropic agents in normal, mutant, and transgenic mice

Relation of Neuromuscular Performance to Regional Bone Mineral Density Among Older U.S. Men. K. M. Winters[1], L. Marshall[1], E. Barret-Conner[2], E. Orwoll[1]. [1]Oregon Health & Science University, Portland, OR, USA, [2]University of California, San Diego, San Diego, CA, USA.

Muscle strength has been examined in relation to bone mineral density (BMD) to assess the influence of mechanical loading on bone. However, measures such as muscle power, general mobility and balance that may also reflect loading patterns have not received similar consideration in relation to BMD. Thus it is uncertain whether BMD is related to physical performance among older adults and whether such a relation is independent of lean body mass. To describe the contribution of neuromuscular performance to BMD in the hip and spine, we conducted a cross-sectional analysis with baseline information from 5,940 US men ages ≥ 65 years enrolled in the Osteoporotic Fractures in Men (MrOS) study. Performance measures were: maximal leg power (watts) (Nottingham Power Rig), grip strength (kg) (handheld dynamometer), dynamic leg strength (seconds to complete 5 chair stands), gait (6-m usual pace) (m/s) and balance (20 cm tandem walk pace) (m/s). Performance data included men who were and were not able to perform each test. For each test, performance data were expressed in quintiles among men who completed that test plus a sixth category containing men physically unable to complete the test. BMD at the femoral neck (FN), trochanter (TR), and lumbar spine (LS), as well as total body lean and fat mass, were obtained with DXA. The relation of BMD in the FN, TR and LS with each performance measure was estimated with generalized linear models. We computed partial R^2 values to estimate the amount of variance in each BMD variable that was explained by a performance measure independent of age, race, height, fat mass, and lean mass. FN BMD and LS BMD were not related to any of the performance measures (partial R^2 all <0.001). However, dynamic leg strength was a significant independent predictor of TR BMD (partial R^2=0.011). Adjusted mean TR BMD was 9.0% lower (p<.0001) among men unable to perform the test, compared with men in the quintile with the fastest repeated chair stand times. Among men who completed the 5 chair stands, TR BMD declined significantly with increasing chair stand time (p-trend <.0001). Results from this cross-sectional study suggest that BMD in the hip and lumbar spine is unrelated to neuromuscular performance. The exception was the relation between dynamic leg strength and TR BMD, which was independent of lean body mass and other factors. This observation is consistent with a previous report. Dynamic leg strength may reflect the repeated application of modest forces on bone at the predominantly trabecular trochanter site. Longitudinal data on neuromuscular performance and BMD are needed to better address this issue.

Bone Loss Following Hindlimb Suspension and Reloading in Mice. M. Xu[1], D. J. Adams[2], M. Barrero*[2], C. C. Pilbeam[1]. [1]Dept. of Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Dept. of Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA.

We are establishing protocols to study the role of cyclooxygensase-2 (COX-2) gene disruption in the bone loss of immobilization, as modeled by hindlimb suspension, and in the subsequent response of bone to reloading. We subjected 6.5 mo old male and female mice in a C57BL/6 x 129 background to hindlimb suspension in specially designed cages modified from the NASA design for rats. Mice were placed in suspension cages and tails were taped 48 h prior to suspension for acclimation. Mice were suspended at a 20~30 degree head-down tilt by taping the outer half of tails and connecting the tape to an overhead rolling bar. Mice had free movement in the rat-sized wire bottom cage with free access to water and standard laboratory chow in a controlled 75 ºF and 12 h/12 h light/dark cycle environment. Ten COX-2 wild type (WT) mice (6 males, 4 females) were suspended for 2 wks and then released from suspension and housed singly in normal cages. Three male WT type mice were housed singly in normal cages as controls. Mice were weighed daily during suspension. Bone mineral density (BMD) of both femora was measured by x-ray densitometry (PIXImus, GE Lunar) and the average BMD for each mouse was used. BMD was measured on the time suspension was initiated (day 0), at the end of 2 weeks of suspension (day 14), and 2 weeks after reloading (day 28). Weights of suspended mice were 6.3 ± 2.0% lower on day 14 than on day 0. Mice regained this weight and more on day 28, being on average 7.1 ± 1.4% heavier than on day 0. Control mice also increased 2-3% in weight over the 4 wks. Femoral BMD in unloaded mice was 7.3 ± 1.0% lower on day 14 than on day 0, a significant decrease compared to control mice (P<0.02). BMD was still 7.9 ± 1.4% lower on day 28, 2 wks after reloading, than on day 0. Three males and 3 female COX-2 knockout (KO) mice, littermates of the COX-2 WT mice, were also unloaded for 2 wks. Weights were 7.0 ± 3.7% lower on day 14 compared to day 0 but were increased 5.3 ± 1.7% compared to day 0 after 2 wks of reloading. Femoral BMD was 8.8 ± 1.6% and 5.7 ± 1.3% lower than BMD on day 0 at day 14 and 28, respectively. Preliminary data indicate that RANKL mRNA was increased and OPG mRNA decreased in hindlimbs by unloading in both COX-2 WT and KO mice. We conclude that tail suspension for 2 wks provides a model to study bone loss in these transgenic mice, that absence of COX-2 expression does not prevent bone loss in this model, and that recovery of bone loss will take more than 2 wks of reloading.

Disclosures: ***M. Xu****, None.*

SU228

Analysis of Trabecular Bone Texture on Magnetic Resonance Imaging of the Distal Radius: Side-to-side Differences in Tennis Players. G. Ducher*[1], S. Même*[2], C. Magni*[3], J. Viala*[4], C. Chappard[1], D. Courteix[1], C. Benhamou[1]. [1]Faculty of Sport Sciences Orléans, ATOSEP, Orleans, France, [2]CNRS Orléans, CBM UPR 4301, Orleans, France, [3]Neuroradiology, Hospital of Orléans, Orleans, France, [4]Radiology, Hospital of Orléans, Orleans, France.

The purpose of this study was to compare the trabecular bone network of the dominant and non-dominant radius in competitive tennis players using magnetic resonance imaging (MRI).

Axial slices were obtained on the dominant and non-dominant distal radius in 20 adult tennis players (10 men and 10 women, age: 23.4 ± 4.8 years) with a spin-echo sequence (TR: 645 ms, TE: 20 ms, field of view: 100×100 mm , pixel size: 195×195 µm , slice thickness: 2 mm) using a 1.5 T MR device (Magnetom Vision, Siemens®). A region of interest (ROI) was manually defined on each slice including the largest trabecular area as possible. To study the intensity and distribution of grey levels of the trabecular network, we selected five methods of texture analysis: grey level histogram, co-occurrence, run length and gradient matrices and wavelets transform. The co-occurrence matrix features the probability distributions of pairs of pixels. The run length method consists in expressing the statistical distribution of the grey level runs in the image. The wavelets transform gives a decomposition of the image in a set of spatially oriented frequency channels. The texture parameters were computed automatically using algorithms (Mazda 3.20 program). Bone mineral density (BMD) was measured at the ultra-distal radius by dual-energy x-ray absorptiometry (Delphi QDR Series, Hologic Inc.®

). The comparison between the dominant and non-dominant radius was performed by a parametric paired t-test.

The "correlation" parameter of the co-occurrence matrices was significantly greater at the dominant radius when compared to its non-dominant counterpart (p=0.02). The non uniformity of the runs, in terms of run length and grey level, was significantly different between both radius (p=0.02). Wavelet analysis revealed a side-to-side difference in the wavelets coefficients for the high frequencies (p<0.05). No difference was observed on the grey level histogram and the gradient matrix. BMD was markedly greater at the dominant radius (0.525 ± 0.080 $g.cm^{-2}$) comparatively to the non-dominant radius (0.488 ± 0.069 $g.cm^{-2}$, p<0.0001), the side-to-side difference reaching 7.4 ± 4.9%.

These data indicate that tennis playing is associated to a higher BMD at the dominant forearm and to significant differences in MRI texture analysis. This study suggests that tennis playing induces not only a higher bone mass but also changes in trabecular bone microarchitecture in the dominant forearm.

Effects of Isokinetic Muscular Strength Training on Tibial Bending Stiffness and BMD in Young Women. W. G. Herbert[1], C. R. Steele*[2], S. M. Nickols-Richardson[1], W. K. Ramp[3], D. F. Wootten*[1], L. E. Miller*[1], C. E. Callaghan*[1]. [1]Human Nutrition, Foods & Exercise, Virginia Tech, Blacksburg, VA, USA, [2]Mechanical Engineering, Stanford University, Stanford, CA, USA, [3]Health Research Group, Inc, Blacksburg, VA, USA.

Cross-sectional bending stiffness (EI) provides information about structural integrity of bone that is not reflected by bone mineral density (BMD by dual-energy x-ray absorptiometry, DXA). Mechanical Response Tissue Analysis (MRTA) is a technology for assessing EI of the human ulna and tibia in vivo.[1] MRTA applies mechanical vibration (60-1600 Hz) transcutaneously to the bone mid-shaft and utilizes impedance response to predict EI. Our device allows measurement of tibial EI for seated subjects, without rigid clamping of the bone ends. Data are processed with a software model that accounts for mass, stiffness, and damping effects of skin and soft tissue, as well as mass, axial stiffness, and damping of bone, and influences of bone displacement at the proximal and distal ends. We studied adaptations in tibial EI and BMD after 32 weeks of high-intensity isokinetic exercise training. Thirty-two women, 18-25 years, trained by concentric (N=22) or eccentric (N=10) modes, with only the non-dominant leg (knee flexion/extension @ $60^{o}{\cdot}s^{-1}$, 6 reps/set, 5 sets/session, 3 d/week) on an isokinetic dynamometer. Subjects were measured at weeks 0, 16, and 32 for leg muscular strength, tibial EI, and tibial BMD with DXA. Total tibia scans were analyzed with user-defined adaptations to the manufacturer-provided forearm software. Nine measures of EI were taken without repositioning the subject and these results used to compute a single score for each test session. The concentric and eccentric groups increased peak leg torque (composite of four tests) of the trained leg by 19% and 27% (p<0.05), respectively. Strength gains in the untrained leg were minimal (+5-8%) for both groups. Tibial EI of the trained leg increased 21% (p=0.03) in the concentric group, with no change in the untrained leg (-0.3%). In the eccentric group, tibial EI of the trained and untrained legs increased only by 10.9% and 7.6% (p>0.05). Total tibial BMD increased only 1.7% (p=0.05) in the untrained leg of the concentric group, with no change in the concentric group trained leg nor in either tibia of the eccentric group. In conclusion, localized high-intensity muscular resistance training increases tibial EI independent of changes in tibial BMD. Further studies are warranted to investigate MRTA applications in assessing risk for osteoporotic and stress fractures and in evaluating effects of interventions for improving bone status.

Genetically Modulated Differences in Trabecular Bone Volume and Connectivity Influence the Efficacy of a Catabolic Stimulus. S. Judex[1], L. Xie*[1], A. Parhiz*[1], C. Rubin[1], L. Donahue[2], S. Xu*[1]. [1]Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA.

Genetic variability is a strong determinant of osteoporosis. The degree by which genetically determined peak bone mass and micro-architecture can influence the rates of bone loss when the skeleton is exposed to a catabolic stimulus is, however, unclear. Here, we subjected a genetically heterogeneous population, displaying large variations in bone morphology, to disuse and hypothesized that indices of baseline bone morphology are related to a differential deterioration of trabecular morphology. Fourty-three female, second generation (F2) BALBxC3H mice were subjected to three weeks of disuse (hindlimb suspension). In vivo micro-computed tomography quantified longitudinal changes in trabecular morphology of the distal femur including bone fractional volume (BV/TV), connectivity density (Conn.D), and trabecular thickness (Tb.Th). Mice were scanned prior to initiating disuse and during each subsequent week. Over the 3-wk experimental period, bone volume fraction diminished by an average of 52%±21% (p<0.001). Supporting the genetic influence on this large variability in bone loss, data were normally distributed with losses ranging from 16%-89%. The average rate of bone loss was similar between the first and second week (20% and 21%) but increased to 29% during the third week. Similarly to bone volume fraction, trabecular connectedness and trabecular thickness decreased significantly by 59%±25% and 20%±9%, respectively (p<0.001). Deterioration of the micro-architecture was also progressive in nature: Conn.D. (Tb.Th) decreased from 20% (6%) in the first week to 25% (6%) in the second week to 36% (8%) in the third week. Changes in bone volume were highly correlated with alterations in connectivity density (r2=0.85) and trabecular thickness (r2=0.75). Baseline bone volume fraction and connectivity density (but not trabecular thickness) were good (inverse) predictors of the change in BV/TV and Conn.D resulting from disuse (r2=0.36-0.46). Similar to data from astronauts that may lose between 0% and 24% of their trabecular bone quantity during 6-mo of space flight, these longitudinal in vivo data describe the large variations in bone loss in a genetically heterogeneous mouse population. The moderately high correlations between baseline bone morphology and the magnitude of bone loss suggest that some genes have simultaneous, if not inverse, influences on both traits. Extrapolated to humans, these data also indicate that people with lower peak bone mineral density may also suffer from higher rates of bone loss during conditions of space flight, bedrest, or aging. Supported by NASA.

Loss of Half Cbfa1 Gene Dosage Further Reduces Bone Formation Rate in Tail-Suspended Mice while Loading Totally Resumes Bone Formation Rate to Normal Level In Vivo in The Absence of Half Cbfa1 Gene Dosage. R. Salingcarnboriboon[1], K. Tsuji[1], T. Komori[2], A. Nifuji[1], M. Noda[1]. [1]Dept. of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Dept. of Molecular Medicine, Osaka University Medical School, Osaka, Japan.

Molecular mechanisms underlying reduction of bone formation in unloaded condition have not yet been fully understood. In in vitro experiments, Cbfa1 has been suggested to be involved in Flexercell-induced stretching stimuli. However, roles of Cbfa1 in unloading induced bone loss in vivo have not yet been known. The purpose of this paper is to examine the roles of Cbfa1 in unloading-induced bone loss and loading-induced bone formation in vivo. Tail-suspension (TS) was conducted using 9-11 wk-old Cbfa1 heterozygous knockout mice (Cbfa1+/-) (HT) and wild-type (WT) littermate. The mice were subjected to TS for two weeks. In the endosteal as well as periosteal surface of the cortical bone in the mid-shaft, TS reduced bone formation rate (BFR) as reported previously. In the absence of Cbfa1 half gene dosage (HT) BFR as well as mineral apposition rate (MAR) were totally suppressed and were almost undetectable. These observations indicate that full Cbfa1 gene dosage is necessary for the maintenance of bone formation even in TS mice. In contrast, BFR as well as MAR were similar between WT and HT mice in the loaded group, indicating that loading totally resume BFR and MAR even in the absence of half Cbfa1 gene dosage. In parallel to these observations in the diaphyseal cortex, cortical bone thickness was reduced by TS in WT mice, while the loss of half Cbfa1 gene further reduced cortical bone thickness after TS. Similar to BFR, loading totally resumed the thickness of the diaphyseal cortex even in the absence of half Cbfa1 gene dosage. RT-PCR analysis of the cortical bone envelope indicated that Cbfa1 mRNA expression was reduced significantly by TS in WT mice. Cbfa1 mRNA levels were about half of the WT in HT mice. In contrast to WT, this Cbfa1 mRNA level was not altered even after TS in HT mice suggesting the presence of unidentified mechanisms downstream to Cbfa1 could be involve in TS induced further suppression of BFR in these mice. Osterix mRNA level was reduced by half again by TS in WT. In HT mice, Osterix mRNA level was also reduced to half even in loaded group and the level was not anymore altered in TS group. Intriguingly, these observations are specific to cortical envelope since in the cancellous bone, basal levels of bone volume in WT and HT mice were similar and TS suppressed similarly the levels of cancellous bone volume in WT and HT mice. These data indicate that Cbfa1 is a critical target of loading stimuli to alter osteoblastic activity and bone formation in adult mice.

Differences in Opposing Hip Bone Density in Patients With Scoliosis. S. M. Strot*, L. Cole*, N. C. Grinnell*, T. M. DeFransisco*, E. A. Mossman, M. R. McClung. Oregon Osteoporosis Center, Portland, OR, USA.

Weight-bearing exercise, activity performed by an individual supporting his or her entire weight, is commonly recommended to slow age-related bone loss and as a general measure to maintain bone strength. Lack of weight-bearing exercise, as in cases of amputation and paralysis, is known to cause bone atrophy and decreased weight-bearing potential. In cases of scoliosis, an individual may preferentially bear their weight on one side or the other, depending on direction and severity of the curvature. This preferential weight-bearing may result in a combination of increased bone formation on preferred weight-bearing side and/or bone loss on the opposite side. The differential effects of this may result in discordant measurements of bone mineral density (BMD) in the hip.

The purpose of this study was to determine if there is a significant difference between BMD measurements of each hip in patients with scoliosis, and to determine if the difference is affected by the degree of spine curvature.

We examined dual-energy X-ray analysis (DXA) scans performed on a Lunar Prodigy densitometer (GE Lunar, Madison, WI) in 205 patients with scoliosis. Six of these were excluded due to biconcave or indeterminate curve direction. Mean age of the remaining 193 females and 6 males was 66.8 years. Hips on the side matching the concave direction of scoliosis were compared against hips on the convex side. Concave-side hips had a significantly higher mean total hip BMD that those on the convex side (0.878 to 0.864, t=3.65, p<0.0005). Degree of spine curvature was determined from the DXA images and categorized as mild, moderate, or severe. Among the mild, moderate, and severe curvature groups, the difference between convex- and concave-side BMDs was 0.012, 0.014, and 0.018g/cm^2, respectively. However, the differences between these groups were not statistically significant by ANOVA (p=0.85). These data suggest that while scoliosis may contribute to a disparity in opposing hip BMD in individual patients, it is not possible to generalize about the magnitude of the side-to-side disparity of hip BMD values based on the presence or severity of scoliosis.

Regional Bone Loss Following Tibial Stress Fracture and Tibial Stress Syndrome. J. A. Spadaro, E. C. Rust*, T. A. Scerpella*. Orthopedic Surgery, Upstate Medical University, Syracuse, NY, USA.

The loss of regional bone density (BMD) following traumatic injury to bone in the upper or lower extremity is often rapid and dramatic (5-25% in 2-6 months), but has not been studied following repetitive loading injuries. We report results of an initial cross-sectional study of bone density changes in the tibia following tibial stress fracture (TSF) or medial tibial stress syndrome (MTSS, 'shin splints') in running athletes.

BMD of the injured and un-injured tibia was measured in 15 collegiate lacrosse and track athletes with documented unilateral TSF or MTSS (age 18-24, median 20 yr) using dual energy x-ray absorptiometry (DXA)(GE-Lunar DPX-IQ). With IRB approval and informed consent, a measurement was obtained 2-8 months after injury onset in 3 regions surrounding the injury site and the BMD was compared to the corresponding regions in the un-injured side BMD of the un-injured hip BMD was also measured as an indicator of general bone density.

Results showed that all subjects except one had bone loss on the injured relative to the un-injured tibia (mean loss 8.3 ± 5% global, 9.6 ± 7% center, p<0.001). BMD losses in TSF and MTSS subjects were not statistically different as were the losses among males vs. females (table 1). There was no clear difference seen thus far in the effect of time since injury, suggesting a persistence of the loss as found after traumatic fractures. Interestingly, all subjects in this group save one had higher than average hip BMD (mean Z-score: 1.6 ± 0.9) and there was an inverse relation between the amount of the tibial BMD loss and the normal hip Z-score (fig. 1).

We conclude that TSF and MTSS injuries in young healthy individuals appear to be associated with a substantial, rapid and persistent loss of BMD in the injury region. The presence of a unilateral loss after a unilateral injury in athletes with excellent BMD suggests a post-injury etiology, such as hyperemia accelerated resorption, rather than a pre-existing osteopenia.

Table 1: Mean % BMD loss in injured tibia vs un-injured tibia following TSF and MTSS injury. (All p<0.01).

Subject type	N	Proximal Region	At Center	Distal Region	Global Region
TSF	9	-9.2	-17.0	-6.1	-8.0
MTSS	6	-6.1	-10.9	-11.0	-8.6
Females	8	-8.5	-9.2	-6.7	-8.6
Males	7	-6.0	-10.0	-9.5	-7.9
All	15	-7.3	-9.6	-8.0	-8.3

Differentiating the Contribution of Material and Structural Properties to Changes in Bone Mechanical Strength Caused by Disuse Models for Osteoporosis and Antiresorptive Therapies. R. E. Thacker*, T. A. Bateman. Bioengineering, Clemson University, Clemson, SC, USA.

It has been demonstrated that antiresorptive therapies and models for osteoporosis increase and decrease, respectively, the mechanical strength of bone. The aim of this study is to determine the differential contribution of structural and material properties to these changes in strength.

Female Balb/C mice, aged 6 weeks were examined (n = 16/grp). Ten days prior to beginning treatment, calcein was administered to represent extant bone of a known age. A second label was given the day treatment begun. Of the five groups examined, two disuse models for osteoporosis were used (decreasing bone strength) and two antiresorptive therapies (increasing bone strength). The five "treatment" groups were: 1) control (no treatment), 2) hindlimb suspension (HLS), 3) sciatic neurectomy (NX) 4) osteoprotegerin (OPG 20mg/kg) and 5) zoledronate (ZOL 8mg/kg).

Structural properties are being investigated via microCT. Software provided by Scanco, INC. determines cross-sectional area (CSA) as well as the principal moments of inertia (Imax and Imin) for the entire length of the diaphysis (80 9 micron thick slices sampled over the 8mm diaphysis). For analysis of the material component of the bones we performed mineral composition assays (whole bone properties) and microhardness indentation (site specific properties). NS indicates a non significant difference compared to controls.

Structural analysis demonstrates that both CSA and Imin (the most relevant MOI for three point bending) increase at the mid diaphysis of the OPG (3%^{NS}, 5%^{NS}, for CSA, Imin resp) and ZOL (3%^{NS}, 9%) treated mice compared to untreated controls. While for the disuse models both CSA and Imin were negatively affected: HLS (-11%, -12%) and NX (-6%, -10%). Compositional analysis showed an increase in mineral constituents of both the OPG (3.5%) and ZOL (3.0%) treated mice and a decrease for HLS (-1.6%) and NX (-0.4^{NS}). Microhardness indentation of extant bone (indicated by the first calcein label) showed no differences in the hardness values between any of the groups.

It appears that the antiresorptive therapies affect whole bone material properties more than structural properties, and the disuse models affect structural properties more than material properties. Though whole bone percent mineralization was significantly altered for OPG, ZOL and HLS, this did not translate to site specific changes in material properties as measured by microhardness indentation. It is possible that microhardness indentation is not sensitive enough to observe these changes (nanoindentation is in progress). The study was approved by Clemson's Animal Care and Use Committee.

Bone Density in Female Rowers. K. Ackerman[1], M. Walcott*[2], N. Glass*[2], M. LeBoff[2]. [1]Medicine, Hospital of the University of Pennsylvania, Philadelphia, PA, USA, [2]Medicine, Brigham and Women's Hospital, Boston, MA, USA.

Female endurance athletes often suffer from the well documented "female athlete triad:" amenorrhea, disordered eating, and osteoporosis. Available data, however, indicate that female athletes who participate in weight-bearing sports (i.e. gymnastics and weightlifting) have higher bone densities than do non-exercising women and women who participate in exercises with less mechanical strain (e.g. running). Although there is increased participation in women's rowing, little is known about the impact of rowing (a sport that includes a high force loading or resistance training) on skeletal health.

To evaluate the effects of rowing on bone density and body composition we recruited 28 rowers age 18-31 years (25 ± 4 yrs) who were trained athletes with 2000 meter ergometer best scores of 6:36 to 7:44 minutes. At the time of enrollment each athlete completed a training, dietary, menstrual, and medication survey, and underwent a DXA scan of the hip, spine, and whole body (Hologic, QDR 4500). Mean total hip Z-score was 0.921, mean hip neck Z-score was 0.507 and mean hip trochanter Z-score was 0.890. Mean spine Z-score was 0.693, and mean total body Z-score was 1.057. In addition, mean body fat composition was 20.41%. Seven women were oligomenorrheic with <9 menses/year either currently or prior to their 18th birthdays. But when these women's values were assessed separately from the larger group, the oligomenorrheic women's Z-scores were not significantly different from the others'. This preliminary data of elite rowers show that rowers have normal bone density compared with age-matched women according to a manufacture's database. Rowing may even have a protective effect on bone density in women with menstrual irregularities. While the total body bone density is greater than age-matched controls, larger ongoing studies that directly compare bone health in rowers versus other athletes will help elucidate the relative benefits of different sports in the maximization of peak bone mass in women.

Regulation of RANKL Promoter Activity Is Associated with Histone Remodeling in Murine Bone Stromal Cells. X. Fan[1], E. M. Roy*[1], T. C. Murphy*[1], M. S. Nanes[1], S. Kim[2], J. Pike[2], J. Rubin[1]. [1]Medicine, Emory University/VA Medical Center, Decatur, GA, USA, [2]Biochemistry, University of Wisconsin-Madison, Madison, WI, USA.

Receptor activator of NFκ-B ligand (RANKL) is essential for osteoclast formation, function and survival. Although RANKL mRNA and protein levels are modulated by $1,25(OH)_2D_3$ and other osteoactive factors, regulatory mechanisms remain unclear. In this study, we show that transiently transfection with 2kb or 2kb plus exon1 of a RANKL promoter sequence conferred neither $1,25(OH)_2D_3$ response nor tissue specificity. The histone deacetylase inhibitors trichostatin A (TSA) and sodium butyrate, however, strongly increased RANKL promoter activity. A series of 5'-deleted RANKL promoter constructs from 2020 to 110 bp of transcription start site showed at least 4-fold increased activity after TSA treatment. TSA also dose dependently enhanced endogenous RANKL mRNA expression with 50 μM of TSA treatment causing equivalent RANKL expression to that seen with 1 nM $1,25(OH)_2D_3$. Using a chromatin immunoprecipitation (ChIP) assay in the ST2 mouse stromal line, we showed that TSA significantly enhanced the acetylation of both histone H3 and H4 on the RANKL promoter. There was stronger increase in acetylation of histone H4 than that of acetylated histone H3 on the RANKL promoter, 294-fold and 12.5-fold increases respectively. A similar increase in acetylated histone H4 on the RANKL gene locus was seen after $1,25(OH)_2D_3$ treatment. ChIP assay did not, however, reveal localization of VDR/RXR heterodimers on the putative VDRE of the RANKL promoter indicating that $1,25(OH)_2D_3$-receptor does not utilize this sequence. To explore the role of H4 acetylation in $1,25(OH)_2D_3$ stimulated RANKL, we added both TSA and $1,25(OH)_2D_3$ together. While the combination further increased acetylation of H4 on the RANKL locus, surprisingly, TSA inhibited $1,25(OH)_2D_3$-induced RANKL mRNA expression by 70% at all doses of $1,25(OH)_2D_3$ studied. These results suggest that TSA stimulation of endogenous expression of RANKL involves enhanced acetylation of histones on the proximal RANKL promoter. In the $1,25(OH)_2D_3$ stimulated state, however, TSA mediated inhibition of histone deacetylase represses the $1,25(OH)_2D_3$ effect, suggesting that preventing histone deacetylation blocks $1,25(OH)_2D_3$ action on this gene. Chromatin remodeling is therefore involved in RANKL expression.

Mechanically Induced Osteocyte Signaling Explains Regulation of Osteoclast Resorption Directionality and Coupling of Formation to Resorption in Cortical Bone Remodeling. R. Ruimerman*[1], R. van Oers*[1], E. Tanck*[2], P. Hilbers*[1], R. Huiskes[1]. [1]Biomedical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands, [2]University of Nijmegen, Nijmegen, Netherlands.

In cortical bone basic multi-cellular units (BMU's) of bone resorbing osteoclasts and bone forming osteoblasts replace old bone by new, forming secondary osteons. The coordination between resorption and formation suggests a coupling mechanism[1] between osteoclasts and osteoblasts, which origin is unknown. Equally unknown is what guides osteoclast resorption in its directionality. The alignment of osteons along the dominant loading direction suggests that mechanical forces are involved.[2] It was hypothesized that osteocytes, serving as mechanosensors, control BMU activities by sending signals through the osteocytic canalicular network.[3]

In this study we tested whether these hypotheses can explain that osteoclasts resorb bone in the main loading direction and that bone formation follows in such a coordinated manner. For that purpose we developed a computational theory, assuming that (1) osteocytes are mechanosensors. Relative to the signal experienced they send biochemical messengers, through the canaliculi, to the internal bone surface. (2) Osteoblasts form bone relative to the strength of the osteocyte signals. (3) Osteoclast activity is inhibited by the osteocyte signals. They resorb bone where low osteocyte signals are received, while they retract from surfaces receiving high osteocyte signals.

We tested this theory in 2-D FEA computer-simulation. The initial configuration consisted of a small piece of compact bone with an initial cutting cone with three osteoclasts. Osteocyte density was set to 1600 mm^{-2}. When the simulation started, the osteoclasts resorbed bone in the principal loading direction, producing a tunnel of 175 μm wide. Osteoblast formation closely followed, forming a new osteon. Reduced external loads on the bone increased the number of osteoclasts active in the cutting cone and the diameter of the osteon formed. Increased loads had the opposite effects. Rotation of the external loads, relative to the longitudinal bone axis, caused the cutting cone to bend accordingly, eventually forming a crooked osteon.

We conclude that the theory describes a cellular-level regulatory mechanism, capable of translating mechanical signals to orient osteoclast resorption in the main loading direction. It also shows that coupling of osteoclast resorption to osteoblast formation through mechanobiological signaling is a viable proposal.

Atorvastatin Stimulates Osteoprotegerin Production by Primary Human Osteoblasts. V. Viereck*[1], C. Grundker*[1], S. Blaschke*[2], K. Frosch*[3], M. Schoppet*[4], G. Emons*[1], L. C. Hofbauer[4]. [1]Gynecology and Obstetrics, Georg-August-University, Goettingen, Germany, [2]Nephrology and Rheumatology, Georg-August-University, Goettingen, Germany, [3]Trauma Surgery, Georg-August-University, Goettingen, Germany, [4]Medicine, Philipps-University, Marburg, Germany.

Recently, HMG-CoA reductase inhibitors (statins) have been shown to exert protective effects on bone metabolism. Because of the widespread use of lipid-lowering statins, prevention of bone loss and fractures would be a desirable side effect. However, the mechanisms how statins affect bone metabolism are still obscure, with some studies showing stimulatory effects on bone formation and others demonstrating inhibition of bone resorption. Here, we evaluated the effect of atorvastatin on osteoblastic production of receptor activator of nuclear factor-κB ligand (RANKL) and osteoprotegerin (OPG), both of which are osteoblast-derived cytokines essential for osteoclast cell biology. While RANKL enhances osteoclast formation and activation and promotes bone loss, OPG acts as a decoy receptor and antagonizes the RANKL effects. In primary human osteoblasts (hOB), atorvastatin increased OPG mRNA levels and protein secretion by hOB by up to 3-fold in a dose-dependent manner with a maximum effect at 10^{-6} M ($P < 0.001$). Time course experiments indicated a time-dependent stimulatory effect of atorvastatin on osteoblastic OPG protein secretion after 24 hrs ($P < 0.001$). Treatment of hOB with substrates of cholesterol biosynthesis that are down-stream of the HMG-CoA reductase reaction such as mevalonate or geranylgeranyl pyrophosphate completely prevented atorvastatin-induced enhancement of OPG production. By contrast, atorvastatin tended to decrease RANKL mRNA levels and protein secretion, although these effect were non-significant. Of note, treatment of hOB cells with atorvastatin enhanced osteoblastic differentiation markers alkaline phosphatase activity and osteocalcin mRNA levels by three- and two-fold, respectively ($P < 0.001$) in a dose- and time-dependent fashion. In summary, our data suggest that atorvastatin enhances the OPG-to-RANKL ratio by primary human osteoblasts which may result in inhibition of osteoclastic bone resorption. Since osteoblastic OPG expression is a positive function of their stage of differentiation, the stimulatory effects of atorvastatin on OPG production may, at least in part, be mediated by promoting their differentiation.

Phosphatidylinositol 3-Kinase Pathway Is Stimulated by Metabolic Acidosis in Bone. N. S. Krieger, K. La Plante*, J. Sullivan*, D. A. Bushinsky. Medicine, University of Rochester, Rochester, NY, USA.

Chronic metabolic acidosis stimulates net calcium (Ca) efflux from bone by alteration of osteoblastic function and stimulation of osteoclastic bone resorption. Acid-induced bone resorption is mediated, in large part, by stimulation of osteoblastic prostaglandin E2 (PGE2) synthesis; however, the subsequent signaling pathways are not known. To determine if PGE2 acts through the EP4 prostaglandin receptor, we incubated neonatal mouse calvariae for 48 h in neutral pH (pH~7.4, [HCO3-] =24 mM, Ntl) or physiologically acid pH (pH~7.1, [HCO3-]=12 mM, Acid) medium in the absence or presence of 1 μM L-161982, a specific antagonist of the EP4 receptor (gift of L. Koch, Merck). Acid medium induced a significant increase in net Ca efflux from bone, which was completely inhibited by L-161982. An inactive isomer (L-161983) had no effect on this Acid induced net Ca efflux. PGE2 binding to the EP4 receptor can lead to activation of phosphatidyl-inositol 3-kinase (PI 3-kinase). To determine the role of PI 3-kinase in acid-induced bone resorption we utilized a specific inhibitor, wortmannin (WTM). Calvariae were incubated in Ntl or Acid medium for 48 h in the absence or presence of 20 nM WTM. Net Ca efflux was stimulated by Acid, compared to Ntl. WTM alone had no effect on Ca efflux in Ntl incubations, but almost completely inhibited the Acid induced Ca efflux. PI 3-kinase is present in both osteoblasts and osteoclasts, thus WTM could be inhibitory in either cell type. Activation of PI 3-kinase leads to the phosphorylation of AKT (pAKT). To determine if activation of PI 3-kinase occurred in the osteoblast, we measured changes in pAKT in primary cells isolated from calvariae, which are almost exclusively osteoblasts. Cells were made quiescent by overnight incubation in Ntl medium in the absence of serum and then medium was changed to Ntl or Acid, each containing 1% serum. At appropriate time points, cells were lysed in denaturing buffer and Western analysis with chemiluminescent detection was performed using a specific antibody to pAKT, followed by normalization using an antibody to total AKT. In response to Acid, pAKT increased at 1 min compared to Ntl. There was no change in total AKT. These results suggest that the acid-induced increase in PGE2 activates the EP4 receptor, which stimulates PI 3-kinase leading to an increase in osteoblastic pAKT which subsequently leads to increased osteoclastic bone resorption.

Interleukin-6 Alters the Gene Expression of RANKL and OPG in Response to Titanium Particulate Debris in Osteoblasts. J. T. Ninomiya, K. G. Gilbertson*, J. A. Struve. Department of Orthopaedic Surgery, Medical College of Wisconsin, Milwaukee, WI, USA.

Aseptic loosening remains the principal cause of implant failure following total joint replacement. Despite advances in materials science and engineering, the generation of particulate wear debris leads to bone resorption and impant failure. Recently, two proteins that play a critical role in osteoclast maturation, receptor activator of NFkB (RANK) and its ligand (RANKL), have been described. These two proteins, along with the soluble decoy receptor, osteoprotegerin (OPG), work in concert to modulate osteoclast activity and bone resorption. The addition of wear debris to osteoblasts increases expression and secretion of

RANKL and IL-6, resulting in increased osteoclast maturation and ultimately, osteolysis and implant loosening. However, the relationships between IL-6 and the gene expression of RANKL are not well described. Therefore, we hypothesized that IL-6 secretion modulates the production of RANKL and OPG in response to particulate debris, resulting in increased osteoclast maturation.

The effects of IL-6 and titanium particles on the gene expression and secretion of RANKL and OPG were investigated in murine osteoblastic MC3T3-E1 cells. Exogenous murine IL-6 and titanium particles were added to cultures, and further experiments included the addition of IL-6 neutralizing antibodies. Real-time PCR was used to monitor changes in OPG and RANKL gene expression. Conditioned media and cell lysates were collected and used to determine the effects on osteoclast maturation using a murine marrow cell assay.

Following incubation, the addition of exogenous IL-6 yielded a 3.0-fold induction in RANKL and a 1.4-fold induction of OPG mRNA compared to unstimulated controls. Titanium particles alone increased the expression of both RANKL (3.0-fold) and OPG (1.2 fold) at 24 hours. The addition of anti-IL-6 neutralizing antibody decreased the expression of both RANKL and OPG in comparison to particles alone. Osteoclast maturation was also reduced to control level by the addition of IL-6 antibodies to cultures containing particles (48 hours).

These results demonstrate that IL-6 decreases osteoclast maturation predominantly by decreasing RANKL gene expression and subsequent osteoclast maturation in the presence of titanium particles. Blockade of the effects of IL-6 using IL-6 antibodies decreased the changes in RANKL mRNA levels and inhibited osteoclast maturation. These findings suggest that IL-6 plays an autocrine role in response to particulate wear debris by enhancing osteoclast maturation through an increase in the ratio of RANKL to OPG.

Study of the Aromatase Cytochrome P-450 Gene (*CYP19*) Promoter Usage in Osteoblast Cells. Effects of vitamin D, dexamethasone, 17β-estradiol and testosterone treatments. A. Enjuanes*[1], N. García- Giralt*[2], D. Grinberg*[2], A. Supervía*[1], S. Ruiz-Gaspà*[1], M. Bustamante*[2], L. Mellibovsky*[1], A. Díez-Pérez[1], X. Nogués[1], S. Balcells*[2]. [1]Urfoa, IMIM-Hospital del Mar, Barcelona, Spain, [2]Departament de Genetica, Universitat de Barcelona, Barcelona, Spain.

Aromatase cytochrome P-450 catalizes the conversion of androgens into estrogens and its presence in bone cells has been documented. Given the potential role of aromatase in osteoporosis and the incomplete understanding of *CYP19* gene regulation in osteoblast cells, we have undertaken a detailed study on the promoter usage of *CYP19* gene and the effect of vitamin D, dexamethasone, testosterone and 17β-estradiol treatments in a cultured human osteoblast cell line.

Several plasmids containing the following *CYP19*-promoter regions upstream of a luciferase reporter gene were constructed: pA) promoter II and exon I.3; pB) promoter II, exon I.3, I.3 promoter region and exon I.6; pC) promoter II, exon I.3 and I.3 promoter region; pD) I.3 promoter region and exon I.3; pE) I.3 promoter region; pF) I.6 promoter region; and pG) I.4 promoter region and exon I.4 and pH) I.4 promoter region. MG-63 cells were grown in DMEM supplemented with 10% FCS. *CYP19* promoter vectors and pSVB-Gal control vector were co-transfected in MG-63 cells at 70 % confluency in DMEM without FCS using FuGene Reagent. Six hours after transfection, MG-63 cells were incubated in DMEM with or without FCS for 24 hours with alternative treatments: 1) 100nM dexamethasone (DEX), 2) 100nM $1,25(OH)_2D_3$ (VitD), 3) 100nM $1,25(OH)_2D_3$ + 100nM DEX, 4) 100nM 17β-estradiol, and 5) 100nM testosterone One day later, cells were lysed and chemiluminescent assays were performed to mesure luciferase and β-galactosidase activities. Both transfection experiments and chemiluminescent assays were duplicated at each experimental step and experiments were repeated at least 4 times. Statistical analysis were performed using the SSPS 11.5 software.

In MG-63 osteoblast cells, FCS inhibit significantly promoter activity in all constructs. Construct pA showed the highest levels of promoter activity, with or without FCS. In this cell line, I.4 promoter region plus exon I.4 mediate the stimulation by DEX, and exon I.4 seems to be important for this stimulation. In contrast, exon I.4 seems to negatively affect the VitD stimulation. Promoter I.3 plus exon I.3 mediate the stimulation by VitD in absence of FCS and the exon I.3 seems to be relevant for this stimulation. Testosterone and 17β-estradiol treatments have no effect on these promoters. Finally, I.6 promoter activity was detected but transcriptional levels were not affected by hormonal treatments.

Osteoblast Gene Expression Profiles during Growth of the Immature Skeleton. D. Murray*, C. Farquharson. Gene Function and Developement, Roslin Institute, Midlothian, United Kingdom.

In response to skeletal loading, bones increase their diameter by incorporation and infilling of primary osteons. Comparing chickens with fast (F) and slow (S) growth potential we have previously reported that the tibia of fast growing birds had lowered mechanical properties, likely to be explained by increased cortical porosity. Indirect measurement of osteonal infilling indicated that this process was impaired in the fast strain. The aims of this study were to directly determine the infilling rate of the primary osteons and to compare osteoblastic characteristics of both strains. To quantify the rate of osteon infilling, tibiae were removed from 21-day-old chicks, which had been double labelled with calcein (80 and 8 h before death). The mineral apposition rate was F=11.51μm/day; S=28.16μm/day, P< 0.001 and this data confirms previous histomorphometry results. Osteoblasts were grown and expanded in culture from explants of tibia of 21-day-old birds of both strains (n=4/strain). Osteoblast proliferation was determined by tritiated-thymidine uptake and differentiation by alkaline phosphatase (ALP) activity. At pre-confluency, cell proliferation was higher in the slow growing birds (F=7439dpm; S=11732dpm, P<0.001), but this pattern was reversed at confluency (F=10491dpm; S=1979dpm, P<0.001) and post confluency (F=4564dpm; S=1702dpm, P<0.001) and is a likely consequence of the earlier impairment of proliferation by contact inhibition in the slow growing strain. ALP activity (pNPP hydrol/30 min/mg protein) was only detected at post-confluency and was higher in the fast growing strain (F=1188; S=216, P<0.001). Osteoblastic gene expression was determined by RT-PCR and quantified by densitometry (cnt/mm^2). A higher level of osteopontin (F=382; S=1205, P< 0.01), and BSP (F=33; S=262, P<0.05) expression was observed in the slow growing birds. The serotonin receptor, considered to have a role in mechanoregulation, was more highly expressed in the fast chicks (F=565; S=241, P<0.05) as was Runx2 (F=312: S=72, P<0.001). In conclusion, porosity was confirmed to be due to a lack of infilling within the primary osteons. Osteoblast proliferation was faster in the slow growing birds whereas differentiation was slower. This is in accord with our previous hypothesis that the fast growing birds are characterised by an increase in transit time through the osteoblast lineage, which may be driven by the high levels of Runx2 expression. Osteopontin and BSP are associated with mechanical loading but the significance of the lower expression levels in the fast growing birds requires further study. However, the up regulation of serotonin expression may reflect the greater loads experienced in the fast growing birds in vivo.

ATF4 Mediates PTH-dependent Osteocalcin Gene Expression. G. Xiao[1], D. Jiang*[1], H. Boules*[1], C. Ge*[1], Z. Zhao[1], X. Yang*[2], G. Karsenty[2], R. T. Franceschi[1]. [1]Periodontics/Prevention/Geriatrics, The University of Michigan, Ann Arbor, MI, USA, [2]Department of Molecular and Human Genetics and Bone Disease Program of Texas, Baylor College of Medicine, Houston, TX, USA.

Parathyroid hormone (PTH) is an important peptide hormone regulator of bone formation and osteoblast activity. However, its mechanism of action in bone cells is largely unknown. This study examined the effect of PTH on mouse osteocalcin gene expression in MC3T3-E1 preosteoblastic cells and primary cultures of bone marrow stromal cells. PTH increased the levels of osteocalcin mRNA 4- to 5-fold in both cell types. PTH also stimulated transcriptional activity of a 1.3 kb fragment of the mouse osteocalcin gene 2 (mOG2) promoter. Inhibitor studies revealed a requirement for protein kinase A, protein kinase C and mitogen-activated protein kinase pathways in the PTH response. Deletion analysis of the mOG2 promoter identified an essential region for PTH responsiveness between -116 and -34. This region contains a single copy of the previously described osteoblast-specific element, OSE1 (TTACATCA). Deletion and mutation of OSE1 in DNA transfection assays established the requirement for this element in the PTH response. This OSE1 site was recently demonstrated to bind to activating transcription factor 4 (ATF4), a factor which plays a major role in bone formation (Yang et al., 2004, Cell, 117:387-398). Gel mobility retardation shift assays revealed that MC3T3-E1 cells contain ATF4 and that binding of ATF4 to OSE1 DNA was up-regulated by PTH. Furthermore, PTH treatment increased the levels of ATF4 mRNA and protein in osteoblasts. Collectively, these studies indicate that ATF4 mediates PTH-dependent OCN gene expression.

Functional Role of a Zinc Transporter in Osteoblast Differentiation. Z. Tang*, M. A. Khadeer*, A. Gupta. Biomedical Sciences, University of Maryland, Baltimore, Baltimore, MD, USA.

Zinc (Zn) is an essential trace element that has anabolic effects on bone formation, partly through stimulation of osteoblast proliferation and differentiation. Zn deficiency is commonly associated with retardation of bone growth. The mechanisms for Zn uptake into osteoblasts have not previously been examined in detail. There are several families of plasma membrane Zn transporters that have been characterized in mammalian cells, which function in either uptake or efflux of Zn. ZIP1 (*Z*rt, *I*rt-like Protein) is ubiquitously expressed in most cells, and is responsible for plasma membrane Zn uptake. We have examined the role of ZIP1 in differentiation of human mesenchymal stem cells (hMSCs) that can assume an osteogenic phenotype under the appropriate culture conditions. First, we have demonstrated gene and protein expression of ZIP1 in both osteoblast-like cells and hMSCs. Second, subcellular distribution of ZIP1 showed both a plasma membrane and diffuse cytoplasmic localization. Third, ^{65}Zn-uptake was shown to be enhanced in hMSCs cultured under osteogenic conditions when compared to basal (i.e., non-osteogenic) conditions; the protein expression of ZIP1 was also increased when hMSCs became osteogenic. Fourth, we have examined the role of ZIP1 in the differentiation of hMSCs into an osteogenic phenotype. We have proposed that overexpression of ZIP1 in hMSCs can accelerate or enhance the osteogenic differentiation pathway. For this purpose, a highly purified recombinant adenovirus (rAd) encoding for a GFP-tagged ZIP1 was used to infect hMSCs for seven days. The effects of ZIP1 overexpression were examined under both basal and osteogenic (culture) conditions in the presence of 10 μM $ZnCl_2$. For control Ad infections, we have used a rAD encoding for a GFP-tagged NMDA R1 subunit. Our results demonstrated that overexpression of ZIP1 in hMSCs increased both alkaline phosphatase (ALP) activity and mineralization, as assessed by histochemical staining. Our preliminary data suggests that at least one family of Zn transporters, namely ZIP1, plays a role in the differentiation of hMSCs into an osteoblast phenotype. This study provides further insights into the mechanism of the effects of Zn on osteoblast function.

Endothelin-1 and ETRA, via Osterix, Down-Regulate VEGF in Osteoblastic Cells. G. Qu*, H. P. von Schroeder. Dept. of Surgery & Faculty of Dentistry, University of Toronto, Toronto, ON, Canada.

Endothelin-1 (ET-1) is produced by vascular endothelial cells to play an important role during bone development, remodeling and repair. ET-1 promotes osteoblastic cell proliferation and differentiation, but has the unique effect of down-regulating vascular endothelial growth factor (VEGF) and may thereby control angiogenesis during bone production. Our objectives were to identify the intracellular mechanisms by which ET-1 controls VEGF expression during osteoblastic proliferation and differentiation. ET-1-induced osteoblastic differentiation in rat SBMC-D8 osteoblastic cells, but down-regulated expression of VEGF mRNA isoforms (VEGF120, 164 and 188) by 67% as demonstrated by semiquantitative reverse transcription polymerase chain reaction (RT-PCR) with primers designed to hybridize to three different splice variants of the rat VEGF-A gene. ET-1 also resulted in a 41% reduction of activity of a luciferase reporter construct containing the promoter region of the VEGF gene. As a positive control, BMP-2 treatment resulted in an increase in VEGF mRNA. Endothelin receptor A (ETRA) overexpression was achieved by transfection with ETRA. This also resulted in inhibition of VEGF-A levels by 63% as shown by RT-PCR and resulted in a 49% reduction of activity of the luciferase reporter construct containing the VEGF promoter. ET-1 treatment and ETRA transfection resulted in a 52% and 48% increase of the transcription factor osterix (Osx) mRNA respectively. Transfection of SBMC-D8 cells with plasmid containing Osx transcript resulted in a 43% decrease in VEGF mRNA as determined by RT-PCR. RNA silencing with double-stranded RNA of Osx was highly successful in completely eliminating Osx signal and resulted in an increase in VEGF mRNA by 108% as determined by RT-PCR and an increase of 180% of luciferase reporter activity. During Osx mRNA interference, the addition of ET-1 could not re-establish its inhibitory effect. This study supports the novel inhibitory role for ET-1, via Osx, on VEGF synthesis in osteoblastic cells as a mechanism in the temporal and spatial feedback of angiogenesis to bone formation and resorption.

Involvement of CCAAT Enhancer Binding Protein Transcription Factors In the Activation of Collagenase-3 Transcription. K. Wannemacher*[1], P. Dhawan*[2], X. Peng*[2], N. Selvamurugan*[3], N. Partridge*[3], S. Christakos[2]. [1]Biochemistry, Graduate School of Biomedical Sciences-New Jersey Medical School, Newark, NJ, USA, [2]Biochemistry, University of Medicine and Dentistry of New Jersey, Newark, NJ, USA, [3]Dept. of Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA.

Collagenase-3 (MMP-13) is a member of the matrix metalloproteinase (MMP) gene family which is upregulated in osteoblasts by systemic bone resorbing factors including parathyroid hormone (PTH), prostaglandin E_2 and $1,25(OH)_2D_3$. Matrix degradation by collagenase-3 has been implicated in bone remodeling, bone repair and in PTH and $1,25(OH)_2D_3$ induced bone resorption. CCAAT enhancer binding protein (C/EBP) transcription factors are important in the regulation of differentiation and in the expression of cell type specific genes. Recent studies have indicated the importance of C/EBPs in the regulation of osteoblast gene expression. We recently reported that C/EBPs are targets of $1,25(OH)_2D_3$ in osteoblasts. Similar to the regulation of collagenase-3, not only $1,25(OH)_2D_3$ but also PTH can induce C/EBPβ and δ in osteoblasts. In this study we identified and functionally characterized a C/EBP enhancer element in the proximal promoter of the rat collagenase gene (at -36/-32). We demonstrated by cotransfection experiments and gel mobility shift assay that this element is involved in the inducibility of the collagenase-3 promoter by C/EBPδ. In dose response studies (0.125 - 5 µg C/EBPδ), we found collagenase-3 transcription was maximally induced 5.6 ± 0.2 fold by C/EBPδ. C/EBPβ was also found to activate collagenase-3 transcription. Mutation of the -36/-32 C/EBP site within the wild type -148 promoter reduced basal expression and markedly attenuated the response to the C/EBP proteins. Gel shift analysis indicated the ability of C/EBP β as well as C/EBPδ to interact with this element. Deletion of the Cbfa1 site (-132/-126) did not affect the activation of the collagenase-3 promoter by C/EBPδ or C/EBPβ. Overexpression of Cbfa1 stimulated basal transcription and enhanced C/EBP activation of collagenase-3 promoter activity. Taken together these findings establish for the first time that C/EBP proteins are transcriptional activators of the collagenase-3 gene and suggest interactive effects between Cbfa1 and C/EBP proteins in the regulation of collagenase-3 transcription thus providing new evidence for the importance of these factors in the process of skeletal remodeling.

The Runx2 Transcription Factor Is a Positive Regulator of the Murine Bone Sialoprotein Gene in Osteoblasts. H. Roca*, G. Xiao, R. T. Franceschi. Periodontics, Prevention, Geriatrics, University of Michigan School of Dentistry, Ann Arbor, MI, USA.

Bone sialoprotein (BSP) is an important component of the bone extracellular matrix. Expression of Bsp is primarily restricted to mineralizing cells, (e.g. hypertrophic chondrocytes and osteoblasts). We previously identified a homeodomain factor binding site in the proximal Bsp promoter that partially explains the tissue-specific activity of this gene in vitro and in vivo (Benson et al, JBC 275:13907,2000; Gopalakrishnan Conn Tiss Res 44(S1):154,2003). However, this site cannot account for the known requirement for the Runx2 transcription factor in Bsp expression in vivo (Ducy et al., Gen.Dev 13:1025,1999). To clarify this issue, the present study examined the functional involvement of Runx2 in the expression of the murine Bsp gene. Chromatin immunoprecipitation (ChIP) analysis of the Bsp promoter in MC3T3-E1 (clone 4) cells detected Runx2 bound to a chromatin fragment comprising the region from -210 to -1130 bp. In contrast, ChIP analysis of the promoter region near -1335 which contains a site capable of binding to Runx2 in vitro (Benson et al., JBMR14:3,1999) failed to detect fragments within this region that were immunoprecipitated with anti-Runx2 antibody. From the region where Runx2 binds to the promoter in vivo, we identified two consensus Runx2-binding elements present at -81 base pairs (bp) (site B1) and -172 bp (site B2) in the mouse gene. Both sites (B1 and B2) are well conserved in the mouse, rat and human promoters. Runx2 can bind to both sites as demonstrated by electrophoretic mobility shift assay and supershift experiments using nuclear extracts from MC3T3-E1 cells. Competition experiments showed that Runx2 exhibited 4 to 5 fold higher affinity for site B1 than for B2. DNA transfection experiments using C3H10T1/2 mesenchymal cells showed that a 2472 Bsp promoter fragment was able to direct 3 to 4 fold higher levels of luciferase reporter expression when the cells were co-transfected with Runx2 expression plasmid. Mutation in the B1 site reduced promoter activity by approx. 50%, while mutation in site B2 caused only a small drop (about 15 %) in the promoter activity. However, in the osteoblastic cell line MC3T3 E1 (clone 4) each mutation caused a drop in the promoter activity of 50%, while the double mutant further reduced the activity another 15% (to 35% of wild type promoter activity). In summary, our results provide strong evidence that Runx2 is an important direct regulator of the Bsp gene that can account for much of its osteoblast-specific expression.

BMP2-Induced Alkaline Phosphatase Expression Is Regulated by Dlx5, which Is Interrupted by Msx2 as a Binding Competition to the Common Response Element. Y. Kim*[1], M. Lee*[1], J. M. Wozney[2], J. Cho*[1], H. Ryoo[1]. [1]Biochemistry, Kyungpook National University, Daegu, Republic of Korea, [2]Wyeth, Inc, Cambridge, MA, USA.

Alkaline phosphatase (Alp) is a widely accepted bone marker. Its expression is stimulated by bone morphogenetic protein (BMP)-2 treatment, the activation of BMP receptors and R-Smads, and the expression of Dlx5 and Runx2. However, how BMP-2 induces Alp expression is not clearly understood. We dissected the murine 1.9 kb Alp promoter and found within it a Dlx5-binding cis-acting element by an electrophoretic mobility shift assays and site-directed mutagenesis of the element. Dlx5 and the product of its target gene, Runx2, stimulated Alp promoter activity in an additive manner. However, since Dlx5 continued to stimulate Alp expression in Runx2-/- cells, the Alp stimulatory activity of Dlx5 is independent of Runx2. We also found that overexpression of Msx2 suppressed Dlx5-stimulated Alp promoter activity by competing with Dlx5 for the cis-acting element in the Alp promoter. Moreover, Msx2 levels are constitutively high in C2C12 myogenic cells but decrease over time after BMP-2 treatment. This may explain why BMP-2 treatment of these cells results in immediate Dlx5 expression yet Alp expression commences only 1-2 days later. In other words, Msx2 in high levels counteracts initially the transcriptional activity of Dlx5 in low levels until a threshold Dlx5:Msx2 ratio is reached to the levels that allow the Alp stimulatory activity of Dlx5 to prevail. Thus, Dlx5 transactivates Alp expression, directly by binding to its cognate response element and/or indirectly by stimulating Runx2 expression, and Msx2 counteracts the direct transactivation of Dlx5.

FLP-mediated Recombinantion to Study Gene Function in Differentiating MSC-like KS483 Cells. G. van der Horst*[1], H. Sips*[1], J. Hoogendam[2], C. Löwik[1], M. Karperien[3]. [1]Endocrinology, LUMC, Leiden, Netherlands, [2]Paediatrics, LUMC, Leiden, Netherlands, [3]Endocrinology & Paediatrics, LUMC, Leiden, Netherlands.

The completion of the human genome project necessiates easy and fast test systems to infer gene function. Genetically engineered KS483 cells made suitable for FLP mediated recombination may provide such a model. KS483 cells have MSC-like characteristics, since they can differentiate into osteoblasts, adipocytes and chondrocytes. To enable easy genetic manipulations, we have stably transfected KS483 cells and integrated 1 copy of a FRT-target site into their genome. This site can be used for insertion of DNA by homologous recombination. We isolated 3 KSfrt clones, which have retained pluripotency.

To test the efficacy of the FRT-targeting procedure, the 3 clones were co-transfected with an FRT-targeting vector driving luciferase expression and FLP recombinase. After two weeks, isogenic KSfrt Luc clones were isolated. In the 3 clones luciferase activity was expressed at a constant level at all stages of osteoblast and adipocyte differentiation, indicating absence of positional effects on activity of the inserted targeting vector.

Next we used this methodology to overexpress RunX2. Two weeks after transfection

isogenic clones were isolated which overexpressed RunX2 at the protein level. In differentiation assays, these clones demonstrated increased osteoblast and chondrocyte differentiation, while adipocyte differentiation was inhibited. To test whether FRT-mediated recombination could be used for an siRNA approach, we created an FRT RNAi vector driving the expression of a 19bp RNA duplex targeting RunX2. In the 3 KSfrt RNAi RunX2 clones, osteoblast differentiation was blocked in contrast to the clones expressing a RNAi mtRunX2 construct having a 2 nucleotide mismatch in the 19 basepair duplex. This indicates that integration of 1 copy of the RNAi vector is sufficient to induce a near complete gene knock down.
Subsequently we tested whether the KSfrt Luc clones could be used *in vivo*, a bone marrow ablation assay was performed in which the cells were injected in the marrow cavity. Cell fate was followed by non-invasive bioluminescent imaging and X-rays. Data suggested that the KSfrt Luc clones were normally incorporated in new bone induced by the ablation. In conclusion, KSfrt cells provide a simple and fast model for testing gene function, either by overexpression or by gene knock down, on differentiation into mesenchymal cell lineages both in vitro and in vivo. Furthermore, these cells may be used for the easy generation of lineage specific reporter cell lines. We are now exploiting this model for the systematic knock down and overexpression of components of the Wnt-signalling pathway.

Disclosures: ***M. Karperien****, None.*

Transcription Factors Involved in the Regulation of IL-6 in Mouse Calvarial Osteoblasts by Vasoactive Intestinal Peptide. E. Persson*[1], O. Voznesensky[2], C. C. Pilbeam[2], U. H. Lerner[1]. [1]Dept. Oral Cell Biology, Odontology, Umea, Sweden, [2]Dept. Medicine, University of Connecticut Health Center, Farmington, CT, USA.

The skeleton contains an intense network of nerve fibers expressing neuropeptides, including vasoactive intestinal peptide (VIP). We have previously shown that VIP can regulate osteoclast formation and activity. Interleukin-6 (IL-6) and the related cytokines IL-11, leukemia inhibitory factor (LIF) and oncostatin M (OSM) are potent stimulators of osteoclastic bone resorption. In the present study, we have addressed the possibility that the neuropeptide VIP may regulate the production of and/or sensitivity to the IL-6 family of cytokines in mouse calvarial osteoblasts. Using RT-PCR, real-time PCR and ELISA we could show that VIP stimulated the mRNA expression of IL-6 and the release of IL-6 protein in a time- and concentration-dependent manner. The mRNA expressions of IL-11, LIF, OSM, and their cognate receptors were unaffected by VIP. However, the mRNA level of gp130, the signal transducing protein linked to the receptors in the IL-6 family, was decreased by VIP. In cells transfected with the IL-6 promoter coupled to luciferase, VIP increased luciferase activity. All the effects of VIP were potentiatied by cyclic AMP phosphodiesterase inhibitor rolipram, mimicked by forskolin and shared by PACAP-38, but not by secretin, two peptides also belonging to the VIP/secretin family. The facts that PACAP-38 was equipotent with VIP and that secretin was without effect, indicate that the responses were mediated by the VIP type 2 receptor. EMSA demonstrated that the DNA-binding activity of nuclear extracts to C/EBP was increased by VIP, whereas binding to AP-1 was decreased and binding to NF-κB and CREB was unaffected. Gelshift analysis showed that the C/EBP complex consisted of C/EBPβ and C/EBPδ and that the AP-1 complex could be shifted by a combination of antibodies to c-Jun, JunB, c-Fos, and Fra-1 but not by individual antibodies. RT-PCR showed that the mRNA expressions of C/EBPβ, C/EBPδ, C/EBPγ, c-Jun, JunB, c-Fos, Fra-1 and IκBα, and protein level of IκBα were all unaffected by VIP. Immunocytochemical analysis showed that VIP did not affect nuclear translocation of NF-κB (p50, p65), C/EBPβ or C/EBPδ. These observations demonstrate that VIP type 2 receptors stimulate IL-6 production in osteoblasts by a mechanism likely to be dependent on cyclic AMP/protein kinase A activation and also involving regulation of the transcription factors C/EBP and AP-1.

Phosphorylation Dependent Enhancement of Vitamin D Receptor Mediated Transcription Is Associated with Phosphorylation of C/EBPβ at Thr[188], Nuclear Accumulation of C/EBPβ and Phosphorylation of CREB-Binding Protein. Y. Liu*, S. Christakos. Biochemistry, Graduate School of Biomedical Science-New Jersey Medical School, Newark, NJ, USA.

We previously reported that okadaic acid (OA), an inhibitor of protein phosphatase 1 and 2A, can enhance the transcriptional activity of WT vitamin D receptor (VDR) as well as the transcriptional activity of mutant VDRs (H305Q, F251C, I268T). The enhancement correlated with increased interaction between DRIP205 and either WT or mutant VDRs. We found that VDR was not phosphorylated in the presence of 50 nM OA. To address the possibility that OA may be acting by enhancing the phosphorylation of another protein involved in VDR mediated transcription, we examined C/EBPβ which is a potent enhancer of VDR mediated 24(OH)ase transcription and contains phosphorylation sites for multiple protein kinases, including a conserved mitogen activated protein kinase (MAPK) consensus site at Thr[188]. Immunoblotting with antibodies against a synthetic phosphopeptide corresponding to residues surrounding Thr[188] of C/EBPβ showed that OA (50 nM) promoted the phosphorylation of C/EBP β in UMR 106 osteoblastic cells at 30 min after OA treatment. Phosphorylation of C/EBP β increased 10 fold after 4h OA treatment. No change in the level of C/EBPβ protein was observed after OA treatment. The MEK inhibitor, U0126 (10 μM), prevented the phosphorylation of C/EBPβ observed at 30 min., suggesting that this phosphorylation involves OA activated MAPK signaling. Studies using immunocytochemistry and fluorescence microscopy indicate that OA (50 nM) can also promote the nuclear accumulation of C/EBPβ in UMR osteoblastic cells 2h after treatment. In addition to phosphorylation and nuclear accumulation of C/EBPβ, we also examined CREB-binding protein (CBP) which cooperates with C/EBPβ in regulating VDR mediated 24(OH)ase transcription and has been reported to be essential for ligand dependent transcription of a number of steroid receptors. Treatment of UMR cells with OA (50 nM) consistently resulted in the appearance of a slower migrating form of CBP as visualized by SDS-PAGE and Western blotting. The slower migrating form was no longer detected after subsequent incubation with phosphatase, providing evidence that OA also results in the phosphorylation of CBP. The phosphorylation of CBP was not induced by $1,25(OH)_2D_3$. These findings suggest that transcriptional activity of WT and mutant VDRs can be enhanced by phosphorylation and this may be mediated by increased coactivator binding and nuclear accumulation and phosphorylation of specific VDR cofactors.

Expression of the Bone-Specific Osteocalcin Gene Requires SWI/SNF Chromatin Remodelling Activity. A. Villagra*[1], M. Villagran*[1], F. Cruzat*[1], L. Carvallo*[1], J. Olate*[1], A. van Wijnen[2], J. Lian[2], G. Stein[2], J. Stein[2], A. Imbalzano*[2], M. A. Montecino[1]. [1]Bioquimica y Biologia Molecular, Universidad de Concepcion, Concepcion, Chile, [2]Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

Osteocalcin (OC) is a bone-specific protein that is expressed at late stages of osteoblast differentiation. Transcription of the OC gene is associated with changes in chromatin structure at the promoter region, which are reflected by the presence of two DNase I hypersentive sites (DHS). These DHS span all the key regulatory elements that control basal tissue-specific and vitamin D3-enhanced OC gene transcription. Among the cellular complexes that possess chromatin-remodelling activity, are the SWI/SNF complexes. These complexes include a catalytic subunit containing ATPase activity, which in higher eukaryotes can be either BRG-1 or BRM. Mutations in the ATPase domain of BRG-1 or BRM that abrogate the ability of these proteins to bind ATP, result in the formation of inactive SWI/SNF complexes. To gain understanding into the molecular mechanisms involved in the chromatin remodelling events that are linked to the OC gene transcription, we have stably transfected osteoblastic cells with constructs encoding for Flag-tagged mutated versions of BRG-1 and BRM under the control of an inducible promoter. We found that overexpression of these ATPase mutant proteins results in the formation of inactive SWI/SNF complexes that bind to the OC promoter. This interaction correlates with a significant inhibition of both basal and vitamin D3-enhanced endogenous OC transcription as well as with a marked decrease in nuclease hypersensitivity. Together our results indicate that SWI/SNF complexes have an important role in the chromatin remodelling events that accompany transcriptional activity of the OC gene in osteoblasts.

Lef1-Suppression Accelerates Osteoblast Differentiation and Modifies Gene Expression Profiles. R. A. Kahler[1], J. J. Westendorf[2]. [1]Graduate Program in Microbiology, Immunology and Cancer Biology, University of Minnesota, Minneapolis, MN, USA, [2]Department of Orthopaedic Surgery, and The Cancer Center, University of Minnesota, Minneapolis, MN, USA.

Activation of the Wnt signaling pathway via LRP5 Wnt coreceptor increases bone mass. Lef1 is one of the transcription factors responsible for translating the Wnt/ß-catenin signaling cascade into gene expression changes. We recently demonstrated that Lef1 and ß-catenin antagonize Runx2-dependent activation of the osteocalcin promoter. We have also identified multiple Lef1 isoforms in murine osteoblasts that are likely to be products of alternative splicing or alternative promoter usage and may act as dominant negative proteins. Lef1 DNA binding activity decreases during osteoblast maturation. We therefore hypothesize that the regulated expression of specific Lef1 isoforms is crucial for osteoblast maturation. To determine the importance of some of these Lef1 isoforms in osteoblast differentiation, we produced MC3T3-E1 preosteoblast cell lines that express short hairpin RNAs (shRNAs) targeting exon 11 of Lef1 and have reduced Lef1 expression. Lef1-suppressed cells do not grow faster than control cells but they differentiate at a faster rate as they produce alkaline phosphatase, osteocalcin mRNA and mineralized nodules three to four days before control cells expressing an shRNA against firefly luciferase (Ffl). We hypothesize that the reduction of Lef1 expression alters gene expression to promote osteoblast maturation. By probing Affymetrix Mouse Genome 430A gene chip arrays, we identified 48 genes that were differentially expressed by more than two fold in Lef1-suppressed cell lines as compared to the control Ffl line ($p<0.005$). Many genes that were reduced in Lef1-suppressed cells were extracellular matrix genes, including procollagen XI alpha 1 (Col11a1; 6.5 fold), asporin (4.0 fold), fibulin 5 (2.6 fold), and procollagen III alpha 1 (2.1 fold). We confirmed reduced Col11a1 expression in our Lef1 shRNA cells by real-time quantitative PCR. Examination of the promoter revealed three potential Lef1/Tcf binding sites. Lef1 activates the Col11a1 promoter two to three fold and addition of ß-catenin enhances activation in a concentration dependent manner. Mutations in Col11a1 cause both Marshall and Stickler syndromes, which are characterized by craniofacial abnormalities and thickened calvaria. These data suggest that Lef1 regulates osteoblast function by differentially controlling genes such as Col11a1 and osteocalcin.

Coactivator PGC-1a Is PTH-Induced and Synergizes with Nurr1 to Regulate Promoter Activity in Osteoblasts. J. Nervina, C. Magyar*, F. Pirih*, I. Ozkurt*, S. Tetradis. UCLA School of Dentistry, Los Angeles, CA, USA.

We have shown that PTH induces expression of the NGFI-B nuclear orphan receptor Nurr1 through cAMP-PKA signaling in bone. Nurr1 induces osteocalcin (OCN) expression through an NGFI-B response element (NBRE)-like site in the proximal promoter. While nuclear receptor transactivation is greatly enhanced by coactivators, no coactivator for Nurr1 is known. PPARg coactivator-1a (PGC-1a) is a promising candidate since it is cAMP-induced and synergizes with nuclear receptors to increase transcription. *We hypothesize that PGC-1α is a PTH-induced primary response gene that synergizes with Nurr1 to induce target gene transcription in osteoblasts.* First, using real time PCR we show that 10 nM PTH for 2 h maximally induced PGC-1α mRNA in primary mouse osteoblasts (MOBs) and calvaria organ culture. PKA activation with 10 μM forskolin induced PGC-1α, while PKC activation with 1 μM PMA and calcium signaling with 1 μM ionomycin did not. Also, 100 nM PTH(3-34), which activates PKC and calcium but not PKA, did not induce PGC-1α. Confirming primacy of cAMP signaling in PGC-1α induction, PTH-induced PGC-1α markedly decreased when PKA but not PKC signaling was inhibited. Protein synthesis inhibition with 3 μg/ml cycloheximide caused superinduction of PTH-induced PGC-1α expression. Next, to investigate PGC-1αs potential function as a Nurr1 coactivator, MOBs were cotransfected with Nurr1 and/or PGC-1α expression vectors and a consensus 3xNBRE-luciferase construct. Nurr1 induced promoter activity 3.5 fold, while PGC-1α had no effect. PGC-1α and Nurr1 together induced promoter activity 10 fold. Then, to examine whether the same transcription factor-coactivator interaction can regulate endogenous promoters, MOBs were transiently cotransfected with Nurr1 and/or PGC-1α expression vectors and the rat (-1050)OCN-luciferase construct. Nurr1 increased OCN promoter activity 3 fold, while PGC-1α had no effect. Importantly, PGC-1α and Nurr1 together increased OCN promoter activity 10 fold. This synergy required Nurr1-DNA binding, since a mutation of the NBRE-like sequence in the proximal OCN promoter abolished both Nurr1- and Nurr1-PGC-1α-induced transactivation. Finally, to test for protein-protein interaction, recombinant Flag-PGC-1α and Nurr-1 proteins were co-incubated. Flag-PGC-1α protein co-immunoprecipitated with Nurr1 antibody, and Nurr1 protein co-immunoprecipitated with Flag antibody. *We conclude that PGC-1α is a PTH-induced coactivator that binds to Nurr1 to synergistically increase OCN promoter activity in osteoblasts.* Taken together with published data, our findings suggest that Nurr1 and PGC-1α may be pivotal mediators of cAMP-induced osteoblast gene expression.

A Novel Secreted, Cell-surface Glycoprotein Containing Multiple EGF-like Repeats and One CUB Domain Is Highly Expressed in Human Osteoblasts. B. Wu*, Y. Su*, M. Tsai*, R. Yang. Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan Republic of China.

We have previously identified a novel family of secreted, cell-surface proteins expressed in human vascular endothelium. To date, two family members have been described, sharing a characteristic domain structure including an amino-terminal signal peptide followed by multiple copies of EGF-like repeats, a spacer region and one CUB domain at the carboxyl terminus. Thus, this family was termed SCUBE for Signal peptide-CUB-EGF-like domain containing proteins. Here we described the identification and characterization of one additional member of the SCUBE family named SCUBE3 in humans, sharing an overall 60% protein identity and a similar domain structure with other family members. Real-time quantitative reverse transcriptase-PCR and Northern blot analyses revealed that this gene is highly expressed in human primary osteoblasts. Western blot analysis confirmed that hSCUBE3 protein is expressed in a variety of osteoblast-like cell lines. Consistently, immunofluorescent staining demonstrated that hSCUBE3 is colocalized with type I collagen-positive osteoblasts in mouse skeleton. Overexpression of hSCUBE3 in human embryonic kidney 293T cells resulted in a secreted glycoprotein that can form oligomers, tetherered to the cell-surface. Interestingly, the secreted hSCUBE3 protein can be further proteolytically processed by a serum-associated protease to release the EGF-like repeats from the CUB domain. Moreover, the hSCUBE3 mRNA is down-regulated upon the treatment of lipopolysaccharide in human osteoblast-like SaOS-2 cells. The SCUBE3 gene is mapped to human chromosome 6p21.3, a region that has been linked with the locus for a rare form of metabolic bone disease, Paget's disease of bone 1. Together, this novel secreted, cell-surface osteoblast protein may act locally and/or distantly through a proteolytic mechanism, and may play an important role in bone cell biology.

In Vivo **Bone Formation of Bone Marrow-Derived Cells Correlates With CD105, CD166, and Thy1 Cell Surface Markers.** J. E. Dennis[1], K. Renshaw*[2], A. Awadallah*[1], K. Goltry*[2]. [1]Biology, Case Western Reserve University, Cleveland, OH, USA, [2]Aastrom Biosciences, Inc., Ann Arbor, MI, USA.

The purposes of this study were to determine if stromal cell markers correlate with *in vivo* bone formation and to derive optimal culture conditions for the expansion of osteogenic cells.

Identical human bone marrow mononuclear cell aliquots were inoculated into two fully automated, self-enclosed Aastrom RepliCell™ System (ARS) bioreactors and cultured for 12 days with continuous medium perfusion. On day 12, populations of cells were obtained from each bioreactor: A Total Cell Population (TCP) obtained by a standard trypsinization, and an Adherent Cell Population (ACP) obtained by trypsinization after non-adherent cells depletion. Both populations were evaluated by flow cytometry prior to *in vivo* osteogenesis assessment. For *in vivo* bone formation, cells are combined with porous calcium phosphate ceramics and implanted sub-cutaneously into NOD/SCID mice; after 6 weeks, the ceramics were harvested, prepared for histology and scored. Both TCPs and ACPs were tested at ceramic loading concentrations of 5, 10, 25, and 50 million cells/ml. Empty ceramics and mesenchymal stem cell (MSC)-loaded ceramics served as positive and negative controls. A total of 12 mice were used in each experiment (N=6 for each TCP and ACP sample; N = 12 for negative and positive controls);implantation sites were randomized. Three TCP and ACP cohorts and two cohorts comparing two culture conditions (with and without growth factors) were used to derive the correlation values (N=10).

The bone scores showed that ACP consistently showed higher bone scores than the TCP at all four loading dilutions. Empty controls showed only trace amounts of bone and the positive control MSC bone scores were consistently high. To derive the Total Bone Score (TBS), the scores for each cell loading dilution were summed. A graph of the relationship between TBS and selected flow cytometric markers and colony forming units-fibroblastic (CFU-f) are shown in Figure 1. There is a strong correlation between bone scores and the CD-14-/Thy-1+ and CD-166+ (ALCAM) cell populations, and with the CD-105+ (endoglin) population. Interestingly, there was little correlation between total CFU-f and *in vivo* bone scores. The endoglin, Thy1 and ALCAM markers appear to be predictive markers for osteogenic potential in these cell populations.

Effects of Bisphosphonate (YM529) on Osteoblastic Function and Differentiation in Bone Regeneration after Drill-Hole Injury in Mice. M. Nagashima*, A. Sakai, S. Uchida*, S. Tanaka*, M. Tanaka*, T. Nakamura. Orthopaedic surgery, University of occupational and enviromental health, Kitakyushu, Fukuoka, Japan.

Recently, bisphosphonates have been shown to have direct effect on osteoblasts, but the effects on bone regeneration in vivo are not elucidated. In this study, we investigated to clarify the effect on osteoblastic function and differentiation at the bone regeneration of drill-hole injury during the bone turnover reduced by bisphosphonate (YM529).

Male C57BL/6N mice, 8 weeks of age, were assigned to two groups with respective dose of 0 (vehicle control; VC group) or 0.1 (YM529 group) mg/kg body weight of the agents, intravenously injected once a week. At 10 weeks of age, six mice each from VC and YM529 groups were sacrificed (day 0). The remaining mice were subjected to drill-hole injury at the diaphysis of bilateral femurs. Femoral specimens were obtained at 7, 10, 14, 21, and 28 days after surgery. Histomorphometric study revealed that, in the YM529 group, the bone volume of the regenerating bone at the injured site did not significantly differ at 7 and 10 days, but the medullary bone mass was larger and the regenerated cortical bone volume was smaller compared to those in the VC group at 21 and 28 days. Expression levels of mRNAs in the regenerating site were evaluated at 0, 3, 5, 7, 10, 14, and 21 days. Osterix, BMP-2, and type I collagen mRNAs in the YM529 group were significantly lower than those in the VC group at day 0. At 3 and 5 days after injury, cbfa1, osterix, BMP-2, type I collagen, and osteocalcin mRNAs in the YM529 group were similar to those in the VC group. At 7 days, osterix, BMP-2, and osteocalcin mRNAs in the YM529 group were significantly higher than those in the VC group. Only osteocalcin mRNA in the YM529 group was significantly lower than that in the VC group at 14 days. Compared to the VC group, RANKL and TRACP mRNAs in the YM529 group were significantly higher throughout the experimental period. To evaluate bone marrow osteogenic capacity, samples taken from femurs at 0 and 5 days after injury were used for CFU-f assay and mineralized nodule formation. In the YM529 group, the numbers of CFU-f and ALP+CFU-f were reduced compared to controls at day 0. At 5 days, the numbers of CFU-f and ALP+CFU-f were similar in both the YM529 and VC groups. At day 0, the area of mineralized nodule formation was significantly smaller in the YM529 group than that in the VC group. At 5 days, there was no significant difference between the YM529 and VC groups.

These data indicate that bisphosphonate does not affect the osteoblastic function and differentiation in initial medullary bone regeneration. But, in the period of cortical bone formation at 14 days and thereafter, bisphosphonate may affect the osteoblastic differentiation.

Visualizing Levels of Osteoblast Differentiation by a Two Color Promoter-GFP Strategy: Type I Collagen-GFPcyan and Osteocalcin-GFPtpz. I. Bilic-Curcic*[1], M. S. Kronenberg*[1], J. Bellizi*[1], X. Jiang*[1], E. Gardiner*[2], D. W. Rowe[1]. [1]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Garvan Insitute, Sydney, Australia.

For understanding cellular and molecular mechanisms of osteoblast differentiation it is necessary to develop visual markers that reflect the progression of cells to full osteoblast differentiation in cell culture that should be readily transferable to in vivo models of bone formation.

The purpose of this study is to show the feasibility of generating transgenic mice containing two promoter constructs driving distinguishable GFP isomers at different stages of osteoblast differentiation to identify cells at different levels of development both in cell culture and intact mouse bone. A 3.9 kb fragment of the human osteocalcin (hOC) promoter and a 3.6 kb fragment of the collagen promoter (Col3.6) linked with visually distinguishable GFP's, topaz and cyan, were used for multiplex analysis of osteoblast lineage progression. Transgenic mice for each construct, identified as pOBCol3.6GFPcyan and hOCGFPtpz, were individually characterized and then crossed. Temporal and spatial expression of both transgenes was analyzed in vitro and in vivo. In marrow stromal and neonatal calvarial cell cultures of crossed transgenic lines the pOBCol3.6GFPcyan low intensity positive cells appeared on day 7 and its expression continued as high intensity GFP positive cells that contributed to the formation of nodules. The hOCGFPtpz transgene expressing cells appeared at day 15 in nodules undergoing mineralization. In the mineralizing nodule we observed the activation of hOCGFPtpz in cells that were originally only cyan positive. The intensity of tpz in double GFP positive cells gradually increased as a concomitant decrease in cyan expression was detected.

In the histological analysis, the double transgenics illustrate a spectrum of osteoblast differentiation. Cells expressing cyan are present in the primary spongiosa and extend a short distance along the cortical bone. Double expressing cells can be found in trabeculae in the secondary spongiosa and lower cortex and along the surface of cortical bone. The majority of cells on the surface of cortical and trabecular bone and osteocytes are only tpz positive.

Thus a spectrum of osteoblast differentiation can be observed in bone nodules in primary culture and within bone. Because genetic disorders of bone may ultimately exert their effect by interfering with the orderly progression of progenitor to fully mature bone cell, this approach may be useful to identify the cellular consequence of a gene mutation as progenitors progress through stages of differentiation in cell culture and intact bone.

Bone Nodule Formation Via *In Vitro* Differentiation of Murine Embryonic Stem Cells. S. K. Bronson, K. Dunham*, J. Heaney*, N. Woll*. Cellular and Molecular Physiology, The Penn State University College of Medicine, Hershey, PA, USA.

The process of bone formation can be approximated in vitro, in the form of a mineralized nodule. Osteoprogenitors can be found in fetal and neonatal calvaria, and in the bone marrow. Mesenchymal stem cells (MSCs), the immediate precursor to the osteoprogenitor are found in the marrow, and likely in numerous other sites throughout the organism. These progenitors, when placed into culture, establish colonies that proliferate, differentiate into osteoblasts, and secrete and mineralize matrix over a period of 3 weeks. The overlapping differentiation potential of embryonic stem cells (ESCs) and the MSCs found in adult organisms led us to perform the following experiments. ESCs were allowed to form embryoid bodies (EBs). EBs were disrupted and plated at concentrations as low as 30 cells/cm^2. By 8 days post-plating a significant percentage of the colonies have morphology characteristic of other types of osteoblast cultures. By three weeks in culture these colonies go on to form layered, mineralized nodules as visualized by fixation and staining with the von Kossa technique. Up to 75% of colonies are mineralized. From EBs that range in size from 250-2500 cells approximately 1 in 80 cells is capable of forming a mineralized nodule. We have isolated RNA from entire plates and individual colonies at different stages of the differentiation process and have used QRT-PCR to quantify the expression of genes characteristic of the osteoblast lineage as well as genes characteristic of other lineages and stem/progenitor cells. Runx2, twist 1 and 2, osterix, type I collagen and osteocalcin are all transcriptionally upregulated in the osteoblast culture as differentiation progresses. Gene expression in individual colonies consistently reflects cell and colony morphology. Differentiation of an ESC line with an integrated bacterial artificial chromosome-based osteocalcin-driven GFP reporter was analyzed with confocal microscopy to further document the presence of mature osteoblasts. Differentiation of ES cells into the osteoblast lineage in vitro will be a valuable tool for addressing pertinent questions about the proliferation, differentiation, survival, and intercellular communication between cells of the bone lineage in vitro. In vitro differentiated cells can also provide an important testing ground for therapeutic applications in humans.

BMP Regulation of SOST and Osterix Expression During Embryonic Osteogenesis. A. Nifuji, Y. Ohyama*, Y. Maeda*, M. Noda. Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan.

Sclerostin (SOST), a member of the cystine-knot superfamily, is essential for proper skeletogenesis since loss of function mutation in SOST gene results in sclerosteosis featured with massive bone growth in humans. To understand the function of SOST in developmental skeletal tissue formation, we examined SOST gene expression in embryonic osteogenesis in vitro and in vivo. During osteoblastic differentiation in primary calvarial cells, the levels of SOST expression were increased along with those of alkaline phosphatase activity and nodule formation. In situ hybridization study revealed that SOST mRNA expression was observed in osteogenic front in embryonic 16.5 day postcoitum (E16.5) embryonic calvariae and this expression persisted in the peripheral area of cranial bone in the later developmental stage (E18.5). These temporal and spacial expression patterns in vivo and in vitro were in parallel to those of osterix (Osx), which is a critical transcriptional factor for bone formation. Similar co-expression of SOST and Osx mRNA was observed when the primary osteoblastic calvarial cells were cultured in the presence of BMP2 in vitro. Moreover, endogenous expression of SOST and Osx mRNA was inhibited by infection of noggin-expressing adenovirus into the primary calvarial osteoblastic cells, suggesting that endogenous BMPs are required for these cells to express SOST and Osx mRNA. Thus, expression and regulation of SOST under the control of BMP were closely associated with those of Osx in vivo and in vitro.

The Effect of Enamel Matrix Derivative (EMD) on Gene Expression in Osteoblasts. S. P. Lyngstadaas*[1], S. Reppe*[2], H. Berner*[1], J. E. Reseland*[1]. [1]Oral research laboratory, University of Oslo, Oslo, Norway, [2]Department of Medical Biochemistry, University of Oslo, Oslo, Norway.

Enamel matrix derivative, obtained from developing porcine teeth, is composed mainly of amelogenin proteins. It is used topically in periodontal surgery to regenerate lost connective tissues and bone. It has been shown that EMD stimulates local growth factor secretion and cytokine expression by periodontal ligament cells. The effect of EMD components on primary bone cells and bone growth, however, is unclear

The effect of EMD(50 µg/ml) on gene expression in primary human osteoblasts were compared to the effect of parathyroid hormone (PTH; 10^{-8}M). Micro array analysis of prepared material was performed using Hu-133A chips containing cDNA oligonuclotides representing more than 22 000 transcripts. Confirmative real-time PCR analysis was performed using the ABI Prism 7900HT Sequence Detection System and the 7900HT Micro Fluidic Card containing 8 ports. The effect of treatments was calculated relative to untreated cells, as signal log ratio.

We found that 254 genes were regulated more than 2 times with both EMD and PTH, and no genes were found to be regulated at least 2 times in the opposite direction by EMD and PTH. A summary of effect of EMD on genes grouped by major biological processes is listed in the table.

A specific effect of EMD on bone formation and enhance osteoblast maturation was found by increased alkaline phosphatase activity in the medium, as well as increased expression and secretion of osteocalcin and collagen type, whereas Runx2 expression was not affected. A possible interactive role of EMD in osteoclastogenesis can be deduced from the observed 16 fold increase in IL-6 and 2.5 fold increase in osteoprotegrein secretion to the media.

Lack of an Effect Of The HIV Protein Tat on Indices of Osteoblastic Cell Function. B. Kang[1], J. Xu*[1], H. Hu*[2], V. Ganapathy*[2], C. M. Isales[3]. [1]Institute of Molecular Medicine and Genetics, Medical College of Georgia, Augusta, GA, USA, [2]Biochemistry and Molecular Biology, Medical College of Georgia, Augusta, GA, USA, [3]Medicine, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA.

Patients infected with HIV have a higher incidence of osteopenia and osteoporosis even prior to the development of opportunistic infections or beginning anti-retroviral therapy. The cause of bone loss in these patients is unknown although measurement of serum markers of bone turnover suggest a problem of increased bone resorption rather than a problem with bone formation. To examine the underlying pathophysiology further, the osteoblastic cell line MC3T3 were transfected with the HIV Tat cDNA to express Tat protein. Tat is a protein encoded by HIV genome that facilitates multiplication of HIV-1 in the host cell. We used a pGEM2-Tat cDNA construct with a 295 bp fragment encoding the first exon of HIV-1 Tat gene and a CMV promoter. Transfected cells were grown in the presence of Geneticin (G418) according to the Lipofectamine (Invitrogen) protocol. The pcDNA3.1 vector by itself was transfected into MC3T3 cells as a control. The expression of Tat in the stably transfected MC3T3 was analyzed by measuring Tat mRNA and protein. Tat protein expression in transfected MC3T3 was assessed by immunocytochemistry using a monoclonal antibody against HIV-1 Tat (obtained through the AIDS Research and Reference Reagent Program, Division of AIDS, NIAID, NIH, contributed by Dr. John Karn). In order to assess whether the expression of the HIV Tat affected indices of osteoblastic function, we measured: RANKL, OPG, alkaline phosphatase, osteocalcin, Cbfa1 and collagen type I expression using real-time PCR light cycler (Roche). Three independent measurements per sample were performed; the specificity was confirmed by melting curve analysis and agarose gel eletrophorosis.
The quantified individual RNA expression levels were normalized for the respective tubulin expression levels. No significant difference was found in gene expression between control and Tat expressing osteoblastic cells.
We conclude that, consistent with the in vivo data, Tat protein expression does not impact indices of osteoblastic cell growth and differentiation and suggests that HIV effects on bone turnover are more likely mediated by effects on bone resorption rather than formation.

Imaging GFP Reporters in Frozen Sections of Decalcified and Non-decalcified Mouse Bone. X. Jiang*[1], Z. Kalajzic*[1], P. Mate*[1], A. Braut*[2], J. Bellizzi*[1], M. Mina*[3], D. W. Rowe[1]. [1]Genetics & Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Medical and Dental University, Rijeka, Croatia, [3]Dept of Pediatric Dentistry, University of Connecticut Health Center, Farmington, CT, USA.

This is a progress report of the available type I collagen - GFP reporter mice and the implementation of histological techniques to evaluate their expression pattern in sections of mouse bone. Four different colors of GFP (cyan, sapphire, emerald and topaz) have now been studied extensively in bone section to know which colors and filter sets can be used to develop a multiple fluorescent color analysis. Recent transgenic mice suggest that dsRedII is also compatible with healthy mice providing a 5th color that can be multiplexed. Methods for combining GFP imaging with other fluorescent techniques have been developed to allow simultaneous co-localization of the GFP signal to traditional histological methods. Examples include TUNEL, immunofluoresence for surface or intracellular antigens and fluorescent chromatin stains to counter-stain non-GFP expressing cells. Significant progress has been made in preparing frozen non-decalcified section that allow simultaneous imaging of GFP and fluorescent labeling of new matrix formation. Calcein, tetracycline, xylenol orange and alizarin complexone can be used in various combinations with the different GFP colors to assess which population of GFP+ cells are actively depositing new bone. The histology has shown that not all pOBCol3.6GFP+ cells on the bone surface are depositing mineral and regions of mineral deposition do not necessarily have overlying Col3.6GFP+ cells. However essentially all pOBCol2.3GFP+ cells are associated with mineralization. Finally, techniques have been developed to sequentially image for GFP and then process the sample for a histological stain that destroys the GFP signal. The original GFP image is then co-localized with the stained image by overlying the two image files. Examples include chemical stains such as H&E and alizarin red (mineralized section), enzymatic stains such as TRAP, AP or lac Z (for ß-gal expressing transgenic mice) and nucleic acid based procedures such as BrdU and in situ hybridization. The sectioning procedures are based on tape transfer of full longitudinal frozen section of mouse bone. A web site is being developed to provide more detail of the procedures
(http://skeletalbiology.uchc.edu/30_ResearchProgram/304_gap/index.htm, click Lineage in vivo) and examples of the type of histological sections that can reveal a complexity of cellular organization within bone that may not be appreciated by traditional histological methods.

Evidence for Gene Expression of the Neuronal Cell Surface Protein, Neurexin 3ß, in Adult Mesenchymal Stem Cells and Osteoblast-like Cells. B. D. Aggarwal*, S. Kanthala*, K. G. Danielson. Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

Neurexins comprise a family of neuronal cell surface proteins that serve as neuronal transmembrane cell adhesion molecules and may function in cell signaling and recognition. The neurexin family consists of three neurexin genes that each encode two mRNA forms (a and ß) based on the transcription start site. The a-neurexin proteins are longer with three laminin/EGF-like domains while the ß-neurexins are truncated forms that retain a short signal peptide and ß-neurexin specific sequence followed by the C-terminal portion of a-neurexin domain III. Alpha but not ß-neurexins are highly conserved in mammals with 95% homology and the six primary transcripts (three a and three ß) are subject to extensive splicing. Following detection by differential display of an uncharacterized DNA sequence located 50 kb downstream of a neurexin gene, we hypothesized that adult mesenchymal stem cells (MSCs) or osteoblast-like cells from trabecular bone may express these cell surface proteins and transcriptional activity of these neurexin genes may be modulated during differentiation *in vitro*. A human bone marrow stromal cell line, hMPC32F, previously characterized in our lab was used in these studies and RT-PCR was utilized to monitor gene expression of the neurexin genes. We also utilized human osteoblast-like cell lines, hTBC-1 and hTBC-2, that express low and high alkaline phosphatase activity respectively. Neurexin 3ß was markedly expressed in hMPC32F cells grown in serum free conditions with insulin, transferrin, selenium, (ITS+) in monolayer and this expression was not altered by treatment of cells with 10^{-9} to 10^{-6} M dexamethasone for 6 hr. Identity of the neurexin 3ß amplified fragment was confirmed by sequencing. Neurexin 3a, in contrast, was barely detectable under the same conditions. Gene expression of the neuronal cell surface ligand for ß-neurexins, termed neuroligin, was not detected in hMPC32F cells. In further studies, hTBC-1 osteoblast-like cells derived from trabecular bone did not express neurexin 3ß in monolayer culture or when maintained in chondrogenic conditions as a cell pellet in serum free medium supplemented with TGF ß1 for 26 days. However, the osteogenic hTBC-2 clonal cell expressing high levels of alkaline phosphatase expressed neurexin 3ß transcripts in monolayer culture and this expression was down-regulated when treated with osteogenic supplements for 21 days. Neurexin 3ß may represent a new, previously unrecognized cell surface protein expressed in adult mesenchymal cells that is modulated during cell differentiation.

Microarray Validation of Osteoblast Lineage Differentiation by GFP Marker Genes. I. Kalajzic*[1], A. Stahl*[2], W. Yang*[2], R. Gupta*[3], S. Garg*[3], L. Achenie*[3], J. Feyen[2], D. W. Rowe[1]. [1]Department of Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Bristol Myers Squibb, Princeton, NJ, USA, [3]University of Connecticut, Storrs, CT, USA.

We generated a number of GFP reporter mice to assess lineage progression in vitro and in intact mouse bone. Based on temporal and special expression patterns low intensity signal from the pOBCol3.6GFP transgene marks preosteoblasts, while pOBCol2.3GFP identifies osteoblasts . A comprehensive microarray study was performed to confirm the validity of the GFP assignments. Cultures were established from each transgenic line and harvested at day 7 for low level or absent expression from pOBCol3.6GFP cultures or at day 17 for strong or absent expression from pOBCol2.3GFP cultures. Each culture was separated into positive or negative subpopulations by FACS sorting from which RNA was extracted and used in the Affymetrix hybridizations chips, 74 A, B & C. Three biological replicates were performed for the day 7 and 15 cultures and the pattern of gene expression across the four populations was performed by an adaptive centroid clustering algorithm (Biotechol. Prog. 19:1142,2003). Transition from a 3.6 negative to positive cell is associated with 36 genes with significant down regulation and none that are up regulated. Two patterns were observed: (1) genes that are down regulated in 3.6+ cells and remain low at the later stages of differentiation. Genes characteristic of myofibroblasts populate this group; (2) genes that are down regulated in 3.6+ and 2.3+ cells but which continue to elevate in 2.3- cells. Examples include cell surface expressed genes and adipocytic genes. Two patterns of expression are present in the pOBCol2.3+ cell population. (1) 64 genes with significant up regulation in 2.3+ cells that show limited expression in the other populations. Many are genes associated with osteoblast differentiation although a number were unanticipated. (2) 255 genes that show high expression in both 3.6 cell populations that either begin to fall or remain unchanged in the 2.3- population but are greatly reduce in the 2.3+ population. This group contains a number of gene that are up regulated in microarray studies of total bone cell cultures that in fact are repressed in the osteoblastic population. Thus a low intensity Col3.6GFP+ cell show early evidence of restriction in the progenitor cell differentiation potential relative to the GFP- population suggesting it has progressed toward an osteogenic (and possibly other) fate. Col2.3GFP+ have many markers of a mature osteoblast. This study justifies the continued develop of a wider repertoire of promoter-GFP reporter construct to further deconvolute the osteoprogenitor lineage.

Butyltin Compounds Inhibit the Ossification *in vivo* and Differentiation of Osteoblasts *in vitro*. H. Hagiwara[1], Y. Ishihara*[2], T. Sugizaki*[1], Y. Tsukamoto*[3]. [1]Department of Biological Engineering, Toin University of Yokohama, Yokohama, Japan, [2]First Department of Hygiene & Public Health, Tokyo Women's Medical University, Tokyo, Japan, [3]Department of Biological Sciences, Tokyo Institute of Technology, Yokohama, Japan.

Tributyltin is used mainly as antifoulants on ships and fishnets, as wood preservatives, and as biocides for cooling systems, and is an endocrine disruptor for many wildlife species. The formation of bone is easily influenced by the exposure of osteoblasts and osteoclasts to chemical compounds. However, information on the effects and action mechanisms of environmental contaminants in the modeling and remodeling of mammalian bone is not fully available. We examined the effects of butyltin compounds on bone formation. When tributyltin chloride (TBT) (1 mg/kg body weight) was administered subcutaneously to pregnant mice at 10, 12, and 14 days post coitus, fetuses at 17.5 days post coitus revealed the inhibition of calcification of supraoccipital bone. In contrast, monobutyltin trichloride (MBT) did not affect the fetal skeleton. Therefore, we examined the effects of TBT and its metabolites (dibutyltin dichloride, DBT, and MBT) on bone metabolism using rat calvarial osteoblast-like cells (ROB cells). Animals were treated and maintained in accordance with

ethical guidelines and approved by the Tokyo Institute of Technology and Tokyo Women's Medical University animal protocol. The viability of ROB cells was not affected by the exposure of the cells to 10^{-10} M to 10^{-7} M TBT. However, TBT reduced the activity of alkaline phosphatase (ALPase) and the rate of deposition of calcium of ROB cells. In addition, the expression levels of ALPase mRNA and osteocalcin, which are markers of osteoblastic differentiation, were depressed by the treatment with TBT. TBT inhibited ALPase activity and the deposition of calcium to a greater extent than did DBT. MBT had no effect on the osteoblast differentiation of ROB cells. Tributyltin is known to inhibit the activity of aromatase. However, the aromatase inhibitor aminoglutethimide did not reproduce the inhibitory effects of TBT on osteoblast differentiation. In contrast, we found that this compound increased the level of intracellular calcium of osteoblasts. Our findings indicate that TBT might have critical effects on the formation of bone both *in vivo* and *in vitro* although its action mechanism is not clarified.

T Cell Cytokines Synergistically Induce Human Mesenchymal Stem Cells Into The Osteoblast Phenotype Via A p38 MAPK Regulated Induction Of Autologous BMP-2. L. Rifas. Department of Pediatrics, Washington University School of Medicine, St. Louis, MO, USA.

T cells have been linked to increased bone formation in inflammatory diseases as well as heterotopic bone formation in fibrodysplasia ossificans progressiva. We tested the hypothesis that human activated T cells (ACT) induce mesenchymal stem cells (BMSC) into differentiated osteoblasts. We have previously demonstrated that ACT conditioned medium (ACTTCM) induces the osteoblast phenotype in BMSC. We now report that ACTTCM induces BMSC to produce BMP-2, a potential autocrine mechanism for the observed differentiation process. ACTTCM induced BMP-2 in a time dependent manner over a 48 hr period. The active principle of ACTTCM was found to be a mixture of four cytokines at physiological levels: TNF-α (120 pg/ml), TGF-β (300 pg/ml), interferon-gamma (IFN-γ, 6 ng/ml) and IL-17 (2 ng/ml) (TTII). TTII, like ACTTCM, induced autologous BMP-2, osteoblast specific genes and mineralization of matrix. Combinations of up to three of the cytokines failed to induce BMP-2 above control levels while a combination of all four cytokines synergistically induced BMP-2 10-fold as assessed by ELISA. IFN-γ appeared to be the key cytokine for synergism. BMSC were pre-incubated in the absence or presence of a specific inhibitor of p38 MAP kinase, SB203580 (1-20μm), prior to 24 hr cytokine(s) treatment. SB203580 completely inhibited BMP-2 production even at the lowest dose. Incubation of BMSC for 21 days in the absence or presence of SB203580 and TTII resulted in induction of alkaline phosphatase and matrix mineralization in only the TTII alone treated cultures. Gene array analysis (Affymetrix U133 Plus 2.0) revealed that BMP-2 gene expression was absent in control cells but was induced by TTII within 24 hrs. Also significantly up-regulated were OSF-2, Wnt5A, osteopontin, osteonectin, osteoprotegerin, collagen type I, cadherin 11, connexin 43, C/EBPβ and interferon responsive genes, including IRF-1 (22-fold), known to enhance cytokine synergistic actions. We demonstrate, for the first time, that four T cell cytokines, TNF-α, TGF-β, INF-γ and IL-17, at physiological levels, can act synergistically to induce BMSC into the osteoblast phenotype via induction of autologous BMP-2. These data indicate that in inflammatory diseases, activated T cell cytokines may initiate accelerated bone formation and/or heterotopic bone formation by inducing mesenchymal stem cells into the osteoblast phenotype.

Ghrelin in Acylated and Unacylated Form Is an Autocrine Stimulator of Osteoblast Proliferation via the MAP- and PI3-kinase Pathways but not via Its Cognate Receptor GHS-R1a. B. C. J. van der Eerden[1], P. J. D. Delhanty*[1], C. Gauna*[1], H. A. P. Pols[1], H. Jahr*[2], H. Chiba*[3], A. van der Lely*[1], J. P. T. van Leeuwen[1]. [1]Internal Medicine, Erasmus MC, Rotterdam, Netherlands, [2]Orthopedics, Erasmus MC, Rotterdam, Netherlands, [3]Pathology, Sapporo Medical University School of Medicine, University of Sapporo, Japan.

Ghrelin is a 28 amino acid growth hormone secretagogue originally identified in the oxyntic mucosa of the stomach. Ghrelin is present in two forms: acylated and unacylated (UAG), the latter of which was formerly supposed to be not active but recently shown to have peripheral actions. Ghrelin acts through its cognate receptor, the growth hormone secretagogue receptor 1a (GHS-R1a) but a variant exists (GHS-R1b) believed to be non-functional. Recent evidence suggests that ghrelin has an effect on bone independent of growth hormone. Therefore, we were interested in the expression of ghrelin and both GHS-R1 subtypes as well as the role of ghrelin in human bone osteoblast growth.

As a first inventory, using real-time PCR, we detected ghrelin and GHS-R1b but not GHS-R1a mRNA in human bone biopsy samples. Next, we measured expression of these genes during dexamethasone-induced differentiation of human osteoblasts (SV-HFO cells) and determined the effect of ghrelin and UAG on proliferation. Differentiation is characterized by maximum alkaline phosphatase activity around day 14 of culture and mineralization thereafter up to day 23. Overall, ghrelin mRNA was expressed at higher levels in differentiating than non-differentiating cells, but was not increased during culture in either group. GHS-R1b mRNA expression was low during the first 19 days of culture, but rose significantly during the last phase of mineralization; in differentiating cells reaching 400% (p=0.004) of initial levels by day 23. GHS-R1a mRNA was not detected in human osteoblasts. Cell proliferation was dose-dependently-stimulated by both ghrelin and UAG with a peak of 155-170% at 1 nM and 182% at 10 nM, respectively. The proliferative response to ghrelin and UAG declined with culture time and state of differentiation. The growth effects of ghrelin and UAG were blocked by the inhibitors of ERK activation U0126 and PD98059 as well as PI3 kinase activation, LY294002.

In summary, ghrelin is expressed in human osteoblasts and stimulates osteoblast proliferation in the absence of its cognate receptor GHS-R1a, indicating the involvement of GHS-R1b or a novel ghrelin receptor signaling via the MAPK and PI3-K pathways. In conclusion, these data provide evidence for new autocrine roles and novel signaling mechanisms for ghrelin and UAG in bone.

Enrichment and Characterization of Primitive Mesenchymal Stem Cells from Rat Bone Marrow Stroma. S. Uchida[1], S. Zhang[1], T. Inoue*[2], D. von der Kooy*[2], J. E. Aubin[1]. [1]Medical Genetics and Microbiology, University of Toronto, Toronto, ON, Canada, [2]Surgery, Division of Anatomy, University of Toronto, Toronto, ON, Canada.

Cells identified as mesenchymal stem cells (MSCs) reside within bone marrow stroma, however, significant enrichment and rapid isolation of these cells remains elusive. The purpose of this study was to isolate and characterize MSCs from young adult rat bone marrow stromal cell populations by using their ability to efflux Hoechst dye, i.e., reside in a side population (SP). Freshly isolated total bone marrow or the stromal fraction pre-cultured for 7 days was incubated with Hoechst 33342, then analyzed and sorted on a Moflo sorter. Sorted cells were divided into three groups: SP, non-SP and total unfractionated population (total). To investigate multilineage potential, sorted fractions were cultured at various densities under osteogenic, chondrogenic, myogenic, adipogenic and neurogenic differentiation conditions and analyzed by histo- and immunohistochemistry and quantitative real time PCR for the expression of lineage related marker genes. A very small proportion of total marrow (0.08±0.02%) or of stromal (0.5±0.34%) cells formed a distinct SP. The SP of total bone marrow did not form CFU-O, CFU-ALP or CFU-F in vitro under any of the conditions tested. However, the stromal cell SP cultured for 4 weeks under osteogenic differentiation conditions formed a much higher number of CFU-O (alkaline phosphatase (ALP) and von Kossa positive; 28±7.7 vs 0.7±0.7 vs 0.9±0.6), CFU-ALP (43±5.2 vs 3.4±1.6 vs 5.2±2.8), and CFU-F (15.6±8.2, vs 3.2±1.7 vs 6±2.5) than the non-SP and Total respectively. The stromal cell SP cultured at high density in micromass cultures with TGF-B1 also formed many more Alcian blue-positive, type II collagen-positive cartilage nodules than did the non-SP and Total (24±5.3 vs 5±2 vs 5.2±2.3 respectively). Similarly, under adipogenic conditions, the stromal cell SP formed many more adipogenic colonies than the non-SP and Total (26±5.3 vs 1.3±0.5 vs 4.5±1.9). Growth under myogenic conditions also resulted in the presence of desmin-positive cells and real time PCR confirmed much higher expression of MyoD and MyH6 in the SP compared to non-SP.. In addition to mesenchymal lineage differentiation, stromal SP cells grown under neurogenic conditions gave rise to cells exhibiting a neuronal-like morphology and expressing bIII tubulin and nestin. These findings suggest that the SP of bone marrow stroma is enriched for putative MSCs compared to the non-SP and Total. In conclusion, Hoechst 33342 dye exclusion may be a useful enrichment stratagem for primitive osteoprogenitors and other multi-lineage precursors in bone marrow stroma.

Effect of Platelet-Rich-Plasma on Bone Marrow Stromal Cell Differentiation. T. R. Meury*[1], L. Kupcsik*[1], T. Stoll*[2], M. Alini*[1]. [1]Cell Biology & Biochemistry, AO-Research Institute, Davos-Platz, Switzerland, [2]Biosurgery, Global Synthes, Bettlach, Switzerland.

Platelets contain many important factors involved in wound healing, including PDGF-AA, -AB, -BB, VEGF, IGF, EGF and TGF-β. Platelet-rich-plasma (PRP) is autologous plasma that has a platelet concentration above baseline (~1Mio platelets/μL vs. ~0.2Mio platelets /μL). PRP can be produced from blood by two simple centrifugation steps. The effect of PRP on bone formation during fracture healing *in vivo* is not clear yet. We performed *in vitro* experiments investigating the effect of PRP on bone marrow stromal cell (BMSC) differentiation towards an osteogenic phenotype.

Human blood samples were obtained with patient consent in CPDA-containing monovettes and were centrifuged at 200g for 15min at RT. The plasma supernatant was transferred to a new tube and was centrifuged at 2'000g for 10min at RT. The top 50% of the supernatant (platelet-poor-plasma, PPP) was removed and PRP was produced by resuspending the pellet in the remaining PPP. In order to release its potent factors, PRP needs to be activated. This was done using one of three different methods: addition of bovine thrombin (100U/mL), repeated freeze-thaw cycles (5x) and sonication. After activation, the PRP was centrifuged at 18'000g for 10min at RT and the supernatant, containing just the released factors (PRF = PRP-released factors) and no more cells or cell debris, was used for our experiments. Human BMSCs, obtained with patient consent, were cultured in IMDM, 10%FBS, nonessential aminoacids, β-glycerophosphate and ascorbic acid. These cells were compared to BMSCs cultured in the same media supplemented with 10%(v/v) PRF. In addition, BMSCs grown in media supplemented with 10mM dexamethasone (Dexa) were used as the positive control. BMSCs proliferation was assessed by measuring the DNA content (Hoechst 33258 assay) and osteogenic differentiation was determined by measuring matrix mineralization ($^{45}Ca^{2+}$ incorporation).

BMSCs grown with the addition of Dexa showed mineralization as soon as after 2 weeks culture time, while BMSCs grown without Dexa showed no mineralization. The addition of 10% PRF to BMSCs grown without Dexa resulted in an up to 40x higher matrix mineralization than BMSCs without Dexa. Cells supplemented with 10% PRF also showed 50-75% higher cell number after 2 weeks than BMSCs grown without PRF. There were no significant differences between the three activation methods.

This data suggests that activated PRP has an osteoinductive effect on BMSCs. Activated autologous PRP could be used to enhance bone healing and may provide an alternative to agents like recombinant growth factors, although in vivo application modalities will require further investigations.

Activation of Notch Signaling Enhances BMP-2-Induced Osteoblast Differentiation. T. Tsukazaki[1], M. Nobta*[2], A. Shibata*[1], H. Shindo*[2], A. Yamaguchi[3]. [1]Division of Oral Pathology and Bone Metabolism, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Division of Orthopaedic Pathomechanism, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Division of Oral Pathology, Tokyo Medical and Dental University, Nagasaki, Japan.

Notch receptors and their ligands are components of an evolutionarily conserved signaling pathway that plays an important role in a variety of cellular function, including cell proliferation, differentiation and apoptosis. However, functional involvement of Notch in bone development remains obscure. In this study, we investigated the functional property of Notch signaling in the differentiation of the cultured osteoblastic cells. Real-time PCR confirmed the expression of Notch-1, -2, -3, -4 and their ligands, Delta-1, -2 and Jagged-1, -2 in MC3T3-E1, C3H10T1/2, bone marrow- derived mesenchymal cells and calvaria-derived osteoblasts. Immunohistochemical study with confocal microscopy demonstrated that these molecules were coexpressed in the undifferentiated cells and osteoblasts appeared on bone defect in a fracture model. Transient expression of wild-type and constitutive active intra-cellular domain of Notch1, Delta1 or Jagged1 alone did not affect ALP activity, but stimulated BMP-2- induced ALP activity as well as promoter activity of ALP. Overexpression of these molecules also enhanced the expression of osteocalcin, Runx2 and osterix. Similar results were also obtained by recombinant Delta1 and Jagged1 proteins that were precoated on culture plate. In contrast, Notch inhibitor LY-411,575 and dominant- negative extracellular domain of Notch1 resulted in an inhibition of BMP-2- induced osteoblast differentiation. The inhibition of endogenous expression of Notch1 by siRNA also blocked not only ALP activity but also Id-1 promoter activity. These results indicate that Notch/Delta, Jagged signaling system plays an important role for osteoblast differentiation. In particular, Notch signaling appears to be essential for BMP-2- induced osteoblast differentiation.

Expression of the Human Urea Transporter HUT11 in Comparison to the Adipogenic Marker aP2 in Subpopulations of Primary Human Osteoblasts. A. Kluever*, M. L. Ponce*, M. Hüfner*, H. Siggelkow. Gastroenterology and Endocrinology, University Hospital of Goettingen, Göttingen, Germany.

Osteoporosis and age related osteopenia are associated with an increase in marrow adipose tissue that correlates with decreased trabecular bone volume. The Human Urea Transporter HUT11 was identified as a gene expressed in primary human trabecular osteoblast precursors which is downregulated as these cells undergo adipogenesis following combination treatment with dexamethasone and 3-isobutyl-1-methylxanthine. HUT 11 is supposed to mark the switch from the osteoblastic to the adipocytic phenotype.

HUT11 gene expression was investigated in a AP negative subpopulation of primary human osteoblasts isolated by magnetic cell sorting and grown under varying osteogenic differentiating conditions. In all experiments the expression of the adipocytic marker gene aP2 (Fatty Acid Binding Protein) was measured simultaneously. Osteocalcin expression served as a marker of advanced osteogenic differentiation. Cells were grown to preconfluence and stimulated for 2 and 7 days with a combination (OF) of beta-glycerophosphat (2mM), ascorbate (50 g/ml), dexamethasone (10^{-8} M), $1,25(OH)_2D_3$ (10^{-8} M) and either TGF-β 1 (1 ng/ml) or BMP-2 (50 ng/ml). The mRNA expression was determined by semiquantitative RT-PCR using an internal standard. In addition unselected osteoblast-like cells were incubated with single factors for 24 h at day 3 and day 27 in culture.

Under basal conditions HUT11 mRNA was maximally expressed and decreased about 70% under all differentiating conditions. Under control conditions aP2 gene expression was low. OF+BMP-2 after two days stimulated aP2 gene expression maximally when also osteocalcin expression was high. In contrast, the addition of TGF-β inhibited the induction of aP2 gene expression by OF. When testing the single factors for 24 h at day 3 and day 27 of culture HUT11 expression was significantly increased by Vitamin C, TGF-β and BMP-2 at day 4 in culture whereas at day 28 TGF-β showed a significant decrease. aP2 expression was very low under all conditions tested at day 4 but increased maximally at day 28 after Dex stimulation. In conclusion, we can confirm a reciprocal relationship between HUT11 and aP2 mRNA expression in osteoblast-like cells. However, we used osteogenic differentiation conditions in contrast to the adipogenic conditions investigated before. We propose two possible explanations for this phenomenon. 1. there is a heterogeneous behaviour of cells under stimulation developing partly to osteoblasts and partly to adipocytes or 2. aP2 mRNA expression under theses conditions is not representative for an adipocytic phenotype because osteocalcin expression increased in parallel.

Disclosures: ***H. Siggelkow****, None.*

PTH Simultaneously Inhibits Cell Proliferation and Apoptosis in Early Primary Osteoblast Cultures. Y. Wang, Y. Liu*, D. W. Rowe. University of Connecticut Health Center, Farmington, CT, USA.

Previously we have shown that primary calvarial osteoblast cultures derived from mice transgenic for stage-specific GFP marker genes respond to an early PTH treatment (day 1-7) with an increase in the expression of fluorescent markers and formation of mineralized bone nodules in the end of cultures at day 21. However, results of DNA quantitation showed that DNA content in PTH-treated cultures was not increased and excluded the speculation that this early PTH treatment stimulates cell proliferation. The purpose of present study was to analyze the effect of PTH on cell proliferation and apoptosis in GFP-marked osteoblast cultures during the first 7 days. Calvarial osteoblasts isolated from mice transgenic for pOBCol3.6GFP, which is activated in the preosteoblast stage, were plated on chamber slides or 6-well dishes and cultured with 25 nM PTH for 7 days. Cell proliferation was analyzed in chamber-slide cultures using a fluorescent BrdU-labeling method. Cell viability was visualized by staining of cultures with EthD-1, a red-fluorescent dead-cell indicator with high affinity for DNA and low membrane permeability. Apoptosis was determined by FACS analysis of cells stained with 7-AAD, a DNA dye that is excluded by live cells. 7-AAD not only stains the dead and late apoptotic cells but also penetrates into early apoptotic cells due to alterations in cell membrane integrity. By day 7 of treatment, the intensity of pOBCol3.6GFP signal was decreased in PTH-treated cultures. In agreement with a decrease in DNA content measurement, BrdU-labeling showed a 25% reduction in the number of cells incorporating BrdU in PTH-treated cultures. BrdU-labeled cells were observed in both GFP(+) and GFP(-) subpopulations but whether a difference in the labeling index between GFP(+) and GFP(-) cells is yet to be determined. In PTH-treated cultures, there was less EthD-1 staining associated with a 23% decrease of apoptosis in the FACS analysis of 7-AAD suggesting that an improvement in cell survival compensates for the reduction in cell proliferation. Preliminary data in the concurrent FACS analysis of GFP and 7-AAD revealed that the PTH-mediated inhibition of apoptosis was more prominent in GFP(+) cells. Because a higher proportion of progenitor population acquires the ability to produce a mineralized matrix as a consequence of the early 7-day exposure to PTH, we suggest that a change in differentiation fate is occurring during the treatment period. The increase in cell survival associated with decrease in both GFP intensity and cell proliferation appears to be a manifestation of the reprogramming effect of PTH on the progenitor population to achieve a full osteoblast differentiation.

Molecular Mechanism of Retinoic Acid Stimulation of Osteoblastogenesis and Inhibition of Adipogenesis. K. Hisada*[1], K. Hata*[1], F. Ikeda[1], T. Matubara[1], F. Ichida*[1], H. Yatani*[1], A. Yamaguchi[2], R. Nishimura[1], T. Yoneda[1]. [1]Dept Biochem, Osaka Univ Grad Sch Dent, Suita, Japan, [2]Dept Pathol, Tokyo Medic and Dent Univ Grad Sch, Tokyo, Japan.

Vitamin A has been long implicated in skeletal development and morphogenesis. Deficiency or excess of vitamin A causes skeletal malformations in newborns or increases fracture risk in adults. Previous studies have shown that retinoic acid (RA), which is a physiologically potent metabolite of vitamin A, stimulates osteoblastogenesis and inhibits adipogenesis. Since osteoblasts and adipocytes originate from the common mesenchymal stem cells, these results suggest that RA plays a role in the commitment of the mesenchymal stem cell differentiation. Here, we studied the molecular mechanism responsible for controlling the mesenchymal stem cell differentiation by RA. To approach this, we firstly determined the effects of RA on osteoblastogenesis using the pluripotent mesenchymal cell line C3H10T1/2 which differentiates to osteoblasts by BMP2 treatment. RA alone induced osteoblast differentiation by elevating ALP activity in C3H10T1/2 cells. This action of RA was enhanced in the presence of BMP2, suggesting functional interactions between RA and BMP2. Consistent with this notion, RA-stimulated ALP activity was increased by overexpression of BMP2-specific signaling molecules Smad1 and Smad4 and RA promoted transcriptional activity of these Smads. Since Runx2 is an essential transcription factor for osteoblast differentiation and is a down-stream molecule of the BMP2/Smad signaling, we determined the relationship between RA and Runx2. Contrary to our expectation, RA did not influence the expression and function of Runx2 and a dominant-negative mutant of Runx2 did not affect the osteobalstogenic activity of RA. Furthermore, RA induced ALP activity in Runx2-deficient calvarial mesenchymal cells. We then examined the effects of RA on adipocyte differentiation using the preadipocytic cell line 3T3-F442A which differentiates to mature adipocytes by insulin treatment. Adipocyte differentiation of 3T3-F442A cells by insulin treatment was inhibited by RA. Furthermore, RA markedly inhibited adipocyte differentiation induced by the overexpression of C/EBPβ or PPARγ, both of which are known to play an important role in adipocyte differentiation. RA inhibited the expression of PPARγ and also blocked C/EBPβ-induced PPARγ expression. In conclusion, our data suggest that RA stimulates osteoblastogenesis in cooperation with Smad but independent of Runx2 and inhibits adipogenesis through suppressing C/EBPβ and PPARγ. RA regulates the commitment of mesenchymal stem cell differentiation to osteoblasts and adipocytes at transcriptional levels.

Bone Fetal Cells for Tissue Engineering. M. Montjovent*[1], N. Burri*[2], S. Mark*[3], C. Scaletta*[2], P. Zambelli*[4], D. Pioletti[1], L. Applegate*[2]. [1]Laboratoire de Recherche en Orthopédie, EPFL, Lausanne, Switzerland, [2]Department of Obstetrics, Laboratory of Fetal Medicine, CHUV Lausanne, Switzerland, [3]Ludwig Institute for Cancer Research, Lausanne Branch, University of Lausanne, Epalinges, Switzerland, [4]Hôpital Orthopédique de la Suisse Romande, Lausanne, Switzerland.

For clinical bone transplantations, tissue engineering techniques based on the delivery of cells to the defect using scaffold materials are currently investigated. Part of the project "Lausanne Association for Bone Tissue Engineering" consists of evaluating the possible use of human fetal bone cells for tissue repair. The aim of this work was to characterize these cells biologically with respect to the induction of their osteoblastic phenotype. Results were compared with adult bone cells. Fetal bone cells obtained from a 16 weeks old fetus were treated with ascorbic acid 50µg/ml and β-glycerophosphate 1mM, with or without additional dexamethasone 10^{-8}M and Vitamin D3 10^{-8}M. Proliferation and ALP enzymatic activity were determined during a 12 days time course, and in vitro mineralization was followed every week by von Kossa staining. The generation time of fetal bone cells was estimated to be 27 hours, whereas this value was significantly higher for adult bone cells and clearly age dependent. Fetal bone cells receiving the differentiation mix showed a strong induction of ALP activity after 4-6 days of treatment. This observation was also verified at a higher passage number. Adult cells showed a lower induction of ALP enzymatic activity. Extracellular matrix analysis demonstrated that fetal bone cells were able to mineralize even without treatment, but the differentiation mix did strongly increase this phenomenon. In this study, we showed that human fetal bone cells posses a high proliferate potential and are able to differentiate into osteoblasts. Now, further investigations are necessary to test the possible use of these cells in a bone tissue engineering model.

1,25(OH)2D3 Regulates Wnt Signaling Pathway in Osteblast-like MC3T3-E1 Cells. Y. Shi*, L. E. Worton*, J. A. Eisman, E. M. Gardiner. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Wnt signaling pathway regulates cell proliferation, differentiation and embryonic development. Recently several lines of evidence indicated that the Wnt pathway is involved in bone biology. Also, 1α,25-dihydroxyvitamin D_3[1,25$(OH)_2D_3$] ,the active metabolite of vitamin D, regulates gene expression through vitamin D receptor (VDR), and has been recently shown to interact with ß-catenin and alter Tcf-mediated transcription in some colon cancer cell lines The present study examined the regulation of the Wnt/ ß -catenin pathway in osteoblast-like MC3T3-E1 cell line.

In this study, Treatment of MC3T3-E1 cells, transiently transfected with a VDR expression vector and the ß -catenin/Tcf responsive TOPFLASH reporter construct, with 1,25$(OH)_2D_3$ caused a dose-dependent repression of ß-catenin/Tcf activity. LiCl (5 to 20mM) activated Tcf activity in a dose-response manner. However, treatment with both 1,25$(OH)_2D_3$ and LiCl reduced Tcf activity even further. In long term mineralizing culture, continuous treatment with 1,25$(OH)_2D_3$(10nM) reduced cell density and slowed cell differentiation, as evidenced by reduced alkaline phosphatase, Von Kossa and Alizarin red staining patterns. Continuous exposure to LiCl also reduced differentiation but, unlike 1,25$(OH)_2D_3$ treatment, was associated with increased cell density. Furthermore, combined treatment with both 1,25$(OH)_2D_3$ and LiCl reduced cell density effect of LiCl, and reduced differentiation compared to either treatment alone. In a 16-day proliferation study, 1,25$(OH)_2D_3$ inhibited cell proliferation dose-responsively in terms of viable cell number and BrdU incorporation, with no change in the proportion of viable cells. LiCl (10mM) had viable cell numbers comparable to vehicle. Surprisingly, combined treatment with 1,25$(OH)_2D_3$ and LiCl brought the viable cell number even lower. Thus our overall results, as previously observed in some colon cancer cell lines, suggest a functional interaction in osteoblasts between 1,25$(OH)_2D_3$ and Wnt response pathways, perhaps through ß -catenin.

TRAIL Regulates Osteocyte-Osteon Structure by Removing Connexons. Y. Li*, C. W. Borysenko, T. Lehmann*, A. Wells*, S. E. Kalla*, V. García Palacios*, H. C. Blair. Pathology, University of Pittsburgh, Pittsburgh, PA, USA.

Bone-synthesizing osteoblasts express Death Receptor-5 (DR5, TRAIL-R2), but do not die when exposed to its ligand, TNF-related apoptosis inducing ligand (TRAIL). Osteoblasts function in multicellular units, osteons, organized by intracellular connections. We previously found that TRAIL markedly reduced intracellular connections in MG63, a human osteosarcoma. Here, we studied how TRAIL affects osteoblast connectivity and cell differentiation in nontransformed osteoblasts. Dye diffusion after microinjection of lucifer yellow showed that serum starvation induced formation of osteon-like cell groups, but that TRAIL eliminated these almost entirely; an osteoblast TNF-family protein, RANKL, and an unrelated cytokine, IL-1, did not affect dye diffusion. The key protein of the gap junction, connexin43 (CX43), forms connexons of hexamers in adjacent cells. Immune localization of CX43 showed increased gap junctions in response to serum starvation, but a dramatic reduction of gap junctions by TRAIL. Doublet-discrimination flow cytometry of cells detached using EDTA showed that physical connectivity was increased by serum starvation but reduced by TRAIL, while control cytokines including TNFα, for which osteoblasts also bear receptors, did not affect connectivity. The osteoblastic actin cytoskeleton was rearranged by starvation, decreasing filamentous actin, although actin quantity was unaffected on Western analysis. However, TRAIL reduced CX43 protein quantity relative to actin. In contrast, real-time PCR showed that CX43 transcription increased with serum starvation; TRAIL and other cytokines did not affect CX43 mRNA. Cell cycle analysis showed that TRAIL decreased cells in S-phase by 80% with a parallel increase in G2, indicating that TRAIL arrests the osteoblast cell cycle. After removal of TRAIL, cells re-established normal morphology and osteoblastic features including alkaline phosphatase per cell, but cell number did not increase as in controls post washout, suggesting that TRAIL terminates osteoblast proliferation. We conclude that DR5 rearranges osteoblast shape with post-transcriptional CX43 degradation, and arrests cell division. TRAIL is expressed in both osteoclasts and osteoblasts, and thus may function during bone degradation, where portions of bone are disconnected for partial degradation of living osteons, of when the bone formation cycle ends.

Connective Tissue Growth Factor (CTGF) Is a Downstream Mediator of Transforming Growth Factor-Beta 1 (TGF- β1) in Osteoblasts. J. A. Arnott*[1], E. Nuglozeh*[1], M. C. Rico[1], T. A. Owen[2], F. F. Safadi[1], S. N. Popoff[1]. [1]Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, [2]Pfizer Global Research and Development, Groton, CT, USA.

Connective tissue growth factor (CTGF) is a cysteine rich, extracellular matrix-associated protein that is a member of the CCN family involved in multiple cellular events including skeletogenesis. Recently CTGF was discovered to be highly expressed in bone, specifically osteoblasts. In osteoblast cultures, CTGF acts as a modulator of osteoblast differentiation, regulating proliferation and terminal differentiation. TGF-β1 is a potent multifunctional cytokine that is known to play a major role in bone development and to regulate cellular functions in osteoblasts including proliferation and collagen synthesis. It is well established that TGF-β1 is a potent inducer of CTGF expression in fibroblasts, mesangial cells and chondrocytes. In studies using fibroblasts, CTGF mediates TGF-β1-induced biological activities including proliferation and extracellular matrix (ECM) production. In these systems, SMAD signaling is critical for TGF-β1 induction of CTGF. The relationship between TGF-β1 and CTGF in osteoblasts has not been investigated. This study focuses on CTGF as a downstream mediator of TGF-β1-induced effects in osteoblasts and the requirement of SMAD signaling for this modulation. Using primary osteoblast cultures derived from neonatal rat calvaria, we demonstrated that treatment with TGF-β1 (5ng/ml) increased CTGF expression at the protein and mRNA level during the proliferative (day 7), matrix deposition (day 14) and mineralization (day 21) phases of the culture. This increase in CTGF was time-dependent with maximal CTGF expression occurring at 16 hours post-treatment with TGF-β1. Interestingly, we also observed that the up-regulation of CTGF occurs concurrently with the activation of SMAD-2, and inhibition of SMAD-2 activation significantly decreased up-regulation of CTGF expression. These results link the induction of CTGF expression by TGF-β1 to this SMAD signaling pathway in osteoblasts. RNAi generated against CTGF was able to knock down CTGF expression in TGF-β1-treated osteoblasts by 80-90% as demonstrated by Western blot analysis. Further studies are aimed at; 1) evaluating the levels of activated SMAD-2 in osteoblasts treated with RNAi, and 2) examining the functional consequences of inhibiting CTGF expression with RNAi on TGF- β1-induced osteoblast proliferation and extracellular matrix (ECM) deposition.

The Effects of Nicotine on Human Osteoblasts Responding to Implant Materials. L. Li*, A. Jhaveri*, G. Gronowicz, H. Zhang*. University of Connecticut, Farmington, CT, USA.

The use of osseointegrated implants for missing teeth has become the standard of care in prosthetic dentistry. Smoking can impair wound healing and is one of the risk factors in dental implants failure. No studies have been performed on the effects of smoking on osseointegration at a cellular level to understand the mechanisms of failure. Nicotine is one of the major toxic by-products in cigarette smoke. Therefore, we studied the effects of nicotine on the function of osteoblasts on dental implant materials. Saos-2 (human osteosarcoma cells) and primary human osteoblasts (HOBs) from healthy non-smokers were used in the osteoblast/implant in vitro culture system, with and without the presence of nicotine. Based on previous studies, after smoking one cigarette, the human serum nicotine concentration is about 10^{-7} M. Therefore, the dose of nicotine used in this study was 10^{-9} M to 10^{-6} M. Titanium implant disks were used and the surface is the same as clinical implants. Attachment, proliferation, differentiation and mineralization of osteoblasts on implant disks were assessed.

At 4 hr, nicotine treatment (10^{-7} M) significantly increased the number of attached Saos-2 cells on implant surface but had no effect on HOBs. Proliferation rates for both Saos-2 and HOBs were not affected by nicotine treatment (10^{-7} M) over 1-5 days measured by cell number counting. [^{3}H] thymidine incorporation at 24 hr with wider range of nicotine concentrations (10^{-9} to 10^{-6} M) also showed no significant difference between treatment groups and control. Differentiation of human osteoblasts on implant surface was determined by alkaline phosphatase (ALP) activity assay. Nicotine inhibited ALP activity in a dose-dependent manner for both cell types. Long-term (2 wk and 4 wk) mineralization assay demonstrated a decrease in calcium content (about 30% less) in osteoblast/implant cultures with the presence of 10^{-7} M nicotine in the medium. In conclusion, nicotine had some effect on osteoblast attachment to the implant surface, no effect on proliferation but inhibited differentiation and mineralization of osteoblasts on the implant surface. The data suggest that smoking related implant failures might be caused by the nicotine-mediated decreased ability of osteoblasts to differentiate and mineralize on the implant surface.

Adrenocorticotrophic Hormone Modulates Adipocyte And Osteoblastic Cell Differentiation. S. Sridhar[1], Q. Zhong[2], J. Xu*[1], R. J. Bollag*[1], W. Bollag*[1], C. M. Isales[2]. [1]Institute of Molecular Medicine and Genetics, Medical College of Georgia, Augusta, GA, USA, [2]Medicine, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA.

We have previously demonstrated the presence of melanocortin receptors in osteoblastic-like cells. Melanocortin receptors are activated by peptides derived from processing of a larger prohormone, pro-opiomelanocortin (POMC) which include hormones such as adrenocorticotrophic hormone (ACTH) and melanocyte stimulating hormone (MSH). In addition, we have shown that POMC derived fragments such as ACTH can be synthetized and released from osteoclastic cells which then stimulate osteoblastic cell proliferation. Osteoblasts and adipocytes are derived from the same mesenchymal stem cell precursor, preliminary gene microarray experiments demonstrated an effect of ACTH on multiple genes involved in cell differentiation. In an effort to further define ACTH effects on cell differentiation we utilized an osteoblastic cell line MC3T3 and a pre-adipocytic cell line 3T3-L1. MC3T3 cells in culture were stimulated with either 1 or 100 nM ACTH (1-24) and gene expression for the osteoblastic markers Runx2, osteocalcin and alkaline phosphatase measured sequentially over ten days by RT-PCR and quantitated by comparing to the housekeeping gene GAPDH. At the end of the ten days of culture either 1 or 100 nM ACTH downregulated both Runx2 and osteocalcin by over 50% while there was no effect on alkaline phosphatase. In contrast, when the adipocytic gene markers lipoprotein lipase (LPL) or stearoyl Coa desaturase (SCD) were measured at the end of ten days in MC3T3, either ACTH 1 or 100 nM increased their expression by over four-fold (adipocytic gene markers were initially undetectable in MC3T3). ACTH had no effect on another adipocyte marker, adipsin.

In 3T3-L1, ACTH 1-24 had no effect on the expression of either Runx2 or osteocalcin while upregulating the expression of LPL (two-fold), SCD (two-fold) and adipsin (ten-fold) at the end of ten days. Similarly, if another osteoblastic cell line, MG63, was utilized and incubated with 10 nM ACTH (1-24) for six days there was a large increase in lipid droplet development as assessed by congo red staining.

Taken together these data demonstrate that ACTH facilitates the maturation of the preadipocytic cell line 3T3-L1 into a more mature fat cell phenotype while promoting the conversion of osteoblastic cells into a more adipocytic phenotype.

Aortic Valve Myofibroblast Cell Undergoes Differentation to an Osteoblast Cell Independent of Osteoclastogenesis. M. Subramaniam[1], H. Hirotani*[2], F. Secreto[1], P. Stern[2], T. C. Spelsberg[1], N. M. Rajamannan[3]. [1]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [2]Molecular Pharmacology, Northwestern University, Chicago, IL, USA, [3]Cardiology, Northwestern University, Chicago, IL, USA.

Calcific Aortic Stenosis is thought to be a passive phenomena. We hypothesize that the mechanism is not passive but instead an active osteoblast differentiation process. We tested whether in vitro myofibroblast cells can undergo osteoblastogenesis and not osteoclastogenesis as a possible mechanism for mineralization. We isolated porcine aortic valve myofibroblasts expressing alpha actin and tested them with growth factors to determine if these cells develop osteoblast characteristics and form calcified nodules. When these cells were differentiated in culture by the addition of TGFb and dexamethasone, they express osteoblast markers and alkaline phosphatase. Alkaline phosphatase activity increased three-fold over control ($p<0.05$) in the TGBb + dexamethasone cells as compared to the controls. Bone-like nodules developed after 27 days in culture with treatment of TGFb and dexamethasone. Distribution of hydroxyapatite coincided with the area of calcium detected by analyzing nodules with cytochemical Von Kossa staining. Finally, semi-quantitive RT-PCR indentified genes specific to osteoblast differentiation. RT-PCR of the mRNA revealed an increased level of mRNA for osteopontin, bone sialoprotein, osteocalcin and Cbfa1 compared to control myofibroblasts that has been treated with vehicle. The responses of these markers indicate the transformation of myofibroblasts to osteoblast-like cells involved in a calcification process analogous to osteoblastogenesis. To determine if myofibroblast cells have an osteoblast-like ability to support osteoclast precursor differentiation, they were cultured with RAW 264.7 monocyte/macrophage precursor cells. The co-cultures were untreated or treated with 30 nM parathyroid hormone (PTH). Co-culture with RAW cells, with or without PTH, resulted in increased TRAP activity, demonstrating that myofibroblast cells act like osteoblasts by activating RANK on the RAW 264.7 cells. TRAP positive multinucleated cells were not detected in the cultures. Culture of the myofibroblast cells alone, or with PTH, or with M-CSF (20 ng/ml) and RANKL (50 ng/ml) failed to increase TRAP activity. In conclusion, these results suggest that dexamethasone and TGFb promotes osteoblastic differentiation in valve myofibroblast cells and TGFb may play a role in the phenotypic conversion of the myofibroblast cell to an osteoblast-like phenotype.

Hormonal Regulation Of Melanocortin Receptor Expresssion In Osteoblastic Cells. C. M. Isales. Medicine, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA.

Melanocortin receptors belong to the seven transmembrane domain, G-protein coupled family of receptors and are widely expressed in the body. We have previously reported that all five melanocortin receptors are expressed to varying degrees in osteoblastic cells. These receptors are activated by fragments derived from a larger molecule, pro-opiomelanocortin (POMC) and include: ACTH, alpha, beta and gamma MSH, and beta endorphin. We have further shown that bone-derived osteoclasts have the ability to synthetize, process and secrete POMC-derived fragments including ACTH suggesting the existence of a paracrine loop in the bone.

In an effort to gain an understanding of the regulation of the melanocortin receptors we utilized the osteoblastic-like cells MG63. MG63 cells were grown to confluence and incubated in the presence of estradiol (1 or 100 nM), dexamethasone (1 or100nM), alpha-MSH (1 or100nM), beta-MSH (1 or100nM), gamma-MSH (1 or100nM), beta-endorphin (1 or100 nM) or ACTH (1 or 100 nM) for six hours and melancortin receptor mRNA expression assessed by Northern blots. We found that MC1R message was significantly upregulated by estradiol, dexamethasone, alpha MSH, beta MSH, gamma MSH, beta endorphin and ACTH. In contrast MC2R was upregulated by estradiol, dexamethasone, alpha MSH, ACTH and beta endorphin and MC5R was significantly upregulated by alpha MSH and ACTH. Expression of either MC3R and MC4R was not changed by any of the hormonal manipulations.

Thus, regulation of melanocortin receptors in osteoblastic-like bone cells is a complex process in which the melanocortin receptor(s) appears to be upregulated by its own ligand.

Transgenic Mice Over-expressing Bone Morphogenetic Protein-2 Inducible Kinase Have Reduced Bone Mass. A. E. Kearns, D. G. Fraser*. Division of Endocrinology, Mayo Clinic, Rochester, MN, USA.

An understanding of mechanisms regulating osteoblast differentiation and function is critical to gain insight into the pathogenesis of osteoporosis. We have previously identified a novel bone morphogenetic protein-2 (BMP-2)-inducible kinase (BIKe) associated with osteoblast differentiation. Over-expression of BIKe inMC3T3-E1 cells decreased alkaline phosphatase activity, osteocalcin expression, and mineralization, which indicates it functions to modulate osteoblast differentiation. We now report the in vivo effect of over-expression of BIKe in osteoblasts of mice. The full coding region of BIKe with an additional FLAG epitope tag on the 3' end was placed under the control of the 3.6-kb alpha1(I)-collagen promoter. Pronuclear injections of the transgene construct into fertilized oocytes of FVB/Cr mice were performed. Transgenic mice were identified among the offspring by Southern blot analysis of mouse tail genomic DNA. All transgenic mice demonstrated germline transmission of the transgene, and appeared normal in growth, weight and fertility. Transgene expression was verified by immunohistochemistry of calvaria using anti-FLAG antibodies. Bone mineral density was measured in adult mice at 20 weeks of age. Transgenic animals had significantly lower bone density of the whole body, vertebrae, and femur by DEXA than wild type animals, although the effect was modest (10-15%). Trabecular bone density was also significantly lower by pQCT measurements. Preliminary data from mice at 10 weeks of age did not show a significant difference between wild type and transgenic animals. Initial bone histomorphometry (n=5 in each group) does not show a mineralization defect. We conclude that over-expression of BIKe in vivo results in modest reduction of bone density by 20 weeks of age, without apparent mineralization defect. This suggests that BIKe over-expression in vivo may affect osteoblast function, as we found with in vitro experiments. The mechanism of this effect requires further investigation.

Lactoferrin - Mechanisms Of Actions In Bone Cells. J. Cornish, A. B. Grey, D. Naot, K. E. Callon*, I. R. Reid. Medicine, University of Auckland, Auckland, New Zealand.

Lactoferrin is an iron-binding glycoprotein that belongs to the transferrin family and is present in milk, other exocrine secretions, and in the circulation. We have previously reported that lactoferrin, at physiological concentrations, stimulates the mitogenesis, differentiation and survival of osteoblasts in vitro. In addition, the local injection of lactoferrin in mice calvaria increases new bone formation in vivo.

We now report that the mitogenic effects of lactoferrin in osteoblast-like cells are mediated through LRP1, a member of the LDL receptor-related family (LRP) of proteins. The specific LRP inhibitor, RAP, inhibits the activation of p42/44 MAPK signalling and the induction of cell proliferation by lactoferrin in primary rat osteoblasts and SaOS2 cells. Lactoferrin-induced osteoblast proliferation is also blocked by an antibody to LRP1. Expression of dominant negative Ras abrogates the ability of lactoferrin to activate p42/44 MAPK signalling in SaOS2 cells. In addition, lactoferrin induces PI3-kinase-dependent phosphorylation of Akt, a critical regulator of cell survival, which may mediate the anti-apoptotic actions of lactoferrin.

Lactoferrin is seen to be endocytosed by primary rat osteoblasts, using confocal laser scanning microscopy. The addition of labelled lactoferrin results in an intracellular vesicular pattern of staining, characteristic of endocytosis. Co-staining with a membrane dye (DiI) reveals co-localisation of lactoferrin with intracellular vesicular structures. Inhibition of endocytosis (using a hypertonic medium or placing the cells at 4°C) results in the absence of intracellular lactoferrin. RAP also blocks lactoferrin endocytosis. Studies using ^{125}I-lactoferrin demonstrate that lactoferrin binds specifically to osteoblastic cells and is internalized by a RAP-sensitive mechanism. However, the signalling and endocytic functions

of LRP1 are independent of each other, since lactoferrin can activate mitogenic signalling in conditions in which endocytosis is inhibited.
In addition to the anabolic effects of lactoferrin in osteoblasts, lactoferrin dose-dependently decreases osteoclastogenesis in mouse bone-marrow cultures, and this is associated with decreased expression of RANKL. We conclude that lactoferrin has powerful anabolic, differentiating and anti-apoptotic effects on osteoblasts, and inhibits osteoclastogenesis. Lactoferrin is a potential therapeutic target in bone disorders such as osteoporosis and may be an important physiological regulator of bone growth.

Cross-Talk Between Cyclic AMP and Intracellular Caclium Signaling Pathways in PTH-responsisve Cells. R. J. Murrills[1], J. J. Matteo*[1], J. L. Andrews*[1], P. Liu*[2], A. Reik*[2], P. D. Gregory*[2], F. J. Bex[1]. [1]Women's Health & Bone, Wyeth Research, Collegeville, PA, USA, [2]Sangamo Biosciences, Richmond, CA, USA.

PTH can activate multiple intracellular signaling pathways in osteoblasts such as the cyclic AMP, intracellular calcium, protein kinase C and MAPK pathways. While the importance of the cyclic AMP pathway is well established, the role of the intracellular calcium pathway, and its relationship with the cyclic AMP pathway is still obscure, particularly at the level of gene transcription. We asked whether activation or inhibition of the cAMP pathway had any influence on PTH's intracellular calcium pathway and also whether the CRE response to PTH and a range of cAMP agonists was enhanced by thapsigargin, a calcium signaling agonist.
We examined intracellular calcium elevation using R45 cells, a 293 cell line stably transfected with an inducible PTH1 receptor, and FLIPR. In these cells thapsigargin (2-10uM) and PTH (100nM) induced a pronounced calcium spike. When cells were pre-incubated for 1 hour with activators or inhibitors of the cAMP pathway, forskolin suppressed the intracellular calcium response to PTH, whereas H-89, a PKA inhibitor, markedly enhanced it. Furthermore, the pattern of calcium influx was modified by H-89, the primary spike being followed rapidly by a secondary spike, suggestive of calcium-induced calcium release. This suggests that PTH1 receptor-mediated intracellular calcium signaling is held under substantial tonic repression by the cAMP pathway.
To examine the effects of calcium signaling on the transcriptional response to cAMP, Saos-2 cells, stably transfected with 15 copies of the CRE linked to a Luciferase reporter, were exposed to test agents overnight, in the presence of thapsigargin, a calcium agonist. While 100nM thapsigargin alone had little effect on the CRE-Luciferase reporter, in combination with all other cAMP agonists, it had a synergistic effect.

cAMP agonist	Fold increase	Fold increase + thapsigargin
Control	1.00	1.8
Forskolin 1uM	15.0	24.9
Forskolin 10uM	27.1	38.8
Rolipram 1uM	4.6	10.2
Rolipram 10uM	8.7	16.6
VIP 1nM	17.7	45.8
Isoproterenol 1uM	18.8	29.9
Isoproterenol 3uM	26.9	34.6

Thapsigargin also had a strong synergistic effect on the CRE response to PTH. From this we conclude that the intracellular calcium signaling pathway synergizes with cAMP agonists on the CRE.
Thus, in contrast to cAMP activation, which has a negative feedback on intracellular calcium signaling by PTH, activation of the intracellular calcium pathway strongly enhances the downstream effects of the cAMP pathway at the level of transcription.

Mechanical Stress Induces the Osteoblast Differentiation and Activates Runx2 and Activator Protein-1 through Diverse MAPK Signal Transduction Pathways. T. Kanno*[1], T. Tsujisawa*[2], W. Ariyoshi*[1], T. Koseki*[3], T. Takahashi*[1], T. Nishihara[2]. [1]Sencond Department of Oral and Maxillofacial Surgery, Kyushu Dental College, Kitakyushu, Fukuoka, Japan, [2]Department of Oral Microbiology, Kyushu Dental College, Kitakyushu, Fukuoka, Japan, [3]Department of Life Long Oral Health Science, Tohoku University, Graduate school of Dentistry, Sendai, Miyagi, Japan.

Mechanical stress (MS) plays a fundamental role to maintain the skeletal mineralization by dictating the cellular and metabolic activity of osteoblastic cells. The bone-specific transcription factor, Runx2 and AP-1 have been thought to be critical factors to regulate the many of osteoblast-specific gene expression and subsequent differentiation through binding to the osteoblast-specific element 2 (OSE2) and AP-1-binding sites. Recent findings revealed that MS activates and phosphorylates the Runx2, followed by up-regulating the osteoblast differentiation through Ras-mediated MAPK pathways. The goal of this study was to evaluate the role of Runx2 and AP-1 in the osteoblast differentiation under the MS conditions. MC3T3-E1 and rat calvarial osteoblastic cells were used in this study. MS up-regulated alkaline phophatase activity and the expression of osteocalcin mRNA. The expression and phosphorylation of Runx2 and AP-1 were detected by RT-PCR and Western blot analysis. Phosphorylation of ERK 1/2 and p38 MAP kinase were found to be significantly activated. ERK 1/2 and p38 MAP kinase were evidently blocked by the MAPK selective inhibitors, U0126 and SB203580, respectively. ERK 1/2 selective inhibitor, U0126 completely blocked the Runx2 and AP-1 activation, however, p38 MAP kinase selective inhibitor, SB203580 did not alter Runx2 phosphorylation but blocked AP-1 activation. In addition, the upstream of p38 MAP kinase was interestingly detected to be up-regulated by MS. Furthermore, RNA interference (RNAi) technique was used to clarify the effect of Ras on the activation of Runx2 and AP-1 in MS-activated oosteoblastic cells. RNAi analysis revealed that ERK signal pathway was apparently inhibited, however, p38 MAP kinase pathway was not. Our results suggest that MS regulates osteoblast differentiation through the induction and activation of diverse MAPK signal transduction pathway and transcription factors, Runx2 and AP-1 in osteoblasts.

Regulation of Human Estrogen Receptor Alpha Transcription by a c-Src/PKC-Dependent Mechanism in Osteoblast-like Cells. M. Longo[1], D. Fortunati*[2], V. De Luca*[3], S. Denger*[4], A. Teti[1], S. Migliaccio[5]. [1]Experimental Medicine, University of l'Aquila, L'Aquila, Italy, [2]Histology and Medical Embriology, University "la Sapienza", Rome, Italy, [3]Pediatric Hospital "Bambino Gesù", Rome, Italy, [4]European Molecular Biology Laboratories, Heidelberg, Germany, [5]Department of Medical Physiopathology, University "la Sapienza", Rome, Italy.

The human estrogen receptor alpha (hERα) gene is driven by several promoters, of which the distal E and F promoters appear specifically active, albeit at low levels, in osteoblast cell lines. In order to identify regulatory pathways affecting hERα expression at the transcription level in the bone tissue, we generated a clone of human osteoblast-like cells SAOS-2 stably transfected with a luciferase reporter gene downstream of the F promoter (SAOS.F-Luc). Over-confluence, a condition whereby cultured osteoblasts acquire a more differentiated phenotype, caused a time-dependent increase of promoter activity in these cells. Over-confluence correlated with marked PKCα de-activation, and generic PKC down-regulation in sub-confluent cells, induced by long-term treatments with PMA (Phorbol 12-Myristate 13-Acetate), also resulted in promoter stimulation at similar levels. Furthermore, treatment of cells with PP1, a specific inhibitor of the non-receptor tyrosine-kinase c-Src, showed that impaired c-Src function, previously shown to enhance osteoblast differentiation, caused a remarkable (~three-fold) increase of promoter activity. Consistently, over-expression of wild-type c-Src resulted in partial promoter inhibition. In PP1-treated cells, enhanced promoter activity was not further increased by PMA. Over-expression of exogenous full-length hERα resulted in modest promoter stimulation, which was insensitive to both estrogen and anti-estrogen treatment. Such effect appeared PKC-independent in that total PKCα expression was not affected by exogenous hERα. The F-promoter contains a putative AP-1 site, but AP-1 activation was virtually unremarkable in over-confluent and PP1-treated SAOS.F-Luc cells as compared to PMA-treated counterparts. Moreover, AP-1 inhibition following treatment with the generic kinase inhibitor DMAP (4-DiMethylAminoPyridine) resulted in a dose-dependent further stimulation, rather than inhibition, of promoter activity in PMA-treated cells. Such stimulation matched a dose-dependent decrease of c-Src activating phosphorylation at its Y416 aminoacid residue. These results point to a strongly PKC/c-Src-dependent and estrogen-independent pathway modulating ERα transcription in osteoblasts, perhaps affecting estrogen responsiveness during osteoblast differentiation.

Phosphophoryn Regulates Osteoblast Differentiation via Integrin Signaling and MAP Kinase Pathway. J. A. Jadlowiec*[1], H. Koch*[2], L. Zhang*[3], P. Campbell*[4], M. Seyedain*[3], C. Sfeir*[3]. [1]Biological Sciences, Carnegie Mellon University, Pittsburgh, PA, USA, [2]Orthopaedic Surgery, University of Greifswald, Greifswald, Germany, [3]Oral Medicine and Pathology, University of Pittsburgh, Pittsburgh, PA, USA, [4]Institute for Complex Engineered Systems, Carnegie Mellon University, Pittsburgh, PA, USA.

Extracellular matrix (ECM) proteins serve as both a structural support for cells and also as a dynamic bionetwork that directs cellular activities. ECM proteins such as those of the SIBLING family (Small Integrin-Binding LIgand Glycoprotein) could possess inherent growth factor activity. Phosphophoryn (exon 5 of dentin matrix protein 3) is a member of the SIBLING family and has been implicated in biomineralization as a nucleator/modulator of crystal formation. In this study, we demonstrate that PP may also have a signaling role. Quantitative real-time PCR technology was used to demonstrate up-regulation of *Runx2*, *Osx* and *Ocn* in primary human adult mesenchymal stem cells (hMSC), a mouse osteoblastic cell line (MC3T3-E1), and a mouse fibroblastic cell line (NIH3T3). Further, PP increased OCN protein production in hMSC and MC3T3-E1. ALP activity and calcium deposition were enhanced in hMSC. An $\alpha_v\beta_3$ integrin-blocking antibody significantly inhibited rPP-induced expression of *Runx2* in hMSC, suggesting that signaling by PP is mediated through the integrin pathway. Our data further shows that PP signals via the MAP kinase pathway; treatment of hMSC with rPP caused activation of the p38 component. These data demonstrate a novel signaling function for PP in regulating the expression of bone gene markers in addition to its hypothesized role in biomineralization. The implication is that PP could be combined with growth factors in novel tissue-engineered approaches for an enhanced therapeutic effect.

Phosphodiesterase Inhibitors Stimulate Osteoclast Formation by Inducing TRANCE Expression in Calvarial Osteoblasts. M. Yim[1], E. Cho*[1], R. Kamijo[2], M. Takami[2]. [1]College of Pharmacy, Sookmyung Women's University, Seoul, Republic of Korea, [2]Department of Biochemistry, Showa University, Tokyo, Japan.

Phosphodiesterases (PDEs) are enzymes that degrade intracellular cAMP. In the present study, 3-isobutyl-1-methylxanthine (IBMX) and pentoxifylline, PDE inhibitors, induced osteoclast formation in cocultures of mouse bone marrow cells and calvarial osteoblasts. These inhibitors induced the expression of the osteoclast differentiation factor TNF-related activation-induced cytokine (TRANCE, identical to RANKL, ODF, and OPGL) in osteoblasts. Induction of TRANCE expression by IBMX was suppressed by a protein kinase A (PKA) inhibitor, H89, an ERK1/2 inhibitor, PD98050, and a p38 MAPK inhibitor, SB203580, suggesting that activation of PKA, ERK and MAPK is involved in TRANCE expression by IBMX. Further, rolipram, a selective inhibitor of PDE4 (a PDE isozyme), also induced osteoclast formation and TRANCE expression. These results suggest that PDE4 is a key regulator of TRANCE expression in osteoblasts, which in turn controls osteoclast formation.

Statins Stimulate Phosphatidylinositol 3 Kinase (PI 3 K) Signaling during Osteoblast Differentiation: A Mechanism of New Bone Formation in Osteoporosis. N. Ghosh-Choudhury. Pathology, UTHSC at San Antonio and South Texas Veterans Health Care System, San Antonio, TX, USA.

Recently, statins are shown to induce expression of bone morphogenetic protein-2 (BMP-2), resulting in new bone formation. This action of statin is important in preventing osteoporosis. However, the signaling mechanism by which statins stimulate BMP-2 expression and, therefore, osteoblast differentiation is not known. Incubation of 2T3 mouse osteoblasts and fetal rat calvarial cells with lovastatin or simvastatin increased PI 3 K activity in anti-phospho-tyrosine immunoprecipitates in a dose-dependent manner, indicating association of this enzyme with signaling complex containing tyrosine phosphorylated proteins. One of the downstream targets of PI 3 K is Akt kinase. Lovastatin increased Akt kinase activity as measured by immunecomplex kinase assay of the Akt immunoprecipitates. Ly294002 (Ly), a pharmacologic inhibitor of PI 3 K, blocked lovastatin-induced lipid kinase and also Akt kinase activities, indicating that the PI 3 K regulates lovastatin-induced increase in Akt kinase activity. In order to study osteoblast differentiation, we examined the expression of osteopontin and type I collagen, two late markers of osteoblast differentiation, using Northern analysis. Lovastatin increased expression of mRNAs for both these proteins in 2T3 cells. Treatment of these cells with Ly prior to lovastatin blocked both osteopontin and type I collagen expression. These data represent the first evidence that PI 3 kinase regulates lovastatin-induced osteoblast differentiation. Lovastatin was originally reported to induce BMP-2 in 2T3 cells. We confirmed this observation using RNase protection assay with a BMP-2 specific probe. Ly inhibited expression of BMP-2 in response to lovastatin, indicating that PI 3 K regulates this process. Using transfection assay of BMP-2 promoter-luciferase reporter plasmid, we examined the mechanism of BMP-2 expression. Both lovastatin and simvastatin dose dependently increased transcription of BMP-2 in a decreasing potency, simvastatin > lovastatin. Ly inhibited statin-induced BMP-2 transcription. Together, these data demonstrate for the first time that lovastatin stimulates PI 3 K signaling and that this signal transduction pathway is necessary for expression of osteopontin and type I collagen, two late markers of osteoblast differentiation necessary to form new bone. Furthermore, these data provide the first evidence for a novel mechanism of statin-induced BMP-2 expression and hence osteoblast differentiation involving PI 3 K signaling. Thus design of small molecular mimetics that stimulate PI 3 K signaling may enhance new bone formation in patients with osteoporosis.

Dynamics of Focal Adhesions in Osteoblastic Cells on Biomaterial Surfaces. A. Diener*[1], B. Nebe*[1], U. Bulnheim*[2], F. Lüthen*[1], P. Becker*[3], H. Neumann*[3], J. Rychly[4]. [1]Department Internal Medicine, University of Rostock, Rostock, Germany, [2]Diagnostik Nord GmbH, Rostock, Germany, [3]DOT GmbH, Rostock, Germany, [4]Experimental Research Center, University of Rostock, Rostock, Germany.

The mechanisms of cell adhesion to the extracellular matrix which are of fundamental importance for function, survival, and growth of cells involve the formation of focal adhesions to facilitate integrin signaling. These adhesions are not stable but move to enable cell migration and extracellular matrix formation. We studied the dynamic behaviour of focal adhesions in stationary osteoblastic MG-63 cells on the surfaces of different biomaterials which are used as permanent or transient bone implants. As a marker for focal adhesions we used GFP-tagged vinculin, a cytoskeletal protein, that was transfected into living cells. On all surfaces that we have tested a mobility of focal adhesions was observed. On collagen coated cover slips the adhesions moved with a speed of 60 nm/min. The speed was reduced on titanium surfaces independently of the roughnesses of the surfaces and was still more restricted on stainless steel. This suggests that the ability of cells to format the extracellular matrix is impaired on these material surfaces but the reduced mobility could strengthen cell adhesion. In contrast, cells on a CaP/SiO xerogel composite which can be used as a degradable carrier for osteoblastic cells to regenerate bone revealed an increased mobility of focal adhesions compared with cells on collagen coated cover slips. To test, whether this increased mobility correlates with biological functions we measured proliferation with DNA cytometry and the expression of three functional proteins in a real time RT-PCR. Proliferation of cells on the xerogel composite was reduced compared with cells on cover slips. In contrast, expression of collagen I, osteopontin, and osteocalcin was distinctly increased on the material. Thus, on the xerogel composite increased mobility of focal adhesions correlated with cell differentiation whereas cell cycle progression was rather inhibited . In conclusion, surface characteristics of implant materials control the dynamics of focal adhesions which correlate with the functional behaviour of osteoblasts. Therefore, analyses of the dynamics of focal adhesions in cells on biomaterials appear to be a suitable approach to evaluate the biological activity of bone implants.

Runx2 Induces Osteoblast and Chondrocyte Differentiation and Enhances Their Migration by Coupling with PI3K-Akt Signaling. T. Fujita*[1], C. A. Yoshida*[2], M. Koida[1], T. Komori[2]. [1]Pharmacol, Setsunan Univ, Hirakata, Japan, [2]Developmental and Reconstructive Medicine, Nagasaki Univ, Nagasaki, Japan.

Runx2 and phosphatidylinositol 3-kinase (PI3K)-Akt signaling play important roles in osteoblast and chondrocyte differentiation. We investigated the relationship between Runx2 and PI3K-Akt signaling. Forced expression of Runx2 enhanced osteoblastic differentiation of C3H10T1/2 cells and MC3T3-E1 cells and enhanced chondrogenic differentiation of ATDC5 cells, whereas these effects were blocked by treatment with IGF-I antibody or LY294002 or adenoviral introduction of dominant negative (dn)-Akt. Forced expression of Runx2 or dn-Runx2 enhanced or inhibited cell migration, respectively, while the enhancement by Runx2 was abolished by treatment with LY294002 or adenoviral introduction of dn-Akt. Runx2 upregulated PI3K subunits (p85 and p110beta) and Akt, and their expression patterns were similar to that of Runx2 in growth plates. Treatment with LY294002 or introduction of dn-Akt severely diminished DNA binding of Runx2 and Runx2-dependent transcription, whereas forced expression of myrAkt enhanced them. These findings demonstrate that Runx2 and PI3K-Akt signaling are mutually dependent on each other in the regulation of osteoblast and chondrocyte differentiation and their migration.

Receptor Tyrosine Kinase Orphan Receptor 2 (Ror2) Binds Notch2 Receptor and Regulates its Transcriptional Activity in Osteoblastic Cells. J. Billiard[1], L. M. Seestaller-Wehr*[1], J. Ross*[2], P. V. N. Bodine[1]. [1]Women's Health Research Institute, Wyeth Research, Collegeville, PA, USA, [2]Protein Technologies, Wyeth Research, Collegeville, PA, USA.

Ror2 is an orphan receptor tyrosine kinase with no known ligand or association with a signaling pathway. To address a possible signaling mechanism of Ror2 receptor, we identified potential Ror2 binding partners by mass-spectroscopy analysis. U2OS human osteosarcoma cells were transiently transfected with flag-epitope-tagged Ror2 or empty vector, and the whole-cell extracts were immunoprecipitated on flag affinity agarose, resolved by SDS-PAGE and analyzed by mass spectroscopy. This approach identified eight potential Ror2 binding partners, including the Notch2 receptor.

Notch2 is a single-span transmembrane receptor that is activated by cleavage and nuclear translocation of its intracellular domain (N2IC). In the nucleus, N2IC activates transcription of target genes, including Hes1. We cloned the human N2IC and confirmed Ror2 interaction with it in U2OS over-expression system by immunoprecipitation studies.

Ror2-N2IC interactions had functional consequences on Notch signaling. Luciferase expression driven by Notch-responsive Hes1 promoter was stimulated 4-fold after co-transfection of U2OS cells with N2IC. In contrast, co-transfection with Ror2 dose-dependently inhibited N2IC-induced activation of this promoter.

Despite its ability to interact with Ror2, N2IC had no effect on Ror2 kinase activity as assessed by *in vitro* Ror2 autophosphorylation, and Ror2 did not phosphorylate N2IC *in vitro* either.

Since both Ror2 and Notch receptor families have been previously implicated in control of osteoblastic differentiation, their physical and functional interactions may have profound consequences on osteoblast development and bone formation.

Notch Signaling Is Activated by Binding of Periostin or CCN3 to Notch1 in Osteoblasts. H. Tanabe*[1], I. Kii*[1], N. Amizuka*[2], K. Katsube*[3], A. Kudo[1]. [1]Department of Life science, Tokyo Institute of Technology, Yokohama, Japan, [2]Department of Oral Anatomy, Niigata University, Niigata, Japan, [3]Department of Molecular Pathology, Graduation School of Tokyo Medical and Dental University, Tokyo, Japan.

Periostin, a 90kDa secreted protein, is known to express in periodontal ligament and periosteum in bone. However, the periostin involvement in bone formation remains unclear. To find the periostin function in bone formation, we studied the periostin association with CCN3 (NOV) or Notch1 and the periostin effect in Notch signaling. CCN3 is a 50kDa secreted protein, which associates with Notch1 and activates Notch signaling in the myoblastic cell line. Because Notch signaling plays a fundamental role in osteoblast differentiation, CCN3 is possibly important for osteoblast differentiation. First, using RT-PCR, we detected expressions of periostin, CCN3 and Notch1 in MC3T3-E1, the mouse osteoblastic cell line. Next, we performed immunohistochemistry of an adult mouse tooth. As a result, periostin, CCN3 and Notch1 were shown to co-localize in the periodontal ligament. To investigate interaction of these 3 proteins, we examined whether periostin associates with CCN3 or Notch1. NIH3T3 cells were co-transfected with periostin-HA and CCN3-FLAG or Notch1-FLAG, then immunoprecipitation was performed by using an anti-FLAG antibody. In this experiment, periostin was co-precipitated with Notch1 or CCN3. We also examined the association of periostin with CCN3 in a medium of MC3T3-E1, which is performed by immunoprecipitation using an anti-CCN3 antibody, and revealed that periostin was co-precipitated with CCN3. These results suggested that periostin associates with CCN3 or Notch1 in absence of Notch1 or CCN3. To investigate whether periostin/Notch1 or CCN3/Notch1 association could activate Notch signaling in osteoblasts, we examined the effect of periostin or CCN3 on the promoter activity of Hes1 in TSB13, the mouse osteoblastic cell line, since Hes 1 is a downstream target gene activated by Notch signaling. We observed that both periostin and CCN3 increased the Hes1 promoter activity dose-dependently up to 2 times. Taken together, theses results suggested that interaction of periostin and CCN3 may regulate bone formation through regulating Notch signaling.

The Wnt Pathway in Human Bone and Bone-Related Cells: Taqman Gene Expression Analysis. L. V. Hale*, D. L. Halladay*, R. J. S. Galvin, J. E. Onyia*, C. A. Frolik. Bone & Inflammation, Eli Lilly/Lilly Research Laboratories, Indianapolis, IN, USA.

The Wnt glycoproteins comprise a highly conserved family of secreted lipid modified signaling molecules. These proteins modulate cell-to-cell interactions and are powerful regulators of cell proliferation and differentiation. The conventional Wnt signaling pathway (canonical) involves proteins that directly participate in gene transcription and cell adhesion. Proteins included in this pathway are the Wnts, Frizzleds (FZDs), Dickkopfs (DKKs), Lipoprotein Related Proteins (LRPs), secreted Frizzled Related Proteins (sFRPs), and Kremens. Recently, several studies have implicated this canonical Wnt pathway in bone formation. It has been shown that mice deficient in LRP5 develop osteopenia while an activating mutation of the LRP5 gene in mice leads to an increase in bone mass. Human LRP5 inactivation similarly reduces bone mass while activation enhances bone density. Finally, deletion of the Wnt antagonist, sFRP-1, enhances trabecular bone formation in adult mice. To identify which of the Wnt pathway genes might be of interest in human bone formation we have employed Taqman Gene Expression Analysis to assess the mRNA from human osteoclasts (cord blood cells treated with RANKL and MCSF), human preosteoclasts (cord blood CFU-GM cells), human adult bone, SaOS-2 osteosarcoma cells, and primary human osteoblasts (hOBs). We have found that genes for FZDs 1-8 are expressed to some degree in all tissues/cells tested. FZD 9 is found only at very low levels in SaOS-2 cells and hOBs. FZD 10 is expressed only in preosteoclasts and osteoclasts and in the bone tissue analyzed. Wnts 2, 3, 3a, 7a, 8a, and 14 are not detected in any tissues/cells tested. Wnt 15 is found only in osteoclasts, Wnt 6 only in SaOS-2 cells, Wnt 4 only in bone, and Wnt 16 only in hOBs. Wnts 1, 5a, 10b, and 11 are prevalent across all or most tissues/cells tested while Wnts 2b, 5b, 7b, 10a, and 16 demonstrate no particular patterning. DKK1 is present only in bone, SaOS-2 cells and hOBs. DKKs 2 and 3 are found in all or most of the samples tested. DKK4 is negative in all tissues/cells. Kremen 1 is expressed in all tissues/cells tested, however, Kremen 2 is negative across the panel. sFRPs 1-3 are relegated to bone and cells of osteoblastic lineage while sFRP-4 is found across the test panel. sFRP-5 is only present in bone. LRP5 and 6 are found in all tissues/cells tested. Although these data do not pinpoint which Wnt pathway genes are involved in regulation of human bone formation, they do indicate that many components of the pathway are present in bone and bone-related cells.

Bisphosphonates Affect Osteoblast (UMR-106) GTPase Activity. Q. Sun[1], R. W. Katz[2], S. A. Morris[3], X. Fan*[1], J. P. Bilezikian[1]. [1]Division of Endocrinology, College of Physicians and Surgeons, Columbia University, New York, NY, USA, [2]Oral Medicine, College of Dentistry, New York University, New York, NY, USA, [3]Medical Affairs, NPS Pharmaceuticals, Parsippany, NJ, USA.

Bisphosphonates (BPs) are an important class of anti-resorptive medications for the treatment of metabolic bone disease. Although these compounds classically affect the osteoclast, recent studies suggest that bisphosphonates also affect osteoblast function. We previously reported that BPs affect the signal transduction pathways used by teriparatide [(rhPTH(1-34)] . It is not known how teriparatide and BPs could be used for maximal therapeutic effect, therefore our laboratory is interested in identifying possible molecular targets of BP action in osteoblasts. In this report, we characterize the effect of BPs on the prenylation and function of small soluble GTPases and their effect on cell density in-vitro. We hypothesize that BPs inhibit prenylation of GTPases in a representative osteoblast cell line, that this affects GTPase function, and that altered cell viability may be one result. In UMR-106 cells, risedronate reduced the amount of prenylated small GTPases identified by C14-labeled mevalonate to 20% of control levels but alendronate had little effect (63 % of control value). The steady state levels Rho A, Rab-6, and Rap-1 in cell homogenates as measured by immunoblotting was not affected by BP treatment. Overnight incubation of UMR-106 cells with alendronate or risedronate increased total cellular GTPase activity (161 % for alendronate and 172 % for risedronate respectively). Bisphosphonate treatment reduced total protein of harvested cultures by 31% (alendronate) and 36% (risedronate). Similar decreases were noted when total DNA was measured as a reflection of cell density (alendronate was 75% and risedronate was 67% of control values). Cell death, as indicated by propidium iodide influx, increased by BPs (risedronate two-fold greater than alendronate). We conclude that BPs affect GTPase prenylation, the levels of three representative GTPases are unaffected, and that BPs stimulate total GTPase activity. In addition, BPs differentially increase the number of non-viable UMR cells and suppress cell accumulation in overnight culture. The observation that BPs and teriparatide influence osteoblast functions complicates the manner in which these two classes can be used for optimal advantage.

RANK Ligand Stimulates Cathepsin K Expression via TRAF6 and c-Jun. A. F. Martinez*, M. Pang*, M. Gyda*, W. Balkan*, B. R. Troen. Miami VA GRECC, University of Miami School of Medicine, Miami, FL, USA.

Cathepsin K (CTSK) is a secreted protease that plays an essential role in osteoclastic bone resorption. Receptor activator of NF-κB ligand (RANKL), a member of the TNF superfamily of cytokines, is a critical mediator of osteoclastogenesis that also stimulates CTSK expression in monocytic cells. Little is known about the mechanism whereby RANKL regulates CTSK expression. We have therefore begun to study the regulation of CTSK expression in osteoclast precursors (RAW 264.7 cells), which can be readily differentiated to bone-resorbing osteoclasts by RANKL treatment. Real-time RT-PCR reveals that RANKL stimulates CTSK mRNA expression in a dose- and time-dependent manner. CTSK protein expression is also induced by RANKL. Transfection analysis with CTSK promoter-luciferase plasmids demonstrates that two regions upstream of the transcription initiation site (-1628 to -1089 bp and -698 to -395 bp) are responsible for most of the constitutive activity of the promoter. Both RANKL treatment and a constitutively active TRAF6 expression vector separately stimulate expression of CTSK promoter driven luciferase in transfected cells. In cells stably transfected with the 1628 bp CTSK promoter-luciferase plasmid, RANKL stimulates CTSK promoter activity in a dose-dependent manner. RANKL treatment markedly enhances phosphorylation of both JNK and c-jun. Furthermore, co-transfection of a CTSK promoter-luciferase plasmid with a dominant negative c-jun expression vector inhibits stimulation of CTSK promoter activity by both TRAF6 overexpression and by RANKL treatment. Therefore TRAF6 and c-jun play major roles in the RANKL-mediated regulation of CTSK expression. This model system will permit us to further characterize and identify the specific motifs and nuclear binding factors that regulate CTSK gene transcription.

Cross-Talk Between RANKL and Interferon Gamma in the Regulation of Cathepsin Gene Transcription in Pre-Osteoclastic Cells. M. Pang*, A. F. Martinez*, J. Jacobs*, W. Balkan*, B. R. Troen. Miami VAMC GRECC, University of Miami School of Medicine, Miami, FL, USA.

Receptor activator of NF-κB ligand (RANKL) and interferon gamma (IFN-γ) are critical and opposing mediators of osteoclastogenesis, exerting stimulatory and inhibitory effects, respectively. Cathepsin K (CTSK) is a secreted protease that plays an essential role in osteoclastic bone resorption. We are examining the role of IFN-γ in the regulation of CTSK expression in the murine monocytic RAW 264.7 cell line, which can be readily differentiated to bone-resorbing osteoclasts upon RANKL treatment. Real-time RT-PCR reveals that RANKL stimulates CTSK mRNA expression in a dose and time-dependent fashion, but that RANKL does not alter the expression of cathepsin L (CTSL) and cathepsin S (CTSS) mRNA. IFN-γ markedly stimulates both CTSL and CTSS expression, but fails to significantly alter CTSK expression. Whereas IFN-γ inhibits the stimulation of CTSK by RANKL, RANKL suppresses the stimulation of CTSL and CTSS by IFN-γ. Transient transfection analysis with a CTSK promoter-luciferase plasmid containing the 1628 bp upstream of the transcription initiation site demonstrates that IFN-γ treatment dramatically suppresses both constitutive CTSK promoter activity and the RANKL stimulation of CTSK promoter driven luciferase expression. Similarly, in stably transfected cells, IFN-γ inhibits CTSK promoter activity and ablates its induction by RANKL. Since IFN-γ does not appear to directly inhibit endogenous CTSK mRNA expression, the suppression of CTSK promoter activity in the transfected cells by IFN-γ alone is likely due to the presence of only the 1628 bp immediately upstsream of the transcription initiation site. In conclusion, IFN-γ and RANKL differentially regulate cathepsin K, S and L gene expression in pre-osteoclastic cells. There appears to be significant cross-talk between the signal transduction pathways mediating the responses to RANKL and IFN-γ. This differential regulation of cathepsin gene expression presents a model system to investigate further the divergent effects of RANKL and IFN-γ upon osteoclastic differentiation.

Orally Active Cathepsin K Inhibitor, YD-1901, Prevents Bone Resorption *in vitro* and *in vivo* in Rats. M. H. Son*[1], J. I. Lim*[1], J. S. Yang*[1], M. K. Kim*[1], W. Y. Kwak*[1], H. D. Kim*[1], J. H. Park*[1], S. S. Lee*[1], H. J. Kim*[1], H. J. Shim*[1], S. H. Kim*[1], C. H. Lee*[2], J. Y. Shim*[2], N. C. Kim*[2], Y. Huh*[2], T. D. Han*[2], W. Chong*[2], H. Choi*[2], B. N. Ahn*[2], S. O. Yang[3]. [1]Dong-A Pharm. Co., Ltd., Yongin, Republic of Korea, [2]Yuhan Co., Ltd., Kunpo, Republic of Korea, [3]Department of Radiology, Eulji University Hospital, Seoul, Republic of Korea.

Cathepsin K has been shown to play a major role in bone matrix degradation during osteoclastic bone resorption. In this study we disclosed the anti-resorptive activities of a novel candidate *in vitro* and *in vivo*.

YD-1901 is a reversible and potent inhibitor of human and rat cathepsin K with an IC50 of 7.0 and 450 nM, respectively. Also, it inhibited bone resorption by rabbit osteoclasts cultured on bone slice with an IC50 of 37 nM. Pharmacokinetic analysis in the rat revealed YD-1901 to be 85% orally bioavailable when administered as a solution.

For *in vivo* evaluations, YD-1901 was given orally to thyroparathyoidectomized rats. It inhibited PTH-induced bone resorption dose-dependently with an ED50 of 69 mg/kg. When given orally twice daily for 4 weeks to young (3-month-old) ovariectomized (OVX) rats, YD-1901 (50 and 100 mg/kg) completely prevented estrogen deficiency-induced bone loss evaluated by bone densitometry and ashing for the specimen. Furthermore, when old (14-month-old) OVX rats were treated with YD-1901 for 12 weeks, it also prevented bone loss significantly ($p<0.05$) in the femur and vertebra. YD-1901 (50 and 100 mg/kg) decreased the level of urinary DPD/creatinine dose-dependently without affecting elevated serum osteocalcin.

These results suggest that an orally active YD-1901 that inhibits human cathepsin K: 1) blocks bone resorption *in vitro*; and 2) completely prevents estrogen deficiency-induced bone loss in old as well as young rats.We conclude that YD-1901 has the therapeutic potential for the treatment of diseases characterized by excessive bone loss including osteoporosis.

Anti-resorptive Activities and Pharmacokinetic Properties of a Potent Cathepsin K Inhibitor, OST-4510. C. H. Lee*[1], T. D. Han*[1], Y. Hur*[1], J. Y. Shim*[1], N. C. Kim*[1], W. Chong*[1], B. Ahn*[1], M. H. Son*[2], J. S. Yang*[2], M. K. Kim*[2], W. Y. Kwak*[2], S. Y. Sung*[2], H. D. Kim*[2], J. H. Park*[2], S. S. Lee*[2], H. J. Shim*[2], S. H. Kim*[2], H. S. Lee*[3]. [1]Yuhan Research Institute, Yuhan Corp., Gunpo, Republic of Korea, [2]Research Laboratories, Dong-A Pharm. Corp., Ltd., Yongin, Republic of Korea, [3]School of Pharmacy, Wonkwang University, Iksan, Republic of Korea.

Cathepsin K has been shown to play a major role in bone matrix degradation during osteoclastic bone resorption. In this study we investigated the anti-resorptive activities and pharmacokinetic properties of a novel cathepsin K inhibitor, OST-4510, *in vitro* and *in vivo*.

OST-4510 is a reversible and potent inhibitor of human and rat cathepsin K with IC50 values of 1.3 and 150 nM, respectively. It showed highly selective profile against human cathepsin B, L, and S with an IC50 of greater than 400 nM. OST-4510 inhibited bone resorption by rabbit osteoclasts cultured on bone slice with an IC50 of 14 nM. When OST-4510 was given orally to thyroparathyoidectomized rats, it inhibited PTH-induced bone resorption dose-dependently.

OST-4510 (10 mg/kg) had a good oral bioavailability of 40% and showed favorable pharmacokinetic profile in rats. It was also metabolically stable in rat, monkey and human liver microsomes. Furthermore compound B did not inhibit the activities of five major human CYP450s nor induce CYP3A4.

These results suggest that an orally active OST-4510 that selectively inhibits human cathepsin K: 1) blocks bone resorption *in vitro* and *in vivo*; and 2) has favorable pharmacokinetic characteristics. We conclude that inhibition of cathepsin K by OST-4510 is a promising approach to the treatment of osteoporosis and other metabolic bone diseases.

The Effects of Trypsin-Cleavage and Reduction on the Phosphatase Activity and Reactive Oxygen Species Generating Activity of Human Recombinant Tartrate-Resistant Acid Phosphatase. K. Kaarlonen*[1], H. Ylipahkala*[1], S. L. Alatalo*[1], A. J. Janckila[2], H. K. Väänänen*[1], J. M. Halleen[3]. [1]Institute of Biomedicine, Department of Anatomy, University of Turku, Turku, Finland, [2]Veterans Affairs Medical Center, Louisville, KY, USA, [3]Pharmatest Services Ltd, Turku, Finland.

Tartrate-resistant acid phosphatase (TRACP) is an enzyme with unknown biological function that contains a redox-active iron in its active site. In addition to the acid phosphatase activity, TRACP is also capable of generating reactive oxygen species (ROS). Two forms of TRACP circulate in human blood, a sialic acid-containing form TRACP 5a with a pH-optimum of 5.2 and low specific activity and a non-sialylated form TRACP 5b with a pH-optimum of 5.8 and high specific activity. Serum TRACP 5a is derived from macrophages and serum TRACP 5b from osteoclasts. We produced human recombinant TRACP protein using baculovirus expression system, purified it using cation exchange and gel filtration chromatography, and cleaved the purified enzyme with trypsin. β-mercaptoethanol was used to reduce the disulfide bridge and ascorbate to reduce the redox-active iron. Trypsin cleaved the 35 kD monomeric native recombinant TRACP protein into two subunits of 23 and 16 kD that were linked together with a disulfide bridge. In Western analysis, a monoclonal antibody specific for serum TRACP 5a recognized the non-cleaved protein, but not the cleaved subunits. The cleavage together with reduction by β-mercaptoethanol changed the pH-optimum of the phosphatase activity from 5.4 to 6.2 and activated the enzyme. Thus, antigenic properties and pH-optimum of the phosphatase activity of the non-cleaved reduced recombinant enzyme were similar to those of serum TRACP 5a, and after cleavage similar to those of serum TRACP 5b. Reduction with ascorbate activated both the monomeric and cleaved enzyme. Both trypsin-cleavage and reduction by ascorbate increased the ROS generating activity of TRACP. We conclude that the structure of TRACP contains at least three features that may be important for regulating its activity, the cleavage site for proteases, the disulfide bridge in the polypeptide chain and the redox-active iron in the binuclear iron center. Our results suggest that the osteoclast-derived TRACP 5b circulates in blood in an active cleaved form, and the macrophage-derived TRACP 5a in a less active non-cleaved form.

Monokine Induced by Interferon-gamma (MIG) Is Involved in Osteoclast Adhesion and Migration through STAT1-dependent Pathway. Z. Lee[1], H. Kwak*[1], H. Jin*[1], H. Ha*[2], H. Kim[2]. [1]National Research Laboratory for Bone Metabolism, Chosun University Dental College, Gwangju, Republic of Korea, [2]Department of Cell and Developmental Biology, College of Dentistry, Seoul National University, Seoul, Republic of Korea.

The bone remodeling process is accompanied by complex changes in the expression levels of various genes in osteoclasts. Receptor activator of nuclear factor κB ligand (RANKL) may contribute to this process. We found that monokine induced by interferon-γ (MIG) gene was up-regulated in osteoclast precursors by treatment with RANKL through the cDNA array analysis. MIG is a member of a superfamily of CXC chemokines and is involved in the directed **migration and adhesion in** macrophages, T and B cells that have been implicated in inflammation. The relative abundance of differentially regulated MIG was confirmed by RT-PCR and Western blotting in osteoclast precursors treated with RANKL. RANKL could activate the phosphorylation of Ser727 in STAT1 and p38 MAPK inhibitor suppressed it. And, STAT1 deficient mice did not express the MIG in the response to RANKL in the osteoclast precursors. Therefore, we provide that the first evidence demonstrating that RANKL can activate serine phosphorylation of STAT1 via p38 MAPK pathway to produce the MIG, although NF-kB pathway is involved in the induction of MIG. MIG induced by RANKL could stimulated the migration and adhesion of CXCR3-expressed osteoclast precursors derived by M-CSF with autocrine or paracrine mode. This study provides evidence that MIG carries out the recruitment function of osteoclast precursors to bone remodeling site from bone marrow or peripheral blood.

Osteoclasts Are Essentially Required for Normal Bone Morphogenesis. M. Nakamura[1], H. Horiuchi*[2], M. Mogi*[3], K. Takaoka[4], N. Takahashi[5], N. Udagawa[1]. [1]Biochemistry, Matsumoto Dental University, Shiojiri, Japan, [2]Orthopaedic Surgery, Shinshu University School of Medicine, Matsumoto, Japan, [3]Pharmacology, Aichi Gakuin University, Nagoya, Japan, [4]Orthopaedic Surgery, Osaka City University School of Medicine, Osaka, Japan, [5]Institute for Oral Science, Matsumoto Dental University, Shiojiri, Japan.

Osteopetrosis is an inherited disorder characterized by an increase in bone mass due to reduced bone resorption. It has been reported that the osteoclast deficiency in osteopetrotic op/op mice is due to a mutation in the coding region of the M-CSF gene. Using op/op mice, we explored roles of osteoclasts in ectopic bone formation induced by bone morphogenetic protein (BMP). Collagen sponge disks containing human recombinant BMP-2 were implanted into the dorsal muscle pouches in op/op and wild-type mice for 3 weeks. Bisphosphonate (risedronate) was injected into op/op and wild-type mice every day for 3 weeks. Bone mineral density of each ossicle was measured by single energy x-ray absorptiometry. Quantitative histomorphometric analysis was also performed. Bone mineral density of BMP-induced ectopic bone in op/op mice was about 3-fold higher than that in wild-type mice. Histological examination revealed that BMP induced higher calcified trabecular bone formation in op/op mice than in wild-type mice. Interestingly, the periphery of ectopic bones formed in op/op mice showed extremely rough surface, whereas that in wild-type mice showed smooth ones. Bisphosphonate treatment further enhanced ectopic bone formation in op/op mice. We previously reported that serum levels of RANKL were markedly elevated in osteoprotegerin (OPG)-deficient mice, but were unaffected by bisphosphonate administration. Unexpectedly, serum levels of RANKL in op/op mice were as high as those in OPG-deficient mice, whereas those in wild-type mice were under detectable levels in the RANKL assay. Treatment of op/op mice with bisphosphonate treatment sharply decreased the elevated levels of serum RANKL. These results suggest that BMP-induced ectopic bone formation is accurately enhanced in the absence of osteoclasts, and osteoclasts are involved in normal bone morphogenesis. Our results also suggest that bisphosphonates may be directly involved in bone formation without inhibition of osteoclastic bone resorption. Further studies will elucidate the mechanism of bisphosphonate action in BMP-induced bone formation in osteoclast-deficient mice.

BMP Tightly Regulates in vivo Osteoclast Formation in OPG-deficient Mice. Y. Yamamoto*[1], S. Matsuura*[2], H. Horiuchi*[3], M. Nakamura*[4], H. Ozawa*[2], T. Noguchi*[1], N. Udagawa*[4], N. Takahashi*[5]. [1]Periodontology, Aichi-Gakuin Univ.,School of Dentistry, Nagoya, Japan, [2]Second Department of anatomy, Matsumoto Dental Univ., Siojiri, Japan, [3]Orthopedic Surgery, Shinshu Univ., Matsumoto, Japan, [4]Biochemistry, Matsumoto Dental Univ., Siojiri, Japan, [5]Institute for Oral Science, Matsumoto Dental Univ, Siojiri, Japan.

OPG is a decoy receptor for RANKL. OPG-deficient ($OPG^{-/-}$) mice exhibit aberrant bone metabolism characterized by accelerated bone resorption and formation. Serum levels of RANKL are shown to be extremely high in patients with OPG-deficient juvenile Paget's disease and in $OPG^{-/-}$ mice. These findings raise a possibility that OPG deficiency may accelerate osteoclast formation inside and outside the bone tissues. Using $OPG^{-/-}$ mice, we examined osteoclast formation in ectopic bone induced by BMP implantation. Collagen disks containing human recombinant BMP-2 or vehicle were implanted into dorsal muscular pouches of $OPG^{-/-}$ and wild-type mice, and recovered at different time points. Osteoclasts and osteoblasts appearing in the collagen disks were detected by enzyme histochemical staining for TRAP and ALP, respectively. Monocytes/macrophages and RANKL-expressing cells were detected by immunohistochemical staining with anti-F4/80 antibody and anti-RANKL antibodies, respectively. TRAP-positive cells and ALP-positive cells appeared simultaneously surroundings of the BMP-containing collagen disks implanted for 1 week into $OPG^{-/-}$ mice and wild-type mice, preceding the onset of calcification. The number of TRAP-positive cells was increased with the increase in periods of implantation, and was significantly higher in the disks harvested from $OPG^{-/-}$ mice than those from wild-type mice. Neither TRAP-positive cells nor ALP-positive cells appeared in BMP-deficient collagen disks implanted even into $OPG^{-/-}$ mice. F4/80-positive macrophages, precursors of osteoclasts, were similarly detected in both BMP-containing and BMP-deficient collagen disks implanted into $OPG^{-/-}$ mice. When collagen disks containing BMP together with OPG were prepared and implanted into $OPG^{-/-}$ mice, ALP-positive osteoblasts and F4/80-positive macrophages appeared in the disks, but TRAP-positive osteoclasts did not. RANKL-expressing cells were detected surroundings of BMP-containing disks but not BMP-deficient disks at 1 week. These results suggest (i) that locally expressed RANKL rather than circulating one is important for osteoclast formation; (ii) that mineralization of bone tissues is not absolutely required for the osteoclast induction; and (iii) that BMP plays important roles in osteoclast differentiation through the induction of osteoclastogenesis-inducing cells.

Study of Osteoclast Apoptosis in a Human Model of Osteoclast Differentiation. S. Roux, P. Lambert-Comeau*, C. Saint-Pierre*. Rheumatology, University of Sherbrooke, Sherbrooke, PQ, Canada.

Survival and apoptosis are of major importance in the osteoclast (Oc) life cycle, and can lead to crucial changes in bone resorption. Although major advances have been made in our understanding of the mechanisms of Oc apoptosis in rodents, little is known about Oc apoptosis in humans.

In the present study, cord blood monocytes (CBMs) were used as the source of human Oc precursors, and were cultured for 3 weeks in presence of M-CSF (25 ng/ml) and RANKL (100 ng/ml). At the end of the cultures, immunohistochemistry was performed to evaluate Oc markers using anti-RANK and anti-CTR antibodies, in addition some experiments were performed on bone slices. After the 3-week culture period, apoptosis was evaluated by a TUNEL-derived method. Finally, TRAIL receptor expression was evaluated by immunohistochemistry, using antibodies directed against TRAIL-R1, -R2, -R3 and -R4.

When cultured in presence of M-CSF and RANKL, CBMs formed multinucleated cells (MNCs) that express RANK and CTR (respectively 72 ±2 and 75 ±4 % of the MNCs, n=5), and these cells were able to resorb bone when cultured on bone slices. At the end of the cultures, apoptosis was evaluated 24 hours after removing RANKL and M-CSF, and in presence of potential apoptosis inducers. The percentage of apoptotic MNCs was 44 ±9 % in control cultures, 47 ±9 % in presence of TRAIL at concentration of 10 ng/ml (ns) and 63 ±9 % at 100 ng/ml (p=0.0012 vs controls), 52 ±9 % in presence of TGFb1 at 0.1 ng/ml (ns), and 63 ±7 % at 1 ng/ml (p=0.0045 vs controls) (n=8). In addition we found that MNCs expressed TRAIL receptors, TRAIL-R1 was expressed in 67 ± 2 %, TRAIL-R2 in 55 ±4 %, TRAIL-R3 in 49 ±6 %, and TRAIL-R4 in 36 ±8 % of the MNCs (n=3).

We have shown that CBMs represent a suitable model of human osteoclast differentiation. In this model, apoptosis was induced by the removal of survival factors (M-CSF, RANKL), and the rate of apoptosis significantly increased in presence of TRAIL and TGFb1. In addition, osteoclast-like cells expressed TRAIL-receptors, both TRAIL-R1 and -R2 that are able to transduce apoptosis, and TRAIL-R3 and -R4 that are decoy receptors. Taken together the results suggest that, at least in part, the TRAIL pathway could be involved in osteoclast apoptosis in humans.

Mechanisms of Parathyroid Hormone-Related Protein and Interleukin-1a Induced Expression of Receptor Activator of NF-kB Ligand in Human Periodontal Ligament Cells. H. Fukushima[1], H. Kajiya[2], F. Okamoto*[2], E. Jimi[2], W. Motokawa*[1], K. Okabe[2]. [1]Department of Oral Growth and Development, Fukuoka Dental College, Fukuoka, Japan, [2]Physiological Science and Molecular Biology, Fukuoka Dental College, Fukuoka, Japan.

Physiological root resorption during shedding of human deciduous teeth leads to eruption of permanent teeth and formation of functional occlusion. Root resorption of human deciduous teeth is mediated by osteoclast-like cells (odontoclasts). We examined the effects of PTH-related protein (PTHrP), IL-1a, TGF-b and EGF, which are all secreted from the tooth germ, on tartrate-resistant acid phosphatase positive (TRAP+) cell formation using co-culture of human periodontal ligament (PDL) cells and mouse bone marrow cells. Of these factors examined, only PTHrP and IL-1a promoted TRAP+ cell formation in co-cultures. PTHrP induced receptor activator of NF-kB ligand (RANKL) mRNA expression in PDL cells and slightly reduced osteoprotegerin (OPG) expression. IL-1a up-regulated RANKL and down-regulated OPG mRNA expression. Inhibition of the cAMP/PKA signaling pathways with cAMP/PKA inhibitors Rp-cAMP, H89 or PKI did not affect PTHrP- and IL-1a-induced TRAP+ cell formation. IL-1a- but not PTHrP-induced TRAP+ cell formation was completely blocked by pretreatment with either NS-398, a selective inhibitor of cyclooxygenase (COX)-2 or PD98059, a specific inhibitor of extracellular signal-regulated kinase (ERK). Pretreatment with NS-398 and PD98059 also inhibited both the up-regulation of RANKL and the down-regulation of OPG expression in PDL cells by IL-1a. IL-1a activated ERK phosphorylation and pretreatment with PD98059 greatly inhibited COX-2 mRNA expression in PDL cells by IL-1a. These results suggest that PTHrP and IL-1a released from the tooth germ stimulate odontoclast formation by increasing relative expression level of RANKL versus OPG in PDL cells via separate signaling pathways.

RANKL Induces The Osteoclast-Specific P3 Calcitonin Receptor Promoter In Stably Transfected RAW 264.7 Cells By Mechanisms Involving NFATc1 and p38 MAPK. N. Kawanabe[1], G. Wang*[2], S. Lee[1], J. A. Lorenzo[1], D. L. Galson[2]. [1]Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Center for Bone Biology, Dept. of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

Calcitonin receptor (CTR) expression is restricted to a spectrum of tissues that include osteoclasts, brain, kidney and reproductive organs. Recently, a murine CTR promoter fragment (P3) was found to enhance the expression of CTR in osteoclasts but not in brain or kidney cells. To characterize this promoter, we established stable RAW 264.7 cell lines, which contain a GFP reporter gene driven by the P3 CTR promoter fragment (P3-GFP RAW cells), and assessed if RANKL-treatment stimulated promoter activity coincident with osteoclast-like (OCL) formation. Using flow cytometry, we found that P3 CTR promoter activity, which was measured as mean GFP fluorescence intensity, was significantly enhanced by RANKL in P3-GFP RAW cells from day 1 to day 4 compared to untreated controls (1.5 fold on day 1, 3.8 fold on day 2, 5.0 fold on day 3 and 4.5 fold on day 4, all $p<.05$). In addition, on day 2 80-90% of the P3-GFP RAW cells had a GFP fluorescence intensity that was above levels in untreated cells. RAW 264.7 cells stably transfected with promoterless GFP constructs had minimal fluorescence in all conditions (>7.4-8.9 fold less than untreated P3-GFP cells). We also compared the mRNA expression of several osteoclast markers (CTR, TRAP, MMP-9) and the transcription factor NFATc1 using RT-PCR. NFATc1, which is an important regulator of osteoclastogenesis, binds and stimulates P3 CTR. RANKL enhanced (> 2 fold) TRAP and NFATc1 mRNA on days 1-4, MMP9 mRNA on days 2-4 and endogenous CTR mRNA on day 3-4. To confirm that RAW 264.7 cells have features of osteoclasts, we performed bone resorption and calcitonin (CT) binding assay. RAW 264.7 cells formed bone resorption pits on bovine bone slices and had calcitonin binding ability after 4 days of RANKL treatment. Cyclosporine A, an inhibitor of NFATc1 activation, blocked both RANKL-induced P3 CTR activity and osteoclastogenesis. Treatment of the cultures with SB202190 (a p38 MAP kinase inhibitor) also blocked RANKL-induced P3 CTR activity.

These results demonstrate that the activity of the P3 CTR promoter fragment is rapidly (< 1 day) stimulated by RANKL in RAW 264.7 cells. Enhancement of this activity was coincident with increases in NFATc1 mRNA expression and blocked by specific inhibitors of NFATc1 and p38 MAPK. These findings imply that RANKL-induced regulation of the P3 CTR promoter in osteoclasts is mediated by NFATc1 and p38 MAP kinase.

A Role for the Sodium/Bicarbonate Exchanger, NBCn1 in Colony Stimulating Factor-1 (CSF-1)- Dependent Akalinization and Cell Survival in Osteoclasts. P. Bouyer*[1], T. Itokawa*[1], H. Sakai*[2], W. F. Boron*[1], K. Insogna[1]. [1]Yale University, New Haven, CT, USA, [2]Hamanomachi Hospital, Fukuoka, Japan.

Osteoclasts are short-lived, and increased osteoclast survival plays a role in the pathogenesis of skeletal diseases such as estrogen-deficiency bone loss. CSF-1 promotes osteoclast survival and the mechanism for this effect is currently under study. A rise in cytosolic pH has been linked to inhibition of apoptosis but the effect of CSF-1 on intracellular pH in osteoclasts has not been reported. We therefore measured cytosolic pH in freshly isolated neonatal rat osteoclasts and murine osteoclast -like cells (OCLs), prepared by co-culture on collagen-coated plates, before and after exposure to 2.5 nM CSF-1. Cells were loaded with the pH sensitive dye BCECF to monitor intracellular pH (pHi) and the fluorescence excitation ratio I490/I440 converted to pHi values by using the high-K+ nigericin technique. In the presence of 5% CO_2/22 mM HCO_3^- , CSF-1 caused a significant rise in pHi from 7.14 to 7.36 ($p<0.02$). The alkalinization persisted as long as CSF-1 was present in the solution. In HEPES buffer, the response to CSF-1 was markedly attenuated with pHi only increasing from 7.13 to 7.16. The mean CSF-1-induced increase in pHi was significantly attenuated in HEPES as compared CO_2/HCO_3^- ($p < 0.007$). Changing the sequence in which cells were exposed to the two buffers did not alter the results. OCLs demonstrated responses similar to those seen in freshly isolated osteoclasts. EIPA, an inhibitor of Na-H exchangers and concanamycin A, a proton pump inhibitor, did not attenuate the CSF-1-induced rise in pHi. The rise in pHi induced by CSF-1 was not affected by EIPA (Na-H exchange inhibitor), concanamycin A (proton-pump inhibitor), or DIDS (which inhibits many HCO_3^- transporters), but was completely abolished by the removal of extracellular sodium. This inhibition profile is reminiscent of that for the electroneutral Na/HCO_3 co-transporter, NBCn1. Single-cell RT-PCR in osteoclasts as well as RT-PCR in OCLs demonstrated expression of NBCn1. NBCn1 protein expression was confirmed by immunocytochemical studies in freshly isolated osteoclasts. After 4 hours of serum starvation, CSF-1 reduced the number of apoptotic cells by 45% in CO_2/HCO_3^- buffer but was without effect on cell survival in HEPES buffer. This study provides the first evidence that osteoclasts express a Na/HCO_3 co-transporter, and that the activity of this transporter is regulated by CSF-1. Preventing the activation of NBCn1 markedly attenuated the ability of CSF-1 to prevent osteoclast apoptosis, pointing to a new pathway mediating osteoclast survival.

CD11c$^+$ Myeloid Dendritic Cells Develop Osteoclastic Phenotype and Function During Immune Activation in Bone Microenvironment. M. Alnaeeli*[1], A. Marleau*[2], B. Singh*[2], J. Penninger*[3], A. Y. Teng*[1]. [1]Microbiology and Immunology, University of Rochester, Rochester, NY, USA, [2]Microbiology and Immunology, University of Western Ontario, London, ON, Canada, [3]Austrian Academy of Sciences, Institute of Molecular Biotechnology, Vienna, Austria.

Bone remodelling is controlled by cytokines, growth factors/hormones, osteoblasts & osteoclasts (OC). OC stem from hematopoietic precursors of monocyte/macrophage lineage; their development & maturation is know to require M-CSF & RANK-RANKL signalling. Professional antigen-presenting cells (APCs), dendritic cells (DCs), can prime naïve T-cells, then activate & regulate the immune response. Activated T-cells express RANKL during immune activation; thus, linking T-cell-immunity to bone remodelling, critical in inflammatory bone disorders like arthritis, periodontitis & osteomyelitis. Periodontitis, the prime cause of alveolar bone loss around teeth in adults (worldwide prevalence >80%). To study the contribution of DCs to bone loss during immune interactions with T-cells, mCD11c$^+$ myeloid DCs were purified from mouse BM (IL-4 & GM-CSF), followed by co-culture with naïve CD4$^+$T cells & *Actinobacillus actinomycetemcomitans,* a key human pathogen (JCI 66: R59, 2000), or mitogen ConA in hydroxyapatide-coated plates. The results of quantitative & clonal analyses show that myeloid CD11c$^+$DCs are activated & develop OC phenotype by expressing tartrate-resistant acid phosphatase (TRAP; $p<0.03$) with significantly elevated bone resorptive activity (lacunae formations; $p<0.02$) and up-regulation of calcitonin receptors on cell surfaces with varying GM-CSF-R levels ($p<0.05$; immunofluorescence & FACS), compared to the controls. Importantly, after adding osteoprotegerin, the natural decoy ligand of RANKL, their OC phenotype & function are abolished ($p<0.02$ & 0.03, respectively). Further analyses of genetically mutated BM-derived precursors indicate that these DCs stem from the myeloid progenitors for OC differentiation, distinct from the classical monocyte/macrophage lineage. In conclusion: **i)** CD11c$^+$myeloid DCs function as professional APCs to prime naïve CD4$^+$T cells for immune activation; in addition, they can develop OC phenotype & function by resorbing bone *in-situ* after receiving RANKL from activated T cells; **ii)** these myeloid DCs may be manifest OC phenotype as OC precursor in the bone microenvironment when appropriately stimulated *in vitro*. Thus, these novel findings will have potentially significant implications on our understanding of the inflammatory bone disorders associated with T-cell-mediated immunity such as periodontitis, arthritis, osteomyelitis and immune surveillance of tumor-associate bone metastasis.

Ara-C Enhanced Osteoclast Differentiation Induced by RANKL Mediated by TRAF-2 Expression. M. Koide*[1], S. V. Reddy[2], S. Fujita*[1], T. Sobue[1], T. Noguchi*[1]. [1]Periodontology, Aichi-Gakuin University, Nagoya, Japan, [2]Medicine/Division of Hematology, University of Pittsburgh, Pittsburgh, PA, USA.

Ara-C (1-β-D-Arabinofuranosylcytosine) is a potent anti-cancer agent used to treat myelogenous leukemia. Ara-C has been shown to induce differentiation of myeloid leukemia cells by NF-κB activation. Although efficacy and toxicity of Ara-C has been evaluated in patients with acute myeloblastic leukemia, the role of Ara-C in associated hypercalcemia of malignancy as well as myeloid cell differentiation is yet unknown. RANK receptor and RANK ligand (RANKL) play a central role in osteoclast differentiation. We show that Ara-C enhanced osteoclast differentiation of RAW 264.7 (RAW) cells induced by RANKL. The other hand, Ara-c did not significantly affect osteoblast proliferation and alkaline phosphatase activity in primary osteoblast cells. Ara-C at high doses (0.1-1 μM) induced NF-κB activation by two fold in these cells. Ara-C also significantly increased AP-1 transcription factor expression in RAW cells. Western blot analysis further demonstrated that Ara-C induced TRAF-2 protein expression, however did not change TRAF-6 protein levels in RAW cells. Therefore, our data suggested that Ara-C has additional effects to enhance osteoclast formation by RANKL. The cellular signaling mechanisms associated with Ara-C effect are mediated through increased expression of TRAF-2 modulating the NF-κB and AP-1 activation during osteoclast differentiation.

Toll-Like Receptor 9 Activation on Osteoclastic and Osteoblastic Lineage Cells Modulate Osteoclastogenesis. A. Amcheslavsky*[1], H. Hemmi*[2], S. Akira*[2], Z. Bar-Shavit[1]. [1]Experimental Medicine and Cancer Research, Hebrew University, Jerusalem, Israel, [2]Host Defense, Osaka University, Osaka, Japan.

Bacterial infections cause pathological bone loss by accelerating differentiation/activation of the bone-resorbing cell, the osteoclast. CpG oligodeoxynucleotides (CpG-ODNs), mimicking bacterial DNA, modulate osteoclast differentiation via Toll-like receptor 9 (TLR9) in a complex manner: they inhibit the activity of the physiological osteoclast differentiation factor, RANKL in early osteoclast precursors (OCPs), but markedly stimulate osteoclastogenesis in cells primed by RANKL. The osteoclastogenic effect of TLR9 is mediated by TNF-α. In the current study we use TLR9 deficient mice (-/-) to examine the role of this receptor in osteoclastogenesis. RANKL induces in vitro differentiation of bone marrow derived OCPs in both, -/- and +/+ mice. LPS modulated RANKL-induced osteoclastogenesis in cells derived from -/- mice in a similar manner to its effects in +/+ derived cells. On the other hand, CpG-ODN failed to exert neither stimulatory nor inhibitory effects on -/- derived cells. Intracellular events known to participate in osteoclast differentiation were examined. RANKL and LPS induced TNF-α synthesis, phosphorylation of p38 and ERK, as well as nuclear translocation of NFκB similarly in the wild type and TLR9 deficient mice. CpG-ODN affected normally the wild type mouse, but did not modulate any of the above events in -/-. Finally, we examined the relative contribution of osteoclast and osteoblast (OB) lineage cells in the involvement of TLR9 in osteoclastogenesis. Since both, OCPs and OBs express TLR9, and CpG-ODN induces TNF-α synthesis in these cells, we used co-cultures in the following combinations: 1) OCP(+/+)/OB(+/+); 2) OCP(-/-)/OB(-/-), 3) OCP(+/+)/OB(-/-); 4) OCP(-/-)/OB(T+/+). CpG-ODN increased TNF-α levels in OCP(+/+)/OB(+/+), but not in OCP(-/-)/OB(-/-). The ODN induced TNF-α synthesis in OCP(+/+)/OB(-/-) almost similarly to OCP(+/+)/OB(+/+), but not in OCP(-/-)/OB(+/+). Modulation of osteoclastogenesis by CpG-ODN in the mixed co-cultures mirrored the TNF-α response. No modulation was observed in OCP(-/-)/OB(-/-), while inhibition of the activity by 20% and 50% was observed in OCP(+/+)/OB(-/-) and OCP(-/-)/OB(+/+), respectively. In conclusion, CpG-ODN modulates osteoclastogenesis in TLR9 dependent manner. Activation of TLR9 in OCPs is more crucial to induction of osteoclastogenesis than activation of the osteoblastic TLR9.

Spontaneous Osteoclastogenesis In Postmenopausal Osteoporosis. P. D'Amelio*[1], A. Grimaldi*[2], C. Tamone*[2], G. P. Pescarmona*[3], G. Isaia[2]. [1]Dpt of Internal Medicine, University of Torino, Torino, Italy, [2]Internal Medicine, University of Torino, Torino, Italy, [3]Dpt of Genetics, Biology and Biochemistry, University of Torino, Torino, Italy.

There are no evidences for increased osteoclast formation in postmenopausal osteoporosis. The aim of the present study is to evaluate a possible increase in spontaneous osteoclast formation from peripheral blood mononuclear cells (PBMC) in postmenopausal osteoporotic women with respect to healthy subjects.

Bone mineral density, markers of bone turnover and cultures of PBMC were performed in 18 women affected by postmenopausal osteoporosis and in 15 controls. PBMC were obtained with Ficoll-Pacque method. All cell incubations were performed in triplicate in 96 well plates [$2x10^5$ cells/well] or on dentin slices [$1x10^6$ cells/well] using αMEM, supplemented with 10% fetal bovine serum, benzyl penicillin (100 IU/ml) and streptomicin (100 μg/ml). In order to verify the cytokine production by PBMC cultures, supernatants were collected at day 3 and 6 and tested for TNF α and RANKL. The data obtained were compared between patients and controls by one-way ANOVA and correlated by Pearson's coefficient. On the 10th day the cells were fixed and stained for Tartrate resistant acid phosphatase (TRAP) and stained immunohistochemically for the expression of vitronectin receptor (VNR). In all the subjects we measured supernatant levels of TNF α and RANKL with ELISA method. On 21st day of culture, dentine slices were stained with toluidine blue and examined by light microscope.

The resorption was as the percentage of surface area reabsorbed.
In patients the number of osteoclasts was 48.21 ± 30 per 10^5 cells, while in the controls it was 10.41 ± 13 (p=0.000). The percentage of bone resorption was higher in patients with respect to controls (9.5±8.5 vs 0.85±5.6, p=0.048). The levels of TNF α and RANKL were higher in patients (Tab.1).
We found inverse correlations between BMD measured at lumbar spine and femoral neck with number of osteoclasts (r=-0.6, p=0.001), RANKL (r=-0.77, p=0.000) and TNF α (r=-0.6, p=0.000); the correlations between cross laps, RANKL (r=0.4, p=0.02) and TNF α (r=0.48, p=0.006) are direct.
Our data demonstrated an increased spontaneous osteoclastogenesis in postmenopausal osteoporosis: this increase may be explained by the higher production of TNF α and RANKL by PBMC cultures of these patients.

	Patients	Controls	p
TNF α (pg/ml) day 3	53±16.3	32.9±6.6	**0.000**
TNF α (pg/ml) day 6	31.9±8.2	33.9±9.5	NS
RANKL (pg/ml) day 3	2±1.4	0.14±0.2	**0.000**
RANKL (pg/ml) day 6	2.4±1.2	0.4±0.6	**0.000**

Cyclic AMP/Protein Kinase A Signals Enhance Osteoclastic Differentiation through TAK1 in Osteoclast Precursors. Y. Kobayashi*[1], I. Take*[1], T. Mizoguchi*[1], N. Udagawa[2], N. Takahashi[1]. [1]Institute for Oral Science, Matsumoto Dental University, Shiojiri, Japan, [2]Biochemistry, Matsumoto Dental University, Shiojiri, Japan.

PGE_2 synergistically enhances RANKL-induced osteoclast differentiation of the precursors. Here, we studied the mechanism of synergistic action of PGE_2 on RANKL-induced osteoclast differentiation. Using RT-PCR, mRNA expression of PGE_2 receptor subtypes (EP1, EP2, EP3, EP4) was examined in osteoclast precursors, bone marrow macrophages (BMMϕ) and RAW 264.7 cells (RAW cells). Both BMMϕ and RAW cells expressed EP1, EP2 and EP4 mRNAs. PGE_2 synergistically enhanced RANKL-induced osteoclastic differentiation of BMMϕ or RAW cells. PGE_2 stimulated cAMP production in RAW cells. The synergistic action of PGE_2 on RANKL-induced osteoclastic differentiation of RAW cells was mimicked by dibutyryl cAMP and inhibited by H-89, a PKA inhibitor, suggesting that the synergistic action of PGE_2 is mediated by the cAMP/PKA system through EP2 and EP4 in the precursors. RANKL-induced degradation of IκBα and phosphorylation of MAPKs in RAW cells were enhanced by PGE_2 in a cAMP-dependent manner, suggesting that PGE_2 signals crosstalk with an upper-stream effector(s) of those signaling molecules. We searched the effectors having a consensus sequence (RRXS motif) in RANKL-induced signaling molecules, and found that TGF-β activated kinase 1 (TAK1) possesses the RRXS motif at 409-412. The immuno-precipitation study revealed that the Ser^{412} residue of TAK1 was phosphorylated by PGE_2 in RAW cells. Over-expression of the $S^{412}A$ mutant TAK1 completely inhibited PGE_2-induced phosphorylation of endogenous TAK1 in RAW cells. We then examined whether the Ser^{412}Ala TAK1 serves as a dominant negative mutant in PKA-mediated enhancement of RANK-, TNF receptor- and Toll like receptor 4-induced signals. Forskolin, an activator of adenylyl cyclase enhanced RANKL-, TNFα- and LPS-induced degradation of IκBα and phosphorylation of p38MAPK in RAW cells transfected with mock or wild-type TAK1. However, the synergistic effects of forskolin were completely abolished by the transfection of the mutant TAK1 into RAW cells. Over-expression of the mutant TAK1 also abolished the synergistic effect of PGE_2 on RANKL-induced osteoclastic differentiation of RAW cells. Furthermore, the mutant TAK1 inhibited the synergistic effects of forskolin on both TNFα-induced osteoclastic differentiation and LPS-induced IL-6 production. These results suggest that phosphorylation of the Ser^{412} residue in TAK1 is essential for cAMP/PKA-induced up-regulation of osteoclast differentiation and proinflammatory cytokine production in macrophages of osteoclast precursors.

PGE_2 Storongly Inhibits Human Osteoclast Differentiation. I. Take*[1], Y. Yamamoto*[1], H. Tsuboi*[2], Y. Kobayashi[1], S. Kurihara*[3], N. Udagawa[4], N. Takahashi[1]. [1]Institute for Oral Science, Matsumoto dental University, Nagano, Japan, [2]Department of Orthopaedic Surgery, Osaka University Graduate School of Medicine, Osaka, Japan, [3]Department of Orthodontics, Matsumoto dental University, Nagano, Japan, [4]Department of Biochemistry, Matsumoto dental University, Nagano, Japan.

PGE_2 is proposed to be a potent stimulator of bone resorption in experimental animal models. PGE_2 strongly enhances osteoclast formation induced by RANKL in cultures of mouse bone marrow-derived macrophages or mouse macrophage-like RAW264.7 cells. However, it is well known that administration of cyclooxgenase-2 (COX-2) inhibitors into rheumatoid arthritis patients does not always suppress the bone resorption in the chronic inflammatory lesions. In the present study, we explored the effect of PGE_2 on human osteoclast formation. CD14-positive ($CD14^+$) monocytes were prepared as osteoclast precursors from human peripheral blood, and cultured with RANKL and M-CSF in the presence or absence of PGE_2 and its related products. After culture for 7 days, cells were fixed and stained with anti-vitronectin receptor (CD51) antibody to identify osteoclasts formed in culture. $CD14^+$ cells were also co-cultured with SaOS4/3 cells which were shown to support osteoclastogenesis in response to PTH. mRNA expression of PGE_2 receptor subtypes (EP1-4) was examined in $CD14^+$ cells using RT-PCR. Intracellular cAMP production in $CD14^+$ cells was determined by ELISA. In contrast to murine macrophage cultures, PGE_2 as well as PGE_1 at 10^{-6} M completely inhibited osteoclast formation induced by RANKL and M-CSF in $CD14^+$ cell cultures. A specific EP2/4 agonist (PGE_1 Alcohol) but not an EP1 agonist (17-phenyl-trinor-PGE_2) inhibited human osteoclast formation induced by RANKL and M-CSF. H-89, a PKA inhibitor, rescued the inhibitory effect of PGE_2 on human osteoclast formation, and dibutyryl cAMP, a cell-permeable analogue of cAMP, inhibited it induced by RANKL and M-CSF. $CD14^+$ cells expressed EP2 and EP4 mRNAs. Both PGE_2 and EP2/4 agonist enhanced cAMP production in $CD14^+$ cells. PGE_2 also inhibited osteoclast differentiation induced by TNF-alpha and M-CSF in $CD14^+$ cell cultures. In addition, PGE_2 strongly inhibited osteoclast formation induced by PTH in cocultures of SaOS4/3 cells and $CD14^+$ cells. NS398, a COX2 inhibitor, enhanced PTH-induced osteoclast formation in the co-culture. These results suggest (i) that PGE_2 is a potent inhibitor for human osteoclastogenesis, (ii) that the EP2 and EP4-induced cAMP-PKA pathway is involved in the inhibitory effect of PGE_2 on human osteoclast formation, and (iii) that administration of COX-2 inhibitors to patients with elevated bone resorption may bring the result opposite to the expectation.

Dimerization of Receptor Activator of Nuclear Factor Kappa B (RANK) Is not Sufficient to Induce Fully Maturated Osteoclasts. T. Miyamoto[1], K. Iwamoto*[1], Y. Sawatani*[1], N. Hosogane*[2], M. Yagi*[1], N. Fujita*[1], Y. Toyama*[2], T. Suda*[1]. [1]Cell Differentiation, Keio University School of Medicine, Shinjuku, Japan, [2]Orthopaedics, Keio University School of Medicine, Shinjuku, Japan.

Osteoclasts are the bone resorbing multinulcear cells derived from hematopoietic stem cells. Two cytokines, macrophage colony stimulating factor (M-CSF) and receptor activator of nuclear factor kappa B ligand (RANKL), a member of the tumor necrosis factor (TNF) ligand family, is essential for osteoclastogenesis. M-CSF induces expression of RANK, and subsequent RANKL binding to RANK transduces signals for differentiation, survival and bone resorption via c-Fos and TRAF6, and this signal selectively induces NFATc1 expression. RANKL likely induces a receptor homotrimer like other family member such as TNFa and CD40 ligand, which transduces an appropriate differentiation signal to osteoclasts; however, whether a differentiation signal can be generated through formation of homodimers is unknown.
To address the signaling mechanism of the RANK receptor, we analyzed the effect of a homodimer inducer RANK-FKBP36v on osteoclastogenesis. The FKBP36v was fused to the C-terminus of RANK lacking the extracellular domain, and the resulting construct was transduced to RAW264.7 cells. The dimerization of this fusion protein was induced by addition of the chemical inducer of dimerization (CID) AP20187. Such treatment resulted in induction of TRAP-activity in a dose dependent manner, with an efficiency equivalent to that of induction by RANKL. Induction of NF-kB activation is comparable between CID-induced and RANKL-induced osteoclasts. However, CID-induced osteoclasts showed a relatively low pit forming activity on the dentine slices and multinucleation. Moreover, the expressions of the calcitonin receptor, cathepsin K and nuclear factor of activated T cells 1 (NFATc1) were low compared with RANKL binding. Thus, signaling induced by RANK-dimer is sufficient to induce TRAP enzymatic activity and NF-kB activation, while it is not enough to generate fully matured osteoclasts through NFATc1.

Cloning and Function of a Novel Orphan Seven Transmebrane Receptor Expressed in Osteoclasts. M. Yagi*[1], T. Miyamoto[1], Y. Sawatani*[1], N. Hosogane*[2], N. Fujita*[1], Y. Toyama*[2], T. Suda*[1]. [1]Cell Differentiation, Keio University School of Medicine, Shinjuku-ku Tokyo, Japan, [2]Orthopaedics, Keio University School of Medicine, Shinjuku-ku Tokyo, Japan.

Normal mineral homeostasis, skeletal formation and its maintenance are controlled by the coupled actions of two cell types in bone, osteoblasts and osteoclasts. Osteoclasts are bone resorbing cells, and their control is essential to prevent skeletal abnormalities characterized by osteoporosis or osteopetrosis.
Here we report the identification and characterization of a novel osteoclast specific receptor. This receptor is an orphan seven transmembrane receptor isolated by DNA subtraction method between oteoclasts and macrophages. Osteoclasts and macrophages are derived from common precursor cells (c-Kit+ c-Fms+ [RANK-]), and M-CSF alone induces macrophage whereas M-CSF and RANKL mediate osteoclastogenesis. To isolate osteoclast specific molecules, we have generated two cDNA libraries, and DNA subtraction method was performed. 103 molecules including previously known as osteoclast specific genes such as TRAP(ACP5) and cathepsin K were isolated. Among the molecules, we have identified a novel orphan receptor that specifically expressed in osteoclasts. This receptor has no homological molecules or conserved domain. This molecule has 1492bp cDNA with 4 exons spanning 15kb of genomic DNA, and start codon is located at 2nd exon. The 5' promoter resion of this receptor contains three consensus NFAT bindig motif within 200bp upstream of transcriptional start sight. Reporter assay revealed that an essential transcription factor for osteoclastgenesis NFAT is involved in the transactivation of this receptor. Overexpression of this receptor in RAW264.7 cells represents an abnormal actin ring formation suggesting that this receptor might be involved in the skeletal organization during osteoclastgenesis.
In order to analyze the function of this molecule, we have generated genetically null mouse. We knocked EGFP cDNA in second exon in frame to this molecule at the position of multi-transmembrane lesion located at 2nd exon. The birth rate of this genetically modified mouse follow Mendelian law indicating that no embryonic and perineonatal lethality were observed. Now we analyzed the gross morphological changes and histrogical evaluation of bone morphology in various stages to investigate the effect of this orphan receptor on osteoclastgenesis.

CD69 and Osteoclast Inhibitory Lectin have Similar Effects on Osteoclasts and Their Progenitors. J. M. W. Quinn[1], C. T. Gange*[1], H. Zhou[1], B. J. Jenkins*[2], A. Nakamura*[1], B. A. Cromer*[1], L. E. Purton*[3], C. Ly*[1], D. E. Myers*[4], T. J. Martin[1], K. W. Ng[5], M. T. Gillespie[1]. [1]St. Vincent's Institute of Medical Research, Fitzroy, Victoria, Australia, [2]Ludwig Institute of Cancer Research, Parkville, Victoria, Australia, [3]Peter Macallum Cancer Institute, Melbourne, Victoria, Australia, [4]Dept. Physiology, The University of Melbourne, Parkville, Australia, [5]Dept. Diabetes and Endocrinology, The University of Melbourne, Fitzroy, Australia.

CD69 is a membrane-bound lymphocyte activation marker with a C-type lectin extracellular domain similar to that of osteoclast inhibitory lectin (OCIL), an osteoclastogenesis and bone mineralisation inhibitor and a counter-receptor for the NK cell receptor Nkrp1d. No cellular actions or ligands of CD69 extracellular domain are known. Due to the similarity between CD69 and OCIL we compared their cellular expression in bone-derived cells and the cellular action of recombinant soluble CD69 and OCIL on osteoclast lineage cells (viz. osteoclast formation and survival, and hematopoietic cell colony formation), and compared their respective carbohydrate binding specificities. We identified CD69 and OCIL mRNA expression by murine bone marrow and bone marrow derived macrophages (from which osteoclasts derive) and murine macrophage/osteoclast lineage RAW264.7 cells. Murine osteoblasts expressed OCIL but not CD69 mRNA. CD69 and OCIL dose-dependently inhibited osteoclastogenesis from murine bone marrow cells and human cord blood progenitors (treated with RANKL and M-CSF) but not from RAW264.7 cells. M-CSF- and GM-CSF-dependent hematopoietic colony formation were also reduced by CD69 and OCIL, but formation of multi-lineage colonies was not affected. RANKL-stimulated osteoclast survival was not affected by CD69 or OCIL, but both proteins enhanced osteoclast survival in the absence of exogenous survival factors. Using ELISA methodology we found CD69 and OCIL both bound fucoidan, λ-carageenan, heparan sulphate and chondroitin sulphate but not unsulphated glycosaminoglycans. Thus, CD69 and OCIL show striking similarities in carbohydrate binding and their effects on osteoclast lineage cells. These results are the first demonstration of cellular actions of CD69, and identify new roles for CD69 and OCIL in bone metabolism.

Single Deficiency of FcRγ Chain, which Is Required for OSCAR (Osteoclast-associated receptor) Singaling Fails to Reveal Bone Phenotype. Y. Saita*[1], S. Ishikawa*[2], K. Kitahara[1], K. Tsuji[1], H. Kurosawa*[3], A. Nifuji[1], H. Arase*[2], T. Saito*[2], M. Noda[1]. [1]Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, [2]Molecular Genetics, Chiba University Graduate School of Medicine, Chiba, Japan, [3]Orthopedics, Juntendo University, School of Medicine, Tokyo, Japan.

Bone homeostasis is based on the balance between bone formation and resorption, which are due to the actions of osteoblasts and osteoclasts. The interaction between immune system and skeleton has been observed using mice deficient in molecules required for these systems. Osteoblasts provide RANKL and M-CSF to regulate osteoclastogenesis. OSCAR is expressed specifically in osteoclasts and it is expected to regulate osteoclast differentiation. However, it remained unclear how OSCAR transduces signal for the defferentiation of osteoclasts. Because OSCAR possesses a positively charged amino acid, arginine, within the transmembrane region, OSCAR may associate with ITAM-bearing signal transducing adaptor molecules such as CD3ζ, FcRγ,DAP12 and DAP10. Therefore, the bones of FcRγ-deficient(FcRγ-/-) mice were analyzed. Basal levels of bone volume in FcRγ knockout mice were similar to those in wild type. Bone mineral density, osteoclast number in vivo, and TRAP positive osteoclast-like cell number and the nodule formation in bone marrow cell cultures were all similar between FcRγ-deficient mice compared with wild type mice, in spite of the fact that FcRγ plays a critical role in OSCAR mediated signal transduction. Interestingly, BMP treatment-enhanced alkaline phosphatase level in FcRγknock out mice calvaria derived cells were higher than BMP-treated wild type cells. As recently reported by Koga et al., DAP12 or other accessory molecules would render ITAM-mediated signal to compensate for FcRγ in vivo for osteoclastogenesis.

Osteoclast Differentiation by Distinct Myeloid Lineage Mouse Bone Marrow Cell Populations. T. J. de Vries[1], T. Schoenmaker*[1], B. Hooibrink*[2], W. Beertsen[3], P. J. M. Leenen*[4], V. Everts[5]. [1]Experimental Periodontology, Academic Centre for Dentistry Amsterdam, Universiteit van Amsterdam and Vrije Universiteit, Amsterdam, Netherlands, [2]Cell Biology, Academic Medical Centre, Universiteit van Amsterdam, Amsterdam, Netherlands, [3]Periodontology, Academic Centre for Dentistry Amsterdam, Universiteit van Amsterdam and Vrije Universiteit, Amsterdam, Netherlands, [4]Immunology, Erasmus Medical Centre, Erasmus Universiteit, Rotterdam, Netherlands, [5]Oral Cell Biology, Academic Centre for Dentistry Amsterdam, Universiteit van Amsterdam and Vrije Universiteit, Amsterdam, Netherlands.

Although it has been recognized that osteoclasts can develop from cells of the myeloid lineage at various stages of maturity, little is known about how fast these cell types develop into osteoclasts. Murine bone marrow was fractionated by flowcytometry using CD31 (ER-MP12) and Ly-6C (ER-MP20) expression profiles. Early blasts (ER-MP12^{hi}/20^{-}), myeloid blasts (ER-MP12^{+}/20^{+}) and monocytes (ER-MP12^{-}/20^{hi}) were cultured in the presence of M-CSF and RANKL for 4, 6, 8 and 10 days. Expression of c-Fms and RANK, receptors for M-CSF and RANKL, respectively, was assessed by quantitative real-time PCR and the number of TRAP-positive multinucleated cells was assessed.
Quantitative PCR analysis revealed that all three fractions expressed high levels of c-Fms and RANK. Myeloid blasts developed rapidly into TRAP-positive multinucleated cells and maximal numbers were present after 4 days. At that time point, significantly more osteoclast-like cells developed in this fraction compared to unfractionated bone marrow, early blasts and monocytes. This difference was lost when culturing for a longer period. Osteoclast development by early blasts, monocytes and unfractionated bone marrow reached a maximum at 8 days of culturing. It has previously been shown that cells from the myeloid lineage mature with M-CSF from early blasts to myeloid blasts to monocytes and finally macrophages. To explore further the osteoclastogenic potential of the different cell fractions, each fraction was precultured for 3 days in the presence of M-CSF, followed by an incubation with M-CSF and RANKL for another 4 days. Cells developing from early blasts and monocytes under influence of M-CSF retained their capacity to develop into osteoclasts. In contrast, M-CSF stimulated myeloid blasts lost this potential. These results suggest that within bone marrow myeloid blasts develop fastest in osteoclasts. In contrast to earlier (blasts) and later (monocytes) stages of myeloid differentiation, myeloid blasts loose the capacity to differentiate into osteoclasts when preculured with M-CSF.

Proteomic Identification of the Increase in Creatine Kinase Brain Isoform Expression during Osteoclastogenesis. E. Chang*, Z. Lee, H. Kim. Cell and Developmental Biology, Seoul National University School of Dentistry, Seoul, Republic of Korea.

Recently there has been a great development in proteomics technology. Proteomics approach is an efficient way for the identification of proteins showing differential expression levels between targeted cells and tissues and their reference counterparts. Proteomics approaches also have revealed new links of many proteins to previously unexpected biological responses. We have employed the two-dimensional electrophoresis-based proteomics approach to find proteins of which expression is regulated during osteoclast differentiation. Total cellular proteins from Raw264.7 cells and osteoclast-like cells differentiated from Raw264.7 cells were subjected to isoelectric focusing over the pH range of 3-10, second dimensional SDS-PAGE, and silver staining. Protein spots showing differential levels of expression were picked and processed for in-gel digestion with trypsin. The masses of generated peptides fragments were determined using MALDI-TOF and peptide mass fingerprinting was performed. For some protein spots, tandem mass analyses were carried out. By ESI-Q/TOF tandem mass analyses creatine kinase brain isoform was found to be highly increased in differentiated cells. The increase in creatine kinase brain isoform expression was confirmed by RT-PCR and Western blotting experiments in both Raw264.7 cell and bone marrow cell cultures.

The Role of Ceatine Kinase Brain Isoform for Osteoclast Differentation and Function. E. Chang*, Z. Lee, H. Kim. Cell and Developmental Biology, Seoul National University School of Dentistry, Seoul, Republic of Korea.

We have found that the expression of brain isoform of ceatine kinase is highly up-regulated during osteoclastogenesis by a 2DE-based proteomics approach. To investigate the functional significance of ceatine kinase brain isoform expression in osteoclasts, we examined the effects of blocking the activity of this enzyme or reducing the expression level on osteoclast differentiation and resorption activity. Ectopic expression of two different kinds of dominant-negative forms of this enzyme resulted in a decrease in multinucleated TRAP-positive osteoclasts. A pharmacological inhibitor of creatine kinase also suppressed multinucleated osteoclast formation. During the generation of actin ring structure, creatine kinase brain isoform became colocalized with actin ring. The creatine kinase inhibitor disrupted this colocalization and the resorption function of osteoclasts. Inhibition of the expression of creatine kinase brain isoform by antisense oligonucleotide or RNAi also showed reduced osteoclast multinucleation and activity. Finally, calvarial implant study with the creatine kinase inhibitor revealed reduced osteoclast activity in vivo under conditions where remodeling was stimulated by IL-1 or RANKL. Taken together, these data demonstrate that the brain isoform of ceatine kinase has important roles in osteoclast differentiation and function.

Multiple Nuclei in Osteoclasts Functionally Compartmentalize Gene Regulatory Machinery. L. Saltman*[1], A. Javed[1], S. Hussain*[1], A. J. van Wijnen[1], J. L. Stein*[1], G. S. Stein[1], J. B. Lian[1], Z. Bar-Shavit[2]. [1]Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, [2]Experimental Medicine and Cancer Research, Hebrew University, Jerusalem, Israel.

Osteoclasts are multinucleated cells responsible for bone resorption. *In vivo*, these cells can have more than 20 nuclei, but the functional activities of the multiple nuclei are not understood. To address whether these nuclei serve equivalent roles or have distinct functions, we examined the intranuclear organization of the regulatory machinery for gene expression by *in situ* immunofluorescent staining. As in mononuclear cells, we found osteoclast nuclei to be compartmentalized in functional domains for RNA processing, ribosomal RNA synthesis and mRNA transcription, as detected by antibodies against SC35,

B23 and RNA Pol II, respectively. These three components of gene expression are present in all osteoclast nuclei. We further examined the representation and intranuclear localization of the transcription factors Runx1 and NFκB, which are essential for hematopoiesis and osteoclastogenesis, respectively. We demonstrate that each of these regulatory proteins is localized in nuclear matrix-associated punctuate foci, and that all the nuclei of a single osteoclast contain similar levels of protein. RANKL-induced osteoclast differentiation is accompanied by a significant decrease in the intensity of Runx1 foci and an increased intensity of NFκB foci. Biochemical analyses revealed that Runx1 levels decrease by approximately 70% upon osteoclast differentiation in two established models (mouse bone marrow cells and the macrophage cell line RAW264.7). This is seen for both the RNA and protein and occurred within the first twenty-four hours of differentiation. Runx2 and Runx3 proteins were undetectable by western analysis of the osteoclasts, as well as their monocytic precursors, and further analysis by quantitative RT-PCR indicates that Runx2 and Runx3 mRNA levels are up to 50-fold lower than Runx1. In conclusion, these studies have established that all osteoclast nuclei (i) are not only transcriptionally active but appear to be structurally quite similar; (ii) have similar functional activities; and (iii) downregulate Runx1 expression and protein at the early stages of osteoclast differentiation.

TNF Increases Bone Marrow Osteoclast Precursor Numbers by Stimulating Their Proliferation and Differentiation through up-Regulation of c-Fms Expression. Z. Yao*[1], P. Li*[2], Q. Zhang*[1], E. M. Schwarz[2], L. Ma*[2], P. Keng*[3], B. F. Boyce[1], L. Xing[1]. [1]Pathology, University of Rochester, Rochester, NY, USA, [2]Center for Musculoskeletal Research, University of Rochester, Rochester, NY, USA, [3]Cancer Center, University of Rochester, Rochester, NY, USA.

Osteoclasts (Ocls) are derived from myeloid lineage mononuclear bone marrow progenitors, which proliferate and differentiate in response to growth factors and cytokines to become TRAP+ cells that fuse and form mature ocls. Because specific progenitor cell markers are unavailable, the regulation of TRAP- ocl precursor (OCP) formation has been difficult to study in detail, particularly in inflammatory states in which cytokines, such as TNF are increased. Here, we used wt and TNF transgenic (TNF-Tg) mice and FACS analysis to investigate the effects of TNF on bone marrow OCPs. We used CD11b and Gr-1 as myeloid cell surface markers to flow sort various cell populations and cultured sorted cells with M-CSF and RANKL to determine which bone marrow cell populations comprise OCPs. Ocls formed from $CD11b^+/Gr\text{-}1^{-/lo}$ (153+/-16/well) and $CD11b^-/Gr\text{-}1^{-/lo}$ (17+/-9/well) populations, but not from $CD11b^+/Gr\text{-}1^+$ (0/well) cells. TNF-Tg mice have significantly more $CD11b^+/Gr\text{-}1^{-/lo}$ cells (12+/-3%) than wt mice (6.5+/-0.7%) and significantly more $CD11b^+/Gr\text{-}1^{-/lo}$ cells proliferating in S phase (28+/-2% vs 18+/-2%), but similar numbers undergoing apoptosis. Treatment of wt bone marrow cells with TNF and M-CSF *in vitro* for 3d significantly increased the % of CD11b+ proliferating cells. To test if TNF promotes OCP differentiation, we used c-Fms as a cell surface marker for late OCPs. We found that: 1) TNF-Tg mice have increased $CD11b^+/c\text{-}Fms^+$ cells (5% vs 2% in wt mice); 2) TNF-treated wt bone marrow cells have increased % $CD11b^+/c\text{-}Fms^+$ OCPs (40% vs 4% in PBS-treated cells); 3) Increased c-Fms expression by OCPs is directly associated with ocl forming potency in response to TNF (454+/-9 ocl/well vs 47+/-6 in PBS-treated cells); 4) TNF stimulates c-Fms mRNA expression by OCPs. Furthermore, bone marrow cells, but not spleen cells from the TNF-Tg mice have increased expression of M-CSF, suggesting that TNF promotes increased expression of M-CSF by bone marrow stromal cells. We conclude that OCPs are derived from $CD11b^{+/-}/Gr\text{-}1^{-/lo}$ cells; that $CD11b^+/Gr\text{-}1^{-/lo}$ cells are increased in TNF-Tg mice; and that TNF stimulates the expression of c-Fms by OCPs leading to their proliferation and differentiation under the influence of increased M-CSF production. Thus, a major mechanism whereby TNF promotes bone resorption in inflammatory bone diseases may be increasing the number of bone marrow OCP, which can then circulate to inflamed joints and differentiate further into osteoclasts.

Activation of the Wnt Signalling Pathway Inhibits Osteoclast Differentiation and Bone Resorption. T. A. Althnaian, S. P. Allen*, M. Muzylak*, J. G. Mount*, J. S. Price. Basic Sciences, Royal Veterinary College, London, United Kingdom.

The Wnt signaling pathway is now known to be a critical regulator of osteoblast differentiation and function. However, the role of this pathway in the control of osteoclasts has been little studied. We recently immunolocalised activated β-catenin, a component of the canonical Wnt signalling pathway, in regenerating deer antlers at a site where osteoclasts differentiate *in vivo*. This led us to hypothesise that the canonical Wnt signalling pathway may regulate osteoclastogenesis in regenerating bone. Osteoclast differentiation was induced in high density micromass cultures of antler chondrocytes as we have previously described. Cultures were treated for 9 days with LiCl, an activator of β-catenin via GSK inhibition, or Epigallocatechin-3-gallate (EGCG), which antagonises the transcriptional activation of Tcfs. Activation of Wnt signalling by LiCl significantly decreased the numbers of TRAP positive osteoclasts formed (by 30-40%) and the area of dentine resorbed (by 25-40%), as determined by lectin staining and image analysis. RANKL mRNA expression was down regulated in LiCl treated cultures. EGCG (1-25 micromolar) did not change the numbers of osteoclasts formed but at a dose of 6 μM increased the area of dentine resorbed (twofold). ECGC treatment for 24 hours also dose-dependently induced apoptosis in mature osteoclasts. In sections of antler cartilage, RANKL and the active form of β-catenin were immunolocalised in perivascular tissue, a region where TRAP and vitronectin receptor positive cells were also identified.
In conclusion, this study provides evidence that the Wnt signalling pathway regulates the formation, function and survival of osteoclasts in regenerating bone. Since regeneration generally involves recapitulation of developmental signalling pathways these results suggest that the Wnt pathway may control osteoclast function in the wider context.

Formation of Osteoclasts from Human Umbilical Cord Blood Cells Is Regulated by Chondrocytes, Osteoblasts and Fibroblasts. B. Sukhu*[1], I. Rogers*[2], H. C. Tenenbaum[1], J. Sodek*[1], R. F. Casper*[1]. [1]Dentistry, University of Toronto, Toronto, ON, Canada, [2]Research Institute, Mount Sinai Hospital, Toronto, ON, Canada.

Human umbilical cord blood (HUCB) was shown to contain a greater abundance of haematopoietic stem cells when compared to human adult peripheral blood. As such HUCB could serve as an excellent source of osteoclast precursors. Previous work have shown that osteoclast-like cells generated from HUCB express cathepsin K, tartrate resistant acid phosphate (TRAP) and resorb bone. This study was carried out to characterize further osteoclasts-like cells formed from HUBC. When HUBC cells were grown alone in a-MEM containing 20% fetal calf serum multi-nucleated, TRAP-positive cells with actin ring formation and the ability to resorb calcium phosphate-coated slides were identified. The addition of both GMCSF and RANKL to the culture media increased both TRAP activity and the resorptive ability of these cells. In order to assess the influence of other cell types on osteoclasts formation in HUCB, these cells were grown in co-culture with chondrocytes, osteoblasts and fibroblasts. The results showed that when cord cells were grown in contact with chondrocytes and osteoblasts the number of TRAP positive cells increased considerably. However, when these cells were in co-culture but not in contact with each other the TRAP positive cells were almost diminished. On the other hand, co-culture of cord cells with fibroblasts either in contact or not completely inhibited the formation of TRAP positive cells. Furthermore, it was also seen that conditioned media from osteoblasts inhibited TRAP positive cell formation in a dose dependent manner. These results suggest that osteoclast-like cells can be derived from HUCB and that the formation of these cells was determined by neighbouring cells that produce RANKL and OPG, molecules that regulate osteoclast formation. In addition, the results suggest that membrane bound RANKL may have a more potent effect on osteoclast-like cell formation than the soluble form.

Effect of Nicotine on Osteoclastogenesis in Cultures of Murine Bone Marrow Cells. P. C. Pfeifer*, J. A. Yee. Biomedical Sciences, School of Medicine, Creighton University, Omaha, NE, USA.

Smoking is a risk factor for osteoporosis, but the basis for this relationship is unknown. Although previous studies have examined the effect of nicotine on osteoblasts, few have focused on its effects on osteoclasts. The purpose of this study was to determine if nicotine, a major constituent in tobacco, affected the formation, proliferation, and death of osteoclasts *in vitro*. Cultures were exposed to nicotine at concentrations ranging from 0.05 to 500 μ M, in the absence or presence of 25 nM parathyroid hormone-related peptide (PTHrP). The effect of nicotine on basal and PTHrP-stimulated osteoclastogenesis on days 1-6 was determined by counting the number of TRAP-positive mononuclear cells (pre-osteoclasts), TRAP-positive multinuclear cells (osteoclasts), and the number of nuclei per osteoclast. Effects on cell proliferation were determined by calculating a BrdU labeling index for pre-osteoclasts and TRAP-negative cells. Effects on apoptosis were measured by determining the proportion of TUNEL stained osteoclasts, osteoclast nuclei, pre-osteoclasts, and TRAP-negative cells. Treatment with PTHrP increased the number of pre-osteoclasts and osteoclasts compared to untreated control cultures. Adding nicotine to PTHrP-treated cultures significantly reduced the number of pre-osteoclasts on days 3-6, osteoclasts on days 4-6, and the number of nuclei per osteoclast on day 6. In the absence of PTHrP, nicotine significantly reduced the BrdU labeling index of pre-osteoclasts on day 2, but had no effect on BrdU incorporation in PTHrP-treated cultures. Treatment with nicotine alone or with PTHrP significantly increased the apoptotic labeling index for pre-osteoclasts, osteoclasts, and for nuclei in individual osteoclasts on day 4 and/or day 6. These results demonstrate that nicotine inhibited both basal as well as PTHrP-stimulated osteoclastogenesis *in vitro*. The time-course of the effects of nicotine on the measured endpoints suggests that the decrease in osteoclastogenesis was due to a combination of effects including a decrease in the proliferation of pre-osteoclasts and an increase in the apoptosis of pre-osteoclasts and osteoclasts. These results suggest that bone loss associated with tobacco use may be related to an altered balance between bone formation and resorption.

Disclosures: ***P.C. Pfeifer****, None.*

Active Caspase 3 Is Required for Osteoclast Differentiation. K. H. Szymczyk*, V. Srinivas, C. S. Adams, I. M. Shapiro, M. J. Steinbeck. Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

Caspase 3 is an effector enzyme involved in the execution of many apoptotic pathways. Although typically associated with apoptosis, the active form of this enzyme was recently shown to be essential for cell differentiation, fusion, and morphogenesis. It is not known whether osteoclasts, another type of cell that fuses to form multinucleate cells, requires active caspase 3 for differentiation. Thus, the aim of this study was to test the hypothesis that active caspase 3 is required for osteoclast differentiation. To induce differentiation, RAW264.7 cells were treated with 35 ng/mL of receptor-activator of NF-kB ligand (RANKL) for 4 days. Activity of tartrate-resistant acid phosphatase (TRAP), an enzyme highly expressed by mature osteoclasts, and formation of multinucleate cells were used as indicators of differentiation. After 4 days, the cells were found viable as assayed by Neutral red dye uptake and TUNEL staining. Within in one hour of RANKL treatment, active caspase 3 was detected by confocal microscopy using the caspase 3 substrate PhiPhiLux. To determine the importance of active caspase 3 in pre-osteoclast differentiation, we pharmacologically inhibited caspase 3 in pre-osteoclasts with 200 μM Ac-DEVD-CHO or Z-DEVD-FMK for 60 min before and during RANKL treatment. Pre-osteoclasts that had pharmacologically inhibited caspase 3 did not express TRAP and there was a decrease in formation of multinucleate cells. In addition, we created pro-caspase 3 knockdown RAW264.7cell lines using siRNA technology. Clones were isolated and Western blot analysis confirmed the absence of pro- caspase 3. Procaspase-3 knockdown cells also failed to differentiate after RANKL treatment. Our results clearly illustrate that active caspase 3 is essential for osteoclast differentiation. Targeted modulation of caspase 3 activity provides a new pharmacological approach to controlling osteoclast bone resorption in osteoporosis.

The Role of Bone Matrix in Osteoclast Differentiation and Activation. Z. Shen[1], R. Fajardo*[2], A. Tsay*[1], T. Crotti[1], K. McHugh[3], S. D. Bromme*[4], B. E. Bierbaum*[1], S. R. Goldring[1]. [1]New England Baptist Bone and Joint Institute, Beth Israel Deaconess Medical Center, Boston, MA, USA, [2]Orthopedic Biomechanics Lab, Beth Isreal Deaconess Medical Center, Boston, MA, USA, [3]Orthopedics, Children's Hospital, Boston, MA, USA, [4]Mount Sinai School of Medicine, New York, NY, USA.

Analysis of tissues from patients with rheumatoid arthritis (RA) and bone loss associated with failed orthopedic implants reveals cells with phenotypic features of osteoclasts (OC) localized to the resorption fronts at the interface between the inflammatory tissue and the bone surface. In both conditions there are also cells off the bone surfaces that express Cathepsin K (Cat K) or tartrate resistant acid phosphatase (TRAP). In contrast, expression of the calcitonin receptor (CTR) is confined to cells on the bone surface. The restricted induction of the CTR gene suggests that specific signals are provided by interaction of the OC precursors with the bone substrate that are required for terminal OC differentiation. To directly assess the role of bone matrix in osteoclast recruitment and differentiation, 4 mm discs of murine calvaria were implanted at intramuscular sites in recipient mice. Within several days an inflammatory reaction developed at the circumferential margins of the bone, corresponding with the regions of mineralized bone surface that had been exposed by cutting the discs from the calvarium. The initial cellular response consisted predominantly of macrophage-type cells, as indicated by detection of the lineage specific marker F4/80. Over the next several weeks, Cat K and TRAP expression were induced both in cells on the bone surface, as well as in the immediate surrounding tissue. In contrast, CTR expression was restricted to cells in direct contact with the bone surface, duplicating the pattern of CTR expression in RA and peri-implant tissues. Recent data indicate an essential role of NFATc1 in OC differentiation. A marked up-regulation of NFATc1 was detected on cells associated with the bone surfaces compared with cells distant from the implant. Micro CT imaging revealed a decrease in the disc area over 6 wks consistent with active bone resorption. Pretreatment of calvaria with Type 1 collagenase (Worthington Biochem) resulted in a marked increase in bone resorption area (40.8%). Bone loss associated with CTR, Cat K and TRAP positive cells was noted on both the inner and outer surfaces of the calvaria as well as the cut margins. Removal of the periosteal surfaces by scapel dissection did not enhance resorption. These results indicate the role of the bone substrate in terminal regulation of OC differentiation and provide further evidence that "preparation" of the bone surface contributes to OC-mediated bone resorption.

The Microphthalmia-Associated Transcription Factor (Mitf) Is Required for Proper Bone Development. C. L. Hershey[1], Y. L. Lin[2], D. E. Fisher[1]. [1]Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]OHS-Oral Pathology, University of Kentucky, Lexington, KY, USA.

The Microphthalmia-associated transcription factor (Mitf) is a member of the MiT basic/helix-loop-helix/leucine zipper transcription factor family, which includes Mitf, Tfe3, Tfeb and Tfec, and is required for the differentiation and survival of osteoclasts, melanocytes, retinal pigment epithelium and mast cells. We show here that osteoclasts express all 4 members of the MiT family, including at least 7 Mitf isoforms. A dominant negative mutation in murine Mitf ($Mitf^{microphthalmia}$) results in osteopetrosis due to the lack of mature functional osteoclasts. In contrast, mice carrying null alleles of Mitf have been thought to exhibit no osteopetrotic phenotype (Steingrimsson et al., 1994 and Hemesath et al., 1994). This effect has been explained by the observation that Tfe3 (a close relative and dimerization partner of Mitf) is also expressed in osteoclasts (Weilbaecher et al., 1998) and Tfe3/Mitf double null mice exhibit severe osteopetrosis, whereas neither single null does (Steingrimsson et al., 2002). However, we previously identified a deletion in the *Mitf* gene in the *mib* rat that is expected to behave as a null, yet produces age-resolving osteopetrosis. Based on these results, we sought to further study the null $Mitf^{mga\text{-}9}$ mouse to determine if the lack of Mitf in the mouse also causes a bone phenotype. Based on histological analysis of femurs and tibiae, the null $Mitf^{mga\text{-}9}/Mitf^{mga\text{-}9}$ mice have unresorbed primary and secondary spongiosa compared to control littermates, suggesting a mild osteopetrosis. The osteopetrosis is visible in mice ages 2 to 8 months old, with younger and older mice still under investigation. The increase in bone density was visible in nearly every $Mitf^{mga\text{-}9}/Mitf^{mga\text{-}9}$ mouse examined but varied in severity. Micro CT measurements were used to quantitate the bone phenotype and it was observed that the $Mitf^{mga\text{-}9}/Mitf^{mga\text{-}9}$ mice have increased trabecular bone compared to controls, but relatively similar measures of cortical bone. In *in vitro* osteoclast differentiation assays, the $Mitf^{mga\text{-}9}/Mitf^{mga\text{-}9}$ osteoclasts were more sensitive to decreases in RANKL or MCSF concentrations than control osteoclasts as seen by a decrease in the number of multinucleated TRAP+ cells. This sensitivity to limiting growth factor concentrations likely explains part of the decrease in osteoclastic activity in these mice. The results presented here indicate that loss of Mitf produces a bone phenotype that cannot be fully compensated for by Tfe3 or other MiT family members. This places Mitf among the transcription factors that are fundamentally required for osteoclast differentiation and proper bone development.

In Vivo **Treatment with Celecoxib, an Inhibitor of COX-2, Suppresses Serum Levels of Bone Resorption but not Bone Formation Markers in Ovariectomized Mice.** Y. Kasukawa[1], N. Miyakoshi[1], A. Srivastava[2], K. Nozaka[1], S. Maekawa[1], D. J. Baylink[2], S. Mohan[2], E. Itoi[1]. [1]Orthopedic Surgery, Akita Univ., Akita, Japan, [2]J.L. Pettis VAMC, Loma Linda, CA, USA.

The importance of prostaglandins as mediators of inflammatory cytokines and growth factors in regulating both bone formation and resorption has been well documented. Prostaglandins are produced by the sequential actions of phospholipase A2 and cyclo-oxygenase (COX) from membrane phospholipids. Celecoxib is a highly selective inhibitor of COX-2 and has been shown to be anti-inflammatory in its action. Furthermore, recent findings have shown that celocoxib inhibited osteoclastogenesis *in vitro* and delayed fracture healing *in vivo* in animals but not in humans. Based on these findings, we proposed that celecoxib could be used to suppress elevated bone resorption that occurs due to sex hormone deficiency. To test this hypothesis, celecoxib (4 mg/kg) or its vehicle was administered orally into ovariectomized (OVX) or sham operated mice and serum levels of bone markers were evaluated. The surgery was performed at 8 weeks of age, and the treatment was started daily by gavage for 4 weeks. Blood samples were collected from retro-orbital sinus at 2 weeks after the treatment under anesthesia and from decapitation at 4 weeks after the treatment. Serum C-telopeptide, which has been shown to reflect degradation products of type I collagen that are generated during osteoclastic bone resorption, and osteocalcin, which is a measure of osteoblast activity, were measured using validated assays. C-telopeptide levels were increased by 37% ($P<0.01$) and 60% ($P<0.01$) in OVX mice compared to those in sham mice at 2 and 4 weeks respectively after treatment with vehicle. Celecoxib treatment significantly decreased the serum C-telopeptide levels in the OVX mice at 2 and 4 weeks after treatment (45% and 41% respectively, $p<0.001$). Furthermore, this treatment also decreased the C-telopeptide levels in sham mice at each time point (21% at 2 weeks and 29% at 4 weeks after treatment, $P<0.05$). Serum osteocalcin level was increased as expected in OVX mice compared to sham mice at 4 weeks (69%, $P<0.01$). However, celecoxib treatment did not suppress the elevated serum osteocalcin levels in the OVX mice at either time point. Conclusions:1) Celecoxib treatment blocked OVX-induced increase in serum C-telopeptide levels and decreased serum C-telopeptide levels in sham mice; 2) Celecoxib had no effect on serum osteocalcin levels either in OVX or in sham mice; 3) The confirmation of the hypothesis that celecoxib inhibits elevated bone resorption but not bone formation in OVX mice would provide therapeutic advantage of this drug in the treatment of bone loss that occurs during postmenopausal period.

Analysis of Bone Remodeling in Neonatal Murine Calvarial Cultures by Laser Scanning Confocal Microscopy. K. Suzuki*[1], S. Takeyama*[2], T. Kikuchi*[2], S. Yamada*[1], J. Sodek*[3], H. Shinoda[2]. [1]Dept. Pharmacol., Sch. Dent., Showa Univ., Tokyo, Japan, [2]Div. Pharmacol., Grad. Sch. Dent., Tohoku Univ., Sendai, Japan, [3]CIHR Group in Matrix Dynamics, Fac. Dent., Univ. of Toronto, Toronto, ON, Canada.

We used laser confocal microscopy to examine the effects of bisphosphonates (BP) on bone remodeling in neonatal murine calvariae *in situ*, which provides a unique system with which to study bone formation and resorption in the absence of systemic influences. Responses were determined by fluorescence staining for TRAP activity, F-actin, β3 integrin, osteopontin, ALPase activity, collagen type I and bone mineral in calvariae cultured in the presence of 10μg/ml LPS or 10^{-8}M PTH and/or BP (1~25μM clodronate or 0.1~2.5μM risedronate) for up to 48 hrs. The morphological abnormalities, including retraction of pseudopods and vacuolization of cytoplasm were observed in non-resorbing osteoclasts in BP-treated calvariae. In calvariae cultured in the presence of PTH and BP, the multinucleated osteoclasts were smaller, displayed severe cytoplasmic vacuolization, and the sealing zone was diffuse compared to osteoclasts in calvariae cultured with PTH alone. Furthermore, the presence of actin, osteopontin and β3 integrin along the edge of resorbing osteoclasts, which is required for cell attachment to the resorption site, was markedly reduced. Serial optical sections above the resorption lacunae revealed ALPase-positive and collagen type I-producing cells with morphological features of osteoblastic cells, which fill the resorbed area and proliferate on top of the resorbed area of bone. From XZ (depth) scans of the calvaria double-stained for actin and mineral after culturing under

various conditions, it was evident that cell proliferation had been stimulated in LPS-treated calvariae, regardless of the presence of BP. In control calvariae and clodronate-treated calvaria, little accumulation of cells with ALPase activity was observed, indicating that the proliferation of bone-forming cells occurs in response to accelerated bone resorption induced by LPS. The area of the remaining bone mineral and proliferation of bone-forming cells were measured from the XZ-images of calvariae stained with Alizarin Red S and Alexa Fluor 488-phalloidin, assuming that the ALPase-positive and collagen-producing cells were bone-forming cells. A negative correlation between the area of mineral remaining and cell proliferation was observed in LPS-treated groups, regardless of the presence of BP. In conclusion, laser scanning confocal microscopy of immunofluorescently labeled calvariae maintained *in situ* provides a valuable approach for evaluating the effects of biological agents on bone remodeling.

Antisense Oligonucleotides Targeting Mouse RANK and RANKL Inhibit Hypercalcemia and Ovariectomy-Induced Bone Loss. M. Liu*[1], X. Li[2], Y. Wang*[1], D. Halladay*[1], Q. Zeng*[1], C. Thompson*[2], J. Finger*[2], L. Ma*[1], S. Gregory*[2], H. Bryant*[1], R. Galvin*[1], K. J. Myers*[2]. [1]Lilly Research Labs, Indianapolis, IN, USA, [2]ISIS Pharmaceuticals, Carlsbad, CA, USA.

RANK-RANKL-OPG balance is critical for osteoclast activity and bone resorption. We have developed and characterized modified antisense oligonucleotides specific for mouse RANK and RANKL and have evaluated their activity in murine models of hypercalcemia and ovariectomy-induced bone loss. *In vitro*, the RANK and RANKL ASOs were equipotent at reducing targeted mRNAs in transfected cell lines with IC_{50}s in the 50-75 nM range. In a mouse model of PTH-induced hypercalcemia, 2-wk prophylactic treatment with either the RANK or RANKL ASOs reduced the targeted mRNA in bone by as much as 60%. Treatment with either the RANK or RANKL ASOs also provided dose-dependent reductions in serum calcium. Treatment with the RANK ASO at 30 mg/kg/d showed similar efficacy to the positive control calcitonin, while treatment with the RANKL ASO at the same dosage and regimen was about 50% as effective as the RANK ASO. When adult female mice were treated s.c. at 3, 10, or 30/mg/kg/d one week prior to ovariectomy (OVX) and continuing for five weeks after OVX, both the RANK and RANKL ASOs prevented the OVX-induced bone loss in a dose-dependent manner. The BMD of the 30 mg/kg/d RANK or RANKL ASO-treated groups was maintained at the level of sham-operated mice. A histological assessment of bones from the RANK ASO study revealed a reduction in trabecular bone osteoclast numbers, as well as improvements in trabecular area and thickness.

Previous studies have demonstrated that OPG and RANKL antibodies could inhibit bone resorption. Our results, however, are the first to show that antisense oligonucleotides which directly target and downregulate the mRNA of the RANK receptor or its ligand are effective in reducing bone resorption in rodent models. This suggests that antisense oligonucleotides targeting the RANK signaling pathway could prove useful in the treatment of osteoporosis or other bone diseases characterized by increased bone resorption.

Elucidating Mechanistic Differences in Activation between Large and Small Osteoclasts. D. P. Trebec*[1], K. Li*[2], D. Chandra*[2], J. N. M. Heersche[2], M. F. Manolson[2]. [1]Department of Biochemistry, University of Toronto, Toronto, ON, Canada, [2]Faculty of Dentistry, University of Toronto, Toronto, ON, Canada.

Large osteoclasts (OC) (≥ 10 nuclei) are predominantly observed in diseases associated with excessive bone loss due to increased osteoclastic resorption such as Paget's disease, inflammatory arthritis and periodontal disease [1]. Large OCs were previously shown to resorb more bone than small OCs (≤5 nuclei) [2,3], leading us to hypothesize that size and resorptive activity of osteoclasts are linked, and may result from mechanistic differences in activation. Thus, we have sought to identify factors involved in signaling (c-fms, RANK, TNFR1, IL-1R1, $\alpha_v\beta_3$ SHIP), fusion (SIRPα1), and ion transport (CAII, AE3, V-ATPase) which may differ between large and small OCs. *In situ* hybridization on rabbit OCs demonstrated a 2.7-fold increase in expression of c-fms mRNA in large versus small OCs. Using the differentiated RAW 264.7 cell culture system to examine protein expression by quantitative immunoblotting, we were able to also show an increase (~1.8 ± 0.08-fold) of c-fms protein on large OCs. Significant differences were observed in protein expression of enzymes proMMP9, matMMP9 and pro-cathepsin K (3.8 ± 0.02-, 2.7 ± 0.01- and 2.6 ± 0.08-fold respectively) between large and small OCs. Moreover, increases were noted in expression of receptors on large OCs including: RANK (~2.5 ± 0.3-fold), IL-1R1 (~2 ± 0.6-fold) and TNFR1 (~2.2 ± 0.2-fold). Integrin α_v displayed a 2.8 ± 0.9-fold increase while β_3 was noted to be significantly higher with ~4.5-fold increase in large OCs. In contrast, ~1.5-fold increases in expression of SIRPα1 and IL-1R2 were noted on small OCs as compared to large. Thus, an up-regulation was noted for enzymes MMP-9 and cathepsin K involved in osteoclast resorption as well as for receptors c-fms, IL-1R1, TNFR1, RANK and integrins implicated in osteoclast activity. These findings suggest differences in resorption between the two osteoclast sizes results from a variation in receptor levels with large OCs being more susceptible to activation while small OCs have increased levels of inhibitory (IL-1R2) and fusion receptors. Elucidating specific differences between large and small osteoclasts may result in novel targets for therapeutic intervention to inhibit excessive resorption by larger osteoclasts in a pathological state.

Risedronate and Other Nitrogen-containing Bisphosphonates Are Selectively Internalized from Bone by Osteoclasts and Inhibit Protein Prenylation *in vitro* and *in vivo*. F. P. Coxon*[1], A. Hughes*[1], F. H. Ebetino[2], M. J. Rogers[1]. [1]Bone Research Group, University of Aberdeen, Aberdeen, United Kingdom, [2]Procter & Gamble Pharmaceuticals, Cincinnati, OH, USA.

Bisphosphonates (BPs) target to bone due to their high affinity for calcium ions. During osteoclastic resorption, BPs appear to be released from the bone surface due to acidification and can then be internalized by osteoclasts, where they act by inhibiting the prenylation of small GTPases essential for osteoclast function. However, it remains unclear whether osteoclasts are the only cells in the bone microenvironment that can take up BPs from the bone surface. We have begun to investigate this using a novel fluorescently-labelled alendronate analogue (FL-ALN) and by examining changes in the prenylation of the small GTPase Rap1A.

Bone marrow cells isolated from rabbits were cultured for 24 hours on dentine slices pre-coated with FL-ALN. Confocal microscopic analysis showed that FL-ALN was internalized by resorbing osteoclasts into intracellular vesicles throughout the cell. This pattern of uptake also occurred with FL-ALN in the absence of dentine, and could be prevented by the presence of molar excess of risedronate or other BPs. Although there was no evidence of uptake by other cells in the cultures on dentine e.g. stromal cells, most bone marrow cells were able to internalise FL-ALN from solution.

To examine uptake of bisphosphonates by bone cells *in vivo*, osteoclasts were isolated from rabbit bone marrow cells using immunomagnetic beads and antibody to the vitronectin receptor (VNR). Prenylation of Rap1A was inhibited in the VNR-positive osteoclast fraction from rabbits that had been injected subcutaneously with 1mg/kg risedronate, alendronate, ibandronate, pamidronate or zoledronic acid, demonstrating that osteoclasts internalise these BPs *in vivo*. However, there was negligible effect on Rap1A prenylation in the general population of non-osteoclast, VNR-negative bone marrow cells. A phosphonocarboxylate analogue of risedronate (NE10790, 45mg/kg), which has lower affinity for bone, also inhibited protein prenylation in VNR-positive osteoclasts but not in the VNR-negative bone marrow population, whereas 0.3mg/kg cerivastatin (lacks affinity for bone) inhibited protein prenylation in both fractions.

These data demonstrate that osteoclasts, but not general bone marrow cells, can take up sufficient BP *in vivo* to cause detectable inhibition of protein prenylation. However, it does not exclude the possibility that minor populations of bone marrow cells or tumour cells could also internalize BPs, or that BPs are taken up by some cells to such a low extent that changes in protein prenylation are not detectable.

Degradation of the Organic Phase of Bone by the Osteoclast - a Role for Acidification. K. Henriksen*[1], M. G. Sørensen*[1], S. Schaller*[1], J. Gram*[2], P. Høegh-Andersen*[1], J. Bollerslev*[3], M. A. Karsdal[1]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Ribe County Hospital, Esbjerg, Denmark, [3]National University Hospital, Oslo, Norway.

Osteoclasts degrade the inorganic phase of bone by secretion of acid into the resorption lacuna. This process is mediated by the osteoclast specific proton pump (a3), and the chloride channel ClC-7. However, whether these proteins participate in other functions in the osteoclasts has not been clearly demonstrated.

We have developed an assay using decalcified bone slices and isolated human osteoclasts to evaluate the importance of ClC-7 and the proton pump in the osteoclast mediated degradation of a calcium free matrix. Firstly, we characterized the system to assure that osteoclasts are the principal cells degrading this matrix, and accordingly, we found that RANKL dose-dependently induces degradation of the decalcified bone slices. We characterized the cells with respect to morphology and expression of osteoclastic proteins such as cathepsin K and ClC-7. By cytochemistry we found that both cathepsin K and ClC-7 were present but not localized in a gradient towards the resorption pit as on normal bone. By actin staining we found that osteoclasts on decalcified bone did not form actin rings, but instead appeared motile with a large number of podosomes. Furthermore, resorption pits are not formed on decalcified bones, however migratory "tracks" was found by staining for collagen type I fragments.

To assess the role of acidification in the degradation of decalcified bone, we used osteoclasts from ClC-7 deficient (ADOII) patients and matched controls. We found that ADOII osteoclasts ability to degrade the decalcified matrix was reduced by 40%. In contrast, the reduction in resorption on calcified bone was 80%. Furthermore, we tested inhibitors of chloride channels (NS5818), cathepsin K (CK-I), and the proton pump (Bafilomycin) and we found that NS5818, CK-I and bafilomycin dose-dependently inhibited degradation of decalcified bone, with a maximal effect of 40% in controls. Interestingly, the inhibitors had no effect in the ADOII osteoclasts. In contrast, the addition of a matrix metalloproteinase (MMP) inhibitor resulted in 80% inhibition in both ADOII and controls, indicating an acidification independent role for MMPs in this system.

In conclusion, we show that osteoclastic acidification participates in the degradation of the organic matrix. However, attenuation of acidification has a stronger effect on calcified than decalcified bone, showing that the most important role for acidification, and thus ClC-7, in bone resorption is secretion of acid into the resorption lacunae of the osteoclasts.

Regulation of Osteoclastic Bone Resorption and Bone Mass by the Cannabinoid Receptor 1 Pathway. A. I. Idris*[1], R. J. Van't Hof*[1], I. R. Greig*[1], S. A. Ridge*[1], D. Baker*[2], R. A. Ross*[1], S. H. Ralston[1]. [1]Medicine & Therapeutics, University of Aberdeen, Aberdeen, United Kingdom, [2]Institute of Neurology, University College London, London, United Kingdom.

The endogenous cannabinoid system plays an important role in several physiological processes. In the light of recent data which has shown that neurogenic pathways can play an important role in regulating bone turnover, we studied the role of the endocannabinoids in bone metabolism. The cannabinoid receptor blocking drugs SR144528, SR141617A and AM251 were all potent inhibitors of osteoclast formation and bone resorption *in vitro* with half-maximal inhibitory effects at 5-10μM in osteoblast-bone marrow co-cultures and 0.6-1.0 μM in RANKL stimulated bone marrow cultures. All three compounds caused a 10-15-fold increased in apoptosis of rabbit osteoclasts from basal levels ($p<0.0001$) and inhibited TNF-induced activation of the NFκB pathway (as detected by inhibition of IκB and IKK phosphorylation) and ERK signalling pathway (as detected by inhibition of phospho-ERK). Conversely, the cannabinoid receptor agonist anandamide stimulated osteoclast formation and bone resorption in mouse bone marrow cultures in a dose-dependent manner over the concentration range 1-10μM. Both AM251 and SR144528 (10mg/kg/day for 21 days) prevented ovariectomy (ovx) induced bone loss in mice. Trabecular BMD fell by 12% in ovx/vehicle treated mice, when compared with ovx/sham, whereas ovx mice treated with AM251 lost only 2.5% BMD ($p<0.01$ from ovx) and mice treated with SR144528 gained 2.5% BMD ($p<0.001$ from ovx). Osteoclasts and osteoblasts expressed both CB receptor subtypes (CB1 and CB2), but studies in mice with targeted inactivation of the CB1 receptor showed that this was an important target for osteoclast inhibition. Trabecular BMD was increased by about 10% in CB1 knockouts when compared with wild type mice ($p<0.05$), and osteoclasts generated from RANKL stimulated bone marrow cultures in CB1 knockout mice were significantly resistant to the inhibitory effects of CB antagonists, such that at 0.5μM, AM251 inhibited formation of osteoclasts generated from CB1 knockouts by 5%, compared with 40% inhibition for wild type ($p<0.001$ between groups) . We conclude that cannabinoid receptor antagonist are a new class of antiresorptive drugs and that the endocannabinoid system and the CB1 receptor plays a physiological role in the regulation of bone turnover and bone density.

Bortezomib, a Novel Proteasomes Inhibitor, Approved for Use in Multiple Myeloma, Inhibits Osteoclast Formation and Function. N. Kawanabe[1], K. Anderson*[2], J. A. Lorenzo[1]. [1]Endocrinology, University of Connecticut Health Center, Farmington, CT, USA, [2]Medicine, Harvard Medical School, Boston, MA, USA.

Bortezomib (Velcade ™, Bzb) is a proteasome inhibitor that is used for the treatment of patients with multiple myeloma (mm). Inhibitors of osteoclast action (i.e. bisphosphonates) are known to prolong survival in mm. We determined if some of the beneficial effects of Bzb in mm patients resulted from its affects on bone resorption. The ability of Bzb to block osteoclast formation and bone resorption was measured in cultures of murine bone marrow cells that were stimulated for 4 days to form osteoclast (OCL) by treatment with RANKL and M-CSF (30 ng/ml for each). Cell viability was assessed by a MTT assay. OCL formation was measured as the number of TRAP + multinuclear cells. Resorption was measured as the number of pits formed by cells cultured on bovine bone slices

In the MTT assay, Bzb suppressed murine bone marrow cell viability only at the concentration of 10 nM or higher. There was no significant effect of Bzb at concentrations of 1nM or less. In contrast, Bzb significantly ($p<.01$) inhibited OCL formation in murine bone marrow culture in a dose-dependent fashion over a concentration rang of 100 fM to 1 nM with a maximum inhibitory effect of about 30% at 1 nM ($P<.05$). Time course studies showed that Bzb (1nM) significantly ($p<.05$) inhibited OCL differentiation when added either during the early (first 2 days) or late stages (last 2 days) of culture. . Furthermore, Bzb (1 nM) decreased pit number by about 50 % revealing that Bzb suppresses OCL bone resorption to a greater degree than OCL formation. Examination of mRNA expression of RANK and NFATc1 in murine primary bone marrow cells treated with RANKL for 24 or 48 h demonstrated no differences between control and Bzb-treated cells.

In conclusion, Bzb suppress OCL formation and resorption in vitro at very low concentrations (100 fM to1 nM), which did not affect cell viability. This effect does not appear to involve regulation of NFATc1 or RANK expression by Bzb. It is possible that the beneficial effects of Bzb in mm patients result from its ability block both bone resorption and mm cell function.

Disclosures: ***J.A. Lorenzo****, None.*

SU338

Antisense Oligonucleotides Targeting RANK and RANKL Both Prevent Bone Loss, But Only RANK ASOs Reduce Inflammation in a Rat Model of Adjuvant Arthritis. M. Liu*[1], K. Hull*[1], H. Cole*[1], Y. Wang*[1], J. Finger*[2], L. Chio*[3], N. Kulkarni*[1], J. Hoover*[1], R. S. Galvin[1], Y. Ma[1], H. U. Bryant[1], K. J. Myers*[2]. [1]Bone and Inflammation, Eli Lilly and Co, Indianapolis, IN, USA, [2]ISIS Pharmaceutical Inc, Carlsbad, CA, USA, [3]Eli Lilly and Co, Indianapolis, IN, USA.

Interrupting RANK signaling by inhibitors such as OPG and RANK-Fc can prevent bone loss in rodent arthritis models. RANK and RANKL, in addition to their normal expression in bone cells, are also expressed in the inflamed and proliferating synovium in rheumatoid arthritis. We have developed and characterized modified antisense oligonucleotides (ASOs) specific for rat RANK and RANKL, and have evaluated their activity in an adjuvant arthritis model. In vitro, both the RANK and RANKL ASOs were equipotent at reducing targeted mRNAs, with IC_{50}s in the 50-75 nM range. ASO uptake in normal and arthritic rats was examined by immunohistochemical analysis, using an antibody specific for modified ASOs. Strong ASO localization was seen in both normal and inflamed rat joints in rats dosed via sc, ip, or oral routes. The RANK and RANKL ASOs were dosed prophylactically in the rat adjuvant arthritis model, with daily subcutaneous dosing at 5, 20, or 40 mg/kg beginning one week prior to lipoidal amine/adjuvant administration, and continuing for another 14 days afterwards. X-ray radiographic analysis indicated that both RANK and RANKL ASOs prevented bone erosion in the ankle joint. However, treatment with the RANK ASOs had an unexpected anti-inflammatory effect, dose-dependently reducing paw swelling in arthritic rats. The RANKL ASOs had no effect on ameliorating paw swelling, even at the highest doses tested. Two separate RANK-specific ASOs were found capable of reducing paw swelling. Oligonucleotide A appeared to be more potent in this regard. A 40 mg/kg daily dose of A reduced paw swelling to the same extent as dexamethasone treatment, while 60 mg/kg of Oligonucleotide B daily was required to produce a similar effect. The potency of the two RANK ASOs in reducing inflammation also correlated with their potency in reducing RANK mRNA in bone as well as reducing osteoclast numbers obtained by histomorphometry. The reduction in paw swelling induced by Oligonucleotide A was accompanied by dose-dependent reductions of the pro-inflammatory cytokines IL-1β and IL-6 in synovial fluid.

Although RANK signaling inhibition by agents such as OPG prevents bone loss in a variety of animal models, these agents have never provided a significant anti-inflammatory effect when tested in arthritis models. Our results with antisense oligonucleotides suggest that a therapeutic advantage may be conferred by inhibiting the receptor (RANK) rather than the ligand (RANKL) in an arthritic condition.

Estrogen Regulate Glutathione Reduction in Bone by a Nongenotropic Mechanism of Action: A Requirement for Their Effects on Osteoclastogenesis and on the Apoptosis of Osteoblasts and Osteoclasts. J. R. Chen, L. Han, P. Zimniak*, C. A. O'Brien, T. Bellido, R. L. Jilka, S. Kousteni, S. C. Manolagas. Div. Endocrinol., Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. Arkansas Med. Sci., Little Rock, AR, USA.

Estrogen may provide protection against oxidative stress in a variety of cell types, including osteoclasts, by increasing glutathione levels and thus dispensing of reactive oxygen species (ROS). Conversely, loss of estrogen may increase osteoclastogenesis and loss of bone by decreasing the levels of glutathione in osteoclasts. We investigated whether anti-oxidant actions of estrogen are mediated via the classical genotropic mechanism of estrogen receptor (ER) action, as opposed to extra nuclear (kinase-mediated) actions of the ER, and whether they play a role in the pro- and anti-apoptotic effects on osteoclasts and osteoblasts, respectively. Osteoclasts were generated from murine bone marrow cultures (devoid of adherent stromal support cells) or the murine macrophage cell line RAW264.7 stimulated with RANKL and M-CSF. We report that L-butathionine-(S,R)-sulphoximine (BSO), a specific inhibitor of glutathione synthesis, at 10^{-5} M, abrogated the suppressive effects of 10^{-8} M estradiol (E_2) or 4-estren-3α, 17β-diol (estren) on osteoclastogenesis. Furthermore, BSO abrogated E_2-or estren- induced osteoclast apoptosis. Strikingly, BSO also abrogated the anti-apoptotic effects of either E_2 or estren on primary cultures of calvaria cells, irrespective of whether apoptosis was induced by the topoisomerase inhibitor etoposide or TNFα. Identical results, i.e. abrogation of the suppressive effects of either E_2 or estren on osteoclastogenesis, the promotion of osteoclast apoptosis and the attenuation of osteoblast apoptosis were obtained when glutathione was depleted using the electrophilic agent diethylmaleate (DEM), at 0.1 mM. Further, E_2 or estren stimulated the activity of glutathione reductase (GR) in osteoclasts and this effect could be completely blocked by the ER antagonist ICI 182,780, as well as by the specific inhibitors of Src or MEK kinase, PP1 and U0126. Estrogen or estren had no effect on the activity of GR in osteoblasts, suggesting that in this cell type an alternative pathway of ROS control is involved. These results demonstrate that not only attenuation of osteoclastogenesis (and perhaps remodeling) but also the stimulation of osteoclast and attenuation of osteoblast apoptosis by estrogen involve nonprotein thiol metabolism. These effects are the result of a nongenotropic mechanism of estrogen action mediated by cytoplasmic kinases and probably downstream transcriptional control of nonprotein thiols.

The Anti-inflammatory Sesquiterpene Lactone Parthenolide Blocks Lipopolysaccharide Induced Osteolysis via the Suppression of NF-κB Activity. K. H. Yip*[1], M. Zheng[1], H. Feng*[1], J. Steer*[2], D. Joyce*[2], J. Xu[1]. [1]Orthopaedic Surgery, University of Western Australia, Nedlands, Australia, [2]Medicine and Pharmacology, University of Western Australia, Nedlands, Australia.

Osteolysis induced by bacterial infection underlies many bone diseases. Drugs that inhibit LPS-induced osteolysis are critical in the prevention of bone destruction in infective bone diseases. Here we investigated the potential effect of an herbal extract, parthenolide (PAR) on LPS-induced osteolysis.

In this study, the LPS-induced osteolysis in the mouse calvarian model was used to examine the effect of PAR *in vivo*. RANKL-induced osteoclast differentiation from RAW $_{264.7}$ cells and bone resorption were used to assess the effect of PAR *in vitro*. Assays for NF-κB activation, p65 translocation and IκB-α degradation were employed to determine the mechanism of action of PAR in osteoclasts and their precursors. Flow cytometry and confocal microscopic analysis were used to examine cell apoptosis. Semiquantitative RT-PCR

were employed to determine PAR effect on RANK and TRAF6 gene expression
We found that LPS-induced osteolysis in the mouse calvarian (attached figure, panel A showed PBS injeced control and panel B showed LPS injected group) was blocked by PAR (0.5mg/kg and 1mg/kg), injected simultaneously with LPS (25mg/kg) or 3 days later (panel C, D, E, and F respectively in attached figure). *In vitro* studies showed that low concentration PAR (less than 1μM) inhibited *in-vitro* osteoclastogenesis and bone resorption, whilst higher concentrations (greater than 5μM) dose-dependently triggered apoptosis. Furthermore, PAR inhibited LPS-induced NF-κB activation, p65 translocation and IκB-α degradation in both mature osteoclasts and their precursors. In addition, PAR inhibited NF-κB activation induced by osteoclastogenic factors RANKL, IL-1β or TNF-α, and reduced RANK and TRAF6 expression.
In conclusion, the NF-κB pathway is known to mediate both osteoclast differentiation and survival. These findings indicate that PAR blocks LPS-induced osteolysis via the suppression of NF-κB activity; suggests a possible therapeutic value in bacteria-induced bone destruction.

Osteoclast Apoptosis Is Regulated by the Expression of Immediate Early Genes Egr-1, Egr-2, Egr-3 and Ieg-2 Identified through Microarray Analysis. E. W. Bradley*[1], M. J. Oursler[2]. [1]Cell Biology and Genetics, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Since bone resorption levels depend primarily on the number of osteoclasts present, factors contributing to the survival of osteoclasts increase the amount of bone loss during both normal and pathological bone turnover. In order to better understand the molecular mechanisms by which osteoclasts survive, we have examined *in vitro* generated mouse osteoclast model in which osteoclasts differentiate during co-culture of precursors and stromal cells in the presence of vitamin D and dexamethazone. Removal of the stromal cells from the mature osteoclasts causes apoptosis of about 25% of the osteoclasts and we have explored the signaling pathway by which the surviving osteoclasts repress this apoptosis. We have found that survival of a significant number of osteoclasts is dependant on the activation of the PI3 kinase/MEK/ERK pathway. Inhibition of this pathway using kinase-specific inhibitors as well as inhibition of protein synthesis leads to increased osteoclasts apoptosis. We have further explored expression of downstream targets of the PI3 kinase/MEK/ERK pathway for roles in osteoclast survival following removal of stromal cells. Activation of Elk-1, an Ets transcription factor, was detected five minutes after stromal cell removal. Purified osteoclasts were cultured with and without a MEK specific inhibitor and RNA was isolated for microarray analysis to identify targets of this pathway. Increased transcript levels for several immediate early genes were identified in osteoclasts thirty minutes after stromal cell removal in the absence of MEK inhibition which were not observed in cultures treated with the MEK inhibitor. These genes included the known targets of Elk-1 Egr-1, Egr-2, Egr-3 and Ieg-2 genes, which regulate apoptosis in other cell types. Increased mRNA levels for these genes following stromal cell removal were verified using log phase PCR. Given these results, we hypothesize that activation of the PI3 kinase/MEK/ERK/Elk-1 pathway leads to an increase in the expression of immediate early genes to prolong osteoclast survival, providing new insight into osteoclast survival mechanisms.

The Effect of Aryl Hydrocarbons on Osteoclast Differentiation and Function. I. Voronov*[1], J. N. M. Heersche[1], H. C. Tenenbaum[1], R. F. Casper*[2], M. F. Manolson[1]. [1]University of Toronto, Toronto, ON, Canada, [2]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada.

Smoking is a risk factor for bone related diseases, bone healing, and endosseous implant failure. The mechanisms responsible for the effects of cigarette smoking are uncertain. Polycyclic aryl hydrocarbons (PAHs) are environmental pollutants present in cigarette smoke, exhaust fumes and furnace gases. Aryl hydrocarbons act through the aryl hydrocarbon receptor (AhR), a nuclear transcription factor. Current evidence suggests that PAHs cause loss of bone mass and bone strength, possibly through inhibition of osteoblast differentiation. Here we test the effect of benzo-a-pyrene (BaP), a representative PAH, on osteoclast (OC) differentiation and function.
OCs derived from newborn New Zealand white rabbits were cultured in the presence of 10^{-7}-10^{-9} M BaP and/or vehicle control. After 48 hours incubation period, the cells were stained for tartrate resistant acid phosphatase (TRAP) and counted. At high OC density (and abundant stromal cells), 10^{-7} M BaP induced a 20% decrease of OC numbers compared to control. At low OC density (and low stromal cell number), 10^{-7} BaP increased OC numbers by 20%, suggesting that cell density of stromal cells, OC precursors, or OCs plays a role in OC differentiation. To eliminate the putative indirect effects of stromal cells on OC differentiation, a mouse macrophage cell line RAW 264.7 was utilized. These cells differentiate into OCs when cultured for 5 days in the presence of the receptor activator of NF-κB ligand (RANKL). Treatment with 10^{-5} M BaP decreased OC differentiation, TRAP activity levels, and resorption of bone-like substrata at 50 ng/mL RANKL, but not at 200 ng/mL. The inhibition was reversed by resveratrol, an AhR antagonist. The observation that either receptor antagonist or high concentrations of RANKL could reverse the BaP effects suggested interacting signaling pathways between RANKL and BaP. To test this hypothesis, RT-PCR was performed on the samples exposed to 10^{-5} M BaP in the presence of different concentrations of RANKL (0, 25 and 200 ng/mL) for 24 hours. The samples were analyzed for the presence of mRNA for cytochrome P450 1B1 (CYP 1B1), a gene commonly activated by BaP. Results indicate presence of CYP 1B1 mRNA in the group exposed to BaP only. The levels decreased either in the presence of resveratrol or increasing concentrations of RANKL. These results confirm the hypothesis that the RANKL and PAH signaling pathways interact, possibly by competing for transcriptional coactivators (SRC-1 or p300/CBP), and demonstrate that the negative effect of PAHs on bone remodeling could, in part, be mediated through inhibition of osteoclastogenesis.

A Peptide Antagonist Mimicking a TNF Contact Site of the TNF-α Receptor Inhibits RANKL-Induced Signaling. C. Itzstein[1], K. Aoki[2], H. Saito*[2], R. Blanque*[3], P. Deprez*[3], M. Ishiguro*[4], W. C. Horne[1], R. Baron[1]. [1]Yale University School of Medicine, New Haven, CT, USA, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]ProSkelia Pharmaceuticals, Paris, France, [4]Suntory Institute for Bioorganic Research, Osaka, Japan.

The Receptor Activator of NF-κB (RANK), a member of the tumor necrosis factor receptor (TNFR) superfamily, is essential for osteoclast differentiation and activity. Its interaction with its ligand RANKL induces RANK trimerization and stimulates several signaling pathways. Activation of NF-κB, AP-1 (c-Jun and c-Fos) and NFATc1 induce transcriptional activity, while other downstream effectors, (JNK, p38, Erk1/2, Akt and PI3-kinase) affect actin organization, bone resorption and survival. Two cysteine-rich domains (CRD) in the extracellular portions of TNFR superfamily members contain the ligand-binding sites. We previously showed that a cyclized peptide (WP9QY) that mimics a critical TNF-α recognition site on TNFR I (loop 1 of the CRD3) inhibits RANKL-induced osteoclast differentiation and bone resorption, suggesting that WP9QY inhibits RANKL-induced RANK signaling. To confirm this, RAW264.7 cells were stimulated with 2μg/ml of soluble RANKL at 37°C for 20 minutes in the presence or absence of WP9QY (1-50μM) or 0.5μg/ml of OPG. Like OPG, WP9QY blocked RANKL-induced NF-κB activation in a dose-dependent manner, as shown by the inhibition of both the nuclear translocation of p65, a component of NF-κB, and the induction of DNA binding by NF-κB. It also inhibited RANKL-induced activation of Erk1/2 and JNK kinase in a dose-dependent manner. Finally, WP9QY decreased RANKL-stimulated Akt kinase activity. OPG had similar effects on MAP kinase and Akt activity. In contrast to its effects on RANKL-induced signaling, WP9QY had little effect on the binding of RANK to RANKL. By analogy with other TNF/TNFR family members, two contact sites mediate the RANK-RANKL interaction. Mutating the A-A" loop RANKL contact site, which does not bind the RANK CRD3, abolishes the RANK-RANKL interaction (Lam, JCI, 108:971, 2001), suggesting that this site plays the primary role in RANK binding to RANKL. WP9QY would not be expected to affect this contact site. Structural modeling analysis showed that the presence of WP9QY in the CRD3 contact site changes the conformation of the membrane-proximal part of the RANK extracellular domain, apparently affecting the clustering of the RANK intracellular domains that is thought be required for signaling. In conclusion, our results show that WP9QY inhibits RANKL signaling and prevents a consequent increase in osteoclast function, suggesting that RANKL-induced signal transduction depends critically on the contact of RANKL with the first loop of the RANK CRD3.

The Adaptor and Ubiquitin Ligase Functions of Cbl Have Opposite Effects on Bone Resorption. C. Itzstein, A. Sanjay, T. Miyazaki*, L. Neff*, W. C. Horne, R. Baron. Yale University School of Medicine, New Haven, CT, USA.

Cbl is an adaptor protein involved in the regulation of osteoclast function. $Cbl^{-/-}$ osteoclasts exhibit decreased migration both *in vitro* and *in vivo*. Decreased Cbl phosphorylation in $Src^{-/-}$ osteoclasts (OCs) is associated with a decrease in bone resorption. Downstream of integrins, Cbl forms a tri-molecular complex with Pyk2 and Src in OCs, promoting OC motility and bone resorption. Cbl also acts as an ubiquitin ligase, down-regulating both receptor and non-receptor tyrosine kinases, including the M-CSF receptor (c-Fms) and Src. Although RANK is not itself a tyrosine kinase, it has been suggested that Cbl regulates the surface expression of RANK. However, the structural basis of Cbl's dual functions as an adaptor and an ubiquitin ligase is not fully elucidated. Structurally, the N-terminal half of Cbl includes a tyrosine kinase binding (TKB) domain and a RING finger that is responsible for the ubiquitin ligase activity of Cbl, while the C-terminal half contains a proline-rich region and several regulatory tyrosines that interact with SH3 and SH2 protein-binding domains, respectively. To further investigate the functional roles of various protein binding domains of Cbl, we used the adenovirus system to express myc-tagged wild-type (WT) Cbl, the C-terminal half of Cbl (Cbl-CT) or Cbls containing an inactive TKB domain (CblG306E), a mutated Src SH3 binding site (Cbl6PA) or a mutated PI3-kinase binding site (CblY731F) in murine OCLs, and evaluated their effects on OC cytoskeleton organization and bone resorbing activity. WT Cbl, Cbl-CT, and CblG306E had no effect on actin ring and pit formation. However, over-expression of Cbl6PA or CblY731F disrupted actin organization dramatically and inhibited bone resorption by 25% ($p<0.05$) and 70% ($p<0.001$), respectively, demonstrating that Cbl/Src and Cbl/PI3-kinase interactions play positive roles in OC activity. In contrast, v-Cbl and 70Z-Cbl, which lack ubiquitin ligase activity due to the absence of all or part of the RING finger domain, increased pit formation by 100% ($p<0.001$) and 35% ($p<0.05$), respectively, in $Cbl^{-/-}$ OCLs. These results suggest that Cbl's ubiquitin ligase function is required to down-regulate receptors such as c-Fms or RANK that promote osteoclast formation and activity. Thus, the Src substrate Cbl both promotes osteoclast activity by forming SH2-dependent and SH3-dependent complexes with PI3-kinase and Src, respectively, and reduces osteoclast activity by ubiquitylation-dependent mechanisms.

Dual Action of Melatonin Signaling Activity in Bone Metabolism. A. Moreau[1], S. Forget*[2], D. Wang*[2], B. Azedine*[2], D. Angeloni*[3], F. Fraschini*[4]. [1]Stomatology & Biochemistry, Research Centre Hôpital Sainte-Justine & Université de Montréal, Montreal, PQ, Canada, [2]Bone Molecular Genetics & Musculoskeletal Laboratory, Research Centre Hôpital Sainte-Justine, Montreal, PQ, Canada, [3]Scuola Superiore Sant' Anna & IFC-CNR, Pisa, Italy, [4]Pharmacology, University of Milan, Milan, Italy.

Hormonal modulation of bone metabolism by melatonin has been proposed to proceed through stimulation of osteoblast differentiation and subsequent osteoclast inhibition. However, little is known concerning melatonin signal transduction in osteoblasts and osteoclasts. Expression analysis of both melatonin receptor subtypes was investigated by RT-PCR using RNA isolated from human osteoblast cell line MG-63 and human osteoclasts derived from PBMCs. Gi proteins interaction with melatonin receptor subtypes were determined by co-immunoprecipitation assays with anti-melatonin receptor antibodies and Western blot analysis with anti-Gi protein antibodies. Melatonin effect on osteoclastic resorption activity was evaluated with the pit resorption assay in presence of melatonin alone or in combination with luzindole, a MT2 melatonin receptor antagonist.

MT2 receptor is the subtype predominantly expressed in both cell types. In human osteoblasts, two distinct forms of Gi proteins were found associated with this receptor subtype: a 43 kDa protein (unphosphorylated, active) and a 60 kDa protein (serine-phosphorylated, inactive), with the following preferential affinity order: $Gi_3 > Gi_2$, while Gi_1 proteins hardly interacted with either melatonin receptors. Addition of melatonin (10^{-7}M) abrogated the interaction of phosphorylated Gi proteins and shifted the affinity order toward $Gi_2 > Gi_3$. In human osteoclasts, MT2 receptor was found to couple almost exclusively with unphosphorylated Gi_3 proteins. However, in absence of melatonin, only tyrosine-phosphorylated Gi_1 proteins were found to interact with MT1 receptor subtype. Melatonin treatment of differentiating osteoclasts abrogated completely the maturation process and inhibited the formation of resorption pits by mature osteoclasts. Addition of luzindole relieves this inhibitory effect indicating that it is mediated through MT2 receptor signaling. Moreover, short-term melatonin treatment almost completely abrogated the expression of RANK by mature osteoclasts, suggesting a direct mechanism of osteoclastogenesis inhibition by melatonin. Taken together those results further strengthen the dual role of melatonin in bone metabolism and aging-associated melatonin decrease could lessen the inhibitory action of melatonin on osteoclastogenesis contributing to the development of osteoporosis.

Synergistic Role of Tyrosine Kinase(s) and the Phosphatase PTP-PEST in the Formation of WASP-Arp2/3 Complex, Actin Ring, and Bone Resorption in Osteoclasts. M. A. Chellaiah[1], R. S. Biswas*[1], D. Kuppuswamy*[2], C. Willies*[2]. [1]Biomedical Sciences, University of Maryland, Baltimore, MD, USA, [2]Cardiology Division, Medical University of South Carolina, Gazes Cardiac Research Institute, Charleston, SC, USA.

Bone resorption is the first step in bone remodeling. Actin ring formation has been shown to be a prerequisite for efficient bone resorption in osteoclasts. We have previously shown that transduction of phosphoinositides binding domain containing gelsolin peptides blocked the formation of WASP-Arp2/3 complex (ASBMR, 2003) and actin ring in the osteoclasts. Despite success in identifying the role of kinases such as, Src, PYK2, and FAK in actin ring formation, the potential target protein of these kinases is poorly understood. Thus, our aim is to identify the target protein involved in actin ring formation. Osteoclasts that were either treated with osteopontin (OPN) or expressing constitutively active Src (CA-Src) by adenoviral-mediated delivery, exhibited an increase in WASP-Arp3 complex formation in the actin ring of osteoclasts. *In vitro* kinase analysis of WASP immunoprecipitates showed OPN stimulated phosphorylation of Src, WASP, PYK2 and three other proteins with molecular masses of 100-110 kDa, 120-130 kDa, 35-40 kDa. These proteins were also found to be phosphorylated in osteoclasts expressing CA-Src but not in kinase negative Src (KN-Src). Biochemical and confocal studies revealed that WASP and PTP-PEST form a complex and are colocalized in OPN-stimulated osteoclasts. Measurement of WASP-associated PTP-PEST phosphatase activity exhibited decreased activity levels both in OPN-treated and in CA-Src expressing osteoclasts. Furthermore, OPN stimulation resulted in serine phosphorylation of WASP associated PTP-PEST. Such increased serine phosphorylation with decreased PTP-PEST phosphatase activity was accompanied by an increased tyrosine phosphorylation of WASP and other associated signaling proteins. Experiments with PTP-PEST inhibitor and antisense ODNs to PTP-PEST further confirmed the involvement of PTP-PEST in the tyrosine phosphorylation levels of proteins, formation of WASP/Arp3 complex, actin ring and bone resorption. Taken together, these results suggest that WASP, which is identified in the actin ring of osteoclasts, associates with Src, PYK2, and PTP-PEST. PTP-PEST and tyrosine kinase(s) coordinate the formation of WASP-Arp2/3 complex and the actin ring.

Osteocyte Death Can Occur in Young Bone, More Frequently in Black Than in White Women. S. Qiu[1], D. Rao[1], S. Palnitkar*[1], A. Parfitt[2]. [1]Bone & Mineral Research Lab, Henry Ford Health System, Detroit, MI, USA, [2]Division of Endocrinology and Center for Osteoporosis and Metabolic Bone Disease, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Osteocytes die by apoptosis as bone grows older, leaving empty lacunae in bone matrix. The objective of this study was to determine the frequency of osteocyte death in recently formed bone.

Iliac bone biopsies from 128 healthy women, aged 20-73 years, were used in this study, of whom 34 (16 pre-menopausal and 18 postmenopausal) were blacks and 94 (38 pre-menopausal and 56 postmenopausal) were whites. In the sections stained with Goldner's trichrome, empty lacunae were measured in superficial bone (<25 µm from the bone surface). Empty lacunae in unmineralized osteoid were observed using the sections stained with toluidine blue.

Empty lacunae were found in osteoid tissue (Fig 1), but were not enumerated because too little osteoid was present. In both black and white women, empty lacunae in superficial bone did not significantly increase with age or menopause. However, black women had more empty lacunae than white women in superficial bone ($p < 0.01$), especially when pre-menopausal (Table 1).

The mean age of superficial bone is about 3 years, and the mean age of osteoid is about 2 weeks. The lifespan of osteocytes in cortical bone is about 25 years. The presence of empty lacunae in superficial bone and especially in osteoid indicates that some osteocytes may die very soon after they are formed. A possible explanation is that these fragile osteocytes were differentiated from unhealthy osteoblasts that would have died had they not become osteocytes. The reason for more frequent osteocyte death in black than in white women is unknown.

Serotonin and Dopamine Stimulate Prostaglandin Release and Regulate COX-2 Expression in Osteocytic Cells. M. M. Bliziotes, X. Zhang, K. M. Wiren. Medicine, Oregon Health and Science University/Portland VAMC, Portland, OR, USA.

Neurotransmitter regulation of bone physiology is manifested by the osteopenic phenotypes seen in both serotonin (5-HT) and dopamine (DA) transporter knockout mice. The 5-HT transporter (5-HTT) and 5-HT receptors have been identified in both osteoblasts and osteocytes, while DA transporter expression in bone cells has not been documented. We explored the functional consequences of 5-HT and DA treatment of cultured osteocytes using the clonal murine osteocytic cell line MLO-Y4.

We assessed prostaglandin E2 (PGE2) release into culture media from 5-HT and DA treated subconfluent MLO-Y4 cells using an enzyme immunoassay. The expression of two forms of prostaglandin synthase (COX-1 and COX-2) were analyzed by RT-PCR of mRNA isolated from 5-HT and DA treated cells. Finally, expression of connexin 43 (Cx43) was determined by immunoblot using an antibody generated against a synthetic peptide encoding amino acids 252-271 of rat Cx43.

5-HT and DA (both 100 μM) independently stimulated PGE2 release from MLO-Y4 cells. 5-HT increased medium PGE2 levels by 47% and 50% at 5 and 30 min, respectively, while DA increased PGE2 by 150% at both time points. Surprisingly, both 5-HT and DA (100 μM) decreased steady state mRNA levels for COX-2 after 2 hr of treatment (40% for 5-HT and 80% for DA); DA also decreased COX-1 mRNA by 40%. Both neurotransmitters altered connexin 43 protein expression.

In conclusion, the neurotransmitters 5-HT and DA 1) increase PGE2 release rapidly in osteocytic cells, and 2) reduce transcript levels of the inducible PG synthase COX-2 over a more prolonged period. At equimolar doses, DA is more efficacious than 5-HT in regulating COX-2 expression and PGE2 release.We have documented for the first time DA receptor activation in osteocytic cells. These observations suggest potential mechanisms to explain the phenotypic effects on bone induced by in vivo disruption of the DA and 5-HT transporter genes, which alter extracellular concentrations of these neurotransmitters.

Heat Shock Protein Modulation by Hypoxic Osteocytes. P. Pathare*, T. S. Gross. Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, USA.

Previous studies have indicated that the extracellular matrix protein, osteopontin (OPN) is rapidly upregulated by osteocytes when challenged by disuse (in vivo) or oxygen deprivation (in vitro). In addition to its role in mediating osteoclast attachment and activity, OPN has a broader role in enabling cells to withstand environmental stress. In this context, heat shock proteins (HSP) have been specifically associated with the ability of cells to rapidly respond to and survive biological stress. We therefore hypothesized that HSPs would be upregulated by osteocytes exposed to hypoxia. Following screening studies, we focused on the temporal regulation of HSP90. Osteocyte-like cells (MLO-Y4) were plated at 25% confluence and grown for 24 hr in α-MEM medium containing 2.5% fetal bovine serum and 2.5% calf serum. The cells were exposed to either normal oxygen (19%) or were placed in a commercial hypoxia chamber (< 1% oxygen) and incubated at 37 C for between 4 and 48 hr. As a positive control at each time point, osteocytes were exposed to heat shock (42 C for 20 min) followed by incubation at 37 C. Western blots were performed on whole cell extracts and percent elevation of HSP90 versus control levels was determined using NIH ImageJ. In response to heat shock, we observed a rapid and sustained increase in HSP90 expression (6 hr: 849% elevation, 12 hr: 279% elevation, 24 hr: 80%) that returned to near normal levels only at the 48 hr time point (48 hr: 27% elevation). In response to hypoxia, osteocytes demonstrated upregulation of HSP90 at 12 hr (67% vs control) and 24 hr (43% vs control). HSP90 expression by osteocytes at 4, 8, and 48 hrs did not differ from control levels. In a subsequent experiment, we exposed osteocytes to 0.1 μM of dexamethasone (a synthetic glucocorticoid) for 24 and 48 hr as a means of imposing severe environmental stress upon the cells. We again observed temporal regulation of HSP90, with protein expression was substantially increased at 24 hr (254% vs control) but not at 48 hr (-14% vs control). To our knowledge, this is the first report of HSP modulation in osteocytes. Further, while HSP27 has been implicated as a mediator of the response of osteoblasts to factors such as statins and PGE2, our observations represent the first report of HSP90 modulation by osteoblasts or osteocytes. HSP90 was upregulated in a temporal manner, dependent upon the severity of the imposed stress. Interestingly, HSP90 plays a vital role in the function of the steroid hormone receptor. Given numerous reports of glucocorticoid induced osteocyte apoptosis, it is reasonable to speculate that a condition that induces upregulation of HSP90 (such as hypoxia) would increase the susceptibility of osteocytes to the challenge of glucocorticoids.

In Vitro Functions of Beta1 Integrins in Mature Cells of the Osteoblast Lineage. J. V. Dovi[1], M. C. H. van der Meulen[2], C. H. Damsky[3], J. B. Kim*[4], E. A. C. Almeida[1], R. K. Globus[1]. [1]Gravitational Biology, NASA Ames Research Center, Moffett Field, CA, USA, [2]Cornell University, Ithaca, NY, USA, [3]University of California, San Francisco, CA, USA, [4]Stanford University, Palo ALto, CA, USA.

Beta1 integrins participate in cellular adhesion of osteoblast lineage cells. However, how beta1 integrins influence the physiology of late stage osteoblasts is not understood. To determine the roles of beta1 integrins in mature osteoblasts and osteocytes, we established primary cell cultures from bones of neonatal and adult wild type (WT) or transgenic (TG) mice, which expressed a function-perturbing fragment of beta1 integrin consisting of its transmembrane and cytoplasmic domain. Expression of this fragment was under the control of the osteocalcin promoter. We also generated stably transfected, MLO-Y4 osteocytic cell lines, using either an empty control vector or a vector encoding for the beta1 fragment under the control of the CMV promoter. Basic cellular functions, including adhesion, proliferation, and differentiation were assessed. MLO-Y4 cells expressing the beta1 fragment displayed fewer cellular processes and were more rounded. Some cells expressing the fragment detached from the type I collagen-coated substrate, but remained viable and were able to reattach. Cells expressing the beta1 fragment migrated more slowly into denuded areas compared to controls. Interestingly, MLO-Y4 cells expressing the beta1 fragment displayed a higher proliferative rate compared to controls. In contrast to the MLO-Y4 cell line expressing the beta1 fragment, primary cells from TG mice proliferated during the logarithmic stage of growth at a rate similar to WT controls, and formed nodules to a similar extent as WT controls. Cells isolated from long bones of both WT and TG adult mice displayed long, interconnecting processes and therefore resembled osteocytes. Despite similar morphological appearances, binding to type I collagen was 10-fold lower in osteocytic cells from TG mice compared to those from WT mice. In conclusion, we have demonstrated that primary cells of the osteoblast lineage expressing the function-perturbing beta1 fragment are able to differentiate, as judged by the formation of mineralized nodules and osteocytic morphology, despite a defect in type I collagen binding. These results raise the possibility that other adhesion molecules are redundant with beta1 integrin function during terminal differentiation of osteoblasts.

Dickkopf (Dkk)-1 Is an Osteocyte-expressed and Glucocorticoid-inducible Inhibitor of LRP5 Signaling. V. Kasparcova*, H. Glantschnig, L. P. Freedman, S. Harada. Molecular Endocrinology/Bone Biology, Merck Research Laboratories, West Point, PA, USA.

Both gain of function and loss of function mutations of LDL receptor-related protein 5 (LRP5) in human, leading to reciprocal bone phenotype, have unambiguously documented the role of LRP5 in bone metabolism and bone mass. In Wnt reporter assays, the high bone mass mutant $LRP5_{G171V}$ was found to be resistant to inhibitory effects of Dkk-1. Accordingly, we found that the mutant $LRP5_{G171V}$ failed to interact with Dkk-1, suggesting the role for the potential involvement for Dkk-1 in LRP5 action in bone. To gain insight into the role of Dkks in bone, we evaluated the expression of Dkks known to associate with LRP5. By real-time PCR analysis of RNA isolated from adult rat tissues, Dkk-1 was found to be abundantly expressed in bone tissues with significant expression also observed in placenta, prostate and uterus. In contrast, expression levels of other LRP5 ligands, Dkk-2 and Dkk-4 in bone were minimal with significant expression of Dkk-2 observed in number of tissues such as kidney, eye and esophagus. These reciprocal expression pattern of Dkk-1 and Dkk-2, know to activate wnt signaling, suggests the unique role for Dkk-1 as a bone expressed inhibitor of Wnt signaling. Accordingly, in MC3T3-E1 osteoblastic cells, Dkk-1, but not other Dkks, suppressed osteoblast differentiation induced by Wnt3a. By *in situ* hybridization, expression of Dkk-1 was found predominantly in osteocytes of cortical bone of adult rat tibiae and adult mouse femur with less significant expression observed in osteoblasts on trabecular bone. No expression of Dkk-1 was found in osteoclasts or growth plate chondrocytes. Osteocyte apoptosis has been linked to glucocorticoid-inuduced osteoporosis. Interestingly, expression of Dkk-1 in adult rat diaphysis was markedly induced by treatment with methyl predonisolone in a dose dependent and time dependent fashion with the significant stimulatory effects observed at 4 days. In contrast, expression of osteoblast markers, such as type I collagen and osteocalcin, in diaphysis were suppressed by methyl predonisolone. These results, in combination with recent reports on osteocyte-selective expression of sclerostin, a binding protein of bone morphogenetic proteins, responsible for a high bone mass disease “sclerosteosis”, support the role for osteocytes in bone mass homeostasis by controlling Wnt and BMP signaling in bone.

The Contribution of BMD Correlation to Fracture Risk Prediction by Bone Density Measurements at Distant Skeletal Sites. G. M. Blake, I. Fogelman. Nuclear Medicine Department, GKT School of Medicine, London, United Kingdom.

The most reliable BMD measurement for predicting fracture risk at any given site in the skeleton is one made at the fracture site itself. This study examines the hypothesis that fracture prediction by measurements made at sites remote from the fracture site can be explained by BMD correlation. We show that the correlation hypothesis predicts the relationship $\beta_{dist} = r\,\beta_{frac}$, where β is the gradient of the exponential relationship between fracture risk and Z-score, β_{dist} is the β-value for the distant BMD site, β_{frac} that at the fracture site, and r is the correlation coefficient between the Z-scores at the two sites. In practice it is necessary to consider the effect of measurement errors on the relationship between r and β. We show that the effect of the errors at the distant site is to reduce both β_{dist} and r in a way that preserves their original relationship. When the effect of errors at the fracture site is taken into account, the overall effect on the (r, β) plot is for the data point representing the fracture site to lie below the linear trend of the points representing distant sites, thus predicting a characteristic signature for the overall relationship. We tested the correlation hypothesis by using data from the Study of Osteoporotic Fractures to examine the (r, β) plots for hip, spine and forearm fractures. For the hip, the data are consistent with the equation $\beta_{dist} = r\,\beta_{frac}$. This suggests that hip fracture prediction by distant sites is adequately explained by BMD correlation, and that measurements made at distant sites provide no additional information about fracture risk over and above that provided by hip BMD itself. However, for spine and forearm fractures the (r, β) plots are consistent with the expected effects of the BMD measurement errors. This suggests that in the case of these fractures, measurements at distant sites do provide additional information about fracture risk, and that they do this by retaining some of the information about bone that was lost because of the measurement errors at the fracture site. Overall, this study points to the importance of BMD correlation as a key factor in explaining the ability of measurements made at distant sites to predict fracture risk.

Site-Specific Reductions in Bone Density in Canadian Aboriginal Women: The First Nations Bone Health Study. W. D. Leslie[1], C. J. Metge*[2], H. A. Weiler*[3], C. K. Yuen[1], J. Krahn*[1], M. Doupe*[1], E. A. Salamon[4], P. Wood Steiman*[5], J. D. O'Neil*[1], C. R. Greenberg*[1], L. M. Lix*[1], L. L. Roos*[1], A. Tenenhouse[6]. [1]Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada, [2]Faculty of Pharmacy, University of Manitoba, Winnipeg, MB, Canada, [3]Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada, [4]Department of Medicine, University of Manitoba, Winnipeg, MB, Canada, [5]Asssembly of Manitoba Chiefs, Winnipeg, MB, Canada, [6]Department of Medicine, McGill University, Montreal, PQ, Canada.

Canadian Aboriginal women are at increased fracture risk compared with the general population (JBMR 18:S151, 2003), but little is known about the burden of osteoporosis in this population. The First Nations Bone Health Study (FNBHS) recruited a random age-stratified (25-39, 40-59 and 60-75) sample of urban and rural Aboriginal women (n=225) and age-matched White women (n=183). All subjects had forearm and calcaneal BMD measured (Lunar PIXI); urban subjects also had BMD measurements of the lumbar spine, hip and total body (Hologic QDR-4500). Aboriginal women had greater weight (80.5±17.7 vs 76.3±18.2 kg, P=0.018) and BMI (30.4±6.3 vs 28.6±6.9 kg/m^2, P=0.005) than Whites due to more adipose tissue (total body fat 3186±1523 vs 2886±1191 g, P=0.039). Weight correlated positively with BMD (r=0.32-0.56, P<0.001 all sites) and could mask an ethnicity effect. Therefore ANCOVA was used to test for an ethnicity effect in Z-scores (controlling for weight and also age if required) and differences in absolute BMD (controlling for weight and age using main effect and interaction terms). There was a significant effect of ethnicity on BMD of the calcaneus, forearm and total body (lower in Aboriginals). Volumetric BMD (BMAD) did not explain this difference as bone area was virtually identical in Aboriginals and Whites. In conclusion, the FNBHS provides the first comprehensive assessment of bone density in Canadian Aboriginal women, and identified significant site-specific differences in age-and weight-adjusted bone density (lower in Aboriginals for the calcaneus, forearm and total body). Central sites (lumbar spine and total hip) were not affected underscoring the importance of a comprehensive assessment of BMD using multiple sites.

Site	Bone Mass as Z-score Predictor: P	Bone Mass as BMD (g/cm^2) Predictor: P

SU354

Is Bone Densitometry Appropriate in Women under 50? E. Koshy*, A. L. Dolan*. Rheumatology, Queen Elizabeth Hospital, London, United Kingdom.

Bone densitometry should only be performed if it alters management. The Royal College of Physicians guidelines state that there are no proven treatments available for premenopausal women. This retrospective, cross-sectional, observational study aims to identify if referral of women under 50 years old for densitometry is appropriate and as a consequence establish guidelines for referral indications in this age group.

Women under 50 years old referred to a District Hospital by general practitioners and hospital physicians were identified from the hospital database over a 4 year period. The referral indications and scan outcomes were studied. Risk factors for osteoporosis were also examined.

301 patients were identified. 65% of referrals were requested by GPs and 35% by hospital doctors. 41% of patients had abnormal scans. The most frequent indication for a DXA scan request was 'premature menopause' 27% (43/160) of all the primary request indications and of them 37% were abnormal. Steroid use accounted for 19% (30/160) of exclusive requests and 47% were abnormal. Family history represented 14% (22/160) of the exclusive referrals and 27% were abnormal. Referral based on osteopenia / previous fracture as a primary or co-existing indication, accounted for 37 scans and 54% were abnormal. 11 patients were referred because of amenorrhoea alone and of this group, 64% had abnormal scans. Anorexia nervosa and inflammatory bowel disease were the medical conditions associated with the highest proportion of abnormal scans, 57% and 52% respectively. Low calcium/vitamin D intake, a BMI <20 and amenorrhoea were risk factors associated with a lower BMD in this sample.Focused use of bone densitometry in women under 50 can identify patients with future fracture risk who may merit osteoporosis prevention. When referral for premature menopause, family history, steroid intake or a medical condition are the exclusive indications, approximately a third of scans are abnormal. The medical conditions most associated with a lower BMD are anorexia and inflammatory bowel disease. In premenopausal women treatment options may be predominantly with calcium and vitamin D, but selective DXA does seem to identify a significant number who would benefit from bone pretection

Rate of Mammography and Bone Mineral Density Testing in Postmenopausal Women. Y. Chen, P. B. Landsman*, S. K. Brenneman, S. M. Teustch*, L. E. Markson*. Merck & Co., Inc., West Point, PA, USA.

Postmenopausal women (PMW) are at increased risk for breast cancer and osteoporosis-related fractures; about one in two will have an osteoporosis-related fracture and one in eight will receive a diagnosis of breast cancer during her lifetime. Mammography screening and treatment reduces mortality by approximately 16%; BMD screening and treatment can reduce osteoporotic fracture rates by almost half. There have been longstanding evidence-based guidelines by the US Preventive Services Task Force (USPSTF) recommending mammography screening every 1-2 years for women aged 40 and older. More recently, the USPSTF guidelines have recommended routine osteoporosis screening in women 65 years of age and older and in those 60 years and older with risk factors. We sought to describe the utilization of mammography and bone mineral density (BMD) testing in PMW age 50 and older. The 2000 Medstat MarketScan ® Research Databases containing medical claims of employees, retirees, and dependents of over 100 large employers covered by over 300 healthcare plans was used for the analysis. Study sample was women age 50 years and older continuously enrolled in a health plan in 2000. CPT codes for mammography and BMD were used to identify women who had tests performed during the one-year study period. Number of women, not number of tests, was used to calculate testing rate. Rates of mammography (number of women with mammography per 1000 person years) and rates of BMD testing (number of women with BMD testing per 1000 person years) and the ratios of the two rates by age group are shown in Table below.

Age	# women	Rate of mammography	Rate of BMD testing	Ratio
50-54	174,940	448	79	6:1
55-59	140,452	516	112	5:1
60-64	118,325	536	131	4:1
65+	281,230	383	121	3:1

Mammography rates are approximately half the minimum recommended frequency (every other year). No benchmarking is available for assessing BMD testing rates. Compared to mammography, BMD testing appeared to be much less frequently utilized even in women 65 years who are at higher risk for fractures. The lack of clear guidelines on testing frequency may contribute to these findings in this cross-sectional data. Preventive care for osteoporosis in PMW may need more attention.

C-reactive Protein Levels Are Associated with Decreased Bone Mineral Density in Mexican Americans. B. W. Whitcomb*[1], J. M. Bruder[2], R. L. Bauer[2], M. C. Mahaney*[3], R. P. Tracy*[4], C. M. Kammerer[5], B. D. Mitchell[6]. [1]Preventive Medicine and Epidemiology, University of Maryland, Baltimore, Baltimore, MD, USA, [2]Medicine, University of Texas Health Science Center, San Antonio, TX, USA, [3]Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA, [4]Biochemistry, University of Vermont College of Medicine, Burlington, VT, USA, [5]Human Genetics, University of Pittsburgh School of Publ;ic Health, Pittsburgh, PA, USA, [6]Medicine/ Endocrinology, University of Maryland, Baltimore, Baltimore, MD, USA.

Accelerated bone loss is frequently observed in rheumatoid arthritis, Crohn's disease, and other autoimmune diseases suggesting that inflammation may play a role in increased bone resorption. To determine if inflammation contributes to overall levels of bone mineral density (BMD) in a non-selected population, we measured serum levels of C-reactive protein (CRP) and evaluated the correlation with bone mineral density. Study participants (n = 650) ranged from 18 to 96 years of age and were members of 34 large families of Mexican American decent. These families were recruited between 1997-2002 as part of the San Antonio Family Osteoporosis Study, a population-based family study of osteoporosis and cardiovascular disease. Serum CRP levels were measured using a competitive immunoassay (antibodies and antigens from Calbiochem, LaJolla, CA) and BMD was measured at the hip (total and neck), spine (L1-L4), and forearm (ultradistal radius) by dual x-ray absorptiometry (DXA). We performed linear regressions of BMD at each site on CRP, adjusted for age, sex, and body mass index (BMI), using a variance component procedure to account for the familial correlations in BMD between study subjects.

Initial analyses revealed CRP levels to be correlated with increasing age ($p < 0.001$) and increasing body mass index ($p < 0.001$). After adjustment for age, sex, and BMI, serum CRP was significantly associated with BMD at the total hip ($p = 0.03$), femoral neck BMD ($p = 0.01$) and forearm BMD ($p = 0.01$), though not with spine BMD ($p = 0.14$). The impact of CRP levels on BMD was modest, with a one standard deviation unit increase in CRP associated with a decrease of only 0.01 units (95% CI: 0.006, 0.014), or 1.0%, in femoral hip neck BMD. The correlations between CRP and BMD did not differ significantly by sex, nor did they differ significantly between subjects older and younger than age 50. These results are consistent with the hypothesis that systemic inflammation contributes to increased rates of bone resorption and bone loss. Furthermore, systemic inflammation may be a common pathway contributing to the joint occurrence of subclinical atherosclerosis and decreased BMD seen in this and in other populations.

Bone Mineral Density of the Lumbar Spine and Knee Osteoarthritis in Korean: Data from the Korean Arthritis Study Group. I. H. Park*[1], M. S. Park,ES Moon,WI Noh,JM Kim,YG Kim,SH Lee,YJ Cho*[2]. [1]Orthopedic Surgery, Kyungpook University Hospital, Taegu, Republic of Korea, [2]Multicenter, Seoul, Pusan, Chunbuk, Kwangju, Republic of Korea.

A prospective, nation-wide multicenter study was carried out under the title of "Risk factors of knee osteoarthritis(OA) in Korean" by Korean arthritis study group. This study was one of the cross-sectional analysis from those data to evaluate the relationship between bone mineral density(BMD) of the lumbar spine and knee OA. One-hundred sixty-two South Korean from 40- to 64-year-old were eligible. Men were 27, and women were 135. Age was matched between OA and control group. Osteoarthritis of the knee was defined by both OA scales of WOMAC TM 3.01 by professor Bellamy and Kellgren-Lawrence grade III or IV using bilateral standing anteroposterior, lateral and tangential knee radiographs. Erythrocyte sedimentation rate(ESR), cross-reacting protein(CRP), and rheumatoid arthritis(RA) factor were all checked to exclude other arthritis than OA. BMD of the lumbar spine was measured by DXA after adjusting precision error at every center. The results were as Table 1, 2, 3. After adjusting body mass index, there was no statistical significance(p=0.05) between the lumbar spine BMD, T-score and knee OA. However, it seems that OA group showed higher BMD and T-score of the lumbar spine both in men and women in spite of lower mean age than control group. More data would be needed to clear out the possible inverse relationship between knee OA and osteoporosis.

Table 1

Mean Age (years)	Male	Female	Total
OA	56.7	56.1	56.2
Control	55.1	53.7	54.0

Table 2

BMD(gm/cm^2)	Male	Female	Total
OA	1.2127	0.9963	1.0353
Control	1.1097	0.9935	1.0177

Table 3

T-score	Male	Female	Total
OA	0.84	-0.79	-0.38
Control	-0.43	-0.93	-0.79

The Choise of Phantom Is Crucial for Quality Assessment in Longitudinal Studies. N. Emaus*, G. K. R. Berntsen, R. M. Joakimsen*, V. Fønnebø*. Department of community medicine, University of Tromsø, Tromsø, Norway.

Densitometer performance is of ultimate importance in the acquisition of valid data in longitudinal studies. In a longitudinal population based study lasting more than six years, using two single absorptiometry (SXA) devices, we were concerned that densitometer performance could influence bone loss estimates.

We had three sources for evaluation of densitometer influence; data from the aluminium wedge phantom (AWP) provided by the manufacturer, data from the European forearm phantom (EFP), which is a semi-anthropomorphic phantom, and repeated measurements, in 1994-95 and 2001, at the forearm in 3346 women and 2291 men aged 25 to 84 years at baseline.

The AWP measurements were performed daily in both studies. When the EFP became available in 1999, we obtained measurements from both densitometers and we continued to use this phantom throughout the 2001 survey.

Starting the second survey, one of the densitometers underwent a major repair. In addition, both densitometers had the x-ray tube replaced later in the survey. These events were considered equivalent to densitometer changes, giving a total of six participating densitometers and eight possible baseline-follow up densitometer combinations in the study.

The mean follow up time was 6,4 years (SD 0,6). The mean overall crude bone loss was 0,0185 g/cm² or 4,14 % (0,00285 g/cm²/year or 0,64%/year). The population bone loss varied between densitometer combinations from 0,0145 g/cm² to 0,0213 g/cm² (p<0,001). The observed variation in bone loss on the different densitometer combinations was interpreted as differences in densitometers' measurement level, because the population groups did not differ significantly with regard to sex, age and baseline BMD. The EFP measurements revealed that two of the densitometers measured a higher BMD-level than the others. After change of x-ray tube, we registered a significant lowering of one densitometer's measurement level, whereas "wear and tear" over time did not alter densitometer function. The EFP measurements predicted the observed variation between densitometer combinations in the population material. This was in surprising contrast to the producer supplied AWP which did not capture these differences. After adjustment according to the EFP data, the overall crude bone loss was reduced to 0,0174 g/cm² or 3,92 % (0,00269 g/cm²/year or 0,61%/year). We conclude that densitometer performance during longitudinal studies might influence the accuracy of bone loss estimates. As changes in performance are not detected by aluminium wedge phantoms, quality control of BMD measurements in longitudinal studies should be performed with daily measurements of anthropomorphic hydroxyapatite phantoms.

Bone Mineral Markers in South Indian Post Menopausal Women. C. V. Harinarayan*[1], U. V. Prasad*[1], M. Suresh*[1], A. V. Hebbani*[1], P. V. L. Srinivasa Rao*[2], M. Dhananjaya Naidu*[3], P. R. Parthasarathy*[3], E. G. T. Kumar*[1], D. Sudhakar*[1], L. B. Aparna*[2], D. Prasanna Kumar*[1]. [1]Endocrinology and Metabolism, SVIMS, Tirupati, India, [2]Biochemistry, SVIMS, Tirupati, India, [3]SV University, Tirupati, India.

To study the bone mineral markers in serum and urine in south Indian postmenopausal women.

Postmenopausal women (n=437) were evaluated for their dietary intake patterns, bone mineral markers in serum and urine.

The mean ± standard error of mean (SEM) of age (yrs), weight (kg), BMI of the 437 patients were 52±0.4; 62±0.4; 27±0.3 respectively. The serum albumin (gm/dl), creatinine (mg/dl), LH and FSH(IU/l) were 3.96±0.02;0.9±0.01;26±0.8; 65±1.8 respectively. The dietary calcium, phosphorous (mg/day) and phytate/calcium ratio were 322±4; 676±7; 0.56±0.01. The whole group was sub-classified based on 25(OH)D levels into: Group - 1-severe deficiency(<5 ng/ml); Group - 2 moderate deficiency(5-10 ng/ml); Group - 3 -mild deficiency(10-20 ng/ml) and Group - 4 -vitamin D sufficiency(>20 ng/ml). The bone mineral marker parameters of the respective group are depicted in the table below:

Parameter	Group - 1	Group - 2	Group - 3	Group - 4
S.Calcium(mg/dl)	9.63±0.13	9.67±0.05	9.68±0.04	9.76±0.07
S.Phosphorus(mg/dl)	3.4±0.2	3.4±0.05	3.45±0.04	3.57±0.06
S.Alk.Phos(IU/l)	106±15	117±6	106±3.5	107±7.3
S.TRAP(IU/l)	6.5±1.5(4)	5.9±0.4(27)	5.7±0.3(49)	7±0.7(9)
25(OH)D(ng/ml)	4.15±0.2	7.88±0.14	14.86±0.2	26±0.65
PTH ntact (pg/ml)	39±5	25.5±1.7	25±1.2	25±1.5
Ca/Cr ratio	0.16±0.02	0.17±0.01	0.18±0.01	0.18±0.01
PEI	0.03±0.03	0.005± 0.008	-0.02±0.02	-0.01±0.008
Urinary DPC(nmol/mmol of cr)	15.6±6(4)	6.35±0.9(27)	7.9±0.4(51)	8.7±1.9(10)
Urinary OH Proline	4.8±0.09(4)	8.43±1.3(24)	6.6±0.71(47)	5.6±2.3(10)

Values are Mean ± SEM; Parenthesis - patient number

There was no significant difference in the dietary pattern in the subgroups. The dietary calcium intake of the whole group is inadequate compared to the Recommended Daily/ Dietary allowances (RDA) of national guidelines. About 80% of the study group had varying degrees of 25(OH)D deficiency {severe deficiency 4% (19); moderate deficiency 24%(104) and mild deficiency 52% (226)} . Only 20% of the population have normal 25(OH)D levels. Serum PTH negatively correlated with 25(OH)D levels (r -0.2; p <0.01) and positively with SAP (r 0.8; p <0.01). A significant positive correlation (p<0.01) was observed between dietary phytates with SAP (r 0.6); dietary calcium with phytates (r0.75) and SAP (r 0.65).

In all postmenopausal women diet should be enriched with calcium and vitamin D supplemented while considering HRT. The dietary calcium insufficiency and 25(OH)D deficiency could reflect fallaciously as osteopenia in BMD measurements.

Dietary Determinants of BMD in Hong Kong Chinese Elderly Men and Women - Mr and Ms OS. W. W. Y. Lau*[1], E. M. C. Lau[1], D. T. K. Choy*[1], S. Y. S. Wong[2], J. Leung*[1], L. M. Lee*[1], H. Lynn[2], P. C. Leung*[3]. [1]Jockey Club Centre for Osteoporosis Care and Control, The Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China, [2]Department of Community and Family Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China, [3]Department of Orthopaedics and Traumatology, The Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China.

Not many large cohort studies had been done on the dietary intake of Hong Kong Chinese elderly. Mr OS and Ms OS (Hong Kong) is a large cohort study to address the dietary intake of Chinese elderly in Hong Kong in relation to their bone mineral density (BMD). A total of four thousand men and women, stratified by age and sex, were recruited. They were ambulatory and community dwelling elderly aged 65 to 94 years. A 260 items food frequency questionnaire based on the method of Block food frequency questionnaire with local and Chinese food added was administered at baseline. The results were analyzed by a locally developed nutrients analysis program containing food database from US, UK and China to produce estimation of daily caloric and nutrients intake. BMD in the whole body, total hip and total spine were measure by Dual Energy X-ray Absorptiometry (Hologic QDR 4500W). The mean nutrient intake was higher in men than in women. The mean intake for men was 2102 Kcal, 88 g protein and 68 g Fat whereas women was 1605 kcal, 67 g protein and 49 g fat. In both elderly men and women, the calcium intake was 633 mg and 583 mg respectively, which is much lower than US Dietary Reference Intake of 1200 mg per day. In relation to the total spine BMD, positive association (p<0.05) were found in a multiple regression model (adjusted for age and body weight) with intake of calcium, vitamin A, B1, B2 and phosphorous for women whereas no significant association between BMD and any nutrient intakes in men was found. In relation to the total hip BMD, positive associations were observed with intake of energy, calcium, protein, carbohydrates, vitamin A, B1, B2, C, phosphorous, iron and zinc for elderly women. For men, only intake of calcium was found to have a significantly positive association with total hip BMD.

The results suggested that dietary intake has a larger effect on BMD in elderly women than in men. However, increased calcium intake does play an important role in relationship with higher BMD in both gender although the mean dietary calcium intake in Hong Kong Chinese elderly is still below recommendation level. Further public education may be needed in this area for bone health promotion.

Assessment of Calcium and Vitamin D Intake Using a Modified Food Frequency Questionnaire in Aboriginal and White Women Residing in Manitoba: The First Nations Bone Health Study. H. A. Weiler*[1], W. D. Leslie[2], E. A. Salamon[3], P. Wood Steiman*[4], C. J. Metge*[5], C. K. Yuen[2], M. Doupe*[2], J. D. O'Neil*[2], C. R. Greenberg*[2], L. M. Lix*[2], L. L. Roos*[2], A. Tenenhouse[6]. [1]Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada, [2]Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada, [3]Department of Medicine, University of Manitoba, Winnipeg, MB, Canada, [4]Assembly of Manitoba Chiefs, Winnipeg, MB, Canada, [5]Faculty of Pharmacy, University of Manitoba, Winnipeg, MB, Canada, [6]Department of Medicine, McGill University, Montreal, PQ, Canada.

The Canadian Multicentre Osteoporosis Study (CaMos) used a food frequency questionnaire (FFQ) to capture calcium intake from 15 food categories. The assessment of calcium and vitamin D intake in the Manitoba First Nations Bone Health Study (FNBHS) was modified from the riginal CaMos FFQ to include food sources also culturally relevant to Aboriginal women. The FNBHS FFQ included 14 additional foods (commercially available and traditional) identified through 1-on-1 meetings and focus groups with urban and rural Aboriginal women. The objective of this study was to compare dietary calcium and vitamin D intakes obtained using the original CaMos and adapted FNBHS FFQs. Over 2 years, 199 Aboriginal and 139 White women completed a FFQ. The CaMos and FNBHS FFQs correlated well for calcium (r=0.9304, P<0.0001) and vitamin D intake (p=0.856, P<0.0001). In all analyses the FNBHS FFQ gave higher values for calcium and vitamin D intake (see table) than the CaMos FFQ, regardless of ethnicity. Foods making contributions to calcium intake (>20 mg/d) were fortified orange juice, pizza and pizza pops, other cheeses and evaporated milk. Foods making contributions to vitamin D intake (>4 IU/d) were evaporated milk, soy drink, macaroni and cheese dinner, eggs and margarine. Evaporated milk, eggs and margarine were critical for accurately assessing calcium and vitamin D intake in the northern rural Aboriginal group. Calcium intake was similar in Aboriginal and White women (T-test P>0.2), but vitamin D intake was higher in the Aboriginal women (T-test P=0.0157). This work demonstrates the importance of identifying and including food items that are culturally relevant to the study population.

Group - FFQ Used	Calcium Intake (mg/d)	P value between FFQ	Vitamin D Intake (IU/d)	P value between FFQ
All (n=338) - FNBHS FFQ	958±678	<0.001	382±471	<0.0001
All (n=338) - CaMos FFQ	758±594		226±403	
Aboriginal (n=199) - FNBHS	922±746	0.003	433±550	0.001
Aboriginal (n=199) - CaMos	715±629		234±459	
White (n=139) - FNBHS	1010±566	0.0044	308±315	0.0136
White (n=139) - CaMos	820±537		215±307

Low Vitamin K Status Is Associated with Markers of Bone Turnover in Men and Women. K. M. Shedd*[1], D. M. Cheng*[2], C. M. Gundberg[3], G. E. Dallal*[1], D. P. Kiel[4], K. E. Broe*[4], B. Dawson-Hughes[1], S. L. Booth[1]. [1]Tufts University, Boston, MA, USA, [2]BU School of Public Health, Boston, MA, USA, [3]Yale University, New Haven, CT, USA, [4]Hebrew Rehab Center for Aged & Harvard Medical School, Boston, MA, USA.

Low vitamin K status has been associated with reduced bone mineral density and greater hip fracture risk in men and women. Since bone turnover is an independent predictor of fracture, we studied the association between vitamin K status and biochemical markers of bone turnover. Cross-sectional associations between markers of bone formation [Total Osteocalcin (TOC)] and bone resorption [N-telopeptide (NTx)] and biochemical measures of vitamin K status [percent undercarboxylated osteocalcin (%ucOC) and phylloquinone (K1)] were examined in 335 subjects (mean age 56y; female 38%) participating in the Offspring Framingham Heart Study (Study A), and 452 subjects (mean age 68y; female 59%) participating in a vitamin K intervention trial (Study B). In study B, all biochemical measures were made at baseline prior to randomization. In both studies TOC and %ucOC were measured by the same RIA, and K1 was measured by HPLC. In Study A, NTx was measured by RIA in urine; in Study B, NTx was measured in serum. Separate linear regression models were fitted for each marker of bone turnover. Each model included a single biochemical measure of vitamin K status and adjusted for age, weight, triglycerides, sex, and menopausal status (for Study A only as all women in Study B were postmenopausal). K1 was inversely associated with TOC in both Study A (β=-0.040, p=0.02) and Study B (β=-0.010, p=0.05), although the association was marginally significant in Study B. In both studies %ucOC, a marker of poor vitamin K status, was positively associated with NTx (β=0.008, p<0.0001 for Study A and β=0.001, p=0.002 for Study B). However, there was

no association between K1 and NTx in either study (β=-0.009, p=0.54 and β=0.002, p=0.63 for Study A and Study B, respectively). The congruency of the results obtained in these two independent studies suggests that lower vitamin K status may be associated with higher levels of bone turnover markers in men and women, and may contribute to the increased fracture risk observed in persons with lower vitamin K status.

Hypovitaminosis D among Healthy Adolescent Girls in the UK. J. L. Berry[1], G. Das*[2], S. Crocombe*[3], M. McGrath*[2], M. Z. Mughal[3]. [1]Vitamin D Research Group, University of Manchester, Manchester, United Kingdom, [2]Central Manchester Primary Care Trust, Manchester, United Kingdom, [3]St Mary's Hospital for Women & Children, Manchester, United Kingdom.

There has been a resurgence of vitamin D deficiency rickets among toddlers in the UK and we have recently observed an increase in the number of adolescents presenting with symptomatic vitamin D deficiency. This cross-sectional study was designed to determine the prevalence of hypovitaminosis D among healthy adolescent schoolgirls. 51 (28%) out of 182 girls [13 white Caucasian and 38 non-white; median(range) 15.3(14.7-16.6) yrs] attending year 10 of an inner city multiethnic girls' school took part in the study. We assessed their serum concentration of 25-hydroxyvitamin D (25OHD) and related it to dietary intake of vitamin D, estimated duration of sunshine exposure and the percentage of body surface area exposed (%SAE). 37 out of 51 (73%) girls were vitamin D deficient (25OHD concentrations <12 ng/ml) and 9 (17%) were severely deficient (25OHD concentrations <5 ng/ml). The median(range) 25OHD concentration of white Caucasian girls (13.2(7.3-29.3) ng/ml) was significantly higher ($p<0.001$) than that of non-white girls (5.9(2.3 to 17) ng/ml). The estimated intake of vitamin D in white Caucasian and non-white groups was 1.9µg/day and was not related to 25OHD concentration. For the whole group, 25OHD concentration was related to the estimated sunshine exposure (r=0.38; p=0.007) and %SAE (r=0.41; p=0.003). In white Caucasian girls the estimated sunshine exposure and %SAE were significantly higher than that of non-white girls, p=0.003 and p=0.001 respectively. Hypovitaminosis D is common among healthy adolescent girls; non-white girls were more severely deficient. Reduced sunshine exposure rather than diet explains the difference in vitamin D status of white Caucasian and non-white girls. Since vitamin D is essential for bone mass accrual during adolescence, vitamin D supplements should to be given to girls with reduced sunshine exposure.

Fluoride Intake Influences Cortical Bone Characteristics in Young Children. J. M. E. Gilmore*[1], S. M. Levy[1], T. A. Marshall*[1], E. M. Letuchy*[2], T. L. Burns*[3], M. C. Willing[4], K. F. Janz*[5], J. C. Torner*[2]. [1]Preventive and Community Dentistry, University of Iowa, Iowa City, IA, USA, [2]Epidemiology, University of Iowa, Iowa City, IA, USA, [3]Public Heath Genetics, University of Iowa, Iowa City, IA, USA, [4]Pediatrics, University of Iowa, Iowa City, IA, USA, [5]Health and Sports Studies, University of Iowa, Iowa City, IA, USA.

Fluoride intake is thought to affect mineralization of both teeth and bones. Few studies have comprehensively assessed fluoride intake and related findings to bone measures. The aim of this study was to investigate the associations between fluoride intake from birth to age 5 on the cortical bone characteristics of healthy young children measured by peripheral quantitative computed tomography (pQCT) at age 9. The 189 subjects (98F/91M) are participants in the Iowa Bone Development Study, a component of the Iowa Fluoride Study (IFS). Subjects provided detailed questionnaire data 2-5 times per year concerning fluoride intake from water, beverages, selected foods, dentifrice, and dietary supplements. Individuals' multiple water sources and major beverages were assayed for F content. Cortical bone content (CRT_CNT), density (CRT_DEN), area (CRT_A) and wall thickness (CRT_THK_C) at the 20% distal radius were assessed by pQCT using the Norland Stratec XCT 2000 (software version 550, circular ring model) with a voxel size of 0.4 mm, scan speed of 20 mm/sec and a slice thickness of 2.4 mm. Fluoride intakes at 1, 3, 5 years and cumulative 1-5 year intake (AUC) were the focus of this analysis. Fluoride intake at age 5 years, but not at earlier ages was associated with cortical bone characteristics of children at age 9 years. Mean fluoride intake from all sources at age 5 years was 0.77 mg/day (range: 0.18 - 2.50). Intake at 5 years showed an inverse univariate association with CRT_DEN, CRT_A and CRT_THK_C, and a positive association with periosteal (PERI_C) and endosteal (ENDO_C) circumferences ($p < 0.10$, except PERI_C circumference $p > 0.50$). Regression models adjusted for age, gender and body size revealed fluoride intake at 5 years was predictive of CRT_DEN ($p < 0.02$, estimated $\beta = -21.47$), CRT_THK_C ($p < 0.10$, estimated $\beta = -0.12$), PERI_C circumference ($p < 0.01$, estimated $\beta = 1.00$) and ENDO_C circumference ($p < 0.05$, estimated $\beta = 1.78$). Further exploration of dietary fluoride intake and its implications for bone growth and development through adolescence is warranted.

A Moderately Low Magnesium Diet Exerts Few Changes in the Leg Bones of Growing Rats. J. M. Welch[1], C. M. Weaver[1], J. E. Sojka*[2]. [1]Foods and Nutrition, Purdue University, West Lafayette, IN, USA, [2]Veterinary Clinical Sciences, Purdue University, West Lafayette, IN, USA.

Dietary intake of magnesium (Mg) by 14-18 year old American girls is estimated to meet only 60% of their Recommended Dietary Allowance (RDA). Although severe Mg deficiencies adversely affect the skeleton, it is unknown if these suboptimal Mg intakes are detrimental. We examined the effects of a moderately low Mg diet on the appendicular skeleton, using growing rats as an experimental model. Female F-344 rats, aged 7 weeks, were assigned to either a low Mg diet (Mg-, 0.02% Mg, n=20) or a control diet containing 100% of the Mg requirement for a rodent (Mg+, 0.05% Mg, n=22) for 8 weeks. Upon completion of the study, rats were euthanized and their leg bones removed. Mechanical strength of the ulnas was measured by axial compression, and metaphyseal and diaphyseal sites on the ulna, radius, humerus, femur, tibia, and fibula were scanned by peripheral quantitative computed tomography (pQCT). Images were analyzed for total, cortical, and trabecular volumetric bone mineral density (BMD); bone area (BA) of total bone as well as cortical, and trabecular fractions; cortical thickness, and periosteal and endosteal circumferences. Final body weight did not differ between groups. The Mg- diet resulted in small decrements in bone length (mean 1.5%) which were only significant in the ulna. Ulnar breaking strength, stiffness, and energy to failure did not differ between groups. The Mg- diet did not result in significant changes in shaft or distal sites of any bones, nor proximal sites of the lower leg bones. In the proximal femur, the Mg- diet resulted in a 4.4% (p=0.04) decrease in total BA and a 2.2% (p=0.04) decrease in periosteal circumference. Additionally, in the proximal humerus, cortical BMD decreased by 1.5% (p=0.04). This study indicates that a diet moderately low Mg, fed to female rats from early puberty through sexual maturation, did not diminish bone strength, and induced few changes in the geometry and density of the appendicular skeleton.

Risk Factors of Bone Fractures in Bialystok Osteoporosis Study (BOS). J. E. Badurski[1], N. A. Nowak*[1], A. Dobrenko*[1], J. Supronik*[2], J. Lis*[3], S. Daniluk*[1], E. Z. Jeziernicka*[1]. [1]Centre of Osteoporosis & Osteoarticular Diseases, Bialystok, Poland, [2]Departament of Rheumatology, Sniadecki Hospital, Bialystok, Poland, [3]Medical Departament, Eli Lilly, Bialystok, Poland.

In the first part of the Bialystok Osteoporosis Study (BOS) it was proved that 14.8% (out of 727) of the women aged from 46 to 89, mean 59.3 ± 9.4, have their BMD at Femoral Neck (FN) T-score -2.5 and lower (WHO criteria of osteoporosis)[1]. 222 low energy fractures (30.5% out of 727) have been noticed, ¾ of which have affected women with BMD over FN T-score -2.5. The subject of the present analysis was risk factors of fracture influencing the BOS cohort. From among 50 potential risk factors known from other epidemiological studies, statistically significant, BMD - independent impact on increase of fracture risk are that as follow: advanced age, long-term steroid therapy, hematological diseases, poor standard of life, kidney diseases and alcohol abuse. Factors, which decreased fracture risk were: oestrogen use, breast feeding and high body mass index. Also the odds ratio (OR) of fracture was increasing as the bone mass was decreasing, the age increasing as well as hematological and kidney diseases effecting. The fracture risk was decreasing owing to good standard of life and education (using more than one source of information about osteoporosis) and childbirths. Results of our epidemiological studies, as well as Rotterdam Osteoporosis Study [2] and Study of Osteoporosis Fractures [3], lead to a conclusion that over 50% of all fractures appear among persons with FN T-score > -2.5. The generalization of BOS data on whole Polish women population would indicate the following relations between number of fractures, their frequency, bone mass and age: The number of women after menopause living in Poland in 1999 - 6 000 000, the number of women over 45 years old with FN T-score < -2,5 - 900 000 (15%), the number of all fractures among women after menopause - 1 500 000 (25%). The number of fractures appeared to be significantly bigger than the number of persons with osteoporosis according to WHO criteria. It indicates the necessity to distinction osteoporosis and fractures BMD-dependent from that of BMD-independent [4].References: [1]. Nowak NA et al:, Postepy Osteoartrol.2003,14(1):1-5

The Estimation of the 5-year Probability of Fracture in a General Population of Elderly Women. T. P. van Staa[1], P. Geusens[2], H. Leufkens*[3], S. Gehlbach*[4], C. Cooper[4]. [1]Procter&Gamble Pharmaceuticals, Egham, United Kingdom, [2]Limburg University Center, Diepenbeek, Belgium, [3]Utrecht University, Utrecht, Netherlands, [4]University of Southampton, Southampton, United Kingdom.

The aim of this study was to develop a simple clinical tool for assessing 5-year risks of fractures in elderly women of a large general population.

The study population consisted of all women aged 50+ included in the THIN Research Database (THIN contains computerised medical records of all patients at general practices in the UK, similar to the UK General Practice Research Database). Women currently using oral glucocorticoids were excluded. The period of follow-up was divided into 6-month intervals, with risk factors assessed at each interval. Using Cox proportional hazards models, a risk score, indicating the association to risk, was initially estimated from age, body mass index (BMI), disease and drug history. Routine laboratory data and GP exercise assessment were also used (data available for about 8 and 25% of the records, respectively). The 5-year risk of fracture (survival function) was estimated for each sum of scores. This was done for osteoporotic (O) and hip (H) fractures. Osteoporotic fractures included radius/ulna, humerus, rib, femur/hip, pelvis and clinically symptomatic vertebral fractures.

A total of 388,533 women were included in the study (with 22,832 O and 7184 H fractures) and the average follow-up per person was 7.9 years. The risk scores are summarised in the table:

	O	H
Age 60-69 years	6	12
70-79	11	24
80-89	16	34
90+	19	38
Prior fracture	7	7
Fall history	6	6
BMI < 20	3	6
> 26	-2	-5
Early menopause	0	7
CNS medication	4	6
Hospitalisation chronic disease	4	5
Hemoglobin < 7.5 mmol/l	2	3
Albumin < 33 g/l	0	4
Lack of exercise	1	3

The 5-year risk of osteoporotic fracture for patients with scores of 20, 30, 40, and 50 was 11.1, 23.2, 44.6, and 73.4%, respectively. Hip fracture scores of 30, 40, 50, and 60 corresponded to 5-year hip fracture risks of 2.3, 5.7, 13.7, and 30.6%, respectively. For a 75-year female with low BMI and fracture and fall history, the 5-year risk of osteoporotic fracture was 18.7%. The corresponding hip fracture risk was 7.5%.

In conclusion, this risk score allows for an assessment of an individual's risk of fracture and could be used for targeting patients for further investigation, such as bone densitometry.

Quantitative Ultrasound of the Calcaneus but not Biochemical Markers of Bone Turnover Are Associated with Fractures in Frail Older People with Vitamin D Deficiency: The FREE Study. C. Chen*[1], M. Seibel[2], L. March*[1], I. Cameron*[1], R. Cumming*[3], P. Sambrook[1]. [1]Institute of Bone & Joint Research, University of Sydney, Sydney, Australia, [2]ANZAC Research Institute, University of Sydney, Sydney, Australia, [3]Public Health, University of Sydney, Sydney, Australia.

Background: Biochemical markers of bone turnover have been reported to predict fracture risk independent of bone mass in postmenopausal women. We investigated their use in predicting fractures in the frail elderly.

Methods: case-control study of 159 pairs of older people living in residential care facilities who were participants in the Fracture Risk Epidemiology in the Frail Elderly (FREE) study. The cases were the first 159 respondents who had sustained a fracture during study follow-up, where serum samples were available. For each case, a control was selected based on gender, age, institution type and follow-up period. We measured one bone resorption marker (carboxyterminal cross-linked telopeptide of type I collagen, ICTP) and two bone formation markers (bone alkaline phosphatase, BAP, and intact aminoterminal propeptide of type I procollagen, PINP) in serum. Bone ultrasound attenuation (BUA) was measured in the calcaneus using a McCue Cuba II machine.

Results: the mean age of subjects was 86.8 years (range 69.7-110.4; 86% female). 35% were living in nursing homes and 62% of subjects had hypovitaminosis D (25OH D < 31 nmol/L). There was no difference between cases and controls in mean serum 25OH D or PTH. There were significant differences between cases and controls for calcaneal BUA ($p < 0.01$). However, no significant differences were detected for either the resorption marker or the two formation markers between fracture cases and controls (analysed as either total fractures, vertebral or hip fractures). This was also the case after stratifying for age, gender and renal function. Only 12% of BAP values and10.6% of PINP values were above the postmenopausal reference range, however 75% of ICTP values were above the postmenopausal range. For females, significant correlates with increased ICTP, PINP and BAP included higher PTH, lower BUA and older age.

Conclusion: in the frail elderly with a high prevalence of vitamin D deficiency, calcaneal ultrasound but not biochemical markers of bone turnover are useful for predicting fractures. The lack of a biochemical response may be due to the fact that in this vitamin deficient population, bone resorption is already disturbed, possibly confounding the relationship between bone turnover and fractures seen in younger subjects.

SU369

Incidence and Costs of Hip Fractures Compared to Acute Myocardial Infarction in the Italian Population: A 3 Years Study. P. Piscitelli[1], P. Camboa*[1], N. Rosato*[1], V. Dattoli*[1], V. Gigante*[1], E. Viola*[1], F. Fitto*[2], F. Avitto*[3], G. Termini*[4], G. Iolascon*[5], M. Rossini*[6], S. Adami*[6], G. Guida*[5], A. Angeli[7]. [1]AUSL Le/2, Maglie (Le), Italy, [2]Casa di Cura Città di Lecce, Lecce, Italy, [3]EDRA, Milan, Italy, [4]AISO, Palermo, Italy, [5]II University of Naples, Naples, Italy, [6]University of Verona, Verona, Italy, [7]University of Turin, Turin, Italy.

This is the first study aimed to analyze incidence and costs of hip fr. in Italy vs a severe-perceived disease, such as acute myocardial infarction (AMI) in people aged ≥ 45. Since Italy is a country with high life expectancy, it represents an appealing case study for age-related diseases. The study examined 3 years data (1999, 2000, 2001) from the national ICD-9CM diagnosis database. We considered codes 820.0 and 820.1 (cervical hip fr.), 820.2 and 820.3 (intertrochanteric fr.), 820.8, 820.9, 821.1 (other hip fr.) and 410 (AMI). As showed in table 1, the incidence of hip fr. increased with age and was highest in women.

Table 1. Incidence of hip fr/10.000

Age	Hip Fr. **1999**		Hip Fr. **2000**		Hip Fr. **2001**	
	M	F	M	F	M	F
45-64	3.6	4.9	3.7	4.5	3.2	4.9
65-74	13.6	30.1	13.9	29.8	14.2	29.7
75+	72.8	163.9	77.9	165.8	82.2	178.9

The incidence of hip fr. was comparable to the incidence of AMI. We observed 84,188 hip fr. vs 97,913 AMI in 2001; 79,763 hip fr. vs 89,125 AMI in 2000; 78,708 hip fr. vs 86,100 AMI in 1999. To evaluate the costs, we analyzed all the proper DRGs. Table 2 shows that **direct costs of hospitalization for hip fr. in Italy are higher than those for AMI**. Table 3 shows total costs of hip fr. in 2001 including rehabilitation and indirect costs. It confirms an exceedingly high social impact of hip fr., despite unacceptable lack in the perception of their severity.

Table 2. Direct costs (Euros) of hospitalization for hip fr. compared to AMI (overall and ≥ 65 y.o.)

YEAR	Hip Fr. ≥ 45 y.o	AMI ≥ 45 y.o	Hip Fr. >65 y. o.	AMI >65 y. o.
1999	490,800,000	450,175,000	401,800,000	296,595,000
2000	519,300,000	498,667,000	403,300,000	286,515,000
2001	*564,600,000*	*523,463,000*	**438,400,000**	**323,230,000**

Table 3. Total costs of hip fr. in elderly (year 2001)

YEAR 2001	
No. of hip fr. (>65 y.o.)	81,400
Direct costs (hospital. >65 y.o.)	438,400,000 Eur
1 month rehabilitation	416,000,000 Eur
Indirect costs	170,900,000 Eur
Total	**1,025,300,000 Eur**

Disclosures: ***P. Piscitelli****, None.*

SU370

POF1 - Incidence of Peripheral Osteoporotic Fractures Hospitalized in France during 2001. M. Maravic*[1], C. Le Bihan*[1], J. Richard*[1], P. Landais*[1], P. Fardellone[2]. [1]Service de Biostistique et Informatique Médicale, Hôpital Necker Enfants Malades (APHP), Paris cedex 15, France, [2]Service de Rhumatologie, Centre hospitalier universitaire, Amiens, France.

To describe incidence of three peripheral osteoporotic fractures (POF) (upper extremity of humerus and hip, lower extremity of radius and/or ulna) in women and men older than 45 years, hospitalized in France during 2001.

Hospitalizations for each POF in women and men older than 45 years were selected from the dataset of French private and public hospitals in 2001.

Incidence rates (CI 95%) were standardized on age and gender according to the census of French population.We analysed the effect of age (46 to 65 years versus 66 to 80 years versus ≥ 81 years) (Chi-square test, $\alpha = 0.05$) and the existence of a geographical difference between North-South and East-West (Chi-square test, $\alpha = 0.025$) on the incidence of each type of POF.

130 471 hospitalizations for POF (12% humerus, 27% radius and/or ulna et 61% hip, sex ratio 0.27) were registered.

Incidence of POF for 10^6 inhabitants (CI 95%) standardized on age and gender			
Site / gender	**46-65 years**	**66-80 years**	**≥ 81 years**
Humerus / women *	293 (280 - 306)	1366 (1331 - 1402)	3280 (3188 - 3372)
Humerus / men *	238 (226 - 250)	401 (379 - 424)	1083 (1004 - 1163)
Radius / women *	1131 (1106 - 1156)	3541 (3483 - 3598)	4921 (4808 - 5034)
Radius / men	533 (516 - 551)	490 (466 - 515)	789 (721 - 857)
Hip / women *	412 (397 - 427)	4172 (4110 - 4235)	27629 (27364 - 27893)
Hip / men *	445 (429 - 461)	2139 (2087 - 2190)	13740 (13457 - 14022)

* Incidence of POF increased significantly with age (p<0.001). We found a significantly increased of POF in the East of France compared to the West whatever the type of POF or gender and in the South compared to the North in women whatever the type of POF and in men only for hip.

This evaluation was based upon data of the French hospitals during 2001. It describes the hospital incidence rate of POF. We confirmed a significant increase of incidence with age. POF were more incident in women and geographical differences seem to exist. This method could be used for annual follow-up of POF incidence trend in France and for international comparisons.

Disclosures: ***M. Maravic****, None.*

SU371

Hip and Other Osteoporotic Fractures Increase the Risk of Subsequent Fractures in Nursing Home (NH) Residents. K. W. Lyles[1], A. P. Schenck*[2], M. A. Carlson*[1], C. S. Colon-Emeric*[1]. [1]Medicine, Duke University Medical Center, Durham, NC, USA, [2]Medical Review of North Carolina, Inc., Cary, NC, USA.

In community dwelling older adults major risk factors for hip fractures include low bone mass, falls, prior fractures, impaired vision and neurological disease. Osteoporotic fractures are also a major cause of morbidity and mortality in NH residents with a reported annual incidence of 3-6% for hip fractures. We hypothesized that prior hip and other osteoporotic fractures would be risk factors for subsequent fractures in NH residents. Using data from North Carolina Minimum Data Set (MDS) assessments of NH residents, we identified all Medicare enrollees who were in NH in 2000 (N:33,520). Using NH Medicare hospital claims from 1996-2000, we defined subjects with a prior diagnosis of hip fracture or other osteoporotic fracture (N=8667) as the study population. We followed these subjects from their entry into the nursing home until the end of 2002 using Medicare hospital claims to determine which subjects sustained a subsequent hip or osteoporotic fracture (N=4005). Cumulative percents of NH subjects in each group that suffered subsequent fractures are depicted below.

For NH residents with no osteoporotic fracture history, the cumulative percent of fractures is 7.5% over the study period, while 16.7% of NH subjects with a prior non-hip osteoporotic fracture and 25.4% of NH subjects with a prior hip fracture sustain subsequent fractures. For NH residents a prior hip fracture or other osteoporotic fracture appears to be a risk factor for further fractures.

Hip Fracture and Ethnicity in Hawaii. F. Singer[1], R. B. Tanaka*[2], F. Lurie*[3]. [1]Endocrinology and Metabolism, Straub Clinic & Hospital, Honolulu, HI, USA, [2]none, None, HI, USA, [3]Straub Foundation, Honolulu, HI, USA.

The state of Hawaii has six different ethnic groups (Black, Chinese, Filipino, Hawaiian, Japanese, and White) of sufficient size as to allow comparative study of hip fracture incidences. The Hawaii Health Information Corporation collects discharge data from all 22 acute care hospitals in the state, which allowed us to obtain information on hip fracture discharges (ICD9 820.X) and ethnicity from 1995-2001. Using available on-line U. S. Census Bureau information from the year 2000, we calculated hip fracture incidences over that period. For each ethnicity, fracture rates were determined separately for females and males in three different age groups: 60-69, 70-79, 80+ years. Using the confidence limits provided by the Census Bureau, differences between ethnicities in the six different matched age/sex categories were tested for significance. Also, we calculated that the pretest probability of one ethnic group having a higher incidence than a second in each of six age/sex-matched comparisons is 1/64. Therefore we considered the appearance of this pattern in the data to be of significance.

Results: The incidence of hip fracture in Whites was higher than each of the five other ethnic groups in each of the six age/sex-matched categories, without exception. The incidence of hip fracture in Japanese was higher than in Chinese in all six age/sex-matched categories. The risk of hip fracture in Whites was three times (p<.05) that of Filipinos, females and males, in the 70-79 year-old age group.

Significance: This study provides comparative hip fracture incidences for the largest number of different ethnic groups observed in a single location during a single time period. It confirms results from other less comprehensive studies and adds new data regarding the Filipino and Hawaiian populations. The consistency of results showing that Whites have a higher hip fracture incidence than each of five other ethnic groups suggests a change in point of view: Rather than asking the question, "Why do Japanese (or Chinese) have a lower incidence of hip fracture than Whites?" for example, we should be asking, "Why do Whites have a higher hip fracture incidence than everbody else?"

Fracture Risk in Individuals 65 Years and Older: Association with Season, Snowfall and Sunshine. H. A. Bischoff-Ferrari[1], J. E. Orav*[2], J. A. Barrett*[3], M. Beach*[4], J. A. Baron*[5]. [1]Div. of Aging and Rheumatology, Brigham and Women's Hospital, Boston, MA, USA, [2]Div. of Biostatistics, Brigham and Women's Hospital, Boston, MA, USA, [3]Dept. of Community and Family Medicine, Dartmouth Medical School, Hanover, NH, USA, [4]Dept. of Anesthesiology, Dartmouth Medical School, Hanover, NH, USA, [5]Dept. of Community and Family Medicine and Dept. of Medicine, Dartmouth Medical School, Hanover, NH, USA.

Aims: To investigate seasonal variation and the association of snowfall and sunshine exposure with fracture risk in older persons. To assess seasonal variation of fracture risk in warm and cold climate states, younger and older subjects, and men and women.

Methods: In this population-based analysis, we used Medicare claims for a 5% random sample of the total US Medicare population aged 65 and older to ascertain fractures of the hip (n = 35,007), the distal forearm (n = 16,622), the proximal humerus (n = 9,708) and the ankle (n = 8,520). Weather information was obtained from the US National Oceanic and Atmospheric Administration website (www.noaa.gov). Poisson regression was used to investigate the associations of season and weather factors with fracture risk. All models were adjusted for gender, age (4-year steps) and race/ethnicity.

Results: There was a significant seasonal variation for all of the 4 types of fractures ($p < 0.0001$ for each), with the largest differences occurring between winter and summer months: a 8% increase for the rate of hip fractures, a 19% increase for distal forearm, a 20% increase in proximal humerus fractures, and a 22% increase for ankle fractures. There were winter peaks in both warm and cold climate states for each of the fractures studied and the winter peaks were larger in warm climate states than in colder states. For all fractures, winter peaks were more pronounced in men than in women, and in those younger than 80 than among those who were older. The variability between subgroups was less pronounced for hip fractures than for non-hip fractures.

In winter, snowfall was associated with a reduced risk at the hip (-9% per 10 inches) but an increased the risk of all non-hip fractures (16-34%; $p < 0.05$ at all sites). In summer, sunshine exposure was associated with a decreased risk at the hip (- 6% per week of sunny days) but an increased risk of all non-hip fractures (22%-31%; $p < 0.05$ at all sites).

Conclusion: For each of the fractures, fracture risk was increased in winter compared to summer, and this winter peak was most pronounced in warm states, in men, and individuals between 65 and 80. Our findings are consistent with the idea that hip fractures, which tend to occur indoors among relatively frail individuals, are affected differently by weather factors than the other fractures studied.

Vitamin A Intake and Osteoporotic Fractures. H. E. Meyer*[1], G. B. Smedshaug*[1], E. Kvaavik*[2], J. A. Falch*[3], A. Tverdal*[1], J. I. Pedersen*[2]. [1]Norwegian Institute of Public Health, Oslo, Norway, [2]University of Oslo, Oslo, Norway, [3]Aker University Hospital, Oslo, Norway.

Recent observational studies suggest that moderately increased intake of vitamin A (retinol) increases the risk of osteoporotic fractures. Retinol in oil-based preparations (e.g. cod liver oil) is probably considerably less toxic than retinol in water-soluble, emulsified or solid (i.e. tablets) preparations. A possible adverse effect of retinol could be aggravated by vitamin D deficiency.

We studied the association between retinol intake and fracture risk by using data from a double-blinded randomized controlled trial studying the effect of vitamin D supplementation on fracture risk (1). The study commenced prior to reports of a possible harmful effect of moderately increased intakes of retinol.

The study population consisted of 1144 nursing home residents. The intervention group received ordinary cod liver oil, while the control group received cod liver oil without vitamin D. During the 2 years study period, 76 persons in the control group and 69 persons in the intervention group suffered a nonvertebral fracture, and as previously published there was no difference in fracture incidence between the vitamin D group and the control group (1). The participants were not randomized to different doses of retinol. However, as cod liver oil also contains retinol, both the control group and the vitamin D group received retinol (1.3 mg per daily dose of 5 ml). In addition, around 40 % of the participants took multivitamin supplements at baseline, typically containing around 0.8 mg retinol and 10 µg vitamin D. No attempt was made to stop this supplementation as we found it unethical to do so in this frail population. Those who received retinol both from cod liver oil and supplements thus had an intake of approx. 2.1 mg/d from these sources.

We did not find any difference in fracture risk between those with a moderate intake of retinol and those with a high intake of retinol, irrespective of vitamin D intake from supplements (ranging from 0 to 20 µg/day). For example, the relative risk of any non-vertebral fracture was 1.08 (95% CI 0.67-1.72) in those with a retinol intake of 2.1 mg/day and a vitamin D intake of 10 µg/day compared to those with a retinol intake of 1.3 mg/day and a vitamin D intake of 10 µg/day. Similarly, there was no significant association between retinol intake and hip fracture.

In summary, we did not find any association between a high retinol intake and fracture at two-year follow-up of a cohort of frail elderly.

Recent Trend in the Incidence of Hip Fracture in Tottori, Japan. H. Hagino[1], H. Katagiri[2], T. Okano[2], R. Teshima*[2]. [1]Rehabilitation Division, Tottori University, Yonago, Japan, [2]Department of Orthopedic Surgery, Tottori University, Yonago, Japan.

OBJECTIVE: The purpose of this study was to investigate the recent trend in the incidence of hip fracture in Tottori Prefecture, Japan.

METHODS: Tottori Prefecture is located in mid western Japan and its population was 613,097 in 2001. The percentage of the total population aged 65 years and over was 22.5% in 2001. A survey of all hip fractures in patients 35 years old and over during 1998-2001 was performed in all hospitals in Tottori Prefecture, Japan. Registration information included name, gender, age, place of residence, date of fracture, type of fracture, and treatment. Patients residing in other prefectures were excluded. Duplication of cases was checked by the patients' name and address. The age- and gender- specific incidence rates (per 100,000 person-years) were calculated based on the population of Tottori Prefecture in each year. We compared the data with those in1986-1988 and 1992-1994 when we performed the same survey in Tottori.

RESULTS: Registered numbers in patients were 604, 671, 710 and 729 in 1998, 1999, 2000, and 2001, respectively. The mean age- and gender-specific incidence rates for men in 1998-2001 were 209.0, 449.1, and 780.0 in the age groups of 75-79, 80-84 and over 84, respectively, and those for women were 505.8, 1115.4, and 2066.4, respectively. The incidences age-adjusted to the population structure of 1986 in Tottori Prefecture (≥35 years) for men were 63, 68, 85, 87, 71, 88, 77, 86, 99, and 101, in 1986, 1987, 1988, 1992, 1993, 1994, 1998, 1999, 2000, and 2001, respectively. Those for women were 209, 206, 245, 281, 238, 266, 296, 307, 310, and 309, respectively. The incidence rates for both genders increased significantly from 1986 to 2001; however, the increase was leveled off after 1999.

CONCLUSION: An increase in the incidence rates of hip fractures was observed from 1986 to 2001, but the incidence reached a plateau until 2000 in Tottori Prefecture, Japan.

SU376

High Prevalence of Fracture in Young Adults with Cystic Fibrosis. C. C. Kennedy*[1], A. Papaioannou[1], G. Ioannidis*[2], C. Webber*[3], M. Pui*[3], J. O'Neill*[3], R. Hennessey*[2], S. Hansen*[2], A. Freitag*[1], J. D. Adachi[1]. [1]Medicine, McMaster University, Hamilton, ON, Canada, [2]McMaster University, Hamilton, ON, Canada, [3]Radiology, McMaster University, Hamilton, ON, Canada.

Patients with Cystic Fibrosis (CF) may be at increased risk for fracture due to CF-related bone disease. In this multi-year study in a non-transplant CF cohort, changes in bone mineral density (BMD) and fracture were assessed longitudinally. All adult patients ≥18 years who attended the CF Clinic in Hamilton, Ontario during 2002 and had undergone at least one chest radiograph or dual x-ray absorptiometry (DXA) scan were included in the study. Of 56 individuals, 1 was excluded due to no radiographic data, and 3 were excluded due to a past lung transplant. Chest x-rays and DXA scans were reviewed for the remaining 52 patients. BMD was measured using a Hologic QDR 4500A densitometer at the whole body, proximal femur and lumbar spine. Posterior-anterior and lateral chest x-rays were independently reviewed by two radiologists using Genant's semi-quantitative method, and differences resolved by consensus. Relevant laboratory, spirometry and medication variables were abstracted from clinic charts. The mean (standard deviation [SD]) age of the patients at baseline was 25.2 (9.4) years, mean body mass index (SD) was 20.9 (4.4) kg/m^{2}and 54% were women. At baseline, mean (SD) BMD in g/cm^2 at the whole body, left and right proximal femur, and lumbar (1-4) spine was 1.120 (0.097; n=46), 0.908 (0.126; n=42), 0.894 (0.133; n=43), and 0.972 (0.119; n=46) respectively. Over an average (SD) follow-up of 4.01 (1.45) years, the mean BMD % change at the four skeletal sites was -1.66% (n=34), -2.21% (n=30), -2.49% (n=31), and 0.06 % (n=34) respectively. At baseline, chest x-rays indicated that 16.3% (8/49) of individuals had a grade 1 vertebral fracture. After a mean (SD) follow-up of 3.3 (1.4) years, prevalence of Grade 1 fracture increased to 21.3% (10/47). In this population of young adults with CF, we found a high prevalence of Grade 1 fracture. Although there has been evidence that individuals pre and post-transplant have a high prevalence of vertebral fractures, there has been no previous evidence that individuals across the spectrum of illness severity with CF are at risk for vertebral fractures. Further research is needed to understand the pathophysiology and treatment of CF bone disease in this high-risk population.

High Incidence of Prevalent Fractures in Patients on Chronic Glucocorticoids Despite Normal BMD. N. Lane[1], S. Goldring*[2], S. Broy*[3], J. Stewart*[4], S. Meeves*[4]. [1]Dept of Med, Univ of California, San Francisco, San Francisco, CA, USA, [2]Rheumatol, Beth Israel Deaconess Med Cen, Boston, MA, USA, [3]Illinios Bone & Joint Institute, Des Plaines, IL, USA, [4]Aventis, Bridgewater, NJ, USA.

The ACTIVATE study is designed to determine if providing patients with information on vertebral fractures by instant vertebral assessment (IVA, Hologic) and bone turnover markers affect compliance with risedronate therapy in patients taking oral glucocorticoids (GCs). This ongoing study enrolled 2 groups: patients taking chronic GCs for at least 6 months (treatment, TREAT) or initiating GC therapy (prevention, PREV). The TREAT group accounts for 76% of patients enrolled (261/344). TREAT patients had a mean age of 60.7 yrs (range 27-85) and received 12.8 mg/d GC (range 4.0-90.0; median 10.0) for 78.3 months (range 1-546; median 34); 53.6% were women. Rheumatoid arthritis (41.5%) and polymyalgia rheumatica (12.4%) were the most common diagnoses. Baseline data were evaluated to assess use of oral calcium (Ca) in patients on chronic GC therapy. Baseline T-scores and vertebral fractures were analyzed for those taking or not taking Ca.

At baseline, T-scores for the TREAT group were in the normal range (total hip -0.73; spine -0.84). By IVA, 19.3% (27/140) of women and 23.1% (28/121) of men in TREAT had at least 1 vertebral fracture at baseline (range 0-8 fractures). T-scores were similar between patients who had or did not have a fracture (lumbar spine fracture: No -0.84±1.49; Yes -0.87±1.59; *P*=0.86; hip fracture: No -0.70 ±1.09; Yes -0.91 ±1.10; *P*=0.14).Older age and rheumatoid arthritis were significant predictors of prevalent baseline fracture.

Patients taking Ca supplements had a slighter build: shorter height (165.4 vs 168.4 cm; *P*<0.05), lower weight (80.0 vs 87.2 kg; *P*<0.05), and smaller wrist circumference (16.4 vs 17.1 cm; *P*<0.05). Despite a similar incidence of prevalent fractures, men were less likely to be taking Ca supplements (40.5% men, 60.7% women, *P*<0.05). Ca supplements were less likely to be taken by rheumatoid arthritis patients (31.3% vs 43.5%; *P*<0.05). Baseline fracture incidence was similar across Ca supplementation subgroups [No Ca 20.8% (30/152); Ca 22.4% (24/107)].

According to current guidelines all patients receiving chronic GCs should receive Ca supplementation. Here, Ca utilization was not balanced, with slighter build patients and women more likely to be taking supplements. Despite normal T-scores, prevalent vertebral fractures were found in 20% of TREAT patients at study entry. These data highlight limitations of BMD T-score cut offs commonly used in postmenopausal osteoporosis to identify patients at risk for fracture on GCs, and the need for better education concerning prevention of fracture.

Fracture Burden Contributed By Women With Osteopenia: Geelong Osteoporosis Study. J. A. Pasco[1], M. J. Henry*[1], E. N. Merriman*[1], G. C. Nicholson[1], E. Seeman[2], M. A. Kotowicz[1]. [1]Clinical & Biomedical Sciences: Barwon Health, The University of Melbourne, Geelong, Australia, [2]Medicine, The University of Melbourne, Heidelberg, Australia.

The purpose of this study was to quantify fracture risk associated with normal, osteopenic and osteoporotic areal bone mineral density (BMD) based on WHO criteria. This prospective analysis follows 628 postmenopausal women (median age 74.0 yr, range 60-94) who had BMD assessments 1994-7. 37.1% had normal BMD at the total hip, 48.2% were osteopenic and 14.8% osteoporotic. Subjects were followed until the end of 2002, or until sustaining a fracture, death, or migration from the study region. Post-baseline fractures were identified radiologically.

During the study period 66 women died, 25 left the region, 144 sustained at least one fracture and 393 remained fracture-free, alive and residing in the region, generating 3220 person years of follow-up. After 5 years, the proportion of fractures occurring in each category of BMD was 17.0% normal, 54.2% osteopenia and 28.8% osteoporosis. Using Cox proportional hazards models, both decreasing BMD and increasing age contributed

independently to increased fracture risk. Categorizing age into groups 60-69, 70-79 and 80+ yr, and setting 60-69 yr with normal BMD as the referent group, relative risk (RR) for fracture for the osteopenic women was 2.7 (95%CI 1.1-6.6) for 60-69 yr, 4.7 (2.1-10.9) for 70-79 yr and 6.1 (2.7-14.1) for 80+ yr; RRs for the osteoporotic women were 6.1 (1.8-20.8), 6.2 (2.3-16.8) and 9.3 (4.0-21.8), respectively (all p<0.05). Thus, osteoporotic women have the greatest risk for fracture and this risk increases with age. The RR for fracture among osteopenic women is intermediate between osteoporotic and normal women.
Although women with osteoporotic BMD are at greater risk for fracture, they contribute less than a third to the total burden of fractures occurring in the community. Over half of the fractures arise from women with BMD in the osteopenic range who represent approximately 50% of the population at risk.

Kyphoplasty Restores More Vertebral Height Than Hyper-extension Positioning Maneuvers Alone. S. V. Bukata, J. Koob*, M. Shindle*, J. M. Lane. Orthopaedics, Hospital for Special Surgery, New York, NY, USA.

Kyphoplasty has been shown to restore vertebral height and sagital alignment. Proponents of vertebroplasty have recently demonstrated that many vertebral compression fractures are mobile and positional correction can lead to clinically significant height restoration. To test the hypothesis that positional maneuvers are statistically inferior to kyphoplastic balloon tamps for the reduction of low energy vertebral compressions fractures, a prospective radiographic analysis of 25 consecutive patients with a total of 43 osteoporotic vertebral compression fractures was performed. Patients were were sequentially evaluated for postural and balloon reduction of their vertebral compression fractures. Preoperative standing and lateral radiographs of the fractured vertebrae were compared with prone cross-table lateral radiographs with the patient in a hyper-extension position and on pelvic and sternal rolls. Following positional manipulation patients underwent a unilateral balloon kyphoplasty. Postoperative standing radiographs were evaluated for percent of height restoration related to positioning and balloon kyphoplasty. In the central portion of the vertebrae, the percent restoration with extension positioning was 10.4%, median=11.1%, and after balloon kyphoplasty was 57.0%, median=62.2 (p<0.001). Thus, kyphoplasty provided an additional 46.6% restoration from the positioning alone. With operative positioning, 51.2% of vertebral compression fractures had >10% restoration of the central portion of the vertebral body as compared with 90.7% after balloon kyphoplasty (p<0.002). Although this study supports the concept that many vertebral compression fractures can be moved with positioning, balloon kyphoplasty enhanced the height reduction >5 fold over the positioning maneuver alone and accounted for over 75% of the ultimate reduction. If height restoration is the goal, kyphoplasty is clearly superior in most cases to the positioning maneuver alone.

Low Serum Albumin Levels Predict Incident Vertebral Fractures. J. Finigan[1], A. Chines[2], I. Barton[3], R. A. Hannon[1], R. Eastell[1]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Procter and Gamble Pharmaceuticals, Cincinnati, OH, USA, [3]Procter and Gamble Pharmaceuticals, Egham, United Kingdom.

In an earlier small prospective study, we observed that indicators of frailty such as low serum albumin, low serum thyroid hormone T3 and poor physical strength predicted vertebral fracture but not non-vertebral fracture. This analysis aims to examine the relationship between baseline levels of serum albumin and the incidence of vertebral fractures in a larger cohort.
The subjects were postmenopausal women from the placebo arms of the VERT and HIP trials of risedronate in North America, Europe and Australia. Paired evaluable spinal radiographs at baseline and 3 years were available for 2720 subjects (VERT n=1022, HIP n=1698), mean age 74.1 years. Of these, 2289 had baseline BMD measurements by DXA at the femoral neck. Incident vertebral fractures at T4-L4 were assessed by both quantitative and semi-quantitative methods. Serum albumin was measured at baseline. Data for incident non-vertebral fractures were also available for these subjects and for a further 1636 subjects, of whom 1090 had BMD measurements at the femoral neck. Overall, mean age was 75.5 years (n=4356).
At 3 years, 381 subjects had one or more incident vertebral fractures. The range of albumin values was 29 to 50 g/l (mean 40.9g/l, SD 3.0 g/l). By logistic regression, the unadjusted relative risk of vertebral fracture for each standard deviation decrease in serum albumin was 1.19, 95% CI (1.07, 1.32), p=0.002. In this cohort there was no association between age and incidence of vertebral fracture, but age was inversely related to albumin levels (p=0.028, Spearman's rho = -0.042). Although low femoral neck BMD predicted vertebral fractures (RR=1.89, 95% CI (1.57, 2.27), p<0.001) there was an inverse correlation between femoral neck BMD and serum albumin (p<0.001, r = -0.077). In a multiple stepwise logistic regression, the relative risk of vertebral fracture for each standard deviation decrease in serum albumin, when adjusted for femoral neck BMD, weight and age, was 1.23, 95% CI (1.10, 1.38), p<0.001.
Low serum albumin was not associated with an increased risk of incident non-vertebral fractures in the whole group (n=4356). In the group with data on incident vertebral fractures (n=2720), low serum albumin predicted non-vertebral fracture with an unadjusted relative risk of 1.13, 95% CI (1.01, 1.27), p=0.039. However, when adjusted for femoral neck BMD, weight and age, the association was no longer significant.
We conclude that incident vertebral fractures are predicted by low serum albumin levels. Since serum albumin can be regarded as a marker of frailty, this may indicate that relatively poor health is a risk factor for vertebral fracture.

Disclosures: ***J. Finigan****, None.*

SU381

Validation of Lateral DXA Imaging for Assessment of Vertebral Fractures. C. Wu*[1], H. Genant[1], G. von Ingersleben[1], Y. Chen*[2], C. Johnston*[2], M. Econs*[3], N. Binkley*[4], T. Vokes*[5], T. Fuerst[1], G. Crans*[6], B. Mitlak*[6]. [1]Synarc, Inc., San Fran, CA, USA, [2]UCSF, San Fran, CA, USA, [3]IN Univ., Indianapolis, IN, USA, [4]U of WI, Madison, WI, USA, [5]U of Chicago, Chicago, IL, USA, [6]Lilly Research Labs, Indianapolis, IN, USA.

Standardized visual identification of radiographically depicted vertebral fractures is an established method in osteoporosis research. Lateral spine images from fan-beam dual x-ray absorptiometry (DXA) scanners present an alternative to radiography to detect vertebral fracture. We investigated the utility of lateral DXA imaging combined with visual scoring, Vertebral Fracture Assessment (VFA), by a comprehensive analysis of intra- and inter-reader variation in comparison with radiography.
Study consists of 203 postmenopausal women, enriched for vertebral fractures, each had imaging of lateral spine by DXA using Hologic or GE Lunar scanners and radiography within a short time of each other. Three radiologists expert in vertebral fracture assessment read VFA images and radiographs using Genant semiquantitative method. Assessments were performed independently with radiologists blinded to results when assessing other modality. The radiologists performed second reading of all images 2-3 weeks after the first. Gold standard (GS) readings for each modality were generated. Ability to detect vertebral fracture on VFA images was compared to radiography excluding non-evaluable vertebrae using inter-reader/modality, intra-reader, Kappa statistics, percentage agreement (%), sensitivity (SE), specificity (SP) and positive/negative predictive value (PPV, NPV).
On VFA images 76-89% of vertebral bodies could be assessed while over 98% were evaluable on radiographs. Vertebrae that couldn't be assessed were predominantly at T4-T6 levels. In these 203 women overall prevalence of vertebral fracture was 109/110 (4.1%/4.2%) in the two GS X-Ray, and 82/84 (3.6%/3.6%) in the two GS VFA. Prevalence of only moderate and severe fractures was 51/53 (2.3%/2.3%) in GS X-Ray, and 62/62 (2.8%/2.7%) in GS VFA, respectively.

Inter-Modality, Inter- and Intra-Reader Agreements (1st reading | 2nd reading)

	Inter-Modality		Inter-Reader
VFA Images	0.64-0.69 | 0.65-0.77	0.62-0.74 | 0.63-0.71	0.73-0.88
Radiographic Images		0.75-0.82 | 0.76-0.82	0.81-0.85

Gold Standard VFA versus Gold Standard X-Ray (1st reading | 2nd reading)

	Kappa	Agree (%)	SE (%)	NPV (%)
All fracture grades	0.74 | 0.78	98 | 98	70 | 73	99 | 99
Mod. & Sev. only	0.81 | 0.85	99 | 99	90 | 92	100 | 100

While VFA image quality is inferior to radiography visual detection of vertebral fracture is feasible, and correctly identifies most moderate and severe fractures. For evaluable vertebrae, VFA performance approaches that of radiography. This DXA-based method may provide an important tool for clinical practice and research.

Fracture Rate in Perimenopausal Women Is not Dependent on Previous Change in Bone Mineral Density. Preliminary Results from Prospective Population-Based Study. J. Huopio*[1], H. Kroger[1], R. Honkanen[2], S. Saarikoski*[3], E. Alhava*[4]. [1]Department of Surgery, Kuopio University Hospital, Kuopio, Finland, [2]Bone and Cartilage Research Unit, University of Kuopio, Kuopio, Finland, [3]Department of Obstetrics and Gynaecology, Kuopio University Hospital, Kuopio, Finland, [4]Department of Surgery, University of Kuopio, Kuopio, Finland.

Low bone mineral density (BMD) has been shown to predict future fractures in elderly and in perimenopausal women. Thus, the aim of osteoporosis treatment is targeted to elevate BMD in order to reduce the fracture rate. However, there are no prospective data of how well a change in BMD influences the fracture incidence in perimenopausal women. In the present study we followed 2939 perimenopausal women (mean age at the baseline 59.1 yrs, SD 2.9) for a mean follow-up time of 2.9 yrs (SD 0.9) and all fractures during the follow-up were registered by a questionnaire and validated by radiological report perusal. These women had undergone two consecutive BMD measurements (Lunar DPX) of lumbar spine and femoral neck prior the follow-up period. The mean time between BMD measurements was 5.8 yrs (SD 0.5) and the mean percentual changes in lumbar spine and femoral neck BMD were -1.8 (SD 6.5) and -3.0 (SD 5.7) prior the follow-up. The BMD change was positive in 34 percent of women in lumbar spine and in 26 percent in femoral neck. The weight change correlated significantly (p<0.001) with the BMD change. Altogether, a total of 200 fractures were registered during the follow-up period. The first fracture was taken as the end point in the statistical analyses. BMD change prior to follow-up had no effect on subsequent fracture rate. Follow-up fracture rates were 6.3% and 7.0% in women with positive and negative femoral neck BMD change, respectively (p=0.46 between the groups). Similarly, when the study population was divided into four subgroups according to the amount of change in BMD (1= more than -10% change, 2 = change from 0 to -9.9%, 3 = change from 0 to 9.9% and 4 = change more than 10 %) we still could not see any difference in the fracture rate. We conclude that the change in axial BMD is not associated with fracture rate in perimenopausal women during a short follow-up period.

Disclosures: ***J. Huopio****, None.*

SU383

Fragility Fractures in People with Developmental Disabilities: Risk Factor Analysis. B. Roe*[1], K. Dittberner*[2], W. D. Leslie[1]. [1]Medicine, U of Manitoba, Winnipeg, MB, Canada, [2]St. Amant Center, Winnipeg, MB, Canada.

The impact of osteoporotic fractures on morbidity and mortality in the general population is well-described, and there are effective interventions to prevent fractures in individuals at risk. A population at particular risk includes persons with moderate to severe developmental disabilities, where fractures have been described with minimal or no trauma. A review was conducted of 224 persons with developmental disabilities living in a residential care facility, and found that 40 had sustained a low energy fracture. In total, there were 47 fractures documented, and these were confined to the appendicular skeleton. Demographic information, medication use, and other risk factor data was extracted by chart review, and anthropometric measurements were obtained. Univariate analysis demonstrated higher fracture rates associated with Aboriginal ethnicity (p=0.001), use of anti-epileptic drugs (specifically phenobarbital, p=0.004) and triceps skinfold thickness (p=0.059). Logistic regression demonstrated that the strong association between Aboriginal ethnicity and fractures was not accounted for by other measured variables (adjusted odds ratio [OR] 3.03, 95% CI 1.38-6.69). Phenobarbital use was also a strong independent predictor (OR 2.69, 95% CI 1.18-6.12). The association with anti-epileptic drugs including phenobarbital has been described in an ambulatory population, and has been attributed in part to changes in vitamin D metabolism. The basis for the strong association with Aboriginal status is not clear, and will require further study. The recognition of the high rate of fractures in this population as well as these risk predictors, should lead to increased vigilance for screening, consideration of vitamin D supplementation, and targeted interventions for those found to be at highest risk.

Relationship between Endogenous Hormones and Calcium Absorption in Older Women. S. Goldman[1], J. A. Cauley[1], J. Zmuda[1], K. Ensrud[2]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Epidemiology, University of Minnesota, Minneapolis, MN, USA.

Low levels of fractional calcium absorption (FCA) have been linked to increases in hip fractures. FCA declines with increasing age and menopause. Endogenous sex steroids, calcitropic, and thyroid hormones may underlie these observations. In the present analysis, we tested the hypothesis that serum concentrations of endogenous sex steroids, calcitropic hormones, and thyroid stimulating hormone (TSH) are associated with FCA. The study population included 729 randomly chosen Caucasian women age 65 years and older (mean age 76.3 ± 4.5 years) enrolled in the Study of Osteoporotic Fractures. Women who reported use of hormone replacement therapy that included estrogen at the 4th visit were eliminated resulting in a final sample of 595 women. Serum hormones were measured in frozen samples obtained at baseline and FCA concentration was measured at the fourth visit (average time 6 years later) using a 3-hour single isotope (^{45}Ca) technique. After adjustment for age, weight, weight change between visit 1 and 4, daily dietary calcium intake, calcium and vitamin D supplements lower levels of FCA were found associated with TSH levels <0.9 µU/ml and levels ≥ 2.6 µU/ml. Lower FCA levels were found associated with lower levels of 1,25(OH)$_2$D (<31 pg/ml) (Table). No association was found with serum estrogen, total testosterone, free testosterone, parathyroid hormone (PTH), SHBG, or 25(OH)D.
In conclusion, women with lower serum concentrations of 1,25(OH)$_2$D had lower calcium absorption efficiency compared to women with higher concentrations of this hormone. Additionally, an association between TSH and FCA has not previously been reported in humans prior to this. Although our sample size was small, this association warrants further investigation. Finally, it must be recognized that the 6 year average time interval between measurement of the hormones and FCA could affect the relationships noted.

Longitudinal Study of Bone Mineral Density among Postmenopausal Japanese Women. S. Honda[1], M. Tagawa*[2], K. Aoyagi[3]. [1]Radiation Epidemiology, Nagasaki University, Nagasaki, Japan, [2]Nagasaki A-Bomb Casualty Council, Nagasaki, Japan, [3]Public Health, Nagasaki University, Nagasaki, Japan.

Osteoporosis is considered to be a major health problem for postmenopausal women, because osteoporotic fracture can cause substantial limitation of activity of daily living. To investigate the reduction in bone mineral density (BMD) with aging in postmenopausal women, a longitudinal study was conducted among community-dwelling Japanese women. A total of 195 women, aged from 50 to 69 years old, underwent a baseline survey between May 1994 and April 1995. The mean age of study subjects was 60 (standard deviation (SD) 5.4) years old. In the baseline survey, information about lifestyle factors, menopausal status and medical history of osteoporosis were collected. Those who had been treated for osteoporosis were excluded from the subjects. A body mass index (BMI) was calculated as weight (kg) divided by square of height (m). The BMD of anterior-posterior lumbar spine (L2-L4) was measured by dual-energy X-ray absorptiometry (Hologic QDR 2000). We measured BMD repeatedly until April 2004. The mean number of measurements for each subject was 3.1 (SD 1.6) times and the mean length of follow-up was 5.4 (SD 2.8) years. Association of BMD with age, years since menopause and BMI were analyzed by the Spearman's correlation coefficient (r). Distribution of BMD was compared among lifestyle factors by the Wilcoxon rank-sum test. The change of BMD between the baseline and the end of follow-up was analyzed by the signed rank-sum test. The longitudinal change of BMD was analyzed by linear regression model with age, square of age, years since menopause, BMI and lifestyle factors.
At the baseline, BMD correlated negatively with age ($r = -0.29$, $p < 0.001$) and years since menopause ($r = -0.25$, $p < 0.001$), while BMD correlated positively with BMI ($r = 0.22$, $p = 0.002$). BMD was higher in those who took a walk more than an hour regularly compared with those who did not ($p = 0.04$). However, no significant association of BMD with smoking habit, drinking habit and dietary calcium intake was observed. At the end of follow-up, BMD decreased from 0.796 to 0.784. A significant reduction in BMD was observed in those who were aged 50-54 years old at the baseline (from 0.862 to 0.814, $p < 0.001$) and in those who were aged 55-59 (from 0.807 to 0.791, $p = 0.04$), while BMD did not change significantly in those who were aged 60-69. Linear regression analysis confirmed that BMD reduced quadratically with age, however years since menopause, BMI and lifestyle factors did not have significant impact on the reduction in BMD.
In conclusion, BMD reduces significantly in those who were aged 50-55 years old. Further studies about longitudinal change of BMD and life style factors are needed.

The Effects of Ovariectomy on Bone Quality of Bax-deficient Mice. L. M. Wise*[1], A. Jurisicova*[1], G. Perez*[2], J. Tilly*[2], M. D. Grynpas[1]. [1]Mount Sinai Hospital and University of Toronto, Toronto, ON, Canada, [2]Massaschusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Bax, a pro-apoptotic member of the Bcl-2 gene family, has been previously implicated in the regulation of ovarian life span. While young Bax-knockout (KO) female mice posses three times as many primordial follicles as do wild-type (WT) mice, they do not exhibit a bone phenotype. Aged KO females retain their ovarian function to advanced chronological age, which is accompanied by elevated Bone Mineral Density (BMD) values in comparison to WT age-matched females. These age-dependent differences are also observed through mechanical testing on excised bones. To determine whether the effects of Bax-deficiency are dependent on ovarian cell function, a group of KO (n=10) and WT (n=7) mice were ovariectomized (OVX) at 3 months and were analyzed and compared to age-matched control KO (n=10) and WT (n=12) mice at 7 months. Dual energy x-ray absorptiometry (DEXA) was performed on all mice to determine BMD and tissue composition. To evaluate mechanical properties, 3-point bending, torsion testing, and femoral neck fracture were performed on the femurs, while unilateral compression was performed on the 5th lumbar vertebrae. Structural parameters were evaluated using histomorphometry on sections of distal femora.
The expected reduction in BMD due to OVX was observed in both the WT (-10.8%) and KO (-11.1%) mice. However, the percent fat mass of the KO mice seemed to be significantly less affected compared to the WT mice (0.5% versus 18.1% change). Failure tests on cortical bone indicate that the OVX reduced some mechanical properties in both WT and KO mice. Nonetheless, the OVX-KO mice still have superior mechanical strength compared to the OVX-WT mice (p=0.02). The OVX caused minimal changes in the mechanical properties of the trabecular bone of both WT and KO mice. Trabecular number (Tb.N) was decreased due to OVX in both WT (-34%) and KO (-28%); however, KO mice had greater Tb.N compared to WT mice, in both control (36%) and OVX (41%) groups. Similarly, trabecular separation was lower in KO mice compared to WT mice, in both control (-35%) and OVX (-49%) groups. While the OVX had similar negative effects in bone of both WT and KO mice, the KO bone maintains superior bone quality. Since the bone phenotype is partially maintained when ovary influence is removed, it appears that Bax may have a direct effect on bone cells. The material properties of bone will be evaluated further through mineralization and collagen analyses. By investigating the interactions between mechanical, structural and material properties of bone, some of the direct effects of deregulated cell death on overall bone quality can be determined.

Use of Oral Conditions to Screen for Low Bone Mineral Density in Japanese Women. K. Inagaki*[1], Y. Kurosu*[1], N. Yoshinari*[1], T. Noguchi*[1], E. A. Krall[2], R. I. Garcia*[2]. [1]Dept. of Periodontology, Aichi-Gakuin University, Nagoya, Japan, [2]Dept. of Health Policy and Health Services Research, Boston University, Boston, MA, USA.

The relationships between oral disease indicators and bone mineral density at several skeletal sites have been studied by a number of investigators, with mixed and complex results. The purpose of the present cross-sectional study was to evaluate the associations of periodontal conditions and tooth loss with metacarpal bone mineral density (m-BMD) in a large community-based cohort and evaluate the usefulness of tooth count as a potential simple screening tool to detect low BMD. Subjects were 356 Japanese women (171 premenopausal, mean age 37.9 ± 8.0, 185 postmenopausal, mean age 63.3 ± 7.7). Periodontal status was evaluated by the Community Periodontal Index of Treatment Need (CPITN). M-BMD was measured by computed X-ray densitometry. The proportion of subjects with periodontitis (CPITN 3 or 4) increased as m-BMD decreased. The odds ratio of osteopenia or osteoporosis in relation to periodontitis was 3.2 (95% confidence interval (CI) = 2.0 to 5.3). After adjustment for age and menopausal status, the odds ratio was 2.0 (95% CI = 1.1 to 3.7). Among postmenopausal women, those having fewer than 20 teeth were 1.6 times more likely to have low m-BMD compared to those having more than 20 teeth (Chi-square for trend in postmenopausal group = 4.27, $p < 0.05$). ROC analysis indicated that number of teeth remaining or CPITN score had better than 50/50 chance to correctly identify women with osteoporosis or osteopenia, but the areas under the curve (0.72 and 0.67, respectively) are considered only fair screening tools. These results indicate that periodontitis and tooth loss after menopause may be useful indicators of m-BMD loss in Japanese women but more research is needed.

Postmenopausal Osteoporosis Screening Tool (POST) - Preliminary Data. J. Sirola*[1], M. Tuppurainen[1], J. S. Jurvelin*[1], H. Kröger[2]. [1]Bone and Cartilage Research Unit, University of Kuopio, Kuopio, Finland, [2]Department of Surgery, Kuopio University Hospital, Kuopio, Finland.

The aim was to improve the cost-effectiveness of DXA measurements with Postmenopausal Osteoporosis Screening Tool (POST) that recognises non-osteoporotic women.

The study subjects were selected from the Osteoporosis Risk Factor and Prevention (OSTPRE) Study cohort (13 100 women born in 1932-41), Kuopio, Finland. Random samples were measured with DXA absorptiometry (total neck) at baseline (1989-91) (n=1086 with valid DXA measurement) and 5-year (1994-97) (n=1050 with valid DXA measurement) excluding hysterectomised and biovariectomised women. Mean age of the study subjects was 53 years (48-60 years, baseline) and 59 years (53-66 years, follow-up). Postal inquiries on risk and preventive factors for osteoporosis were collected at the baseline and follow-up. POST was tested in both measurements. Multinomial logistic regressions were performed to identify risk factors for osteoporosis according to which POST was mainly built on. The dependent variable was the three categories WHO classification: BMD over -1 SD normal, -2.5 to -1 SD osteopenic and under -2.5 osteoporotic bone density. Table represents the selected risk factors and their weighting in POST.

Of the present sample 775/632 had normal BMD, 311/383 had osteopenic BMD and 19/33 had osteoporotic femoral neck BMD in baseline/follow-up. POST points varied from 1 to 25 and 3 to 26 in baseline and follow-up. AUROCs for POST in recognizing osteoporotic women were 81 % (95% CI 75 - 87 %, p<0.001) and 82 % (95% CI 77 - 86 %, p<0.001) for baseline and 5-year data, respectively.In OSTPRE population, 42 % (baseline, cut-off POST<13 points) and 38 % (5-year, cut-off POST<14 points) of the total population were determined as non-osteoporotic (BMD >-2.5 SD) with 100 % sensitivity. With baseline criteria (cut-off POST<13 points), 29 % of population were determined as non-osteoporotic (BMD >-2.5 SD) in 5-year measurement with 100% sensitivity.The presented combination of risk factors in POST was more sensitive than any selected risk factor alone or any other possible combination of selected risk factors.

POST may provide useful tool for excluding non-osteoporotic women from DXA measurements thus improving their cost effectiveness. Before adaptation for wider use POST should be validated in other populations.

Postmenopausal Osteoporosis Screening Tool (POST)

Factor	Limits	Points

Illness Representations of Osteoporosis among Osteoporotic Men. O. Edelstein*[1], P. Werner*[1], I. Vered[2]. [1]Gerontology, Faculty of Social Welfare and Health Studies, University of Haifa, Haifa, Israel, [2]Endocrinology, Sheba Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Tel Hashomer, Israel.

Research on illness representations suggests that people construct their own representations of an illness in order to understand and deal with it. The Self-Regulation Model (Leventhal & Diefenbach, 1991), proposes that people's illness representations consist of five components that determine emotional and behavioral reactions to illness.

The aim of the present study was to examine illness representations of osteoporosis among 100 osteoporotic men (mean age 63 yr; mean spine t-score = -2.4; 33% had a low-trauma fracture; 20% had glucocorticoid-induced osteoporosis).

Illness representations were assessed using an adapted version of the Illness Perception Questionnaire (Weiman, Petrie, Moss -Morris & Horne, 1996).

Results of the study showed that the identity (i.e., symptoms) of osteoporosis included bending of the back (62%), back pain (59%), loss of height (51%), and general weakness (26%). Participants reported that the main causes of their disease were their own behavior (56%); lack of physical activity (52%), and other diseases or medications (53%). Osteoporosis was perceived as likely to be permanent rather than temporary (86%), and as an illness that will last for a long time (85%).

Participants' perceptions regarding the consequences of osteoporosis were mild: only 38% agreed that their illness is a serious condition, and 39% agreed that the disease had had major consequences on their life. The main consequence related to the economic and financial effects of the illness (47%). Finally, the majority of the participants believed osteoporosis to be a controllable disease: 80% agreed that what they do can determine whether their illness gets better or worse; and 75% agreed that their treatment will be effective in curing their illness.

In sum, findings of this study showed that osteoporotic men perceived their disease as chronic, as having no serious consequences, and as being controllable. These could have important implications in improving the efficacy and adherence to treatment interventions, and in adjustment to a chronic disease.

Association of High BMD with the Risk of Benign Breast and Uterine Diseases in Postmenopausal Women. C. Ribot[1], F. Tremollieres[1], V. Cances-Lauwers*[2], J. Pouilles*[1]. [1]Hôpital Paule de Viguier, Menopause Unit, Toulouse, France, [2]CHU Purpan, Department of Epidemiology, Toulouse, France.

Recent studies have underlined the possibility that bone mass may represent a marker of cumulative exposure to estrogen and/or estrogen responsiveness in women. A significant association between high BMD and the increased incidence of breast cancer has been reported in postmenopausal women. In this study, we examined the association between bone mass and the incidence of both benign breast and uterine diseases in postmenopausal women. Between 1992 and 2002, 5847 postmenopausal healthy women who were 45 to 75 years old (mean age : 55.4±4.5 yrs) and had never received ERT/HRT underwent a « menopause check-up » including clinical examination and BMD measurements by DXA. A questionnaire including information on reproductive history was collected and the incidence of past or current both benign breast (including benign lumps and cysts, cystic mastitis and/or microcalcifications) and uterine (including myoma and/or polyps) diseases was recorded. Vertebral and femoral BMDs were measured using DXA (Lunar Rad Corp) in all women. Of the whole population, 1214 (20.8%) and 1597 (27.3%) women reported a history of past or current benign breast and uterine diseases, respectively. After adjustment for age and BMI, the odds ratio for benign breast disease in the third and fourth highest quartiles of vertebral BMD compared to the lowest quartile was significantly higher (1.3 [95% confidence intervalle, 1.1-1.6] and 1.6 [1.3-1.9], respectively). The relation was not significant for femoral BMD. As compared with the women in the lowest quartile, the adjusted odds ratio for benign uterine disease in the highest quartile of BMD was also significantly higher at the femoral neck (1.3 [1.0-1.6]) but not at the lumbar spine. These results suggest that bone mass in postmenopausal women is a good predictor of the risk of benign breast and uterine diseases. The mechanisms underlying this relation may be explained by a cumulative exposure to estrogen and/or estrogen responsiveness.

A Prospective Study to Describe the Feasibility of Case Finding for Osteoporosis in primary care at the Annual over 75 Health Check Using the Black Fracture Score. A. L. Dolan*[1], H. Patrick*[2], S. Mendonca*[2], B. Coutinho*[1], D. Oliver*[3]. [1]Rheumatology, Queen Elizabeth Hospital, London, United Kingdom, [2]Bexley PCT, Kent, United Kingdom, [3]School of Health and Social Care, University of Reading, Reading, United Kingdom.

Fracture prevention services have been established in secondary care in the UK to identify patients with incident fractures and risk of osteoporosis, with high pick up rates (eg 40% of wrist fractures osteoporotic). However, a bone health service also requires case-finding from primary care as many patients with risk factors for osteoporosis may not present to hospital or had previous low impact fractures. There are few data on the feasibility of such case-finding in primary care. This study uses the 'Over 75yr check' to identify such patients and plan preventative management and to assess the effectiveness of the 'Black Fracture risk score' to identify those at high risk of hip fracture. (Black OI 2001). Patients scoring ≥ 5 have a 9% chance of suffering a hip fracture in the next 5 years.

Patients aged 75-80yrs attending for a voluntary annual nurse led check completed the Black score. Those scoring ≥ 5 were offered bone densitometry at the local hospital. Nurses received 2 training sessions on the protocol. Ethics consent was obtained.

558 patients completed assessment from 13 practices, out of a potential population in the age group of 1929. 222 were male, 336 female . 280 had a Black score of 5 or more (50%). Risk factor assessment showed 95 / 558 (17%) had a fracture after 50, 47% used arms to stand, 3% were on steroids, 3.4% had BMI <20. 4.3% had a previous diagnosis of osteoporosis.174 were referred on for DXA (31% of population assessed) but only 139 attended (25%). Scan outcomes are shown below.

	Total	Osteopenic (T <-1)	Osteoporotic (T<-2.5)	Normal
Hip	119	69	13	37
Spine	139	71	21	47

23 patients were osteoporotic at one or more sites (16.5%), 71 osteopenic (51%) and 45 normal (32%). 50 of those with previous fracture received DXA; 30% of these had osteoporotic BMD.

This community screening programme resulted in a low pickup of osteoporosis (23/558 screened). This reflected low up take of check and offer of scan. Those who attended were less osteoporotic than might be expected from population norms, suggesting they may be an unduly fit and compliant group. The Black score was derived to identify hip fracture risk and is weighted by age and frailty so may not be an appropriate tool to identify low bone density. History of fracture may be a better screen.

The Relative Importance of Lean and Fat Mass on Bone. C. G. Gjesdal[1], J. I. Halse[2], J. G. Brun*[3], G. S. Tell*[1]. [1]Dept of public health and primary health care, University of Bergen, Bergen, Norway, [2]Clinic of osteoporosis, Oslo, Norway, [3]Dept of Rheumatology, Haukeland University Hospital, Bergen, Norway.

While body weight is one of the strongest predictors of bone mineral content (BMC) and bone mineral density (BMD), it is not clear which attributes of a heavy body (e.g. weight in itself, adiposity, muscularity, body fat distribution or frame size) are most strongly associated with bone measurements. Fat mass (FM), lean mass (LM), as well as both tissues have been reported to be determinants of BMC and BMD. The aim of this study was to evaluate the relative importance of FM and LM on BMC.

The study population consisted of 5117 Norwegian men and women 47-50 and 71-75 years old. BMC of total body and femoral neck as well as soft-tissue body composition were measured by dual X-ray absorptiometry (DXA). In order to assess the effects of fat mass on BMC independently of body weight, quartiles of fat mass in 5-kg strata of weight were plotted against BMC. Only strata with at least 40 persons were included. Analyses of variance were used in each stratum to evaluate the influence of FM.

The general pattern observed was that within each stratum the lowest quartile of FM was associated with the highest BMC indicating that LM is more important than FM within each weight group. The figure shows the results for total body BMC among men. Results were similar for women, although the trends were somewhat weaker among the oldest women. Almost identical results were found for femoral neck BMC. Adjustment for differences in height, age, smoking and level of physical activity did not change the overall pattern.

In summary, FM appeared to be inversely associated with BMC for a given bodyweight. Thus there seems to be an effect of fat mass and lean mass beyond the effect of weight in itself.

Performance of a Simple Clinical Tool (FOSTA) for Identifying Japanese Women with Osteoporosis Based upon Quantitative Ultrasound Techniques (QUS) and Vertebral Deformity. K. Aoyagi[1], Y. Abe[1], P. D. Ross[2]. [1]Public health, Nagasaki University, Nagasaki, Japan, [2]Merck Research Laboratories, Rahway, NJ, USA.

The purpose of this study was to evaluate the performance of a simple clinical tool, the Female Osteoporosis Self-assessment Tool for Asians (FOSTA), among postmenopausal Japanese women in a population-based study (the Hizen-Oshima Study) using quantitative ultrasound techniques (QUS) to define osteoporosis (T < -2.5), and vertebral deformity (osteoporotic fracture). The subjects were 523 women ages 43 and older (mean age; 66.1, SD; 8.1 years old) with QUS measurement for calcaneus (stiffness index) and spine radiographs between 1998 and 1999. Lateral spine radiographs were obtained and radiographic vertebral deformities were assessed by quantitative morphometry, defined as vertebral heights more than 3 SD below the normal mean. FOSTA was calculated from the patient's weight and age: FOSTA=0.2 (weight [in kg]-age [in years]), truncated to an integer. Risk categories (high, moderate, and low) were based on previously published criteria. The FOSTA index achieved 96% sensitivity and 29% specificity for osteoporosis (stiffness index T-score < -2.5), which was similar to previous findings using femoral neck and lumbar spine BMD in Japanese women. The index also achieved 99% sensitivity and 22% specificity for vertebral deformity. Using three risk categories, 29% of all women were categorized as high risk (FOSTA<-4). Physicians might be advised to consider treating women with osteoporosis. Among high-risk patients, 73% had osteoporosis and 33% had vertebral deformity. Among women classified as low-risk (18% of all women), only 12% had osteoporosis and 1% had vertebral deformity. Approximately 43% of the moderate risk women had osteoporosis and 12% had vertebral deformity. In summary, the FOSTA index performed well to identify postmenopausal Japanese women with osteoporosis and vertebral deformity. This free and simple risk assessment tool would encourage clinicians appropriate use of BMD measurements for high-risk patients, and initiate appropriate intervention before fractures occur.

SU394

An Evaluation of Osteoporosis Diagnostic Tools for Elderly Caucasian and Chinese Men. H. Lynn[1], E. Lau[1], E. Barrett-Connor[2], M. Nevitt[3], J. Cauley[4], R. Adler[5], E. Orwoll[6]. [1]Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China, [2]University of California, San Diego, La Jolla, CA, USA, [3]University of California, San Francisco, San Francisco, CA, USA, [4]University of Pittsburgh, Pittsburgh, PA, USA, [5]McGuire Veterans Affairs Medical Center, Richmond, VA, USA, [6]Oregon Health and Sciences University, Portland, OR, USA.

Several osteoporosis screening tools have been shown to be effective for selecting women for dual-energy x-ray absorptiometry (DXA) testing, but such evaluations have not been performed in men. This study assesses the performance of the Osteoporosis Self-assessment tool (OST) and the Male Osteoporosis Screening Tool (MOST) in identifying men for DXA testing. OST is based on body weight and age, while MOST is a function of weight and quantitative ultrasound index (QUI) measurement.

Community-dwelling and ambulatory men 65 years old and above were recruited in the U.S. and Hong Kong for the Osteoporotic Fractures in Men (MrOS) Study. Bone mineral density (BMD) was measured by DXA (Hologic QDR-4500W) and ultrasound measurements by a Sahara sonometer. Osteoporosis was defined as a BMD T-score of < -2.5 using race-specific male normative database. Altogether, 4682 U.S. Caucasians and 1914 Hong Kong Chinese with available BMD, OST and MOST values were included in the current analysis.

The prevalence of osteoporosis at the lumbar spine, total hip, or femoral neck was 10% for Caucasians and 13% for Chinese. The area under the receiver operating characteristic curve (AUC) was 0.680 for OST and 0.779 for MOST among Caucasians (Table 1). Among Chinese, OST had an AUC of 0.763 and MOST, an AUC of 0.811. If body weight alone was used as a diagnostic tool, then the AUC was 0.676 and 0.762 for Caucasians and Chinese respectively. Using the top quartile of MOST as a cutoff score, the resulting test had 95% sensitivity, 24% specificity, and 98% negative predictive value (NPV) in Caucasians, and 95% sensitivity, 28% specificity, and 97% NPV in Chinese.

We conclude that MOST performed better in terms of AUC than body weight alone in Caucasian and Chinese men. Moreover, it is a satisfactory osteoporosis diagnostic tool, adequately screening out those without osteoporosis and possibly saving a quarter of the DXA resources.

Table 1. AUC (standard error) of osteoporosis screening tools

		Osteoporosis (T-score < -2.5)			
		Lumbar spine	Total Hip	Femoral neck	Any site*
Caucasian	Weight	0.653 (0.016)	0.802 (0.021)	0.717 (0.016)	0.676 (0.013)
	OST	0.640 (0.016)	0.824 (0.020)	0.742 (0.015)	0.680 (0.013)
	MOST	0.766 (0.014)	0.883 (0.017)	0.807 (0.014)	0.779 (0.011)
Chinese	Weight	0.735 (0.018)	0.831 (0.019)	0.833 (0.019)	0.762 (0.015)

Neuromuscular and Sensorimotor Correlates of Gait and Balance in Women with Wrist Fractures. B. J. Edwards[1], C. Langman[2], P. H. Stern[3], K. Martinez*[4], M. W. Rogers*[4]. [1]Medicine, Northwestern University, Chicago, IL, USA, [2]Pediatrics, Northwestern University, Chicago, IL, USA, [3]Molecular Pharmacology and Biological Chemistry, Northwestern University, Chicago, IL, USA, [4]Physical Therapy and Human Movement Sciences, Northwestern University, Chicago, IL, USA.

A wrist fracture is a risk factor for hip fracture. This is only partially explained by low bone density.

Objective: We hypothesized that extra-skeletal effects (neuromuscular and sensorimotor) NMS measures of gait and balance, and functional measures may also play a role.

Methods: We analyzed NMS, and functional measures in women with falls and wrist fracture. Self-reported fractures occurred in the past 10 years. Falls were "an event which results in a person coming to rest inadvertently on the ground or a lower level and not as a result of a major intrinsic event or overwhelming hazard." NMS measures included visual contrast sensitivity (VCS), depth perception (DP), lower limb proprioception, triceps and quadriceps strength, and hand reaction time. Body sway was measured in the frontal (AP) and lateral plane. These measures form part of Lord's Physiologic Profile Assessment (PPA). Functional measures of balance and gait included the Berg Balance Scale, the Dynamic Gait Index (DGI), the Activities of Balance Confidence (ABC Scale), and timed ten-meter walks.

Analysis: Independent samples t tests were conducted. Cohens-d was calculated for effect size.

Results: 26 fractures (age 73.6 ± 9y) and 23 controls (age 69.7 ± 10y)(p=0.26) were evaluated. Fractures had lower visual contrast sensitivity (p=0.002), impairment in static balance measures (BBS) (p=0.043), and lower bone density (p=0.025). A trend toward lower DGI (p = 0.085), sway (p=0.113), and higher vibratory threshold was evident (p= 0.237)

Conclusion: women with wrist fractures exhibit impairments in static and dynamic balance, and visual contrast sensitivity which combined with lower bone density may predispose them to future hip fractures.

Metabolic Bone Disease among an Ethnically Diverse Cohort of HIV+ Patients with Lipodystrophy. J. R. Curtis*[1], B. Smith*[2], K. Landers*[2], R. Lopez*[1], J. Raper*[1], M. Saag*[1], R. Venkataraman*[1], M. Weaver*[1], K. Saag[1]. [1]University of Alabama Birmingham, Birmingham, AL, USA, [2]University of Maryland, College Park, MD, USA.

Aim: Previous studies report a high prevalence of metabolic bone disease and osteonecrosis among predominantly Caucasian HIV+ patients with lipodystrophy on Highly-Active Anti-Retroviral Therapy (HAART). Given the paucity of data in minorities, we examined the prevalence of these conditions in an ethnically diverse cohort.

Methods: HIV+ patients on HAART with lipodystrophy and hyperlipidemia underwent evaluation for metabolic bone disease including: screening questionnaire and physical exam, 4 day food diary, femoral neck and L2-4 BMD (GE Lunar central DXA) categorized using WHO cutpoints; both hip MRIs (GE 1.5T magnet); and laboratory studies intact-PTH, 25-OH Vitamin D, serum osteocalcin (OC) and urinary N-telopeptide (NTX). Chi-square and t-tests were used for analyses.

Results: 44 patients participated: 23 blacks (10M, 13F), 20 whites (18M, 2F), and 1 Hispanic (1M). Patients were mean age=44.5 (SD=6.7), 66% male, on 3+ drug HAART for 34.1(27.5) months. Blacks had significantly higher femoral neck BMD (1.062 g/cm2) compared with non-blacks (0.948 g/cm2) (p=0.035). Lumbar BMD in blacks (1.272 g/cm2) was not significantly different compared to non-blacks (1.191 g/cm2). Non-blacks appeared more likely to be osteopenic or osteoporotic at any site (59%) compared to blacks (36%) (p=0.050).

Vitamin D deficiency (<34ng/ml) and elevated i-PTH (>65pg/ml) was found in 75% and 23% of patients, respectively. NTX was higher in non-blacks [60.2 (33.9) nM BCE/mM] than in blacks [38.7 (30.9) nM BCE/mM] (p=0.052), suggesting higher bone turnover in non-blacks. No ethnic differences were seen in OC levels. MRI identified 1/32 patients (3%) with bilateral asymptomatic hip osteonecrosis.

Conclusions: The previously-reported burden of bone disease in HIV+ patients with HAART-associated lipodystrophy appears greater in Caucasians compared to Blacks. Future studies to examine genetic and environmental contributions of ethnicity to HAART-associated metabolic bone disease are necessary to devise optimal interventions.

Changes in Bone Mineral Density and Body Composition in Lactating Adolescents. J. L. Mansur[1], A. Malpeli*[2], G. Etchegoyen*[2], S. de Santiago*[3], H. Gonzalez*[2]. [1]Center of Endocrinology and Osteoporosis, La Plata, Argentina, [2]IDIP, Hospital de Niños Sor M Ludovica, La Plata, Argentina, [3]Health Dept, Univ Iberoamericana, Mexico DF, Mexico.

Although decreases in Bone Mineral Density (BMD) and Fat Mass (FM) with partial recovery have been observed in adult lactating women, there are not enough data about adolescents. The aim of the work is to evaluate these changes, at a stage when women have not reached the peak of bone mass.

Patients and methods: we study prospectively 14 women exclusively breastfeeding in day 15 and in month 3 and 6 after delivery. Mean age: 15.1 +/-0.7 years. We evaluate weight, height, BMI, body composition by skinfold thickness and by DEXA (FM and Lean Body Mass:LBM), BMD of Lumbar Spine (LS), Total Hip (TH) and Femoral Neck (FN), and Bone Mineral Content (BMC) of Total Body (TB) with Lunar IQ with pediatric software.

Results: weight: 54.9 (5.3), height: 156 (6.4), BMI: 19.3 (4.3). Calcium intake: 643,98 (231) mg/d.

% FM (DEXA) basal vs 6 mo: p=0.03

Conclusions. In 6 months we observe decreases in FN and TH BMD and TB-BMC, and in FM, while LBM is preserved. The lactating adolescents must be under observation because they have not reached their peak of bone mass.

Changes in BMD, BMC and Body Composition

	basal	3 mo	6 mo
BMD-LS %	100	98,8	100,8
BMD-FN %	100	94,3	94,4
BMD-TH %	100	95,2	94,8
BMC-TBody %	100	97,7	96,8
% FM (DEXA)	34,56	32,82	29,98
% FM (Skinfold)	29,47	28,23	27,02
LBM (kg)	32,77	32,40	33,65

SU398

Bone Response to Lactation: an Important Physiologic Model of Bone Restoration? S. A. Brown[1], D. R. Clemmons*[1], C. J. Rosen[2], A. M. Siega-Riz*[3], M. J. Caminiti*[1]. [1]Endocrinology, University of North Carolina, Chapel Hill, NC, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA, [3]Maternal Child Health and Nutrition, UNC School of Public Health, Chapel Hill, NC, USA.

Lactation is a unique physiological model of bone remodeling as transient losses of bone mineral density (BMD) are completely restored in most individuals after weaning and therefore may represent a model of optimal conditions for bone formation.

The objective of this study is to prospectively assess the role of anabolic (IGF-I) and anti-resorptive hormones (estradiol) on BMD gain during the skeletal recovery phase after lactation.

We are conducting a prospective observational cohort study with planned recruitment of 120 postpartum women. Spine and hip BMD are measured by DXA, and the radius and tibia are assessed by pQCT at four time points: delivery, 3 months postpartum, resumption of menses and 6 months after menses resume. Serum analysis will include IGF-I, IGF binding proteins, estradiol, PTHrP, 25OH vitamin D, 1,25$(OH)_2$ vitamin D, CTx, osteocalcin, BSAP and calcium. Women complete infant feeding diaries, physical activity and food frequency questionnaires.

To date, 34 women have started the study and 14 have completed the 3-month time point. At 3 months, 10 women were exclusively breast-feeding, 1 was partially breastfeeding and 3 breast-fed less than 5 days. The change in spine BMD from delivery to 3 months was -6.3 ± 5.4% (mean ± SD; P<0.001 by paired t-test) and in total hip BMD was -3.5 ± 2.7% (P<0.001). The 11 lactating women lost BMD (spine: -8.6 ± 2.5%; total hip: -4.1 ± 2.5%; P<0.001) and the 3 non-lactating women had no significant changes in BMD of spine (+2.0 ± 4.7%; P=NS) or total hip (-1.3 ± 2.5%; P=NS).

Six women have completed the third time point at the resumption of menses (mean 6.1 months postpartum). These 6 women almost exclusively breast-fed >5 months and the change in spine BMD from delivery to the resumption of menses was -6.9 ± 1.0% (P<0.01), and total hip BMD was -4.4 ± 1.0% (P=0.01).

Four women have reached the final visit at 6 months post return of menses. Two out of the 4 women breast-fed >5 months and had significant losses of 7.3% at spine and 5.0% at total hip at 3 months which was recovered over a 6 month period from the return of menses to the last visit. The final BMD measurements for all 4 subjects were not significantly different from baseline measured at the time of delivery (spine: -1.4 ± 4.2%; total hip: -2.3 ± 2.3%; P=NS).

As anticipated, women who continue to lactate for an extended period lose bone mineral density. The study is ongoing and data will be forthcoming regarding the role of anabolic and anti-resorptive hormones in skeletal bone recovery after lactation as well as trabecular and cortical changes assessed by pQCT.

Postural Stability and Physical Performance Tests in Elderly Subjects with Falls. S. M. Logsdon, J. C. Gallagher, R. Satpathy, S. M. Schmitt. Bone Metabolism Unit, Creighton University, Omaha, NE, USA.

Postural instability has been associated with falls in the elderly and 10% of falls result in fracture. Previous measurements of postural stability have been measured under static conditions. In this study, we used a dynamic measurement of postural stability together with standard functional tests. The Biodex Stability System (BSS) measures the angle of deflection (expressed in degrees) to calculate the anterior-posterior stability index (APSI), the medial-lateral stability index (MLSI) and the overall stability index (OSI). We compared this new measure of postural stability with other measures of physical performance in 122 elderly subjects age 65-85 years. Subjects were either classified as fallers, if they had at least 1 fall in the past year, or non fallers if they had no falls in the past 3 years. BSS tests were performed at two platform stabilities. Timed-up-and-go (TUG) was the time it took for them to stand up, walk 3 meters, and return to the chair. The timed rise (TR) was the time it took to stand up and sit down 3 and 5 times and grip strength (GS) was measured using a Jamar Hand Dynamometer at 90deg of shoulder flexion. The results showed mean BMI for female fallers was less than non fallers (p<.02). There was no significant difference in BMI between the male groups. BSS measurements were repeated on 20 subjects two weeks apart; the intra class coefficient was r=0.85. Both female and male fallers had higher mean scores for OSI, APSI (female p<.02) and MLSI than non fallers, (table). Female fallers had significantly higher scores on the TUG, GS and TR (p<0.01) than female non fallers. Male fallers had significantly higher scores on TUG and TR than male non-fallers (p<0.01), but not for GS. In summary, both postural stability and muscle strength were decreased in fallers than non fallers. Although falls are associated with many causes, the significant differences in postural stability, timed up and go, timed rise and grip strength tests between fallers and non fallers indicate these are useful predictors of falls.

A National Osteoporosis Awareness Campaign for Older Women. K. M. Cody*, R. Kagan*, E. N. Schwartz. Foundation for Osteoporosis Research and Education, Oakland, CA, USA.

The National Osteoporosis Awareness Campaign seeks to 1) promote awareness among older women and their families and caregivers, 2) improve responsiveness of healthcare professionals to the problem and 3) increase support from policymakers to address awareness and improve services for osteoporosis.

The United States Administration on Aging (AoA) requested an action plan for a national osteoporosis awareness campaign targeting women 65 and older**.** To develop the plan, FORE convened a variety of stakeholders at two summit meetings in 2003. More than 100 individuals from a variety of organizations at local, regional, and national levels participated in the development of core elements of the proposed campaign and implementation plan. This broad participation not only ensured diverse input to the development of the plan, but also established the foundation for future collaboration.

During the planning process, the contributors identified and tested components for a comprehensive communications plan. The final plan incorporates the knowledge-based consensus on messages and methodologies that emerged from the Summits. Summit I focused on understanding the current state of awareness, describing key audiences, and identifying, in general terms, the most important message content to be delivered. Summit II focused on refining the messages for diverse audiences and determining the best strategies for message delivery. Following Summit II, FORE conducted five telephone focus group discussions with experts representing diverse groups, and their feedback was incorporated into the final plan.

The Planning Committee reviewed and prioritized the findings from the summits and focus groups and framed a campaign and implementation strategy that supported best practices, had a significant likelihood of success, and promoted sustainable action. As a final appraisal, nationally recognized experts in osteoporosis and health promotion reviewed the proposed plan to ensure that it addressed salient issues and engaged sound strategies.

The recommended framework for the campaign is to: 1) Implement a sustained (5-year) national awareness campaign to be delivered locally and aimed at all women age 65 and older, 2) Promote awareness -- and action -- by primary health care professionals, family members, and policymakers to support awareness and action, 3) Focus significant effort at reaching diverse, underserved and disadvantaged women, 4) Develop national leadership and an infrastructure to support federal, state, and local efforts, and build collaboration and linkages with partners at all levels, and 5) Assess and evaluate effectiveness of the campaign in achieving desired outcomes.

Balance in Women with Osteoporosis and Vertebral Fracture: A Funtional Assessment of Kyphotic Posturing. C. B. Ohashi*, A. P. Sansone*, V. L. Szejnfeld, F. F. Ganança*, J. Natour*. Medicine, Federal University of São Paulo, São Paulo, Brazil.

Falling is an increasing hazard for old people, especially for women, who fall twice as often as men. Although multiple factors often contribute to a fall, impaired balance is an important element. The flexed posturing that occurs in people with osteoporotic vertebral fracture may displace the center of gravity and increase the risk of falls. This study was designed to assess balance in osteoporotic women with vertebral fracture and kyphotic posture. Thirteen consecutive patients with vertebral fracture and 22 patients without fracture, from two tertiary medical centers in São Paulo were invited to participate in this study. Patients were 60 years old or older and had osteoporosis (WHO). Patients with comorbidities that can affect balance were excluded. Spine X-ray were taken in all patients and vertebral fracture was identified by a semi-quantitative method. Anthropomorphic measurements were done, kyphosis was measured by Cobb's technique and a questionnaire regarding history of falls in the last year was answered. Berg Balance Scale and *"Time up and go"* test were used to evaluate balance. Vestibular system evaluation including vectonistagmography and audiometry was also performed.The mean age in the patients with fractures was not significantly different from that of patients without fracture (74,3±SD and 72,03±SD years, respectively). Kyphosis was significantly more pronounced in patients with radiographic fracture than in those without (Mean Cobb angle's 48,2° and 29,5°, respectively). Number of falls in the last year (Mean), Berg Balance scores, vestibular evaluation and "*Time up and go"* in patients with vertebral fractures were not significantly different from those without. Our results demonstrate that balance in women with kyphotic posture by osteoporotic fracture is not functionally impaired.

Effect of Physical Activity on Bone, Muscle, and Fat Masses in Collegiate Male Tennis Players and Non-Athletic Controls. J. Ballard*[1], L. S. Wallace[2]. [1]Health and Kinesiology, University of Texas at Tyler, Tyler, TX, USA, [2]Family Medicine, University of Tennessee Graduate School of Medicine, Knoxville, TN, USA.

The purpose of this study was to evaluate the effect of physical activity, upon bone, muscle, and fat masses in 21 male Intercollegiate Tennis Players (mean age=20.9+2.5 yrs) and 20 Controls (mean age=22.5+2.7 yrs) who had not participated in any high school or college athletics. Every subject underwent hydrodensitometry with measured residual volume, anthropometry with Harpenden Skinfold Calipers at 8 sites, and DEXA measurements. The Hologic QDR-2000 was utilized to assess total body composition and the regional bone mass of each arm. "t" tests between the two groups revealed: 1) Tennis Players had significantly (p<.05) less body fat than Controls as determined by skinfolds (mean sum of 8 skinfolds=76.0+24.5 mm vs. 113.1+52.0 mm) by underwater weighing (mean % body fat=11.3+5.1% vs. 18.7+9.1%), and by DEXA (mean % body fat=13.3+4.1% vs. 21.4+7.5%), 2) Tennis Players had more bone and muscle masses then Controls in trunk and legs but not in arms. Two-way ANOVAs (Tennis Players/Controls X Dominant Arm/ Non/Dominant Arm) revealed; 1) Significant (p<.05) interactions with the Dominant Arm of the Tennis Players having more bone mass than the Dominant Arm of the Controls but less bone mass than the Controls in the Non-Dominant Arm for BMC (g) BA cm2 (cm2) and BMC/BA (g/cm2) at the 1/3, mid, ultra distal sites of the radius and ulna. On the basis of these data, it was concluded that the physical activity involved in intercollegiate tennis resulted in less fat, more muscle and greater bone mass in the Tennis Players when compared to the Controls, except in the Non-Dominant Arm where bone mass of the Controls was significantly (p<.05) greater than that of the Tennis Players. It is not known whether the rather low bone mass of the Non-Dominant Arm in these Tennis Players was a result of transferring mineralization to the Dominant Arm or just a lack of development in this extremity due a relatively low level of force exerted by this arm. Further research is needed in younger tennis players during growing years to evaluate the skeletal development of the Dominant and Non-Dominant Arms.

The Mineral Mass and External Dimensions of the Femoral Neck are Dissociated because of the Differing Behaviour of the Periosteal and Endocortical Envelopes. R. M. Zebaze*[1], M. Ghassan[2], E. Seeman[1]. [1]Endocrinology, Austin Health, Melbourne, Australia, [2]Orthopaedic, Balamand University Hospital, Beirut, Lebanon.

Femoral neck apparent volumetric bone mineral density (FN vBMD) is assumed to be independent of the external volume of the FN. This assumption is valid provided that increases in the external dimensions of the FN and the bone mineral content (BMC) within its periosteal envelope are proportional. In 697 women aged 20 to 87 years, assessed using dual energy x-ray absorptiometry, FN BMC correlated with FN volume before ($r = 0.22$, $p < 0.001$), but not after, adjustment for age, height and weight. FN BMC did not increase as FN volume increased so a 1 SD higher FN volume was associated with a 0.67 SD lower apparent vBMD. Height, weight and age had differing effects on FN BMC and FN volume, that was reflected in vBMD. A 1 SD greater height was associated with a 0.15 SD higher FN BMC, but 0.32 SD higher FN volume and so a 0.13 SD lower FN apparent vBMD. A 1 SD higher weight was associated with a 0.36 SD higher FN BMC, and a 0.20 SD higher FN volume and so a 0.15 SD higher apparent vBMD. A 1 SD increase in age was associated with a 0.13 SD increase in FN volume, a 0.36 SD decrease in FN BMC and so a FN apparent vBMD decreased by 0.41 SD . Ex vivo data, derived using QCT and direct mea-

surement on 26 postmortem FN specimens were confirmatory of the dissociation between bone mineral mass and its external dimensions; BMC and FN volume did not correlate (r = - 0.11; NS). vBMD decreased with increasing FN volume (r = - 0.65; p < 0.001). In tubular bones like the femoral neck, BMC and external volume are independent. Apparent vBMD is size dependent and is lower in bigger bones and higher in smaller bones.
Most of the population differences in bone mass, size and so vBMD may reflect the end result of mechanisms that regulate and co-regulate cellular activity on the periosteal and endosteal surfaces to optimize whole bone's tissue mass, size, its tissue mineral density, size, geometry and architecture to regulate strain. Impairment or failure of adaptation by one trait in the face of a developmental abnormality in another trait during growth, or declining function in another trait during aging, may result in bone fragility.

Bone Size at the Distal Radius Is Inversely Correlated with Volumetric Bone Mineral Density. J. S. Walsh, J. A. Clowes, N. F. Peel, R. Eastell. Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom.

The bone mineral content of the distal forearm is often adjusted for bone size by dividing by area or by estimated volume. This study aims to determine the relationship between bone size and bone mineral density of the radius.
We studied 85 healthy premenopausal women ages 18 to 46 years (mean 29.5 years) who underwent measurement by DXA (Osteometer DTX 200) of the distal forearm and pQCT (Stratec XCT 2000) at the 4% forearm site. The non-dominant arm was measured unless it had been previously fractured.
We found cross-sectional area of the radius by pQCT was negatively correlated with volumetric BMD by pQCT (r=-0.581, p<0.01), but it was not correlated with areal BMD by DXA. However, when an estimate of volumetric BMD was made from the DXA measurement by approximating the section of radius to a cube, we observed a negative correlation (r=-0.374, p<0.01). Both cortical (defined as the outer 55% of the cross-sectional area) and trabecular volumetric BMD by pQCT were negatively correlated with cross-sectional area, although cortical volumetric BMD showed a stronger correlation (r =-0.591, 95%CI -0.714 to -0.433) than trabecular volumetric BMD (r=-0.280, 95%CI -0.464 to -0.071). Height, but not age or body mass index, was a predictor of cross-sectional area in this group.
In postmenopausal women ages 55 to 80 years, we found that the inverse correlation between radial cross-sectional area and volumetric BMD by pQCT persists after correction for age (r=-0.478, p<0.01). Volumetric BMD was lower in women with distal forearm fractures (n=69, mean age 67.4 years) than women without forearm fractures (n=380, mean age 68.1 years) (p<0.01), but there was no difference in cross-sectional area between the fracture and non-fracture groups.
This inverse correlation between cortical volumetric BMD and cross-sectional area at the distal radius may represent an adaptive response that results in changes in cortical mass and bone volume to maintain an optimal cross-sectional moment of inertia. In forearm fracture subjects there is a lower volumetric BMD compared to postmenopausal women suggesting volumetric BMD may be more important than bone size in forearm fracture, and that higher volumetric BMD in smaller bones may overcome their mechanical disadvantage.

Osteopontin Potent Suppresses PTH Actions in Cancellous and Periosteal Bone and Enhances PTH Actions in Endosteal Bone. K. Kitahara[1], K. Tsuji[1], M. Ishijima[2], S. R. Rittling[3], H. Kurosawa*[2], A. Nifuji[1], D. T. Denhardt[3], M. Noda[1]. [1]Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Juntendo University, Tokyo, Japan, [3]Rutgers University, Piscataway, NJ, USA.

Continuous presence of PTH has been shown to be catabolic in cortical bone while it may be anabolic in cancellous bone. Since PTH regulates expression of osteopontin (OPN) in osteoblasts, OPN could play a certain role in PTH actions in bone. To examine cellular basis for the OPN-deficiency effects on continuous PTH treatment on bone, we subcutaneously implanted osmotic pumps infusing 80 μg/kg/day PTH (1-34) for four weeks into the mice. PTH infusion increased bone formation rate (BFR) as well as mineral apposition rate (MAR) in cancellous bone in wild type mice. In OPN-deficient mice, basal levels of BFR and MAR were similar to the basal levels in wild type mice. However, OPN-deficiency further enhanced PTH-dependent increase of MAR and BFR in the cancellous bone. PTH infusion suppressed periosteal BFR and MAR in the cortex of diaphyseal bone. Mineralizing surface (MS/BS) was also reduced in wild type mice. OPN-deficiency further enhanced the suppressive effects of PTH on periosteal BFR via suppression in MS/BS, while periosteal MAR was not affected by the OPN-deficiency. Contrary to periosteum, PTH infusion enhanced BFR and MS/BS but not MAR in the endosteum in wild type while OPN-deficiency blocked such PTH effects in the endosteum. PTH infusion increased osteoclast number per bone surface as well as osteoclast surface against bone surface in wild type mice. In OPN-deficient mice, these osteoclast parameters were further enhanced compare to wild type mice. Continuous PTH-infusion increased the levels of serum calcium in wild type mice as reported previously. In OPN-deficient mice, PTH-dependent increase in the levels of serum calcium was further enhanced. PTH-infusion similarly increased deoxypyridinoline excretion in urine in wild type as well as OPN-deficient mice. These observations indicated that OPN suppresses PTH-actions in cancellous and periosteal bone while it enhances PTH actions in endosteal bone.

Comparison of the Effect of Raloxifene on Bone Between Japanese and Caucasian Postmenopausal Women with Osteoporosis. T. Nakamura*[1], T. Matsumoto*[2], M. Fukunaga*[3], S. Watts*[4], K. D. Harper[4], H. Uesaka*[5], M. Tsujimoto*[5], E. Hamaya*[5], K. Sato*[6], A. Tanaka*[6]. [1]University of Occupational and Environmental Health, Kitakyushu, Japan, [2]Tokushima University, Tokushima, Japan, [3]Department of Nuclear Medicine, Kawasaki Medical School, Okayama, Japan, [4]Eli Lilly and Company, Indianapolis, IN, USA, [5]Eli Lilly Japan Co., Ltd., Kobe, Japan, [6]Chugai Pharmaceutical Co., Ltd., Tokyo, Japan.

The bridging concept in clinical development is a method to apply conclusions from the results of clinical trials developed in some region(s) to new region(s). The efficacy of raloxifene (RLX) for the treatment of osteoporosis has been proven in the large randomized multinational 3 year MORE trial (Ettinger et al, JAMA 1999; 282:637-45). A trial of 1year duration (Morii et al, Osteoporosis Int. 2003; 14:793-800) was also conducted with 284 Japanese postmenopausal women, similar to the MORE patient population, to develop a bridging strategy. Both RLX studies had the same treatment groups (placebo, RLX 60 mg/day (RLX60) and 120 mg/day (RLX120)) and all treatment groups received supplements of calcium and vitamin D_3. Because of the study designs, there was a marked difference in the distribution of baseline lumber spine BMD of patients between the two studies (0.468 - 0.741 g/cm^2 in the Japanese study, and 0.412 - 1.449 g/cm^2 in the MORE study). Moreover, the analysis of baseline BMD by tertile in MORE showed that the percent change in BMD was greater in the group with lower baseline BMD. Therefore we used a distribution-adjusted mean of the MORE study population, which is defined as the weighted mean by adding up the mean percent change in each of the 10 divided equal intervals at a width of 0.03 g/cm^2 in the MORE baseline BMD distribution, multiplied by the relative frequency obtained in the Japanese, and then compare this distribution-adjusted mean percent change in BMD to the Japanese study. The percent change in BMD was similar between the two ethnic populations (difference from placebo with 95%CI; RLX60: 3.92 (3.07, 4.77), RLX120: 3.23 (2.39, 4.07) in the Japanese study, and RLX60: 2.77 (1.92, 3.62), RLX120: 3.01 (2.18, 3.83) in MORE study). These results were supported by the absolute BMD gain after RLX treatment being relatively constant (0.016 g/cm^2 to 0.025g/cm^2 in all groups) regardless of baseline BMD values and this trend was similar for both Japanese and MORE studies. This relevant comparison demonstrates that the effect of RLX on bone is similar between Japanese and Caucasian women with osteoporosis and that the dosage is also similar among ethnic populations, supporting the use of RLX for treatment of postmenopausal osteoporosis in Japan with a bridging strategy.

Ethnicity, Plasma 25(OH)Vitamin D, and Calcium Absorption. M. B. O'Connell[1], S. A. Abrams[2], M. Kleerekoper[3], T. Czilli*[1]. [1]College of Pharmacy and Health Sciences, Wayne State University, Detroit, MI, USA, [2]USDA/ARS Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX, USA, [3]School of Medicine, Wayne State University, Detroit, MI, USA.

The purpose of this study was to determine if lower circulating 25(OH)D concentrations in older African Americans women were associated with lower calcium absorptions than in older White women. Study was IRB approved. Nineteen African Americans and 17 White Americans 65 years or older with normal GI function and no calcium absorption-interfering drugs or diseases were enrolled in Fall 2003. Before the absorption study, each woman ingested daily for two weeks 650 units of vitamin D supplements, 500 mg calcium from OsCal, and an additional 700 mg calcium from Tums or diet. After an overnight fast, each woman received 1.2 mg ^{42}Ca (as $^{42}CaCl_2$) intravenously and 20 mcg ^{46}Ca (as $^{46}CaCl_2$) in 8 oz calcium fortified orange juice and a Swanson's Great Start breakfast with 2 slices of buttered toast. Single hip DXA was measured with a Hologic Sahara unit. Food was withheld for 2 hours. Urine was collected for 24 hrs. Thermal ionization mass spectrometry (TIMS) was used for sample analysis. Fractional calcium absorption was calculated as the relative enrichment of the ^{46}Ca vs. the ^{42}Ca in the 24-hour urine. SPSS was used for statistical analysis with significance defined as $P \leq 0.05$. Mean age (range 65 -93 yr old), weight, height, creatinine clearance, plasma 25(OH)D, 24-hr urinary calcium excretion, DXA femoral neck, and DXA total hip were not significantly different between the two ethnic groups. Mean (SD, range) calcium absorption and plasma 25(OH)D concentration for the African Americans were 13.6% (6.3%, 6-24%) and 20.4 ng/ml (9.0, 7-35) and for the White Americans 13.4% (4.3, 6.7-22.1) and 23.8 ng/ml (5.8, 14-36%), respectively. Fifty-eight percent of the African Americans and 18% of the White Americans had hypovitaminosis D (< 20 ng/ml). No significant relationships for the whole group nor within each ethnic group existed between calcium absorption and age, 25(OH)D, urinary calcium excretion, creatinine clearance, DXA femoral neck, or DXA total hip. No ethnic differences between African American and White American seniors for plasma 25(OH)D nor calcium absorption, assessed with the natural isotope method, were observed.

Enhancement of Intestinal Alkaline Phosphatase Gene Expression by Lactose Feeding. N. Sogabe*, R. Maruyama*, L. Mizoi*, M. Goseki-Sone. Food and Nutrition, Japan Women's University, Tokyo, Japan.

Alkaline phosphatase (ALP) hydrolyzes a variety of monophosphate esters into inorganic phosphoric acid and alcohol at a high pH optimum. In humans, studies on the genes related to this enzyme have demonstrated at least four ALP isozymes: tissue non-specific, intestinal, placental and placental-like. The high activity of intestinal ALP, which is localized at the brush border of intestinal epithelial cells, suggests the participation of this enzyme in the transport of nutrients such as inorganic phosphate across the membrane, but little is known about the physiological function of intestinal ALP. It is well known that lactose promotes the intestinal absorption of calcium (Ca) in the paracelluar process and the promotion of Ca absorption seems to be regulated via the passive transport in the small intestine. However, there are few experimental results on the relationships between Ca absorption and ALP expression. In this study, we investigated the effects of lactose on intestinal ALP activity in rats. A total of 64 Sprague-Dawley strain female rats (6-week-old) were divided into three groups: the control, 3% or 10% lactose groups. On day 0, 1 month or 2 months after beginning the experimental diets, rat intestinal segments from the duodenum, jejunum and ileum were obtained immediately after sacrifice. The segments were slit open longitudinally, and the mucosa was scraped and used for enzyme assay. After two months, the levels of intestinal ALP activity in ileum specimens from the 3% lactose group and the 10% lactose group were significantly higher than that from the control group. Two kinds of mRNAs of rat intestinal ALP (RTIN-1 and RTIN-2) were detected by reverse transcription-polymerase chain reaction (RT-PCR). RTIN-1 and RTIN-2 cDNA sequences have 79% homology at the amino acid level. Real-time RT-PCR demonstrated that the level of RTIN-1 mRNA expression in the ileum specimens from the lactose groups was significantly enhanced. This finding was compatible with the findings of enzymatic activity. Further studies on the mechanism of increased intestinal ALP expression induced by lactose would provide useful data on the relationships among lactose, Ca, phosphate and intestinal ALP, and on the physiological function of intestinal ALP.

The Effects of Interaction of Dietary Protein and Calcium on Calcium Retention: A Controlled Feeding Study. Z. K. Roughead[1], L. K. Johnson*[1], G. I. Lykken*[2]. [1]Grand Forks Hum. Nutr. Res. Ctr., USDA-ARS, Grand Forks, ND, USA, [2]University of North Dakota, Grand Forks, ND, USA.

A high protein intake is thought to decrease calcium retention and is often cited as a risk factor for osteoporosis. However, recent findings indicate that a high meat diet, when combined with typically low calcium intakes, does not decrease and may even improve calcium retention. Under controlled feeding conditions, the objective of this study was to characterize the interaction of dietary protein and calcium. In a 2x2 factorial design, healthy postmenopausal women (n=23, age: 45-68 y; body mass index: 26.9 ± 3.8; L1-L4 BMD T-score: -2.4 to1.6) were randomly assigned to either a low calcium (LC, 600 mg/d) or a high calcium (HC, 1500 mg/d) group and consumed low meat and high meat diets [10% and 20% of energy as protein, LP and HP, respectively] for 7 wk each in a randomized crossover design. After 3 wk of equilibration, the menu was extrinsically labeled with ^{47}Ca-radiotracer and its retention was monitored for 28 d by whole body counting. The data were modeled by the two-component exponential equation: $y = \beta_1 \exp(-k_1 t) + \beta_2 \exp(-k_2 t)$, where y is ^{47}Ca retention, as % dose, t time in hours, and coefficients β_1 and β_2 the turnover (%) at rates k_1 and k_2, respectively. (Below are preliminary results; an additional 4 subjects are currently enrolled in the study).

Table: Retention of ^{47}Ca radio tracer[1, 2, 3]

Diet	Model Parameters				Retention, % dose			
	β_1	k_1	β_2	k_2	Day 7	Day 14	Day 21	Day 28
HCHP	87.1	0.03	13.1[a]	0.0009	14.1[a]	9.9[a]	8.5[a]	7.4[a]
HCLP	87.1	0.03	13.2[a]	0.0009	13.7[a]	9.9[a]	8.4[a]	7.3[a]

Calcium X Protein	0.06	NS	<0.05	NS	<0.03	<0.01	<0.01	<0.01

[1]Least square means, n=13 in HC and n=9 in LC groups. Data from one subject in LC group were omitted because of poor fit.
[2]Data with a common superscript in a column are not different (P>0.05).
[3]NS: P > 0.08.

The interaction of dietary protein and calcium affected the efficiency of calcium retention such that the fractional calcium retention was highest when calcium intake was low and protein intake was high (P<0.01, Table). As expected, a high calcium intake reduced the fractional calcium retention (by >40%). Protein intake modified calcium retention only when calcium intake was low. In summary, under controlled conditions, no antagonistic effect between dietary protein and calcium was detected on whole body calcium retention. However, when calcium intake was low (~600 mg/d), a high protein intake (~20% of energy) enhanced calcium retention. In conclusion, in healthy postmenopausal women, with a typically low calcium intake, a high protein diet may be beneficial to bone health by improving calcium retention.

A Relationship Between Body Composition and Calcium Absorption Efficiency. M. J. Barger-Lux[1], M. S. Dowell*[1], R. P. Heaney[2]. [1]Department of Medicine, Creighton University, Omaha, NE, USA, [2]Creighton University, Omaha, NE, USA.

As part of an ongoing interest in sources of variation in Ca absorption efficiency (CaAbs), we examined its correlates in data collected for another study.

The 56 subjects (23 women and 33 men) were aged 20 to 51 y at entry. All reported ample summer sun exposure and limited non-solar sources of vitamin D. They classified themselves as black (*n*=23), white (*n*=29), or other (*n*=4). Median BMI was 27.1 kg/m^2 (interquartile range, 23.1 to 30.5).

Data were gathered at Visit 1 (after summer sun exposure, Aug. 23 to Sept. 21) and later, at Visit 2 (after winter sun deprivation, Feb. 1 to Mar. 15). We measured body composition (as % body fat by DXA), constitutive skin color (by use of a portable colorimeter with a standard color system), and CaAbs; fasting serum 25(OH)D, vitamin D_3, 1,25$(OH)_2$D, PTH, and Ca; and fasting 2h urine Ca-to-creatinine.

As expected, paired values for CaAbs were strongly related (r = +0.702, P<0.0001). In these data, CaAbs was unrelated to skin color and to 25(OH)D, PTH, and 1,25$(OH)_2$D. However, CaAbs and % body fat were significantly and positively related at both visits, with a stronger relationship after controlling for BMI (r = +0.425, P<0.005 and r = +0.382, P<0.01, respectively).

We conclude that: (1) % body fat may be an important source of variation in Ca absorptive capacity (as an indicator of gut surface area?) and (2) further study is warranted.

Short-term Biological Effects of Calcium from Natural Mineral Water in Young Women with Low Calcium Dietary Intakes. P. Fardellone[1], F. Constant*[2], P. Lefauveau*[1], S. Kamel[1], M. Arnaud*[2], J. Aeschlimann*[3], F. Boitte*[1], M. Brazier[1]. [1]Rhumatology, Hospital, Amiens, France, [2]Nestlé Water Institute, Vittel, France, [3]Nestlé Research Center, Lausanne, Switzerland.

Calcium bioavailability from calcium-rich natural mineral waters has been shown as well as its significant contribution to total calcium intakes and its effects on bone turnover. However, it has not been demonstrated whether or not drinking a natural mineral water with moderate calcium content could have similar effects in subjects with a low calcium diet.

The aim of the study was to assess the short-term biological effects of two waters on calcium homeostasis and bone remodeling in a healthy population of 101 young women (aged 18 to 40 years). Spontaneous dietary calcium intakes were assessed by a food frequency questionnaire and ranged from 200 to 600 mg/day. The subjects were under hormonal contraception in order to standardize their hormonal status. They participated to a randomized cross over study comparing the effects of a natural mineral water (Vittel Bonne Source®) containing 91 mg/L calcium with a mineral-free water. Women, distributed between two groups were maintained on their usual diet and drank 1.5l/day of one of the studied waters for a 8-day period. Water was changed after a 20-day washout period. The blood samples were collected at 8 am and 12 am, at baseline (D0) and after 3 (D3) and 8 days (D8) to measure total and ionized calcium, creatinine, intact parathyroid hormone (iPTH), serum C-telopeptidic fragments (CTX), and osteocalcin. On the morning of the sampling, women were asked to drink 250 ml of the studied water each hour for 4 hours and then 500 ml in the afternoon. On D0, D3 and D8, between 8am and 12am it was observed a significant (P<0.003) higher increase of total and ionized calcium and a deeper decrease of serum CTX and iPTH in the women drinking the natural mineral water when compared with mineral-free water. Moreover, a continuous trend in the increase of total and ionized calcium and in the decrease of serum CTX was observed during the 8-day period in the women drinking the natural mineral water.

In conclusion, natural mineral waters with a calcium content close to 100 mg per liter leads to a decrease of bone turnover in women with low calcium intakes and may have beneficial long-term effects.

Dose Response of Hesperidin, a Citrus Flavonoid, on Bone Mass in Young Intact Rats. M. Horcajada*[1], C. Morand*[1], E. Offord*[2], P. Lebecque*[1], C. Puel*[1], J. Mathey*[1], M. Davicco*[1], V. Coxam[1]. [1]Nutrition, INRA, Saint genès champanelle, France, [2]Nutrition, NRC, Lausanne, Switzerland.

A high consumption of fruit and vegetables has been associated with a positive effect on bone health. An interesting sub-group of flavonoids, flavanones, is present in our diet almost exclusively in citrus fruits. Hesperidin is the main flavanone found in orange fruit (~ 2g/kg), and we have previously reported its ability to affect bone mass and strength in intact and ovariectomized rats. The aim of the current study was to establish the minimum effective dose of pure hesperidin (Hp) which could stimulate bone formation in 3 month-old intact rats.

The dose-response was carried out on 60 young intact Wistar rats, with a time duration of 3 months. The animals were assigned to six groups of ten rats each. One group received a soy-protein-free, semi-purified standard diet (**SH**), while the others were fed the same diet but with added hesperidin at various doses : 0.125% (**SH1**) ; 0.25% (**SH2**); 0.5% (**SH3**); 1% (**SH4**) and 2.5% (**SH5**) of the diet.

Throughout the study period, rats kept growing with the same pattern of body weight evolution in each group and, on day 85, no difference in body composition among groups was detected. At necropsy, femoral mineral density (g/cm²)was significantly increased in SH2 and SH3 (+5% *vs* SH ; $p<0.05$) groups with the same magnitude, this effect was even stronger in SH4 and SH5 groups, when compared to the controls (+6.1% *vs* SH ; $p<0.01$). This impact was achieved in both total and metaphyseal compartments. Diaphyseal femoral density was also increased by Hp consumption starting from the 0.25% dose upwards (SH2 : +4.1% *vs* SH ; $p<0.05$; SH4 : +5.2% *vs* SH ; $p<0.01$). This was paralleled with an enhanced femoral failure load. No differences were observed in BMD or femoral strength, with the lowest dose (0.125%). Plasma osteocalcin concentrations were unchanged in all groups while urinary deoxypyridinolin excretion was significantly decreased in the group from 0.125% - 2.5% (SH1 : -13.3% *vs* SH), indicating a slow down of bone resorption. Plasma hesperetin concentration (aglycone form) increased in a dose dependent manner, each dose inducing a significant difference in plasma level when compared to the lowest dose. A strong correlation with hesperetin intake (24h) was noted ($R^2 = 0.98$) and with urinary DPD excretion ($R^2 = 0.88$).

In conclusion, hesperidin consumption improved both femoral strength and mineral density. This appeared to be linked with a decreased catabolism. The effective dose, in our experimental conditions, was 0.25% hesperidin, corresponding to 1.76µM plasma hesperetin when measured during the post-absorptive period.

Deflection of Glucocorticoid Action on Osteoclasts from TRAP-11ß-HSD2 Transgenic Mice Abrogates the Antiapoptotic Effects of the Steroid. D. Jia, C. A. O'Brien, S. A. Stewart*, S. C. Manolagas, R. S. Weinstein. Div. of Endo/Metab, Center for Osteoporosis, Central Arkansas Veterans Healthcare System, Univ of Ark for Med Sci, Little Rock, AR, USA.

Glucocorticoid-induced bone loss occurs in two phases in humans and mice: a rapid, early phase in which bone mass is lost due to excessive bone resorption and a slower, chronic phase in which bone is lost due to inadequate bone formation. In vitro and in vivo studies have suggested that glucocorticoids may act directly on differentiated osteoclasts to extend their lifespan. To establish whether the increased bone resorption caused by glucocorticoids excess results from direct actions of glucocorticoids on osteoclasts, we have generated transgenic mice expressing human 11ß-hydroxysteroid dehydrogenase-2 (11ß-HSD2), an enzyme that causes rapid pre-receptor oxidative inactivation of glucocorticoids, under the control of the promoter for mouse tartrate-resistant acid phosphatase (TRAP). Taqman RT-PCR showed that the human 11ß-HSD2 transgene was expressed in bone, but not soft tissue, and immunohistochemistry demonstrated exclusive presence of the human protein in osteoclasts. There was no detectable difference at 5 weeks of age between wild-type and transgenic mice in body weight, femur length or vertebral height, compression strength and cancellous histomorphometry. Furthermore, gender differences were not found in the TG mice. Osteoclast precursor-enriched bone marrow cells from either genotype formed TRAP-positive multinucleated osteoclasts in vitro following 5 days of treatment with the receptor activator of NF-κB ligand (RANKL) and macrophage-colony stimulating factor (M-CSF). Baseline apoptosis, assayed by caspase-3 activity, was reduced by glucocorticoids in cultures of wildtype osteoclasts. This effect was greatly attenuated in osteoclasts from the transgenic animals. Likewise, the ability of glucocorticoids to prevent alendronate-induced osteoclast apoptosis in wildtype cells was abrogated in osteoclasts from the TRAP-11ß-HSD2 mice. These results indicate that glucocorticoids exert at least part of their anti-apoptotic effects on osteoclasts by direct actions. These direct effects may play a role in the rapid, early phase of glucocorticoid-induced bone loss and partially override the pro-apoptotic effects of alendronate. Nonetheless, studies of ours presented elsewhere in this meeting suggest that there are also ancillary indirect effects of glucocorticoids on osteoclasts mediated by an increase in RANKL/osteoprotegerin ratio.

Glucocorticoid-Induced Osteopenia at the Axial and Appendicular Bones in Male and Female Mice. J. L. Matthews*[1], V. Shen[2], S. Tellefson*[2], E. Bell*[2]. [1]GlaxoSmithKline Medicines Research Centre, Stevenage, United Kingdom, [2]SkeleTech, Inc., Bothell, WA, USA.

Osteoporosis is a serious side effect of high dose glucocorticoid (GC) treatment in both the male and female populations. There is no commonly accepted GC-induced bone loss animal model that is used to test the safety of new generation GC-like drugs. In this study, we aimed to establish such a model in both male and female animals.

Twenty-seven-week-old male and female Balb/c mice were randomized into treatment groups based on baseline bone area and bone mineral density results. The animals were then given daily subcutaneous injections of vehicle or dexamethasone (DEX, 5 mg/kg). *In vivo* DXA scans were performed pre-dose and after 4, 6 and 8 weeks of dosing. Both axial and appendicular bones were analyzed. DEX administration induced a significant loss in bone mineral density (BMD) at the axial bone, the lumbar spine, and the appendicular bone, the femur, when compared to pre-dose levels. The net BMD loss was about 10% independent of the bone site or gender when examined at 8 weeks. Whereas most of the loss in BMD at the lumbar spine occurred during the last 4 weeks of DEX treatment, the loss of BMD at the femur can be clearly seen at 4 weeks.

In conclusion, we have demonstrated that the use of DEX induced a net bone loss in both the axial and appendicular bones in both genders of mice and that this model can be used as a model for safety testing of new generation GC compounds. The timing of the bone loss differs at these two sites. Based on observed variations in vehicle-treated animals, multiple scans over a longer period of time are recommended to ensure the observation of a net loss of bone.

Glucocorticoid-Induced Osteoporosis in the Mouse: Reduced Bone Strength Is Associated with Loss of Cortical Bone and Altered Trabecular Bone Structure. J. L. Matthews*[1], V. Shen[2], B. P. Hayes*[1], B. Maschera*[1], G. Wakley[3], K. T. Pun*[1], E. Meldrum*[1], S. N. Farrow*[1]. [1]Asthma Biology, GlaxoSmithKline, Stevenage, United Kingdom, [2]Skeletech Inc, Bothell, WA, USA, [3]Anatomy, BioResults Ltd and University of Bristol, Bristol, United Kingdom.

Glucocorticoid-induced osteoporosis (GIOP) is a serious side-effect of high dose glucocorticoid (GC) treatment leading to increased vertebral and neck of femur fracture risk. The aim of this work has been to develop a mouse model of GIOP reflecting the increased fracture risk seen in man and to elucidate structural and dynamic changes associated with increased fracture risk.

Subcutaneous Dexamethasone (Dex)(0, 1, 3, 5 or 10mg/kg) was administered daily to 27 week old female BalbC mice. DXA scans were performed fortnightly and when dose responsive bone loss was evident, a first intraperitoneal injection of calcein was given. A 2nd dose of calcein was given after a further 8 days followed by cull 2 days later. At termination, bone mineral density (BMD) of the right femur was measured by peripheral quantitative computed tomography (pQCT) before 4 point bend tests were performed to assess bone strength. Structural assessment of the left femur was made using microcomputed tomography (microCT) analysis. Compression tests were performed on L5 vertebrae and bone formation rate (BFR) was measured on the L4 vertebrae using dynamic histomorphometry.

The top 2 doses of Dex induced reductions in femur BMD after 4 weeks and by 6 weeks a clear dose responsive effect was evident so termination was at 8 weeks. PQCT confirmed the reduction in overall BMD, which was mainly due to loss of cortical bone. These reductions correlated with reductions in cortical volume and trabecular bone thickness as assessed by micro CT, and with reduced femur strength. Loss of vertebral BMD also correlated with loss of bone strength and reduced BFR.

In conclusion, we have demonstrated that the major clinical features of GIOP in man are reflected in our mouse model . This model provides a powerful system in which to study the mechanisms regulated by GC's in bone, and to evaluate the potential of novel bone-sparing therapeutic approaches.

Osteoporosis Associated with Megestrol Acetate. R. A. Wermers, D. L. Hurley, A. E. Kearns. Endocrinology, Mayo Clinic, Rochester, MN, USA.

Megestrol acetate (Megace) is a progestational agent used in the treatment of metastatic breast and endometrial cancer. It has also been used as an appetite stimulant for patients with human immunodeficiency virus and malignancy, suffering from cachexia and wasting. In addition, it can be beneficial in relieving hot flashes in women and men. Megace has been shown to have a glucocorticoid-like effect and also has been associated with significant suppression of plasma estradiol levels. We describe two postmenopausal women who recently presented to our Metabolic Bone Disease Clinic with severe osteoporosis complicated by multiple vertebral fractures shortly after initiation of high-dose Megace therapy. These patients were shown to have evidence of adrenal axis suppression, but fully recovered after Megace was discontinued. One of the patients manifested clinical features of cortisol excess with facial fullness, abdominal distention, and easy bruising. We speculate that Megace was an important factor in the development of osteoporosis and subsequent fractures, and to our knowledge, this is the first report suggesting such an association. Further study is warranted to clarify the relationship between Megace and its potential for adversely affecting the skeleton.

SU417

A Histomorphometric Study of the Effects of Steroid Treatment on the Cortical Bone of the Iliac Crest. S. Vedi*[1], S. Elkin*[2], J. E. Compston[1]. [1]Medicine, University of Cambridge, Cambridge, United Kingdom, [2]Cystic Fibrosis, Royal Brompton Hospital, London, United Kingdom.

Long-term administration of glucocorticoids for the treatment of a variety of disorders is associated with increased bone loss and fracture risk. The effects of steroid treatment on cancellous bone remodelling and structure are reasonably well documented but there are no reported histomorphometric studies in human cortical bone. The aim of this study was to investigate the effect of long-term glucocorticoids on iliac crest cortical bone in 14 patients, 9 females and 5 males, aged 18-48 years (mean 34.1 + 8.7 years), using Image Analysis. Results were compared with an age matched control group of 10 premenopausal women with untreated endometriosis and 4 males, aged 22-38 years (mean 30.1 + 4.8 yrs). Although, cortical porosity was significantly higher in patients treated with glucocorticoids (8.4 + 8.9 % ; mean + SD) compared with the untreated group (5.1 + 3.9 %; p=0.03), cortical width and area were similar in the two groups. The Haversian canal number and density were also significantly higher in glucocorticoid treated patients (45.9 + 23.2 vs 31.9 + 24.4 and 13.7 + 9.4 vs 6.7 + 3.3 /mm2; p=0.003 and p=0.00005 respectively), but Haversian canal area did not differ significantly between groups.

The mean wall width of the osteons was significantly lower in the treated patients compared to the untreated group (48.8 + 7.1 microns vs. 59.3 + 12.0 microns; p=0.008). Bone formation rate (microns squared/microns/day) and mineral apposition rate (microns/day) were also both significantly reduced in patients receiving long-term glucocorticoid therapy when compared to the untreated group (0.056 + 0.040 vs. 0.095 + 0.058 and 0.59 + 0.12 vs.0.74 + 0.13; p=0.05 and p=0.01, respectively). The proportion of canals with an eroded surface was lower in the treated group when compared with the untreated control group.

These results demonstrate that there is an increase in cortical porosity in patients treated with long-term glucocorticoid therapy, due to an increase in the number rather than size of Haversian canals. Effects on cortical width were not demonstrated, possibly as a result of the relatively small sample size. Overall, these changes would be consistent with increased resorption during the early stages of glucocorticoid treatment associated with and followed by persistent reduction in bone formation..

The Anabolic Effect of Intermittent PTH on Bone Is Partially Prevented by Simultaneous Glucocorticoid Treatment in Aged Rats. H. Oxlund, G. Ortoft*, T. T. Andreassen. Dept of Connective Tissue Biology, University of Aarhus, Inst of Anatomy, Aarhus, Denmark.

Glucocorticoids (GC) are used for the treatment of a wide spectrum of diseases because of their potent anti-inflammatory and immunosuppressive effects, and they are serious and common secondary causes of osteoporosis. In the present study, the effects of simultaneous parathyroid hormone (PTH) and GC injections were investigated on bone static and dynamic histomorphometry. Twenty-seven-month-old female Wistar rats with ceased linear growth were used. The rats were divided at random into the following groups: baseline, vehicle-injected (Veh), PTH-injected (PTH), GC-injected (GC), PTH+GC-injected. Doses: PTH (1-34) 25 :g/kg body weight daily, GC (methylprednisolone) 2.5 mg/kg body weight daily. The treatment period was 8 weeks. The rats were labelled with fluorochromes 3 times during the experiment: alizarine red 20 mg/kg at day 7, calcein 15 mg/kg at day 42, and tetracycline 20 mg/kg at day 52. Bone sections were cut and studied by fluorescence microscopy. Concerning cancellous bone in the proximal tibia metaphysis, 2 mm distally to the epiphyseal growth plate, the trabecular bone volume (TBV) was markedly increased (2p<0.00001) in PTH-injected rats (41.9 [[Unable to Display Character: "]] 2.5 %, mean [[Unable to Display Character: "]] SEM) compared with the Veh-injected rats (7.5 [[Unable to Display Character: "]] 1.5 %). TBV in the PTH+GC group (26.9 [[Unable to Display Character: "]] 1.8 %) was increased (2p<0.0001), but less pronounced compared with the GC group (10.1 [[Unable to Display Character: "]] 1.5 %). Concerning cortical bone at the tibia mid-diaphysis, the PTH-injections likewise induced a pronounced endocortical formation of new bone, resulting in increased (2p< 0.01) bone cross-sectional area (4.67 [[Unable to Display Character: "]] 0.12 mm^2) compared with the Veh-injected (4.13 [[Unable to Display Character: "]] 0.07 mm^2); and the bone cross-sectional area in the PTH+GC group (4.31 [[Unable to Display Character: "]] 0.10 mm^2) was not significantly increased (2p=0.058) compared with the GC group (4.05 [[Unable to Display Character: "]] 0.09 mm^2). The mid-diaphyseal medullary cross-sectional area of the PTH-injected group (0.92 [[Unable to Display Character: "]] 0.06 mm^2) was reduced (2p=0.0001) compared with the Veh-injected group (1.28 [[Unable to Display Character: "]] 0.05 mm^2). The medullary cross-sectional area of the PTH+GC group (1.08 [[Unable to Display Character: "]] 0.05 mm^2) was reduced (2p=0.041) compared with the GC group (1.29 [[Unable to Display Character: "]] 0.08 mm^2), but to a lesser degree. In conclusion, the pronounced anabolic effect of PTH on endocortical and cancellous bone surfaces was partially prevented by simultaneous treatment with GC in aged rats.

The Impact of Endogenous Cortisone on Bone: Demonstration of In Vivo 11beta-Hydroxysteroid Dehydrogenase Type 1 Activity. M. S. Cooper[1], H. E. Syddall*[2], P. J. Wood*[3], P. M. Stewart*[1], C. Cooper[2], E. M. Dennison[2]. [1]Division of Medical Sciences, University of Birmingham, Birmingham, United Kingdom, [2]MRC Environmental Epidemiology Unit, University of Southampton, Southampton, United Kingdom, [3]University of Southampton, Southampton, United Kingdom.

Cortisone is an inactive circulating corticosteroid that can be converted to the active corticosteroid cortisol by the enzyme 11beta-hydroxysteroid dehydrogenase type 1 (11b-HSD1). 11b-HSD1 is expressed in osteoblasts and may play a role in age-related and glucocorticoid-induced osteoporosis. The contribution this enzyme makes to endogenous bone metabolism is however unknown. The kinetics of cortisone to cortisol conversion are such that enzyme activity is proportional to cortisone concentration. To examine *in vivo* 11b-HSD1 activity in healthy subjects we have analysed the relationship between serum cortisone, cortisol, markers of bone turnover and BMD in a cohort of women (n=135) and men (n=170) aged 60-75 years at baseline and followed up 4 years later.

0900 serum cortisone levels at baseline were 55±11 nmol/L in women, 55±9 nmol/L in men. Cortisone levels were negatively correlated with serum osteocalcin (r=-0.16, p=0.06 for women; r=-0.20, p=0.01 for men) but not urinary N-telopeptide of type I collagen (NTx)(r=-0.03 women; r=0.03 men, both NS) suggesting enzyme activity within osteoblasts. Negative correlations between serum cortisone and spine BMD were also apparent (r=-0.18, p=0.04 for women; r=-0.14, p=0.07 for men) but cortisone did not predict femoral neck or total hip BMD or changes at any site over 4 years. In analyses adjusted for adi-

posity, osteoarthritis grade and life style variables the significance level did not change substantially (p=0.08 for both men and women). All these relationships were independent of cortisol concentrations. Serum cortisol itself was not associated with levels of bone markers or BMD at any site.
Circulating cortisone appeared to account for a mean 20-27% inhibition of osteocalcin levels and a 12-15% reduction of spine BMD in both men and women. The association of cortisone levels with spine but not hip BMD may reflect increased glucocorticoid sensitivity at the spine or higher 11b-HSD1 activity at this site.
In normal subjects 11b-HSD1 activity occurs within osteoblasts *in vivo* with high cortisone levels associated with suppression of osteocalcin and low spinal BMD. Although an inactive hormone, cortisone appears to have a role in bone physiology.

Ultrasound Graphic Trace Analysis At Phalanxes In Men And Women Treated With Glucocorticoid. S. Gonnelli[1], A. Montagnani*[1], C. Cepollaro[1], C. Caffarelli*[1], A. Cadirni*[1], N. Nikiforakis*[2], M. Martino*[2], P. Rottoli*[1], R. Nuti[1]. [1]Department of Internal Medicine, Endocrinologic-Metabolic Sciences and Biochemistry,, University of Siena, Siena, Italy, [2]Department of Clinical Medicine and Immunological Science, Division of Respiratory Diseases, University of Siena, Siena, Italy.

Osteoporosis is one of the major complications of glucocorticoid (GC) therapy. It is well known that for a given BMD value GC treated postmenopausal (PM) women present a higher fracture risk than PM osteoporotic women. This finding suggests that the effect of GCs on bone strength can not be wholly determined by conventional DXA. The use of quantitative ultrasound (QUS) and namely the analysis of the characteristics of the ultrasound graphic trace (UGTA), influenced by both quantitative and qualitative properties of bone, could be useful for the assessment of bone status and of fracture risk in GC treated patients.
This study aimed to evaluate the usefulness of QUS parameters at phalanxes in the evaluation of bone status and fracture risk in patients chronically treated with GCs.
We studied 230 patients (145 women and 85 men, mean age 56.1±13.3 years) on treatment with GCs for at least 6 months, and 230 sex- and age-matched controls. In all subjects QUS parameters were measured at phalanxes by Bone Profilers (IGEA, Italy); the parameters evaluated were: amplitude speed of sound (AD-SOS, m/s) and UGTA parameters, namely bone transmission time (BTT, µs), fast wave amplitude (FWA, mV), speed of sound (SoS, m/s) and signal dynamic (SDy, mV/µs²).
AD-SoS and UGTA parameters resulted significantly reduced in GC treated patients than in controls. Moreover, AD-SoS, BTT, FWA and SoS, but not SDy were significantly lower in fracture than in non fracture GC patients. By dividing the GC patients on the basis of gender, we found that in women both AD-SoS and UGTA were lower in fracture than in non fracture patients; but the statistical significance was reached only for AD-SoS ($p<0.05$), BTT ($p<0.001$)and FWA ($p<0.05$). Whereas, only FWA resulted significantly lower ($p<0.05$) in fracture with respect to non fracture males. ROC analysis showed that FWA was able to discriminate between fracture and non fracture patients both in men (AUC: 0.76) and in women (AUC: 0.63), whereas BTT was a discriminative factor for fracture only in women (AUC: 0.70)
Our findings show that QUS at phalanxes can be useful in the assessment of glucocorticoids-induced bone impairment. Among UGTA, BTT resulted as being a good predictor of fragility fracture in women but not in men, and this finding may be explained by the fact BTT is closely related to the cortical thickness of bone, which strongly differs between men and women, suggesting a possible sex dimorphism in GC effect on bone.

SU421

Role of Dehydroepiandrosterone, Insulin-Like Growth Factor I and Vitamin D in the Bone Loss of Cystic Fibrosis. C. M. Gordon*[1], E. Binello*[1], H. A. Feldman*[1], M. S. LeBoff[2], M. E. Wohl*[1], C. J. Rosen[3], A. Colin*[1]. [1]Children's Hospital, Boston, MA, USA, [2]Brigham & Women's Hospital, Boston, MA, USA, [3]St. Joseph Hospital, Bangor, ME, USA.

Patients with cystic fibrosis (CF) are at risk for early osteoporosis. Although the mechanisms that mediate bone loss in this group are still being delineated, nutritional and/or hormonal factors likely contribute. Dehydroepiandrosterone (DHEA), a naturally secreted anabolic hormone, has been shown to decrease bone loss in various conditions including the malnutrition related to anorexia nervosa. The aims of this study were to examine whether baseline serum levels of DHEA, insulin-like growth factor I (IGF-I) and vitamin D, as well as measurements of bone density, were low in patients with CF, and to examine if significant correlations existed between these variables. We studied thirty-two patients (18 females), with a mean age (± SD) of 26.2 ± 7.9 yr and a body mass index (BMI) of 21.4 ± 2.6 kg/m^2 (range 16-28). The protocol was approved by the local Committee on Clinical Investigation. Half of the participants (16/32) had a history of fractures. Serum DHEA sulfate (DHEAS) levels were low in 66% of patients: mean 155.8 ± 121.1 µg/dl, range 10-545. The mean serum IGF-I level was low in 62% of patients: 240.0 ± 90.1 ng/mL, range 116-440. The mean serum 25-hydroxyvitamin D level was 20.2 ± 9.5 ng/ml, range <8-39, and twelve patients (38%) met criteria for vitamin D deficiency (25-OHD ≤ 15 ng/ml). Bone mineral density (BMD) measurements by dual energy x-ray absorptiometry (DXA) showed decreased mean lumbar and hip z scores: -1.0 ± 1.3, range -4.0 to 1.5, and -0.62 ± 0.8, range -2.5 to 1.2, respectively. A lumbar Z-score < -1.0 was seen in 16 patients (50%). Spearman correlation analyses revealed a significant positive correlation between serum DHEAS and weight ($r= 0.59$, $p<0.001$), and DHEAS and total hip BMD ($r= 0.39$, $p=0.033$). IGF-I was positively correlated with BMD of both the spine ($r= 0.39$, $p=0.026$) and hip ($r= 0.56$, $p<0.001$). BMI was also positively correlated with total hip BMD ($r= 0.35$, $p=0.048$). In this pilot study of adolescents and young adults with CF, DHEAS and IGF-I levels were low in over half of the subjects and over one-third of the participants were vitamin D-deficient. Furthermore, a spinal bone density was of potential clinical significance (Z- score < -1) in half of the sample. These preliminary findings suggest that a direct correlation may exist between cortical BMD and levels of both DHEAS and IGF-I. As the anabolic effects of DHEA may be mediated through the skeletal IGF-I system, therapeutic supplementation of this hormone should be investigated. These results also replicate previous recommendations that surveillance for vitamin D deficiency is warranted in this group.

Abnormal Osteoprotegerin And Rankl Levels In Primary Biliary Cirrhosis. Lack Of Association With Osteoporosis And Biochemical Markers Of Bone Turnover. N. Guanabens[1], A. Pares*[2], L. Alvarez[1], A. Monegal*[1], L. Caballeria*[2], D. Ozalla*[1], P. Peris[1], F. Pons*[1], J. Rodes*[2]. [1]Metabolic Bone Diseases Unit, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, [2]Liver Unit, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain.

Background/aims: The pathogenesis of osteoporosis in primary biliary cirrhosis (PBC) is not well understood since both low or high bone turnover have been reported. Osteoprotegerin (OPG) and its ligand (RANKL) regulate osteoclastogenesis, and therefore may influence the development of osteoporosis. However, the clinical utility of circulating OPG and RANKL levels for assessing regulation of bone metabolism in secondary osteoporosis is uncertain.
Patients and Methods: OPG and RANKL levels were assessed in 52 patients with PBC (age: 57 ± 1.5 years) and in an age-matched control group of healthy females. Besides liver function tests, serum bone gla-protein (BGP), as index of bone formation, and urinary amino-terminal telopeptide of collagen I (NTx), as index of bone resorption, were also measured. Bone mineral density of the lumbar spine and femoral neck were assessed for diagnosing osteoporosis (BMD below -2.5 T-score). The overall severity of liver disease was assessed by the Mayo risk score.
Results: OPG levels (pM/l) were significantly higher in PBC (5.5 ± 0.2) as compared to controls (2.9 ± 0.2, $p<0.0001$), whilst RANKL (pM/l) were lower in PBC (0.4 ± 0.1) with respect to controls (1.4 ± 0.3, $p<0.0001$). No correlation was observed between OPG and RANKL. 22 patients (44%) had osteoporosis. No significant differences in OPG and RANKL levels were observed between patients with and without osteoporosis (OPG: 5.9 ± 0.4 vs. 5.2 ± 0.2 pM/l; RANKL: 0.39 ± 0.09 vs 0.44 ± 0.08 pM/l) . OPG was significantly higher in patients with advanced liver disease as defined by high bilirubin levels (OPG: 6.8 ± 0.6 vs. 5.2 ± 0.2 pM/l, $p=0.009$) or by a Mayo score above 4 (OPG: 5.9 ± 0.4 vs 4.9 ± 0.3 pM/l, $p=0.04$). Moreover, a direct correlation was observed between OPG and Mayo score ($p=0.01$). No associations were found between OPG and RANKL with biochemical markers of bone remodeling.
In conclusion, OPG and RANKL are abnormal in patients with PBC, regardless of osteoporosis. The high OPG levels are associated with the severity of the liver disease.

Dissociation between Global Markers of Bone Remodelling and Direct Measurement of Spinal Bone Formation in Osteoporosis. M. L. Frost[1], G. J. Cook[2], G. M. Blake[1], P. K. Marsden*[3], I. Fogelman[1]. [1]Osteoporosis Unit, Guy's, King's & St Thomas' School of Medicine, London, United Kingdom, [2]Dept of Nuclear Medicine, Royal Marsden Hospital, London, United Kingdom, [3]Clinical PET Centre, Guy's, King's & St Thomas' School of Medicine, London, United Kingdom.

Evaluations of global skeletal metabolism have shown that increased bone turnover is a feature of patients with osteoporosis. The non-invasive functional imaging technique of ^{18}F-fluoride positron emission tomography (PET) allows the direct quantitative assessment of bone metabolism at specific sites in the skeleton, including the lumbar spine. The aim of this study was to compare regional skeletal kinetics in 72 postmenopausal women, with a mean age of 61 years, classified as normal, osteopenic or osteoporotic according to their BMD T-score at the lumbar spine. Each woman had a dynamic PET scan of the lumbar spine after injection of 90 MBq ^{18}F-fluoride ion and measurements of biochemical markers of bone formation and resorption. The arterial plasma input function was derived using aorta arterial activity from the PET image. Time activity curves were obtained by placing regions of interest over the vertebrae. A three-compartmental model was used to calculate bone blood flow (K_1) and the net plasma clearance of tracer to bone mineral (K_i), reflecting regional osteoblastic activity with units of ml min^{-1} ml^{-1}. Rate constants k_2, k_3 and k_4, which describe transport between plasma, the ECF compartment and the bone mineral compartment, were also measured. The net uptake of fluoride to the bone mineral compartment (K_i) was significantly lower in the osteoporotic group compared to both the osteopenic and normal groups, with a mean difference of 0.005 ml min^{-1} ml^{-1} (16.7%). The fraction of the tracer in the extravascular tissue space that underwent specific binding to bone mineral (k_3/k_2+k_3) was also significantly reduced in the women classified as osteoporotic. In contrast, levels of bone-specific alkaline phosphatase (Bs-ALP) were significantly higher in the osteoporotic group compared to the normal and osteopenic groups by 35% and 27% respectively. A significant negative correlation ($r = -0.41$) was observed between levels of Bs-ALP and the fraction of the tracer that underwent specific binding to bone mineral. In conclusion, lower values of K_i, a measurement of regional bone formation activity, were seen in women classified as osteoporotic, while levels of Bs-ALP, a measure of global skeletal metabolism were significantly increased. These findings are suggestive of increased global skeletal bone turnover in women with postmenopausal osteoporosis but with relatively reduced regional bone formation at the predominantly trabecular site of the lumbar spine.

Disclosures: ***M.L. Frost****, None.*

SU424

Methadone Maintenance Therapy Is Associated with Low Bone Mass, Increased Markers of Bone Resorption and Altered Neuroendocrine Axes. A. O. Malabanan, T. Kim*, D. P. Alford*, T. C. Chen, M. F. Holick, J. H. Samet*. Department of Medicine, Boston University School of Medicine, Boston, MA, USA.

Opioid use has acute and chronic neuroendocrine effects, which may adversely affect bone health. To assess the effects of methadone maintenance treatment (MMT) on bone health, we conducted a cross-sectional study of 88 patients attending one methadone program, assessing demographic data, bone pain (McGill Pain Survey), bone mineral density (BMD) of the lumbar spine, proximal femur, and wrist, hormonal profile (free testosterone (fT), estradiol (E2), prolactin (PRL), thyroid stimulating hormone (TSH), follicular stimulating hormone (FSH), and luteinizing hormone (LH)) and metabolic bone profile (25-hydroxyvitamin D (25OHD), serum calcium, intact parathyroid hormone (PTH), serum c-terminal telopeptide (CTX) and osteocalcin (OC)). Eligible patients had attended the clinic for at least 1 month, were able to give informed consent, and were not pregnant.

Subject characteristics were as follows: median age 42 years (range 20-66), 61% female of whom 34% were post-menopausal. Bone pain was present in 64%, and vitamin D insufficiency in 32%, as defined by a 25OHD level < 20 ng/ml. The median duration of MMT was 3 years (1 month to 25 years). BMD in female patients at the lumbar spine (L1-4), femoral neck (FN) and 1/3 wrist site were normal in 58%, 76%, and 78%, osteopenic in 38%, 22%, and 20%, and osteoporotic in 4%, 2% and 2%. BMD in male patients at the LS, FN, and 1/3 wrist site were normal in 38%, 38%, and 44%, osteopenic in 38%, 53% and 34%, and osteoporotic in 25%, 9% and 22%. If all sites except for Ward's area are considered, 78% of the females had either osteopenia (58%) or osteoporosis (20%) and 94% of the males had either osteopenia (31%) or osteoporosis (62%).

Male and female patients with abnormally low FN BMD had lower PRL levels (19.8 ± 19.4 vs 30.9 ± 52.0, $p < 0.001$), higher LH (16.7 ± 52.1 vs 7.9 ± 15.3, $p < 0.001$) and FSH (8.7 ± 23.9 vs 4.3 ± 9.4, $p < 0.001$), lower E2 levels (53.5 ± 28.4 vs 80.4 ± 41.2, $p < 0.05$), higher fT levels (3.8 ± 2.7 vs 2.5 ± 2.0, $p < 0.05$), lower TSH (2.5 ± 5.7 vs 2.9 ± 3.4, $p < 0.005$) and higher CTX (0.287 ± 0.128 vs 0.267 ± 0.073, $p < 0.01$) than those with normal FN BMD. 25OHD, intact PTH and OC did not significantly differ between the two groups. Patients on MMT have a high prevalence of low bone density, associated with increases in markers of bone resorption and altered neuroendocrine and sex hormonal axes. MMT patients should be considered at high risk for low bone mass and should be assessed accordingly. Therapy aimed at decreasing bone resorption or correcting the hormonal aberrations may be useful in preventing further bone loss.

The Relationship among the Bone Markers, Serum Homocystine and Bone Mineral Density in Korean Postmenopausal Women. D. Byun*, J. Mok*, J. Yoon*, Y. Kim*, H. Park*, C. Kim*, S. Kim*, K. Suh*, M. Yoo*. Endocrinology, Soonchunhyang University Hospital, Bucheon-Si, Republic of Korea.

There are many factors for the pathogenesis of osteoporosis. Considering the high prevalence of osteoporosis in homocysteinemia, abnormal homocysteine metabolism would contribute to the pathogensises of osteoporosis. We investigated the bone markers, serum homocyteine level and bone mineral density(BMD) in 33 Korean postmenopausal women. Serum homocysteine level was increasing associated with aging(r=0.35, p=0.04). Serum alkaline phosphatase level and urine N-telopeptide were correlated with lumbar BMD(r=-0.4, p=0.02 and r=-0.35, p=0.04). But serum homocysteine level was not correlated with bone markers and BMD. These results suggest that homocystein metabolism may be disturbed in the elderly postmenopausal women but the effect of homocysteine metabolism on bone is weak in Korean postmenopausal women.

Basal Metabolic Rate Is Related to Lumbar Bone Mineral Density and Body Composition in Pre- and Post-menopausal Women at Korea. S. K. Lee[1], H. J. Choi*[2], Y. C. Kim*[2], H. W. Baik*[3], H. J. Kim*[4], K. J. Ahn*[4], K. S. Park*[4]. [1]Biochemistry/Internal Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea, [2]Family Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea, [3]Biochemistry, Eulji University School of Medicine, Daejeon, Republic of Korea, [4]Internal Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea.

Body weight, fat mass or lean body mass are predictors of bone mineral density (BMD). However, few studies have examined relationships between BMD and basal metabolic rate (BMR) which might be related to body composition. In this study, we investigated the associations of body composition, BMR, lumbar BMD, and serum insulin levels in healthy, osteopenic or osteoporotic but otherwise normal, pre- (n=50; 43±7 years) and post-menopausal (n=60; 60±6 years) women at Korea. Body composition analysis and BMR were performed using the bioelectrical impedance analysis method (InBody, Biospace Co.). BMD (g/cm^2) was determined at the lumbar spine (L_1-L_4) for all subjects with dual-energy X-ray absorptiometry scanner (QDR-1000 plus). BMR was higher in pre-menopausal (1172±93 kcal) than that in post-menopausal (1120±87 kcal) women ($p<0.01$). In premenopausal women, BMR was related to age (r=-0.540, $p<0.01$), BMD (r=0.498, $p<0.01$), height (r=0.794, $p<0.01$), weight (r=0.572, $p<0.01$), and lean body mass (r=0.831 $p<0.01$), but not to fat mass and serum insulin level. In postmenopausal women, BMR was related to BMD (r=0.457, $p<0.01$), height (r=0.692, $p<0.01$), weight (r=0.902, $p<0.01$), fat mass (r=0.712, $p<0.01$), lean body mass (r=0.989, $p<0.01$), and serum insulin level (r=0.549, $p<0.01$), but not to age. In conclusion, BMR was related to lumbar BMD, and body composition in pre- and post-menopausal women. However, BMR was related to fat mass and serum insulin level only in postmenopausal women at Korea.

Acidification of the Osteoclastic Resorption Compartment Affects Osteoclast Survival and might be of Regulatory Importance for Coupling of Bone Resorption to Bone Formation. M. A. Karsdal[1], K. Henriksen[1], J. Gram[2], S. Schaller*[1], C. Christiansen[1], J. Bollerslev[3]. [1]Nordic Bioscience, Herlev, Denmark, [2]Ribe County Hospital, Esbjerg, Denmark, [3]National University Hospital, Oslo, Norway.

Systematic studies of osteopetrotic mutations in which osteoclast activity is attenuated and osteoblast function seems unaltered may contribute to our understanding of the coupling principle in bone remodelling.

Osteopetrotic patients suffering from deficient acidification of the osteoclastic resorption lacunae either by a defect in the chloride channel ClC-7 or the vATPase have decreased osteoclast resorption with normal osteoblast function in vivo, suggesting that the coupling principle is challenged. In contrast, Cathepsin K deficient patients suffer from both a decrease in bone resorption and bone formation. Interestingly, only the acidification-attenuated patients display an increased numbers of osteoclasts. We speculated that increased numbers of inactive osteoclasts were linked to attenuated acidification, however with unaltered signalling and stimulation of bone formation.

We investigated the effect of acidification on human osteoclast function and life span, and compared this to Cathepsin K inhibition. We used CD14 preparations of human osteoclasts cultured on bone slices with inhibitors of chloride channels (NS3696), the proton pump inhibitor bafilomycin and the Cathepsin K inhibitor E64 and investigated bone resorption and TRAP positive cell-number. We found that bafilomycin and NS3696 dose dependently inhibited acidification of the osteoclastic resorption compartment and bone resorption. Interestingly, the inhibition of acidification by bafilomycin but not cathepsin K inhibition augmented osteoclast survival, which resulted in a 125% increase in multinuclear osteoclasts compared to controls.

To investigate if attenuated acidification in vivo leads to decreased bone resorption with unaffected bone formation, we used the rat OVX model with once daily oral dosing of NS3696 at 50 mg/kg for 6 weeks starting directly after surgery. OVX induced bone loss and strength was inhibited by more than 50 %. As hypothesised, we observed a decrease in resorption 60% (DPYR), increased TRAP levels and no effect on bone formation evaluated by osteocalcin.

We speculate, that attenuated acidification inhibits dissolution of the inorganic phase of bone and results in an increased number of inactive osteoclasts that are responsible for the coupling to normal bone formation. Thus, we suggest that acidification is essential for normal bone remodelling and that attenuated acidification leads to uncoupling with decreased bone resorption and unaffected bone formation.

Treatment With The TNF-α Antagonist Infliximab Is Associated With Increased Markers Of Bone Synthesis In Patients With Crohn's Disease. M. T. Abreu*[1], L. Y. Kam*[1], E. A. Vasiliauskas*[1], P. Vora*[1], B. Hu*[2], H. Yang*[3], Y. Lin*[3], G. Keenan*[4], J. Gaiennie*[1], C. J. Landers*[1], S. R. Targan*[1], J. S. Adams[2]. [1]Gastroenterology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]Endocrinology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [3]Pediatrics, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [4]Centocor, Inc., Malvern, PA, USA.

Osteoporosis is a common complication affecting Crohn's disease patients. A principal reason for osteoporosis is glucocorticord use but may also include a detrimental effect of inflammatory cytokines including tumor necrosis factor-alpha (TNF-α). We hypothesized that treatment with the TNF-α antagonist infliximab in patients with active Crohn's disease would result in increased bone formation as measured by surrogate markers of bone turnover. Sera from 38 prospectively-enrolled, Crohn's disease patients were examined for levels of bone alkaline phosphatase (BAP), N-telopeptide of type I collagen (NTX), immunoreactive parathyroid hormone (iPTH), calcium, and inflammatory cytokines at baseline and four weeks postinfliximab infusion. Crohn's Disease Activity Index (CDAI; $p<0.001$) and Inflammatory Bowel Disease Questionnaire (IBDQ; $p<0.001$) results were significantly improved at four weeks. For the 22 patients who were taking glucocorticord at baseline examination, the mean decrease in steroid dose four weeks post-infusion was 7.9 mg ($p<0.001$) or 41% of the baseline dose. Patients steroid-free at baseline remained steroid-free at week 4. Infliximab wass associated with a significant increase in BAP ($p=0.01$); no corresponding increase ($p=0.8$) in NTX was observed. When patients were stratified by baseline steroid use, the increase in BAP was greatest in patients who were taking steroids at baseline ($p=0.05$). In summary, treatment with infliximab was associated with increased markers of bone formation (BAP) without an increase in bone resorption (NTX). This effect may be due to a beneficial effect of TNF-α blockade on bone turnover, a beneficial effect on Crohn's disease activity resulting in decreased glucocorticord dose or both. Longer-term studies should address the effect of infliximab on bone mineral density.

Possible Pathogenic Mechanisms in a Mouse Model of Type II Diabetes Mellitus with Severe Osteopenia. S. Yakar[1], W. G. Beamer[2], K. M. Delahunty*[2], C. J. Rosen[2], D. LeRoith[1]. [1]Diabetes Branch, National Institutes of Health, Bethesda, MD, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA.

Several lines of evidence suggest that osteopenia is an important consequence of insulin resistant type 2 diabetes mellitus (DM) although the incidence and pathogenesis of this syndrome have not been clarified. In fact, some studies report no correlation between BMD and HbA1c levels whereas others show a negative relation between DM duration and BMD. In the current study we examined the effects of insulin resistance on BMD in a mouse model of type-II DM. MKR mice express a dominant negative (DN) form of the human IGF-IR under the control of the muscle creatine kinase promoter specifically in muscle on a FVB/N (WT) background. Since the DN IGF-IR forms heterodimers with the endogenous monomers of both the IGF-I and insulin receptors in skeletal muscle, it inhibits the activation of both pathways leading to significant insulin resistance in skeletal muscle and eventually type II diabetes. At 3 weeks of age MKR mice display hyperinsulinemia and dyslipidemia with impaired glucose tolerance. These mice have slightly shorter femurs and weigh significantly less than WT. However, by 8 weeks of age MKR exhibit significant catch up growth such that femur length is identical to WT, and body weight is only 10% lower ($p<0.05$) than WT. At this time MKR demonstrate severe insulin resistance with marked hyperglycemia and lipotoxicity while muscle weight is slightly but not significantly less than WT. BMD measured by pQCT at the pre-diabetic stage (i.e. 3 wk) revealed no significant differences in cortical thickness, periosteal or endosteal circumference, cortical volume or cortical density between MKR and WT($p<0.30$). However, at the frank diabetic stage (i.e. 8 wk), MKR mice display severe osteopenia: results represented as mean±SD (See Table). Taken together these data suggest that type II insulin resistant DM is associated with significant osteopenia. The pathogenic mechanisms responsible for low bone mass in DM include either lipotoxicity and/or glucose toxicity. Further studies are need to delineate the mechanism(s) responsible for impaired peak BMD in DM and to assess whether reduction in hyperglycemia or lipotoxicity rescue the bone phenotype.

Strain -8 week N	FemBMD mg/cc	Cortical thick-mm	Perios Circum-mm

Systemic Inflammatory Mediators in Calcium and Phosphate homeostasis. M. Pazianas[1], M. Hise*[2], C. Compher*[3], S. Benedict*[4], J. C. Brown*[4], B. Kinosian*[1]. [1]Medicine, Univ of Pennsylvania, Philadelphia, PA, USA, [2]Department of Dietetics and Nutrition, University of Kansas Medical Center, Kansas City, KS, USA, [3]Penn Nursing, Univ of Pennsylvania, Philadelphia, PA, USA, [4]Department of Molecular Biosciences, Univ of Kansas, Lawrence, KS, USA.

Inflammatory bone resorbing cytokines have been implicated in the development of osteoporosis. In patients with home parenteral nutrition (HPN) the inflammatory process could be affected by the reduced gut-associated lymphoid tissue or by the presence of the catheter used for HPN administration.

We studied: 1) systemic inflammatory mediators such as C-reactive protein (CRP), tumor necrosis factor alpha (TNF-α), soluble TNF-α receptor p55 (sTNFR-I) and p-75 (sTNFR-II), and interleukin-6 (IL-6); and T cell function ($CD4^+$and $CD8^+$ lymphocytes and phytohemagglutinin (PHA)-induced T-lymphocyte proliferation) , 2) biochemical bone profile: serum Calcium (Ca), Phosphorus (Pi) Parathyroid hormone (PTH), Alkaline Phosphatase, 25(OH) D and $1,25(OH)_2$ D and 3) bone mineral density (BMD) of the spine and the hip in 9 well nourished , clinically stable patients receiving HPN for >2 years.

Inflammatory mediators IL-6, TNFa and TNFa -RII were significantly correlated with PTH, Pi and Ca; T cell function was negatively correlated with spinal BMD (Table 1). However, none of the systemic inflammatory mediators or T cell function correlated significantly with $1,25(OH)_2$ D or 25(OH) D.

Systemic inflammatory mediators could participate in Ca and Pi homeostasis and chronic inflammation might be considered an additional risk factor for the development of metabolic bone disease.

		Correlation	P
IL-6	PTH	0.748	0.033
IL-6	PO4	-0.751	0.032
TNF-α	Ca	-0.754	0.019
TNFRII	Ca	-0.767	0.016
CD4 (%)	Ca	0.852	0.004
CD4/CD8 (%)	Ca	-0.850	0.007

Severity of Liver Disease Does Not Predict Low Bone Mineral Density in Primary Sclerosing Cholangitis. M. S. Campbell*[1], T. Faust*[1], G. R. Lichtenstein*[1], A. D. Rhim*[1], M. Pazianas[2]. [1]Gastroenterology, Medicine, Univ of Pennsylvania, Philadelphia, PA, USA, [2]Medicine, Univ of Pennsylvania, Philadelphia, PA, USA.

Osteopenia is a complication of chronic cholestatic liver disease. It has been suggested that in primary sclerosing cholangitis (PSC), advanced disease stage may predict advanced bone pathology.

This is a retrospective cross-sectional study. We identified 30 PSC patients who had a DXA (dual energy x-ray absorptiometry) scan. Severity of liver disease was assessed using MELD, Modified Mayo Risk score, presence on the liver transplantation list, and history of hepatic decompensation.

From the 30 patients we studied, nine patients (30%) were osteopenic (T-score between -1 and -2.5), and 1 patient was osteoporotic (T-score less than -2.5). Severity of liver disease was no different between patients with and without osteopenia. BMDs were not different between patients listed or not listed for liver transplantation ($p = 0.49$). Univariate regression showed that MELD ($p = 0.99$) and the Modified Mayo Risk Score ($p = 0.25$) did not predict BMD. A satisfactory multivariate model predicting BMD cannot be constructed from our data.

Our study shows that low BMD cannot be predicted by the severity of liver disease in PSC. The decision to order a DXA scan for a patient with PSC should not be influenced by the severity of liver disease.

A Single i.v. Injection of Equipotent Doses of Alendronate, Risedronate, Ibandronate and Zoledronic Acid Exerts a Bone Protective Effect of Similar Magnitude and Duration in Ovariectomized Rats. J. A. Gasser, P. Ingold*, J. Green. Bone Metabolism Unit, Novartis Institutes for Biomedical Research, Basel, Switzerland.

There have been suggestions of differences in the terminal half-life between risedronate and alendronate with regard to the duration of antiresorptive action and their elimination from bone (Mitchell et al, Pharm Res 128:166-70, 2001). To address this question we administered the 4 bisphosphonates (BPs) alendronate (AL), risedronate (RI), ibandronate (IB) and zoledronic acid (ZA) given as a single intravenous dose at low, intermediate and high doses to skeletally mature, eight-month old ovariectomized virgin Wistar rats.

The duration of the bone protective effect of the single dose was monitored non-invasively at 4-weekly intervals for 24 weeks at the proximal tibial metaphysis by pQCT (XCT Research SA, cancellous BMD, cortical thickness) and by *in vivo* microCT (vivaCT40, trabecular architecture).

At the low dose, the bone protective effect of 4μg/kg RI, 2μg/kg IB and 0.8μg/kg ZA was significant at 4 and 8 weeks only. With the intermediate doses (AL 40μg/kg, RI 20μg/kg, IB 10μg/kg and ZA 4μg/kg) bone loss was prevented for up to 8 weeks but cancellous BMD, cortical thickness and trabecular bone volume declined thereafter at the same rate regardless of the BP used. With the high dose (AL 200μg/kg, RI 100μg/kg, IB 50μg/kg and ZA 20μg/kg) full protection was achieved for 16 weeks but bone loss occurred thereafter at a similar rate with all 4 compounds.

These results indicate that, after adjustment of the dose to account for the differences in potency (rel. potency versus AL: RI 2x, IB 4x, ZA 10x), the four bisphosphonates show identical duration of action in vivo after a single i.v. dose. Since the antiresorptive effect of the nitrogen-containing BPs is based on their uptake into the mineral phase of bone and their ability to reduce osteoclast activity by inhibiting protein prenylation, our results suggest that the kinetics of their removal from the matrix do not differ between BPs when equipotent doses are directly compared in vivo under the same dosing regimen.

Use of Differential BMD Thresholds to Assure Adequate Fracture Risk for an International Trial of Zoledronic Acid. E. M. Lau[1], J. A. Cauley[2], J. Caminis[3], T. Rosario-Jansen[3], J. Zhang*[3], S. Farneth*[4], D. M. Black[4]. [1]Prince of Wales Hosp., Shatin, N.T., Hong Kong Special Administrative Region of China, [2]U of Pitt, Pitt, PA, USA, [3]Novartis Pharma, East Hanover, NJ, USA, [4]U of CA, SF, CA, USA.

The HORIZON-PFT is a 3-year, international randomized trial evaluating the effect of once-yearly zoledronic acid on fractures. The two main endpoints are hip and vertebral fractures. Entry criteria include a femoral neck BMD t-score ≤ -2.5, or between -1.5 and -2.5 in the presence of at least 1 vertebral deformity. The design assumed a risk of hip fracture across the entire study of at least 1.8%. Assuring consistent risk across the international cohort to meet that assumption was a priority.

Data published from the Asia Osteoporosis Study revealed that hip fracture risk in Asia is significantly lower than in the US/Europe, despite lower mean BMD. For example, the fracture rate in Hong Kong for women ages 80-84 is about 84% of that in the US; in Thailand it is only 53%. Since both BMD means and hip fracture risk are lower in Asia than in the US and Europe, a lower BMD cutpoint for Asian centers (China, Hong Kong, Korea, Taiwan and Thailand) was necessary to assure adequate hip fracture risk.

For simplicity, we chose to find single cutpoint that could be used in all Asian centers. Reference data for Hong Kong showed a peak mean femoral neck BMD (Hologic) of 0.77 g/cm^2 with a SD of 0.11 g/cm^2. Using this normative data yielded cutpoints for T-scores of -2.5 and -1.5 SD of 0.495 and 0.605 g/cm^2, respectively. These cutpoints were converted to Lunar and Norland values to yield the following BMD entry criterion for Asian sites:

	Non-Asian Countries			Asian Countries		
T score	Hologic BMD cutoff (g/cm^2)	Lunar BMD cutoff (g/cm^2)	Norland BMD cutoff (g/cm^2)	Hologic BMD cutoff (g/cm^2)	Lunar BMD cutoff (g/cm^2)	Norland BMD cutoff (g/cm^2)
T = -1.5	0.683	0.836	0.767	0.605	0.746	0.681
T = -2.5	0.572	0.707	0.644	0.495	0.618	0.559

The study is now fully recruited. The lower BMD thresholds increased the screen failure rate somewhat in Asia where the proportion of screenees ineligible for the study was 67% compared to 58% study-wide. Once the trial is completed in 2006 we will be able to ascertain whether this strategy resulted in a consistent risk of hip fracture across regions.

Significant Reduction of Bone Resorption with Risedronate Treatment in as Soon as One Week. R. Lindsay[1], S. Boonen[2], D. Burgio*[3], T. Johnson*[3], A. Grauer[3], P. Miller*[4]. [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Leuven University Center for Metabolic Bone Disease and Division of Geriatric Medicine, Leuven, Belgium, [3]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [4]Colorado Center for Bone Research, Lakewood, CO, USA.

Risedronate has been shown to reduce vertebral and non-vertebral fractures within 6 months and to preserve parameters of bone micro architecture in postmenopausal women. The objective of this analysis was to monitor the effect of risedronate (RIS) (5mg daily and 35 mg once weekly) on urinary C-telopeptide (u-CTX) over 4 weeks of treatment in healthy postmenopausal women versus placebo. Women were randomised to receive RIS 5 mg/daily (n = 29), RIS 35 mg/weekly (n = 26) or placebo (n = 32). After 4 weeks of treatment, risedronate reduced U-CTX by 53% for the 5mg daily dose and by 49% for 35mg weekly dose compared to baseline (p< 0.001 vs. baseline and vs. placebo). The difference in reduction of turnover was highly significant vs. placebo already at the first follow up measurement at week one for both 5mg RIS (-29.8%, CI -17 to -42%, p<0.0001) and 35mg Ris (-25.1%, CI -14 to -36%, p<0.001) (Fig. 1). Similar changes were observed for serum CTX. Deterioration of micro architecture can be caused by high or unbalanced bone turnover. Risedronate significantly reduces bone turnover as soon as one week after treatment initiation. This may help to explain the preservation of micro architecture and the rapid reduction in vertebral and non-vertebral fractures, experienced during Risedronate treatment.

Comparison of Risedronate, Calcitonin and Active Vitamin D Treatments in Postmenopausal Osteoporosis. N. Ota, Y. Shibata*, H. Ito*. Orthopedics, Nippon medical school, Tokyo, Japan.

The present study was planned to assess the efficacy of risedronate, calcitonin and active vitamin D treatments on bone mineral density (BMD), bone resorption, and chronic low back pain . A total of 121 postmenopausal women with lumbar spine BMD 2 SD or more below the young adult mean and without any fresh vertebral fractures in lumbar spine were randomly assigned to one of the four groups. 35 patients orally took risedronate 2.5 mg daily (risedronate group), 30 patients were injected with eel calcitonin 20 U intramuscularly once a week (calcitonin group), 25 patients received both risedronate and calcitonin (risedronate-calcitonin group), 20 patients orally received active vitamin D (1-OH-D3) 1 microgram daily (vitamin D group) for four months respectively. BMD of the second metacarpal bone was measured with the digital image processing, urinary cross-linked N-terminal telopeptides of type I collagen (NTx) level was measured with enzyme-linked immunosorbent assay and low back pain was evaluated with a visual analogue scale (VAS). There were no significant differences among these groups in baseline characteristics including age, BMD, NTx and VAS. Low back pain was significantly improved in the risedronate, the calcitonin, the risedronate-calcitonin groups, but not in the vitamin D group. Urinary NTx level was remarkably reduced in the risedronate and the risedronate-calcitonin groups, but not in the vitamin D and the calcitonin groups. BMD was increased in the risedronate and the risedronate-calcitonin groups, representing no significant difference. No serious side-effects were recognized in any of the patients during the follow-up. These results suggest that risedronate and calcitonin have proven to have the same efficacy on chronic low back pain, which does not derive from vertebral fractures.

Five Year Risedronate Therapy Normalizes Mineralization: Synchrotron Radiation Micro-Computed Tomography Study of Sequential Triple Biopsies. B. Borah*[1], E. L. Ritman*[2], T. E. Dufresne*[1], S. Liu*[1], P. A. Chmielewski*[1], S. M. Jorgensen*[2], D. A. Reyes*[2], R. T. Turner*[2], R. J. Phipps[1], M. D. Manhart[1], J. D. Sibonga*[2]. [1]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [2]Mayo Clinic College of Medicine, Rochester, MN, USA.

There is a speculation that bisphosphonates cause oversuppression of bone turnover leading to hypermineralization of bone. The goal of this study was to examine the long term effect of risedronate therapy on bone quality, and specifically on the degree of mineralization. The degree of mineralization was measured via Synchrotron μCT in iliac crest bone biopsies taken sequentially at 0, 3 and 5 years from the same patient treated with risedronate (n=7), and in iliac crest biopsies taken from young healthy pre-menopausal women (n=7; mean age 36 years). The high-resolution (4 μm) images obtained from the Synchrotron μCT allowed the detection of small changes in density (g/cc of hydroxyapatite) across trabecular elements. We reported earlier that 3 years of 5 mg daily oral risedronate increased the mean mineralization by 5.1% (p<0.05). After 5 years of continuous treatment with 5 mg daily risedronate, the mean mineralization was significantly higher compared to baseline (p<0.05), but was maintained at the 3 year level, and was comparable to that of young premenopausal healthy women (Figure 1). The mineralization changes in lower and higher mineralization regions were measured independently. The volume ratio of lower to higher mineralized bone was reduced from about 34% at baseline to about 9 - 16% after 3 and 5 year of risedronate treatment (Figure 2) and is consistent with the reduction of bone turnover markers. The ratio of lower to higher mineralized bone in treated patients was comparable to the ratio observed for the young normal group (about 12%, Figure 2). In conclusion, these unique data from the iliac crest biopsies suggest that long term risedronate treatment did not cause hypermineralization and reduced turnover to levels comparable to those found in normal healthy premenopausal women.

SU437

Effect of Alendronate in a Murine Model of Estrogen Deficiency. M. A. Gentile*[1], S. Luell*[2], P. Masarachia[1], E. Carballo-Jane*[2], D. B. Kimmel[1]. [1]Bone Biology and Osteoporosis, Merck Research Laboratories, West Point, PA, USA, [2]Pharmacology, Merck Research Laboratories, Rahway, NJ, USA.

The ovariectomized (OVX) rat is the most frequently-used *in vivo* model for testing agents intended to prevent estrogen deficiency bone loss. However, when investigating the relationship of existing agents to genetic alterations in bone-active enzymes or receptors, mice are often more appropriate. We examined the dose response relationship for alendronate (ALN) to prevent OVX-induced bone loss in adult mice.

Female Balb/c mice aged 11 months, weighing ~25g were divided into groups of 11, OVXd, and begun immediately on 2X/wk subcutaneous (SC) ALN (0, 0.03, 0.1, 0.3, or 1 mg/kg/wk), divided in two equal doses/wk) for eleven weeks. A Sham-OVX group was included.

At necropsy, lumbar vertebrae and femurs were placed in 70% ethanol. Bone mineral density (BMD, mg/cm^2) of the femur was measured by pDXA (Norland Corp., Ft. Atkinson, WI USA). Data were analyzed by Kruskal-Wallis non-parametric ANOVA and Student-Neuman Keuls post-hoc testing. Data for distal femur (DFBMD), central femur (CFBMD), and lumbar vertebrae 2-4 (LVBMD) are reported.

Significant OVX-induced bone loss was not detected at any site. Nonetheless, BMD was higher than in untreated OVX rats with ALN in all three sites. DFBMD, a measurement of the bone site in mice where trabecular bone is best evaluated by DXA, was at or above Sham levels in groups given at least 0.1 mg/kg/wk ALN, testing highly significant at 0.3mg/kg/wk. Other sites, with lower portions of trabecular bone, displayed a similar though less marked response.

The SC ALN dose that completely inhibits bone loss in the OVX mouse appears to be 0.1-0.3mg/kg/wk. For comparison, the SC ALN dose that behaves similarly in the OVX rat is 0.03mg/kg/wk. The osteoporosis treatment dose for human (SC equivalent) is 0.07mg/kg/wk. These data suggest that the SC ALN dose that fully inhibits bone loss in the OVX mouse is ~five-fold higher than in the rat. Past experiments with six-month-old Balb/c, C57BL6, and Swiss-Webster mice in our laboratory have consistently shown estrogen-deficiency bone loss in the distal femur by eight weeks post-OVX. These Balb/c mice, aged 11 months at OVX, may already have experienced significant age-related trabecular bone loss that diminished the amount of bone available to be lost post-OVX.

Risedronate 30mg/day Exhibits Renal & Hepatic Safety Over Wide Range of Serum Steady State Concentrations. P. Miller[1], S. Magowan[2], I. Barton*[3], J. Brown[4], E. Siris[5]. [1]Colorado Center for Bone Research, Lakewood, CO, USA, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [3]Procter & Gamble Pharmaceuticals, Egham, United Kingdom, [4]Le Centre Hospitalier Universitaire, Sainte-Foy, PQ, Canada, [5]Columbia University, New York, NY, USA.

Following oral administration, risedronate is primarily eliminated via the kidneys. As such, risedronate serum concentrations are inversely related to renal function (i.e. creatinine clearance). Serum risedronate concentration is also inversely proportional to the volume of distribution (6.3L/kg). This analysis incorporates both these variables to investigate the effect of increasing serum risedronate concentrations on renal and hepatic function in patients with Paget's disease. 276 male and female patients, enrolled in multiple trials for Paget's disease of bone were analyzed after administration of 30 mg/day of risedronate for 2-6 months. Creatinine clearance was estimated using the Cockcroft-Gault methodology. Predicted risedronate steady state concentrations were estimated based on creatinine clearance and the observed body weight using a standard equation. The lowest serum risedronate concentration (i.e. patient with the largest creatinine clearance value and volume of distribution) was arbitrarily assigned a value of 1. The estimated serum steady state concentrations ranged from 1 to a maximum ratio of 13.2. Patients with x13.2 serum steady state concentrations exhibited no change in renal and/or hepatic function from baseline. No correlations were observed between serum steady state concentration and percent change from baseline for serum creatinine, (R^2= 0.02); alanine aminotransferase (R^2<0.01), and aspartate aminotransferase (R^2= 0.001) across the entire range of serum risedronate concentrations. Based on multiple clinical trial experience, this analysis shows that risedronate 30 mg/day exhibits renal and hepatic safety over a wide spectrum of serum steady state concentrations.

Effect of Risedronate Therapy on Serum Osteoprotegerin Levels in Patients with Postmenopausal Osteoporosis. K. H. Baek*, H. J. Tae*, J. H. Han, M. I. Kang, W. Y. Lee*, K. W. Oh*, K. W. Lee*, C. S. Cho*. Internal Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Bisphophonates are analogs of pyrophosphate with a potent inhibitory effect on bone resorption. They are taken up by osteoclasts and inhibit farnesyl diphosphate synthase, which is essential for osteoclast activity and survival. In addition to the direct effects of bisphosphonates on osteoclasts, there are evidences that these compounds also act on the osteoclasts indirectly through the osteoblasts. In bone remodeling process, RANKL is essential for osteoclasts formation and activation, whereas osteoprotegerin (OPG) neutralizes RANKL. Although OPG is capable of inhibiting bone resorption in vivo, whether bisphosphonates regulate the production of OPG has remained unclear. In this study, we assessed the effects of the risedronate therapy on serum OPG levels in randomized prospective trial. We also investigated the associations of serum OPG levels with various indices of bone metabolism. 111 women (65.8±3.7 years) with postmenopausal osteoporosis were treated with placebo or risedronate (5mg daily) for 6 months and all received 1000mg of calcium and 250 IU of vitamin D. Bone mineral density of lumbar spine were measured before, and 6 months after the treatment. The biochemical markers of bone turnover (sCTx, NTx/Cr and sALP) were measured before the treatment and 1, 3 and 6 months after the treatment. The serum OPG levels were measured before, 1 and 6 months after the treatment. There were negative correlations between the baseline OPG levels and the baseline sALP or sCTx levels(r=-0.22, p<0.05; r=-0.21, p<0.05). A significant correlation was also found between the OPG and lumbar spine bone mineral density at baseline(r=0.26, p<0.05). The women treated risedronate had significant increases in bone mineral density at lumbar spine. Risedronate reduced biochemical markers of bone resorption and bone formation by approximately 50 %. Serum OPG levels were not changed during the treatment period in both risedronate and placebo group. However, in subgroup who showed higher OPG levels initially, OPG levels significantly decreased after risedronate therapy. In conclusion, bisphophonate therapy cause low bone turnover state and this may lead to downregulation of OPG.

The Effect of Risedronate to Prevent Bone Loss in Men under Androgen-Deprivation Therapy for Prostate Cancer. K. Ishizaka*[1], T. Machida*[1], Z. Ozeki*[1], S. Kobayashi*[1], Y. Mizuno[2], S. Masuda*[3], T. Kamai*[3], K. Arai*[3], M. Honda*[3], K. Yoshida*[3]. [1]Urology, Kanto Central Hospital, Tokyo, Japan, [2]Medicine, Kanto Central Hospital, Tokyo, Japan, [3]Urology, Dokkyo University School of Medicine, Tochigi, Japan.

Androgen-deprivation therapy (ADT) decreases bone mineral density (BMD) and increases the risk of fracture in men with prostate cancer. Bisphosphonate administration is possible treatment modality for male osteoporosis, but the effectiveness on bone loss during ADT has not been established. The clinical benefit of risedronate, a highly potent third generation oral bisphosphonate that is approved for treatment of osteoporosis has been studied. 61 prostate cancer patients with a mean age of 79 ± 6 (± SD) who had been treated with ADT for 42 ± 29 months were enrolled in this study with written informed consent. Patients under ADT were treated with oral administration of 2.5 mg risedronate every day for 6 months. The subjects were not treated with supplemental calcium or vitamin D. Bone mineral density (BMD) was measured in femoral neck, lumbar spine and radius UD by dual energy x-ray absorptiometry (DEXA) with EXPERT-XL Imaging Densitometer (LUNAR Co., Madison, WI, USA). The percent change of BMD from baseline to the end of the study was calculated for primary efficacy variable. Urinary N-telopeptide was examined as the bone resorption marker. T-score of BMD before treatment was -1.5 ± 1.2, -1.1 ± 1.8 and -2.6 ± 2.0 in femoral neck, lumbar spine and radius UD, respectively. BMD was kept stable in femoral neck and in radius UD as shown by the percent change of -0.1 ± 4.8 % (95 % CI: -1.45 - 1.78) and 1.1 ± 7.3 % (-1.30 - 3.48), respectively, by the treatment of risedronate. BMD in lumbar spine was significantly increased from the baseline of 1069 ± 488 mg / cm^2 to 1112 ± 497 mg / cm^2 (P<0.001 by t-test) with the percent change of 4.9 ± 8.9 % (95 % CI: 2.32 - 7.39). Urinary N-telopeptide concentration was decreased from the baseline of 64.9 ± 42.2 nmol BCE / mmol Cr to 37.6 ± 22.4 nmol BCE / mmol Cr (p<0.001) after the treatment of risedronate for 3 months. No significant adverse effect was observed except for 1 patient who quitted the treatment because of appetite loss. Risedronate treatment is safe and effective. Longer follow up is desired.

Change in Bone Mineral Density Is Predictive for Fracture Risk Reduction with Ibandronate: Further Insights From a Phase III Study of Intravenous Ibandronate Injection. P. D. Miller[1], S. Epstein[2], H. Huss*[3], K. M. Wilson*[4], R. C. Schimmer[4], R. Wasnich*[5]. [1]Colorado Center for Bone Research, Lakewood, CO, USA, [2]Mt Sinai Medical Center, New York, NY, USA, [3]., Leverkusen, Germany, [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [5]Radiant Research, Honolulu, HI, USA.

The relationship between BMD change and fracture risk with bisphosphonates is yet to be fully elucidated. Previously, we examined this relationship with oral daily and intermittent ibandronate (Boniva®) in BONE.[1,2] Logistic regression demonstrated that a 1% increase in total hip (TH) BMD at years 2 and 3 was predictive for a 9.8% (p=0.0026) and 7.9% (p=0.0084) vertebral fracture risk reduction (VF-RR), respectively, at year 3. To examine this relationship further, we analyzed data from a phase III study of intermittent i.v. ibandronate injections. Unlike BONE, which reported lumbar spine (LS) BMD changes approaching the top of the dose response curve for VF-RR, this study reported suboptimal increases in LS BMD, due to suboptimal doses for the between-dose interval.[3] The relationship between TH and LS BMD change and the rate of new VF at year 3 was explored using a moving averages procedure. The logistic regression model employed in BONE was used to quantify the relationship between TH and LS BMD increase and VF-RR (as prospectively specified in the shared data analysis plan). The moving averages analysis demonstrated a reduction in the percentage of patients with VF with increasing BMD. For example, at the TH, ~16% of patients with a BMD change of -3% experienced a VF, versus ~5% of patients with a BMD change of >+4%. Logistic regression revealed that increase in TH BMD at years 1, 2 and 3 was significantly predictive for VF-RR at year 3 (**Table**). Notably, estimates for this parameter were generally higher than those reported in BONE. Increase in LS BMD at years 2 and 3 was also significantly predictive for VF-RR at year 3 (**Table**). These findings further corroborate that ibandronate-related increases in TH and LS BMD are predictive for VF-RR. The variation in the relationship for the current and BONE analyses is likely the result of the disparity in the positioning of the respective BMD changes on the dose response curve for VF-RR with ibandronate.

Effect of Neridronate and Zoledronic Acid on Bone Turnover in Osteopenic Post-menopausal Patients and in Women Affected by Primary Iperpathyroidim. P. Filipponi[1], S. Cristallini*[1], G. Policani*[1], M. Schifini*[1], B. Frediani[2]. [1]Internal Medicine, U.O. Medicina - Ospedale di Umbertide, Perugia, Italy, [2]Rheumatology, University of Siena, Siena, Italy.

We report preliminary data on the effects of a single intravenous infusion of 2 nitrogen containing bisphosphonates (BPs), Neridronate (Ner, Abiogen Pharma, 100 mg) and Zoledronic Acid (Zol, Zometa, Novartis, 4 mg) on bone turnover in 27 post-menopausal osteopenic patients (L1-4 BMD < -1 SD, T-score; Ner = 15; Zol = 12) and in 13 women affected by primary iper-PTH due to parathyroid adenoma (Ner = 6; Zol =7). Bone turnover was assessed by serum bone specific alkaline phosphatase (bAP) and serum Collagen C-terminal Telopeptide (CTx) during a 6-month follow-up.

In iper-PTH both BPs caused a reduction in bone turnover with a nadir between 7 an 15 days. % change from baseline in bAp and CTx (MEAN±SE) was not statistically different between Ner (bAp = -33.3±6.7; CTx = -40.1±5.4) and Zol (bAp = -34.8±9.2; CTx = -44.3±5.4). After 6 months bone turnover returned to baseline values in both Ner (bAp = 4.9±10.4; CTx = -6.2±7.4) and Zol (bAp = -11.3±7.3; CTx = -0.3±7.5) patients.

In post-menopausal women the suppressive effect of Zol was still evident after 6 months (bAp = -37.4±8.6; CTx = -40,6±4.3), when the % reduction in bone turnover was not statistically different from that observed at the nadir, which occurred between 15 and 30 days (bAp = -42.5±4.7; CTx = -45.3±6.3). In the Ner treated postmenopausal women the suppression of bone turnover at the nadir was similar to that observed after Zol; at 6 months, on the contrary, both bAp and CTx have been returned to baseline values.

We conclude that the effect of Zol was still different from that of Ner in subjects where the bone remodeling was not influenced by drivers physiologically not involved in the control of bone biology.

The mechanism/s responsible for the long lasting suppressive effect of Zol in postmenopausal osteopenic women, but not in iper-PTH, requires further investigation.

Zoledronic Acid Treatment does not Delay The Process of Endochondral Ossification in a Rat Fracture Model. M. M. McDonald*, S. K. Dulai*, D. G. Little*. Orthopaedic Research, The Children's Hospital Westmead, Sydney, Australia.

The process of endochondral ossification of soft callus during fracture repair resembles that of the growth plate. Osteoclasts can contribute to this process, however their role in the invasion and removal of chondrocytes may be redundant. We speculated that while osteoclasts are required for bone remodeling, they may be unnecessary for soft callus removal during fracture repair. We tested this in a closed rat fracture model treated with zoledronic acid (ZA) to specifically target osteoclastic activity.

Three treatment groups were analyzed (n=90): weekly saline (Saline), weekly ZA 0.005mg/kg (Weekly ZA), and a single bolus dose of 0.025mg/kg ZA (Bolus ZA). All doses commenced at 1 week post-op. 10 per group were euthanized at 2, 4 and 6 weeks post-op and subject to analysis by x-ray, QCT scans, histology and histomorphometry.

Plain radiographs revealed no difference in fracture union between groups. At 4 weeks, radiographic fracture union was present in 10% of all samples. By 6 weeks, fracture union was complete in 70% of both Saline and Weekly ZA samples and 90% of Bolus ZA samples.

QCT at 2 weeks showed BMC was increased by 16% in Weekly ZA and 19% in Bolus ZA over Saline ($p<0.01$). By 4 weeks, BMC was increased by 57% and 33%, and at 6 weeks by 80% and 64% respectively ($p<0.01$). Callus volume did not differ between treatment groups at 2 or 4 weeks but was 35% higher for Weekly ZA and 28% higher for Bolus ZA at 6 weeks ($p<0.05$).

At 2 weeks, histomorphometry of the callus showed 8%, 11% and 9% cartilage content for Saline, Weekly ZA and Bolus ZA respectively. At 4 weeks this was reduced to 2% in all groups and by 6 weeks no cartilaginous callus remained. Thus, the percentage of soft callus showed no significant difference at each time point, indicating that ZA treatment did not affect ossification or removal of chondrocytes. However, the ZA groups did show an increase in retention of primitive hard callus, indicating delayed remodeling.

ZA did not delay the process of cartilage removal in endochondral ossification, supporting our hypothesis that osteoclasts are not an absolute requirement for soft callus removal. Moreover, at early time points, ZA treatment led to an increase in callus bone mineral content without an increase in callus size. This may be due to a reduction in the resorption of both primitive hard callus and appositional lamellar bone, thereby providing a scaffold that may be advantageous in some clinical situations. By 6 weeks, there was an increase in callus volume due to ZA treatment. This study indicates that ZA treatment during fracture repair does not delay the phases of endochondral ossification prior to bone remodeling, thus supporting the clinical safety of ZA during fracture repair.

OP-1 and Zoledronic Acid Act Synergistically to Increase Bone Volume and Strength in a Rat Critical Defect Model. M. M. McDonald*, R. Bransford*, C. Godfrey*, N. Amanat*, D. G. Little*. Orthopaedic Research, The Children's Hospital Westmead, Sydney, Australia.

BMPs induce osteoblast differentiation and bone production. However, BMPs also directly up-regulate osteoclasts through BMP receptors and indirectly via osteoblasts through RANK / RANKL. In some clinical situations this may produce high bone turnover, which could limit the volume of callus produced, or lead to over-remodeled callus in stress-shielded situations. Unwanted host bone resorption may also occur[i] . While this resorption can be controlled by bisphosphonate administration in closed defects[2], we hypothesized that bisphosphonates should act synergistically with BMPs in an uncontained defect to produce increased callus over BMP alone.

A rat 6mm critical size defect model was utilized. 15mg of bovine collagen and carboxymethylcellulose carrier, or carrier containing 50µg OP-1 was placed in the defects. Groups consisted of carrier alone, carrier plus systemic zoledronic acid (ZA), OP-1 alone and OP-1 with ZA either given at surgery or 2 weeks post surgery. ZA 0.1 mg/kg was given as a single parenteral dose. Radiographs, QCT, 3-point bend and histomorphometric analyses were performed.

Carrier alone and carrier ZA groups had not united by 8 weeks. Radiological union occurred in all OP-1 groups. OP-1/ZA group BMC increased in the 6 mm defect by 45% in the ZA at surgery group and 96% in the OP-1/ZA at 2 weeks group over OP-1 alone ($p<0.01$). Callus volume increased by 45% in the OP-1/ZA at surgery group and 86% in the OP-1/ZA at 2 weeks group over OP-1 alone ($p<0.01$). BV/TV was increased 72% in the OP-1/ZA at surgery group and 82% in the OP-1/ZA at 2 weeks group over OP-1 alone ($p<0.01$). This was due to a significant increase in trabecular number of 81% and 106% in OP-1/ZA groups over OP-1 alone ($p<0.01$). The increases in callus volume in the ZA at 2 weeks group translated to increases in strength of 107% and stiffness of 148% ($P<0.05$).

Zoledronic acid significantly increased the mineral content, volume and strength of OP-1 mediated callus in this rat femoral critical size defect at an 8-week outcome time-point. Modulation of the high bone turnover state induced by pharmacotherapeutic doses of OP-1 may optimize the amount and mineral content of callus produced, which could be of clinical benefit in obtaining initial bone union.

Efficacy of Risedronate Among Women using Gastric Acid Inhibitors and those at High Risk for Gastrointestinal Side Effects. K. E. Hansen[1], T. D. Johnson*[2], M. V. Gillen*[2], A. Grauer[2]. [1]Medicine, University of Wisconsin, Madison, WI, USA, [2]Proctor and Gamble Pharmaceuticals, Mason, OH, USA.

Women with postmenopausal osteoporosis commonly use proton pump inhibitors (PPI) and H_2-Blockers (H_2B) causing achlorhydria, which could potentially interfere with absorption of bisphosphonates. In addition, patients using PPI/H_2B, NSAIDs, and those with preexisting gastrointestinal (GI) disease are at increased risk of upper GI adverse events. These adverse events may affect compliance and thereby limit clinical effectiveness. Risedronate phase III clinical trials did not exclude such patients, providing an opportunity to examine the anti-fracture efficacy of risedronate among women reporting PPI/H_2B use, and among women at high risk for GI side effects.

We analyzed subgroups of women from the risedronate HIP and VERT phase III studies. Fracture rates were compared for women randomized to placebo, and those randomized to 5 mg risedronate who reported PPI/H_2B use at study entry. Anti-fracture efficacy was also compared in like manner for women with preexisting GI disease, and for women reporting NSAID use who were randomized to risedronate. Fracture incidence was assessed using Kaplan-Meier estimates; relative risk reduction was based on the Cox regression model with adjustment for studies and number of prevalent vertebral fractures; p-values are based on the stratified log rank test.

Subjects were well matched across baseline demographics in terms of age (74 years) femoral neck T-score (-2.5), lumbar spine T-score (-2.5) and prevalent vertebral fractures (58%). Among women randomized to risedronate who reported use of PPI/H_2B, the 1-year reduction in new vertebral fractures was 61%, comparable to the risk reduction for all women randomized to risedronate among individual studies (65% VERT-NA, 61% VERT-MN, 55% HIP). Likewise, among women reporting upper GI disease or NSAID use, fracture risk reduction with risedronate was similar to that obtained among individual studies (see table).

Treatment Group	Incidence*	RR (95% CI)$^+$	Risk Reduction
Patients with Upper GI Disease (n=1,736)			
Placebo	5.8%		
Risedronate 5 mg	2.31%	0.38 (0.22, 0.65)	62%, p<0.001
H_2-Blockers and/ or PPI Users (n=1,258)			
Placebo	7.29%		
Risedronate 5 mg	3.32%	0.39 (0.23, 0.68)	61%, p=0.002
NSAID Users (n=2,870)			
Placebo	6.65%		
Risedronate 5 mg	2.99%	0.41 (0.28, 0.59)	59%, p<0.001

Risedronate provides comparable vertebral fracture protection in women using PPI/H_2B, and among women at high risk for GI side effects, with 1-year fracture risk reductions comparable to all women randomized to risedronate among individual studies.

The Effect of Oral Alendronate versus Intravenous Pamidronate on Bone Mineral Density in Patients with Osteoporosis. M. Vis[1], I. Bultink*[2], B. Dijkmans[1], W. Lems[1]. [1]Rheumatology, VU university medical center, Amsterdam, Netherlands, [2]Rheumatology, Slotervaart Hospital, Amsterdam, Netherlands.

Introduction Bisphosphonates are potent inhibitors of osteoclast mediated bone resorption that can be given orally or intravenously. There are no prospective studies comparing the effect on BMD of intravenous versus oral administered bisphosphonates.

Objective: To investigate the effect of 1-year treatment with oral alendronate 10mg/day or intravenous pamidronate 60mg/ 3months on BMD in patients with osteoporosis.

Methods: Since 2000 the Slotervaart Hospital has an outpatient clinic for patients with osteoporosis. We recruited 40 consecutive patients starting treatment for osteoporosis: 20 starting with oral alendronate 10mg/day and 20 starting intravenous pamidronate 60mg/3 months. The first choice bisphosphonate for treatment of osteoporosis was alendronate. Patients with previous treatment with anti-osteoporotic drugs were excluded, except patients who were treated less than one month with an oral bisphosphonate and were stopped because of gastrointestinal intolerance. Pamidronate i.v. was given in patients with gastrointestinal contraindications or intolerance (<1 month) for oral bisphophonates.

BMD was measured on a Hologic 4500 at the lumber-spine (L1-L4) and the total-hip at the start of treatment and after one year.

Results: A total of 40 consecutive patients were enrolled: 20 in the alendronate group and 20 in the APD group. The baseline characteristics of both groups are shown in table 1.

The change in BMD of the vertebral spine and total-hip in both groups was comparable The BMD of the lumbar spine increased +4.0% in the alendronate and +4.0% in the pamidronate group. The BMD of the total-hip increased both in the alendronate group and the pamidronate group, respectively +3.4% and +2.9%. The increases in the BMD (spine and hip) were significant for both groups compared to baseline (p<0.01). There was no significant difference in change in the BMD between the alendronate and pamidronate groups

Discussion: This study shows that in patients, treatment with intravenous pamidronate seems equally as good as treatment with oral alendronate regarding the effect on BMD. Therefore we suggest that i.v. pamidronate is an alternative for patients who do not tolerate or have a gastro-intestinal contra-indication for an oral bisphophonate

Table1: Baseline chracteristics of the pamidronate and alendronate group

		Alendronate Group (n=20)	Pamidronate Group (n=20)	significance
Age	*mean (SD)*	69 (15)	67 (16)	NS
Sex	n (%)	15 (75)	16 (67)	NS
Postmenopausal status	n (%)	14 (93)	15 (88)	NS
BMI	*mean (SD)*	25.9 (5.5)	23.7 (3.2)	NS
History of Fractures	n (%)	11 (55)	8 (40)	NS
History of prednisone use	n (%)	5 (25)	5 (25)	NS
Current prednisone use	n (%)	5 (25)	6 (30)	NS

Bone-Specific Gene Signatures Associated with Binge Alcohol and Concurrent Anti-Resorptive Treatment of Adult Rats Identified by Gene Expression Array Analysis. J. J. Callaci*[1], D. Juknelis*[1], M. T. Falduto*[2], F. H. Wezeman[1]. [1]Orthopaedic Surgery, Loyola University Chicago, Maywood, IL, USA, [2]GenUs BioSystems, Chicago, IL, USA.

Chronic alcohol abuse reduces bone mass and strength, increasing fracture risk in alcoholics. Molecular mechanisms underlying this vulnerability have not been identified. Skeletal effects of exposure to high blood alcohol concentrations (BAC's) attained during binge drinking have not been studied. We examined the effects of repeated binge-like alcohol treatment and concurrent risedronate therapy in adult male rats and assayed for effects on bone-specific gene expression profiles using microarray analysis. Our hypothesis was that gene signatures would be identified that were descriptive of both alcohol-induced bone loss and risedronate compensation. A binge alcohol treatment model was developed in our laboratory using intraperitoneal (IP) injection to administer a 20% (vol/vol) alcohol/saline solution (3g/kg, 1X/day) on four consecutive days for 1, 2 or 3 weeks in 400 gram male rats, with and without concurrent weekly risedronate treatment (0.5 mg/kg, 1X/week). Seventy-two Sprague Dawley rats were randomly divided into four groups: control, binge alcohol treated, risedronate treated and alcohol plus risedronate treatment. Total RNA isolated from proximal tibial samples was assessed for global gene expression using the Amersham CodeLink gene array platform representing 10,000 rat genes. We found effects of both treatment (alcohol and risedronate) and time on the expression patterns of both bone formation (26 genes) and resorption-specific (11 genes) gene panels with effects of treatment on many bone-specific genes not previously identified in relation to alcohol-induced bone loss. Unique gene expression profiles were found after 1, 2 and 3 weeks of treatment with either agent or with combined treatment. A unique gene signature (151 genes) was also found comprised of genes that showed 2-fold or greater regulation under ethanol treatment but had expression profiles near control levels with concurrent risedronate treatment. This pattern of gene regulation matches the pattern of biological effects of ethanol and risedronate on parameters of bone health previously identified in our laboratory. Our data provides insights into novel mechanisms of action for both alcohol-induced bone loss and bone sparing effects of risedronate. Bone-specific gene signatures indicative of alcohol-induced bone loss and risedronate prevention have many applications including diagnostics and screening of novel bone-sparing therapeutic agents.

Early Effects and Safety of Alendronate (Fosamax®) 70mg Once Weekly (EASY). M. Djandji*[1], J. S. Sampalis*[2], A. C. Karaplis[3]. [1]Clinical Research, Merck Frosst Inc, Pointe Claire, PQ, Canada, [2]JSS Medical Research Inc, Montreal, PQ, Canada, [3]Medicine, McGill Universty, Montreal, PQ, Canada.

Osteoporosis is a highly prevalent condition in older men and postmenopausal women caused by excessive bone resorption in comparison to bone formation. Alendronate (Fosamax®) is a nitrogen-containing bisphosphonate that selectively inhibits bone resorption. The ultimate goal in the treatment of osteoporosis is to reduce the risk of fractures associated with increased morbidity and mortality in the elderly population. Bone turnover measured by urine NTx values is a valid marker for assessing the rate of bone resorption. The purpose of the current study was to evaluate the effectiveness and safety of alendronate (Fosamax®) in reducing bone resorption in patients with osteoporosis over a period of 13 weeks.

METHODS: This was a prospective, single cohort, open label study. Patients included in the study were postmenopausal women and who had a confirmed osteoporosis (Bone Mass Density < 2.5 SD of normal). Patients were treated with alendronate (Fosamax®) 70mg once weekly for three months. The primary outcome measure of the study was absolute and percent reduction of urine NTx levels as a measure of bone turnover at 5 and 13 week of treatment. The current report presents data on patients that completed five weeks of treatment.

RESULTS: There were 238 patients enrolled in the study. 208 completed five weeks of treatment and are include in this report. One patient withdrew due to an adverse event. The majority were female (85%), 91% were Caucasian. The mean (SD) age was 67(11). The baseline mean (SD) urine NTx (nmol BCE/mmol Cr) was 54.7 (31.7) compared to 31.6 (19.6) after five weeks of treatment. The mean (SD) absolute change of 22.9 (29.9) nmol BCE/mmol Cr and percent change of 36.2% (33.4) in urine NTx were both statistically significant ($P < 0.001$). Significant absolute and percent decreases in urine NTx values were observed for the 186 patients that were compliant with treatment and in the 22 patients that missed one dose or more. There were 21 (10%) patients reporting an adverse event attributed to alendronate by the treating physician. The severity of the adverse events was mild for 11 and moderate for 8.

CONCLUSION: This study demonstrates that, using urine NTx as a surrogate marker. Alendronate is effective in reducing bone resorption within the first five weeks of treatment while being safe and well tolerated. Fosamax® Once weekly has a rapid response reducing bone resorption consequently bone loss in patients with osteoporosis. The rapidity of this response may have important implications for the management of osteoporosis.

Long-Term Treatment with a Calcitonin Derivative and Alfacalcidol Reduced the Risk of New Vertebral Fractures. M. Ohama*[1], Y. Honda*[1], Y. Isobe*[1], H. Suzuki*[2], Y. Kato[2], H. Shingu*[1]. [1]Orthopedic Surgery, Seibu Rehabilitation Hospital, Tottori, Japan, [2]Asahi Kasei Pharma Corporation, Tokyo, Japan.

In Japan, combination therapy employing elcatonin (an eel calcitonin derivative) and alfacalcidol is one of the major treatments for primary osteoporosis. However, there is little clinical evidence regarding its long-term use. In this study, we examined data from patients who have been consistently receiving this combination therapy treatment for more than 5 years. All patients selected had been diagnosed with primary osteoporosis according to the guidelines of the Japan Osteoporosis Society and had received the combination therapy of elcatonin 20U i.m. injection (initially, 4 times per month for 3 months and then twice per month) with alfacalcidol 1.0 μg/day oral administration for more than 5 years. Data examined included bone mineral density (BMD: ∑GS/D of CXD), biochemical tests, and radiographs (from Th11 to L5).A total of 17 patients met the profile for inclusion. All were postmenopausal women with an average age of 74.1 years old at the initiation of therapy. The average term of treatment was 6.23 years. BMD increased for four years following the beginning of treatment, and then subsequently decreased. Fresh vertebral fractures occurred in 7 patients (14 vertebral bodies). These fractures occurred during the first two years and after the fifth year in tandem with the BMD decrease. Serum calcium increased during the first two years, and alkaline phosphatase increased after five years had passed. There was no significant change in GOT, GPT, BUN, and creatinine. The combination therapy of calcitonin and alfacalcidol increased BMD during each of the first four years. While new vertebral fractures did occur in the first and second years of treatment, due likely to an insufficient overall effect of treatment, the third and fourth years of treatment showed a complete absence of new vertebral fractures. Thus, for at least the initial four years of treatment, this therapy, on the whole, is effective for primary osteoporosis. In contrast, after more than five years of treatment, BMD decreased from the baseline, leading to vertebral fractures. At the same time, serum alkaline phosphate increased significantly, which may indicate bone turnover was reactivated. These results suggest that after four years, this combination therapy should be replaced by a therapy that reduces bone turnover. The increase of serum calcium during the first two years could have been caused by alfacalcidol, which increases calcium absorption from intestinal tract. This long-term therapy caused no significant change in lung and kidney functions. Thus, this therapy is not only effective but safe for the first four years of treatment.

The Effects of Antiresorptive Agents, Calcitonin and Alendronate, on the Femoral Fracture Healing of Cynomolgus Monkey (Macaca Fascicularis). T. Manabe*, Y. Cao*, S. Mori, T. Mashiba, S. Komatsubara*, Y. Kaji*, H. Norimatsu. Dept. of Orthopedic Surgery, Faculty of Medicine, Kagawa University, Kagawa, Japan.

Antiresorptive agents may disturb the fracture healing because they suppress bone remodeling which is an important process of fracture healing. The effects of antiresorptive agents, calcitonin and alendronate, on the fracture healing were investigated using the fracture model of cynomolgus monkeys (Macaca fascicularis) which have osteonal remodeling same as human beings. Twenty female monkeys aged 18-22 years were divided into CNT(saline vehicle), ELL (elcatonin,Asahi-kasei, Japan,0.5U/kg/day), ELH (elcatonin 5U/kg/day), ALL (alendronate 10ug/kg/day), and ALH (alendronate 100ug/kg/day) groups. Drugs were subcutaneously injected twice a week. After 3 weeks pretreatment, transverse osteotomies were performed at the midshafts of right femora and fixed with AO miniplates. Injection was performed twice a week till the animals were sacrificed at 26 weeks post-fracture. Soft x-ray radiography, contact microradiograph, Micro-CT, biomechanical testing, and histomorphometry were performed on the fractured bone. Endosteal callus area in elcatonin(ECT) and alendronate(ALN) groups was larger than that in CNT, although cross-sectional area and periosteal callus area did not differ among the groups. Fracture Healing Index (FHI) was significantly lower in both ECT and ALN than in CNT. Osteoclast number (N.Oc/BS) in callus was significantly lower in ECT and ALN than in CNT. ALN groups showed lower activation frequency (Ac.f), lamellar bone in callus (lamellar Ar/Ca.Ar), osteoid thickness (O.Th), mineralized surface (MS/BS), and bone formation rate (BFR/BS) compared with CNT. Ultimate load, stiffness, and work to failure of fractured bone were not significantly different among the groups. Although calcitonin and alendronate enlarged endosteal callus, only alendronate significantly suppressed callus remodeling as evidenced by lower lamellar Ar/Ca.Ar.

Six-Month Bone Turnover Marker Results Following Daily Treatment with Fortical® Calcitonin Nasal Spray. N. M. Mehta[1], A. Malootian*[1], E. T. Leary[2], T. Aggoune*[2], T. Carlson*[2], J. P. Gilligan[1]. [1]Unigene Laboratories Inc, Fairfield, NJ, USA, [2]Pacific Biometrics, Inc, Seattle, WA, USA.

Five serum bone turnover markers (BTM) were measured in a 24-week, multicenter, double-blind, parallel design study comparing Fortical® Salmon Calcitonin Nasal Spray and a commercially available positive control. One hundred and thirty four osteoporotic (T score < -2.5) postmenopausal women received 6 months of daily dosing of 200 IU of Fortical or the positive control with calcium and vitamin D supplementation. Two serum markers of bone resorption , C-telopeptide (sCTX, Roche Diagnostics) and N-telopeptide (sNTX, Ostex International) and three serum markers of bone formation, bone specific alkaline phosphatase (BAP, Quidel), osteocalcin (OC, Roche Diagnostics) and procollagen type 1 N propeptide (P1NP, Roche Diagnostics) were measured at baseline, week 4, week 12 and week 24. Serum samples were collected in the fasted state between 8-10 AM. Subjects with accelerated bone turnover were enrolled (i.e. two baseline serum CTX values collected one week apart greater than 0.24 ng/mL). BTM were analyzed in a single batch at the completion of the study. Spine and hip BMD were measured with DEXA at baseline and at six months.

Serum CTX and NTX decreased rapidly following treatment. The Fortical treatment group (n=50) reached -41% and -23 % at 24 weeks from mean baseline values of 0.57 ng/mL CTX and 18.2 nM BCE NTX respectively. The formation markers lagged the resorption markers in response time but not necessarily in magnitude of change. P1NP, OC and BAP decreased by -31%, -25% and -10% from mean baseline values of 55.9 ng/mL, 32.1 ng/mL and 30.6 U/L.

The signal-to-noise ratios of BTM (treatment response at 24 weeks divided by coefficient of variation of markers measured two weeks apart) were greatest for P1NP (5.2), followed by OC (4.2), CTX (3.4), NTX (2.9) and BAP (2.0). Fortical treatment resulted in a modest but statistically significant increase in BMD of 1.3% at the AP spine and 1.1% at the hip at 6 months compared to baseline. The significant decrease in bone resorption and formation markers with Fortical Nasal Spray is greater than that expected from the change in BMD. Serum CTX and P1NP appear to be the most responsive resorption and formation markers respectively.

Decreased Bone Resorption after Soy Isoflavone Supplementation in Postmenopausal Women (60 - 78 Years of Age). L. Harkness[1], K. Fiedler*[2], A. R. Sehgal*[3], D. Oravec*[4], E. Lerner*[2]. [1]Pediatrics, Case Western Reserve University, Cleveland, OH, USA, [2]Nutrition, Case Western Reserve University, Cleveland, OH, USA, [3]Medicine, Case Western Reserve University, Cleveland, OH, USA, [4]Radiology, Case Western Reserve University, Cleveland, OH, USA.

The purpose of this study was to investigate the effect of soy isoflavone supplementation on bone mineral density and markers of bone turnover in postmenopausal women. For this randomized, placebo controlled clinical trial, we used a crossover design to test the effect of soy isoflavone with known isoflavone composition on bone formation, bone resorption, and bone mineral content (BMC) and density (BMD). Postmenopausal women (n= 19), mean age of 70.6 ± 6.3 years, mean time since menopause of 19.1 ± 5.5 years, were given isoflavone supplements for 6 months. The total isoflavone dosage was 110 mg/day (55 mg in a.m. and 55 mg in p.m.) with an isoflavone composition ratio of 1.3:1.0:0.22 genistein: daidzein: glycitein. We observed a 37% ($p < 0.05$) decrease in urinary concentrations of type 1 collagen α1 chain helical peptide (HP), a marker of bone resorption, during the isoflavone supplementation compared to baseline. In addition, there was a significant difference in mean (SE) HP excretion levels when isoflavone was compared to placebo [43.4(5.2) vs. 56.3(7.2) ug/mmol cr] ($p < 0.05$). After the isoflavone supplementation, mean spine L2 BMC was significantly greater compared to control with a difference between the means of 0.3(0.60) g ($p < 0.05$). Mean BMD at L2 and L3 was greater when treatment was compared to control with a difference between means of 0.03(0.04) g and 0.03(0.04) g ($p < 0.05$), respectively. After isoflavone supplementation, there were non-significant increases from baseline for total spine BMC (3.5%), total spine BMD (1%), total hip BMC (3.6%), and total hip BMD (1.3%). In conclusion, the high rate of bone resorption is a key concern during menopausal bone loss and decreasing bone resorption should be part of any intervention strategy. Soy isoflavone, in isolated form, was effective in this study to significantly decrease bone resorption.

Synergistic Interactions among Calcium, Isoflavone and/or Estradiol Supplementation on Bone Mineral Contents and Serum Estradiol and Vitamin D Hormone Levels in Postmenopasal Osteoporosis Rat Model. Y. Lee*, K. Kim*. Seoul National University, Seoul, Republic of Korea.

This study was conducted to investigate how three factors, dietary calcium, isoflavone supplementation, and estrogen replacement, for prevention and treatment of postmenopausal osteoporosis might be associated with bone mineral increments and bone metabolism-related hormones. Seven weeks old female rats (Sprague-Dawley) were designed as a postmenopausal osteoporosis rat model by ovariectomy and low Ca diet (0.1% Ca in diet) for three weeks. The model rats were divided into eleven groups according to the treatments by alone or by combinations of low Ca diet, Ca (0.5% Ca in diet), isoflavone (80ppm in diet), and estradiol (10μg/kg BW by subcutaneous injection). The groups included two sham contols (three and eleven weeks). The experimental treatments were settled for eight weeks. The ovariectomized osteoporisis model rats were characterized by an increase in weight gain and food intake but a decrease in bone weight, length, breaking force and mineral contents (Ca and P) compared with SHAM control rats. In these model rats, body weight gain and food intake were not affected by dietary calcium and isoflavone supplementation but reduced significantly by estradiol administration. The bone mineral contents, especially calcium contents, were increased significantly by the combination treatments of calcium, isoflavone and estradiol compared to alone treatments. Serum estradiol level was lower with ovariectomy and not affected by calcium addition alone, but significantly elevated by isoflavone supplementation alone and increased to the level of SHAM by estradiol injection alone. The combinations of calcium and estradiol, isoflavone and estradiol, and calcium, isoflavone and estradiol treatments significantly augmented the estradiol level above to the SHAM. Serum 1,25-$(OH)_2D_3$ was significantly higher in the overiectomized model rats than in SHAM rats, but declined by calcium addition alone and estradiol injection alone to the level of SHAM, and more decreased by combination of these two treatments, but not affected by isoflavone supplementation. Reduced uterine weight with ovariectomy was enlarged by estradiol injection but not dietary calcium, isoflavone, and their combination.

In conclusion, the synergistic effects among dietary calcium, soy isoflavone supplementation and/or estradiol injection have been observed on the prevention of bone loss and the maintenance of serum estradiol and activated vitamin D levels in the postmenopausal osteoporosis model rats.

Effects Of Calcium Supplementation On Body Weight And Blood Pressure In Normal Older Women - A Randomized Controlled Trial. I. R. Reid, A. Horne*, B. Mason*, R. Ames*, G. Gamble*. Department of Medicine, University of Auckland, Auckland, New Zealand.

High intakes of calcium are now widely accepted as having a beneficial effect on bone health. Recent epidemiological data suggest that high calcium intakes might also result in decreased body weight, which is potentially of even greater health importance. However, there is little evidence available from randomized controlled trials that addresses this important issue. A further related possible benefit from calcium supplementation is reduced blood pressure, which also lacks definitive trial evidence. We have used data from an ongoing, randomized controlled trial of calcium supplementation (1 g/day vs placebo) in the prevention of fractures, to assess the long-term effects of calcium supplementation on body weight and blood pressure.

Body weight measurements were available in 1203 subjects at 30 months (82% of the initial cohort). Body weight (mean ± SE) decreased by 368 ± 132 g in the calcium group and by 369 ± 134 g in those taking placebo. Each of these changes was significant within the respective group, but the changes over time were not different between-groups ($P = 0.93$ for time-treatment interaction by analysis of variance). When these analyses were repeated using data from subjects still taking study medication and with >80% compliance, the changes in body weight were essentially the same. Fat mass (measured by DXA) did not change significantly in either group (calcium group, +163 ± 146 g; placebo group, +113 ± 145g) and there was no difference between-groups ($P = 0.81$). In contrast, there was a significant loss of lean mass in both groups (calcium, -709 ± 62 g; placebo, -667 ± 61 g) but, again, no significant difference between the treatments ($P = 0.63$). No significant differences were found in the changes in blood pressure between the two groups.

We conclude that calcium supplementation in normal postmenopausal women does not result in biologically significant effects on either body weight or blood pressure.

Effects of Isoflavone on Bone Loss In Japanese Postmenopausal Women Depend on Bacterio-typing for Equol: A Randomized, Placebo-controlled Trial. J. Wu*[1], J. Oka*[2], M. Higuchi*[2], I. Tabata*[2], M. Fujioka*[1], F. Sugiyama*[1], N. Fuku*[2], T. Toda*[3], T. Okuhira*[3], T. Ueno*[4], S. Uchiyama*[4], K. Urata*[4], H. Cui*[5], K. Yamada*[1], Y. Ishimi[1]. [1]Division of Applied Food Research, National Institute of Health and Nutrition, Tokyo, Japan, [2]National Institute of Health and Nutrition, Tokyo, Japan, [3]Fujicco Co. LTD., Kobe, Japan, [4]Otsuka Pharmaceutical Co. LTD., Saga, Japan, [5]Department of Nutrition and Food Hygiene, Harbin Medical University, Harbin, China.

The objective of this study was to determine the effects of 24 wk of soy isoflavone intake and walking exercise, and their interaction on bone and lipid metabolism in Japanese postmenopausal women. The bioavailability of isoflavone daidzein was also examined to clarify the potential mechanism of bone-protective effects in human. Subjects, who were postmenopausal within 5 years, were randomly assigned into four groups; (1) placebo (n=33); (2) walking exercise (3 times/week) with placebo (n=31); (3) isoflavone intake (75 mg of isoflavone conjugates, Fujiflavone P40) (n=33); (4) isoflavone plus walking exercise (n=31). Furthermore, the subjects were stratified by “bacterio-typing” for equol, which is an intestinal bacterial metabolite of daidzein. The ability responsible for equol production in individuals was determined and the subjects were stratified by “equol producers” or “nonproducers”. The combined intervention of walking and isoflavone intake resulted in an increase in percentage (%) change in HDL-cholesterol concentration and it was significantly higher than those in placebo and isoflavone alone groups. The interventions also decreased fat mass in whole body and legs, and the % changes were significantly different from those in the placebo group. With respect to BMD, there were no significant differences in baseline and after intervention among the groups. However, the % changes in BMD in "equol-producers" were -0.53 and +0.13 in the whole body and total hip regions respectively, which were significantly different compared with -1.35 and -1.77 in "nonproducers" in isoflavone group. These results were related to the serum equol concentration. In contrast, there were no significant differences in % changes in BMD between the "equol-producers" and "nonproducers" in the placebo, walking and walking plus isoflavone groups. These results suggest that the combined intervention of isoflavone and walking exercise exhibited cooperative effects in modifying lipid metabolism and body composition in postmenopausal women. The preventive effects of isoflavones on bone loss depend on the “bacterio-typing” for equol in human.

Equol, a Bacterial Metabolite of Isoflavone, Prevents Bone Loss in Ovariectomized Mice. Y. Ishimi[1], M. Fujioka*[1], M. Uehara*[2], J. Wu*[1], H. Adlercreutz*[3], K. Suzuki*[2], K. Kanazawa*[4], K. Takeda*[5], K. Yamada*[1]. [1]Division of Applied Food Research, National Institute of Health and Nutrition, Tokyo, Japan, [2]Tokyo University of Agriculture, Tokyo, Japan, [3]University of Helsinki, Helsinki, Finland, [4]Kobe University, Kobe, Japan, [5]Tokyo University of Science, Chiba, Japan.

Soybean isoflavones have similar structures to estrogen and have received attention as alternatives to hormone replacement therapy for the prevention of postmenopausal osteoporosis. We have reported that isoflavones prevent bone loss in both estrogen- and androgen-deficient osteoporotic model mice Daidzein, a major isoflavone found in soybean, is metabolized to equol by gut microflora, and the metabolite exhibits a stronger estrogenic activity than daidzein. However, there is no direct evidence that equol affects bone metabolism. In this study, we examined the effect of equol on the inhibition of bone loss in ovariectomized (OVX) mice. Eight week-old female mice were assigned to five groups; sham-operated (sham), OVX, OVX+0.1 mg/day equol administration (0.1 Eq), OVX+0.5 mg/day equol administration (0.5 Eq) and OVX+0.03 μg/day 17β-estradiol administration (E_2). Equol and E_2 were subcutaneously administerd, using a mini-osmotic pump. Four weeks after intervention, uterine weight was reduced by OVX and restored by E_2 administration. In contrast, equol at doses used in this study did not affect uterine atrophy in OVX mice. Bone mineral density (BMD) for the whole body measured by dual-energy X-ray absorptiometory (DXA) was reduced in OVX mice, while administration of 0.5 mg/day Eq as well as E_2 maintained it. The BMD of the femur and lumber spine was also reduced by OVX, and treatment with 0.5 mg/day Eq prevented the bone loss. In particularly, the BMD of the proximal femur was the same as that of the sham group. E_2 prevented bone loss from all regions induced by OVX. These results suggest that equol, a major metabolite of daidzein, inhibits bone loss apparently without estrogenic activity in the reproductive organs of OVX mice.

Gamma-Glutamyl-Peptide Isolated From Onion by Bioassay Guided Fractionation Inhibits Resorption Activity of Osteoclasts. H. A. Wetli*[1], R. Brenneisen*[2], I. Tschudi*[3], P. Bigler*[4], T. Sprang*[4], S. Schürch*[4], R. C. Muhlbauer[3]. [1]Laboratory for Phytopharmacology, Bioanalytics & Pharmacokinetics and Group for Bone Biology, University of Bern, Bern, Switzerland, [2]Laboratory for Phytopharmacology, Bioanalytics & Pharmacokinetics, Department Clinical Research, University of Bern, Bern, Switzerland, [3]Group for Bone Biology, Department Clinical Research, University of Bern, Bern, Switzerland, [4]Department of Chemistry and Biochemistry, University of Bern, Bern, Switzerland.

The addition of 7% of onion to the diet of rats decreases bone resorption and increases bone mineral content [Nature 401: 343-344, 1999]. This effect is independent of the base excess of onion [J Bone Miner Res 17: 1230-1236, 2002]. Furthermore, an ethanolic extract from onion prevented bone loss in an osteoporosis model and inhibited the resorption activity of osteoclasts in vitro. This suggested that the inhibitory activity of onion on bone resorption could be due to a pharmacologically active compound, prompting us to undertake its isolation and identification.

First, the ethanolic extract was subjected to adsorption column chromatography. Surprisingly, we found no activity in vivo of the flavonoid containing fractions (dose corresponding to 7% onion). Thus, the other, active material was fractionated by reversed phase-medium pressure liquid chromatography and the biological activity of the fractions was tested with the osteoclast pit assay. The active fractions were then further fractionated by normal phase-medium pressure liquid chromatography and finally by semi preparative-reversed phase-high performance liquid chromatography resulting in a single active peak. The structure of this compound was elucidated with high performance liquid chromatography-electrospray ionization-mass spectroscopy and nuclear magnetic resonance.

We found that the single peak is gamma-glutamyl-trans-S-1-propenyl-cysteine-sulfoxide. It has a molecular weight of 306 and inhibits dose dependently the resorption activity of osteoclasts, the minimal effective dose being about 2 mM. As no other peak displayed inhibitory activity it likely is responsible for the effect of onion on bone resorption, a contention that will be confirmed in vivo as soon as sufficient material is available. This will allow to study its mechanism and its role in the activity of the other 25 active vegetable food items we have identified so far.

A Randomised Controlled Trial (RCT) of Calcium Supplementation in Pre-Pubertal Gymnasts Versus Controls: Response at the Mid-&-Distal Radial Sites. K. Ward[1], S. Roberts*[2], J. Adams[1], Z. Mughal[3]. [1]Clinical Radiology, Imaging Science & Biomedical Engineering, University of Manchester, Manchester, United Kingdom, [2]Biostatistics Group, CMMCH NHS Trust and University of Manchester, Manchester, United Kingdom, [3]Pediatric Medicine, CMMCH NHS Trust, Manchester, United Kingdom.

The positive effects of physical activity and calcium upon the developing skeleton are well documented. More recently, studies have shown that they may act interdependently upon the bone.

In this double blind RCT we investigated the effects of 12 months supplementation of 500g calcium carbonate (Calcichew™, Shire Pharmaceuticals) or placebo, upon the peripheral and axial skeleton of pre-pubertal gymnasts (G; 14 hrs of weight bearing activity per week) and controls (C; 6 hrs of weight bearing activity per week). Here we present preliminary analyses of the response to calcium supplementation (CaS) at the distal (4%) and mid (50%) radial sites, assessed using the Stratec XCT-2000 pQCT scanner. We hypothesised that CaS in G would result in greater changes in 1) mid-radial bone dimensions and cortical bone mineral density (BMD) and 2) distal radial bone dimensions and trabecular BMD, than C subjects.

Eighty-six subjects (49 females) participated in the RCT (44G: 42C) and 75 subjects completed the trial (45 females, 39G: 36C). Analysis of covariance was used to test differences in response to treatment between CaS and placebo (Pl) groups, including baseline height, gender, weight bearing activity and treatment as covariates; interactions were also tested.

At the mid-radial site, subjects in the CaS group had a greater increase in cortical BMD (12.3mg/cc, p=0.03) but smaller increase in periosteal circumference (-0.54mm, p=0.04) than those in the Pl group. The change in both endosteal and periosteal circumferences appeared to be different in males and females, however when tested, a treatment-gender interaction failed to reach statistical significance.

At the distal radius a significant interaction between treatment and activity was found G + CaS had greater increase in total bone area (10.52mm^2, p=0.04) than C and G+Pl.

At the mid-radius site the CaS group appear to accrue less bone on the periosteum; extra calcium is deposited within the cortex increasing cortical density. In contrast at the distal radius site CaS appears to have resulted in increased change in bone size without an increase in density. In conclusion, these preliminary data suggest that there may be site, activity and gender specific differences in the response of pre-pubertal children to calcium supplementation.

Positive Effects on Height Remain One Year after the End of a Calcium Carbonate Intervention in 16-18 Year Old Boys. A. Prentice, F. Ginty, S. Jones*, M. A. Laskey*. MRC Human Nutrition Research, Cambridge, United Kingdom.

We have previously shown that calcium carbonate supplementation of 16-18 year old adolescent boys (1000 mgCa/d for 12 months) led to an increase in bone dimensions, statural height and greater bone mineral content (BMC) at the whole-body, spine and total hip. The aim of this follow-up study (FU) was to determine if these effects persisted beyond the supplementation period, thus indicating a long-term effect on growth and bone mineral accretion, or whether the differences had diminished, thus indicating that tempo of growth had been affected. Of the 143 boys who completed the intervention study, 67 (47%) agreed to return for FU measurements at 15.5 (SD3.3) months after the end of supplementation at a mean age of 19.3 (SD0.4) years. Of those (i.e. the FU responders), 55% (37/67) had been originally allocated to the calcium supplemented group (S) and 45% (30/67) to the placebo group (P). Their baseline characteristics were not significantly different from non-FU responders. There was a significant difference between FU responders and non-responders in reported tablet compliance during the intervention study (S and P together: 68% vs 50%, p=0.0003). The significant effects of the calcium supplement on height and DXA variables remained visible when the intervention data were restricted to FU responders and the differences with the placebo group were more pronounced, possibly reflecting the greater compliance of FU responders.

Between the end of supplementation and FU measurements, the FU responders had significant increases in body weight and in whole body and lumbar spine BMC and bone area (BA) (p<0.001), but not in statural height (p=0.49). Similar patterns were observed in the calcium and placebo groups separately. A significant height differential remained between the S and P groups (S-P at FU corrected for baseline: +0.75 (SE0.20)%, *p*=0.0005), equivalent to a difference of 1.3 cm for boys of average height (180 cm). Significant effects of the supplement also remained for whole body BA (+1.43 (0.69)%, p=0.042), spine BMC (+3.9 (SE1.8)%, p=0.035), spine BMD (+2.40 (1.22)%, p=0.054) and intertrochanteric BMC (+4.3 (SE2.0), p=0.037). These findings suggest there were long-term effects of calcium carbonate supplementation on both bone mineral mass and bone size. A further follow-up in young adulthood is planned, after linear growth has ceased in all individuals.

SU460

Effect of Pre- and Probiotics on Isoflavones Bioavailability, Consequences on Bone Metabolism in Postmenopausal Women. J. Mathey*[1], C. Bennetau-Pelissero*[2], M. Davicco*[1], C. Puel*[1], S. Kati-Coulibaly*[1], M. Horcajada*[1], V. Coxam[1]. [1]Nutrition, INRA, Saint-Genès Champanelle, France, [2]Micronutriments, Reproduction, Santé, ENITA, Gradignan, France.

Recently, attention has been focused, as a potential alternative to HRT, on isoflavones (IF), the so-called phyto-oestrogens (occurring in soyfood) that are chemically similar to mammalian estrogens. As bioavailability of these molecules could be improved by modulating intestinal microflora, the present study was undertaken to investigate whether probiotics and fructooligosaccharides (FOS, preobiotics), which are known to modify large bowel flora and metabolism, may exhibit a co-operative bone sparing effect. In that purpose, a two months, randomized, double-blind crossover study was carried out on 39 postmenopausal women without HRT. Volunteers were daily given for one months 100 mg of isoflavones aglycones (powdered soya isoflavones concentrate containing 46.19g/100g total isoflavones (genistin 55%-75%, daidzin 20%-40%, glycitin 1%-5%); Prevastein®HC, Eridania Beghin-Say) introduced in two yoghurts and two cereals bars containing 25 mg of isoflavones each. At the end of the first month, the participants were randomly assigned to three treatments groups all receiving the 100mg/day of isoflavones (IF) for one additional month. Among them, one group received 7g of FOS (FOS, Actilight®, Beghin-Meiji), while the other one was provided with 125 mg of lactic ferments (LF, 50g/100L, lactic bacteria including bifidobacteria, Danone Vitapole). On day 1 (baseline), 30 and 60, blood samples and the 24-h urines were collected in the morning to assess bone alkaline phosphatase (ALP), a marker for

osteoblastic activity and deoxypyridinoline (DPD), a marker of bone resorption, and isoflavones (daidzein, genistein and equol).
In control volunteers (IF), soy consumption was associated with a trend (although non significant) towards lower DPD levels (nM/mMol creatinine) (5.4 ± 0.2 *vs* 4.8 ± 0.2) and higher PAL (microg/l) (13.9 ± 0.5 *vs* 14.7 ± 0.4). On day 60, plasma concentrations of equol, the active metabolite of daidzein, were increased in the probiotics group (LF). This diet was also associated with a trend to an improvement of PAL levels, while DPD concentrations stayed unchanged. On the contrary, as far as prebiotics (FOS) are concerned, a significant decrease in DPD urinary levels was observed, only in early postmenopausal women.
In conclusion, addition of live microorganisms such as bifidobacteria or prebiotics, to an isoflavones-enriched diet may modulate bone turnover by improving bioavailability of those phytoestrogens, although if further longer investigations are warranted.

Effects of Vitamin D, Calcium, and Cheese Supplementation on Urinary Calcium Excretion, Serum 25-OH-D and PTH in Pubertal Girls. A. E. Lyytikäinen[1], E. Helkala*[1], S. M. Cheng*[1], M. Suuriniemi[1], C. Lamberg-Allardt[2], A. Koistinen*[3], S. Cheng[1]. [1]Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, [2]Department of Applied Chemistry and Microbiology, University of Helsinki, Helsinki, Finland, [3]Central Hospital of Central Finland, Jyväskylä, Finland.

This study was a two-year double-blind, placebo-controlled, randomized intervention to evaluate the effect of calcium (Ca), vitamin D (VD) and cheese supplementation on urinary calcium excretion and on serum 25-OH-vitamin D and parathyroid hormone (iPTH) concentration in pubertal girls. The subjects were Finnish girls aged 10-12 years at Tanner stage I-II with dietary Ca intake <900 mg/day. Altogether 143 completed the intervention (Ca+VD, n=37; Ca, n=33; Cheese, n=37; and Placebo n=36). In the Ca+VD, Ca and Cheese group girls received 1000 mg Ca as Ca carbonate tablets (500 mg x 2/day), or as low-fat cheese (100 g/day). The Ca+D group received vitamin D_3 200 IU/day. Over night fasting blood and 24-h urine was collected at baseline, year 1, and 2 during midwinter (Dec-Feb). Urinary calcium was analyzed by absorption spectrophotometry. Serum 25-OH-D and iPTH were analyzed by immunoenzymometric assays (IDS Inc, OCTEIA). The intake of nutrients was evaluated with a three-day food record. No significant differences were found in the compliance with supplements between the groups (70/74/64/72 % for Ca and 76 % for active VD). The mean weight, height, BMI, maturation status, and U-Ca, 25-OH-D and iPTH were similar among the groups at the baseline. During the two-year trial, all groups increased their Ca intake. The total mean Ca intake from diet and supplements was on average 1627 mg/day in the Ca+VD, 1600 mg/day in Ca, 1406 mg/day in Cheese and 831 mg/day in Placebo group. The corresponding figures for total mean VD intake were 6.3, 2.9, 3.2, and 2.6 µg/day, respectively. We found that a 37 % increase in 25-OH-D (from 41.0 to 52.7 nmol/L) in Ca+VD group caused a concurrent 11 % decrease in iPTH (from 28.7 to 23.2 pg/L) during the first year. Compared to other groups, the changes in Ca+VD group differed significantly for 25-OH-D ($p<0.001$) and there was a trend in iPTH changes compared to the Cheese group ($p=0.05$) and the Placebo group ($p=0.057$). At the second year, the 25-OH-D level did not further increase and iPTH concentration remained similar compared to the first year for all groups. We found a similar increase in the urinary calcium excretions in all groups during the trial (mean for all +83 %). Our results indicate that combined calcium (1000 mg/day) and vitamin D supplementation (200 IU/day) caused an increase in 25-OH-D levels and consequently a decrease in the iPTH levels in pubertal girls. Supplemental calcium alone did not effect iPTH levels.

A Survey of Calcium Concentrations in Bottled and Tap Water and Their Significance for Medical Treatment and Drug Administration. S. Morr*, E. Cuartas*, B. Alwattar*, J. M. Lane. Orthopaedics, Hospital for Special Surgery, New York, NY, USA.

Different forms of water vary in calcium content. High divalent ion (i.e. Ca^{2+}, Mg^{2+} etc.) concentration is deleterious to the efficacy of the bisphosphonate group of drugs in osteoporosis treatment. Water with high calcium concentration may also present an alternate pathway of calcium administration. In either case, knowing the actual concentration is critical. We hypothesize that there is considerable variety in the calcium concentrations in the various water sources. Calcium concentrations in various U.S. cities from different regions, as well as different kinds of bottled water, delineated into purified, spring, and mineral, are conjectured to have varying and somewhat predictable Calcium concentrations. In addition, as water filtration systems have gained popularity within the past years, we hypothesize that the water filter removes a significant amount of mineral, including calcium, from the water. Calcium concentrations in various city tap waters, as well as an assorted number of bottled waters were determined through the direct inspection of scientific data. The effect of filtering was also determined by mineral analysis of mineral water directly before and after filtration. The calcium concentration of water varies across the U.S.A. The average Calcium concentration for the selected group of cities was 50.71 mg/L, ranging from 8.3mg/L in Montgomery, AL to 131.0 in Phoenix, AZ. Upon categorization of the selected cities by regional location, the cities in the Northeast, Midwest, and South present with average values of 41.97 mg/L, 42.10 mg/L, and 42.95 mg/L respectively. The West Coast has an average value of 57.73 mg/L. The South presents with the greatest average value with 81.05 mg/L. Most spring waters were found to have a relatively low calcium concentration, with an average of 21.8 mg/L for the selected group. Purified waters constantly present with a negligible Calcium concentration. Mineral waters, on the other hand, were found to generally present with higher calcium concentrations. The selected group had an average of 208.3 mg/L of Calcium. Filtration was found to remove a considerable amount of calcium from the water, removing 89.42% of the Calcium content on average. Calcium concentration in water varied from, as well as within, different regions in the U.S.A. Different forms of bottled waters presented with varying concentrations of calcium. Certain tap and bottled waters present with concentrations of calcium sufficient to exhibit a deleterious effect on bisphosphonate treatment. Alternatively, certain waters may be used as a source of ingested calcium that may provide over 40% of the daily requirement for calcium ingestion.

Design of Compliant Floors to Reduce Impact Forces During Falls on the Hip. A. C. T. Laing*, I. Tootoonchi*, S. N. Robinovitch*. School of Kinesiology, Simon Fraser University, Burnaby, BC, Canada.

Over 90% of hip fractures are due to falls, and fracture risk during a fall depends on the impact force applied to the proximal femur. One strategy for reducing fall impact forces is to decrease the stiffness of the floor, an intervention especially relevant to high-risk environments such as nursing homes or senior centres. Our goals in this study were: (1) to test whether reducing the floor stiffness attenuates peak force during experimental falls on the hip from safe heights; and (2) to develop and use a mathematical (vibratory) model to predict how feasible reductions in floor stiffness reduce peak forces during falls from standing.
Seven young women participated in the experiments (mean age = 23±2(SD) yrs). During the trials, the subject lay on her side, resting her knee and shoulder on rigid side platforms, and her pelvis on a middle platform that was either rigid (having a stiffness of 733 kN/m) or compliant (having a linear stiffness of 18 kN/m, a reasonable lower bound given the known effect of floor compliance on postural stability during standing). A nylon sling and electromagnet was used to lift and instantly release the pelvis from a height of 1.25 or 5.0 cm. Hip contact force was sampled at 960 Hz from a forceplate under the middle platform. We also compared experimental trends to those predicted by a best-fit mass, spring, and damper vibratory model and used the model to predict peak forces during falls from standing.
Peak impact force associated with both floor stiffness ($p<0.001$) and fall height ($p<0.001$), based on repeated-measures ANOVA. In the 1.25 cm fall height condition, average peak forces were 16% lower in the compliant than rigid floor condition (497±81 versus 595±107 N). In the 5.0 cm fall height condition, peak forces were 40% lower in the compliant than rigid floor condition (623±71 versus 1045±88 N). Model predictions of peak force matched experimental data with 14±6% accuracy. Peak forces predicted by the model for falls from standing (with a descent height of 70 cm) were 28% lower for impact on our compliant versus rigid floors (2050 versus 2860 N). The former value is approximately 1.36 standard deviations below the average fracture force of 4100±1510 N for elderly cadaveric femora.
Our results indicate that feasible reductions in floor stiffness may reduce hip impact force during a fall by 28%, to a value that is considerably below the average fracture force. Future work is required to determine the additional benefit provided by damping elements, and to determine threshold values for floor stiffness, below which balance maintenance and recovery is impaired.

Cessation of Training Is Followed by Rapid Loss of Bone Mineral Density, a 8-Year Longitudinal Study in Females. Ö. Valdimarsson, M. K. Karlsson. Orthopeadics, Medicine and Surgery, Malmö, Sweden.

Physical activity at young age increases bone mineral density (BMD) but whether the benefits in BMD are retained with reduced activity level is still controversial. The aim of this study was to evaluate the effect of training and reduced training on BMD in women during an 8-year follow-up. At baseline, dual X-ray absorptiometry (DXA) evaluated BMD (g/cm^2), femoral neck width (cm) and femoral neck volumetric BMD (vBMD; g/cm^3) in 48 active female soccer players with mean age 18.2 ± 4.4 years, in 18 former female soccer players with mean age 43.2 ± 6.2 years and retired since mean 9.4 ± 5.3 years and in 64 age and gender matched controls. The measurements were repeated after mean 8.0 ± 0.3 years when 35 of the at baseline active players had retired since mean 5.3 ± 1.6 years. The at the follow-up still active soccer players had already at baseline a higher BMD in comparison with the matched controls, at the femoral neck (FN) 1.13 ± 0.19 versus (vs.) 1.00 ± 0.13, $p = 0.02$ and at the legs a non significant higher BMD, 1.23 ± 0.12 vs. 1.15 ± 0.11, $p = 0.07$. The yearly gain in BMD during the follow-up was higher in the active players than in the controls, at the leg 0.015 ± 0.006 vs. 0.007 ± 0.012; $p = 0.04$, so that the discrepancy in BMD at follow-up was even larger than at baseline, at the FN 1.20 ± 0.17 vs. 0.99 ± 0.16 and at the legs 1.36 ± 0.10 vs. 1.19 ± 0.09, both $p < 0.001$. The soccer players who retired during the follow-up had at baseline a higher BMD in comparison with the matched controls, at the FN 1.13 ± 0.13 vs. 1.04 ± 0.13, and at the legs 1.28 ± 0.12 vs. 1.20 ± 0.10, both $p < 0.001$. The at follow-up retired players lost whereas the controls gained BMD during the study period, yearly at the FN -0.007 ± 0.01 vs. 0.003 ± 0.02, $p = 0.01$ and at follow-up there was only a discrepancy in BMD at the legs 1.32 ± 0.12 vs. 1.23 ± 0.10, $p = 0.001$. The already at baseline retired soccer players had at study start higher BMD in comparison with the matched controls, in the legs 1.26 ± 0.09 vs. 1.18 ± 0.10, $p = 0.01$. The former players lost whereas the controls gained BMD during the study period, yearly at the trochanter -0.006 ± 0.01 vs. 0.004 ± 0.01, $p = 0.01$. In spite of this, there was still a discrepancy in BMD at follow-up when comparing the players who already at baseline were retired and the controls but at a lesser magnitude, at the legs 1.22 ± 0.10 vs. 1.17 ± 0.10, $p = 0.05$. In summary, this study demonstrates that in girls, intense exercise also after puberty is associated with a higher accrual of BMD and decreased physical activity both in a short term and a long-term perspective is associated with a higher BMD loss. We conclude that physical activity during childhood and adolescence may be used as a prevention strategy of osteoporosis, probably only if the physical activity is advocated lifelong.

The Effect of the Multicomponent Exercise on Bone Mineral Density and Fall Risk Factors in Osteoporotic Women. H. Park*[1], S. Park*[2], T. Komatsu*[3], S. Park*[1], T. Kaminai*[3], H. Okuizumi[3], Y. Mutoh*[1]. [1]Department of Physical and Health Education, The University of Tokyo, Tokyo, Japan, [2]Department of Physical Education, University of Dong-A, Busan, Republic of Korea, [3]Department of Orthopedic Surgery and Rehabilitation, Tokyo Kouseinenkin Hospital, Tokyo, Japan.

Osteoporosis-related fractures in older individuals are increasing and become one of the major health problems in Asian world. However, the effects of exercise intervention for preventing fractures in osteoporotic elderly are unknown and controversial. This study assessed that the multicomponent exercise intervention prevents bone loss in weight-bearing bones and improve fall risk factors in women of 65-year-old or older who were diagnosed with osteoporosis by WHO criteria. Sixty-five osteoporotic women were recruited and randomized into the control (CON) group (n=31) and the intervention (INT) group (n=34). The exercise intervention focuses on four components: exercise for fun, aerobic exercise, strengthening exercise, balance and posture training. This supervised exercise intervention performed 50 minutes a day, 4 days a week for 10 months. The control group retained a sedentary life style and joined in Calligraphy, Singing and Oriental checkers class twice a week. Bone mineral densities (BMDs) in both proximal femur and calcaneus by using dual-energy x-ray absorptiometry were measured repeatedly before and after the ten months experiment in both groups. Dynamic balance (tandem walk, timed get-up and go test), static balance (eyes-open one-legged stand time, postural sway), and leg muscle strength and mobility performances (10-meter rapid walking speed, 40-centimeter step up and down, maximal step length) were also measured as fall risk factor. All practitioners were blinded to group assignment. There were no differences in anthropometric variables and menstruation status at baseline. Ninety-four percent of subjects in the INT group and ninety-three percent of subjects in the CON group completed the 9-month follow-up study. BMD measurements revealed bone losses in both groups, but BMD at femoral neck (0.07 vs. 0.02 g/cm^2, p<. 05) and calcaneus (0.08 vs. 0.03 g/cm^2, p<. 05) in the CON group have more lost significantly compared to the INT group. Fall risk factors in the INT group were substantially greater improved than in the CON group. A total of two fractures occurred during the follow-up, including 2 subjects in the CON group. This randomized and prospective study shows that this multicomponent exercise intervention is beneficial for preventing bone loss in weight-bearing bones and ameliorating the fall risk factors in osteoporotic elderly.

Walking Benefits Bone Mass in Postmenopausal Women. R. A. Brownbill, J. Z. Ilich. School of Allied Health, University Of Connecticut, Storrs, CT, USA.

Studies conflict as to which types of physical activity (PA) best benefit bone mass in postmenopausal women. This study was conducted to determine which types of PA were related to bone mass at various skeletal sites. 136 healthy Caucasian women not taking hormone replacement therapy, mean±SD age 68.6±7.1 (range 57.4-88.64) were enrolled in a 2 1/2 year longitudinal study. PA, bone mineral content (BMC), anthropometrics and diet were assessed every 6 months. BMC of the whole body, femur and lumbar spine were measured with a DPX-MD densitometer. Walks of at least 20 minutes in duration as well as all recreational activities (i.e. aerobics, tennis) were reported as hours per week. Cumulative averages over 2 1/2 years were calculated for PA variables and confounders (age, height, weight, calcium, protein and sodium intake), and used in multiple regression analysis, with BMC measured at 2 1/2 years as the dependent variable. Total hours of walking per week (1.4±1.6) was a significant predictor of whole body BMC, p=0.008, R2 adjusted 61.2. Without age in the model, total hours of walking per week was a significant predictor of femoral neck BMC, p=0.038, R2 adjusted 47.1. Walking was not related to lumbar spine BMC, and recreational activities were not related to any measured bone site. The findings of this study indicate that walking for at least 20 minutes several times per week appears to positively influence bone mass of the whole body and hip and therefore, should be recommended to postmenopausal women.

Lymphatic Flow and Bone Mineral Density. K. J. McLeod[1], J. M. Stewart*[2]. [1]Bioengineering, Binghamton University, Binghamton, NY, USA, [2]Pediatrics and Physiology, New York Medical College, Valhalla, NY, USA.

Recent clinical studies have demonstrated the ability of plantar based vibration to inhibit the loss of bone density in post-menopausal women [1], however, given the very low forces produced by this stimulus, it is unlikely the observed effects would be due to any mechanical loading of the skeleton. Instead, we hypothesized that plantar vibration serves as a neuromuscular stimulus, increasing skeletal muscle pump activity which enhances interstitial (i.e. nutrient) flow to the bone tissue by improving interstitial fluid clearance. Initial studies utilizing strain gage plethysmography to measure microvascular filtration confirmed the ability of plantar vibration to significantly enhance interstitial fluid flow [2]. Here, we tested the third aspect of this hypothesis, that is, whether increased lymphatic flow in the lower limbs was associated with increased bone density.

Strain gauge plethysmography was used to measure calf blood flow, venous capacitance and microfiltration relation in the supine position, in 14 women aged 46-63 years. Hip BMD in these subjects was obtained by DEXA and measurements converted to t-scores. Regression analysis was performed using t-score as the dependent variable, against calf blood flow, filtration coefficient, interstitial pressure, and calculated lymph flow. Hip bone density in this population was not related to blood flow in the lower limbs, however a significant positive correlation between BMD and microfiltration coefficient was observed (R^2 = 0.4). Moreover, a significant positive association between interstitial pressure (threshold pressure for edema) and BMD was also observed (R^2 = 0.44). Further, lower limb lymphatic flow was found to be the strongest correlate of hip t-scores in this perimenopausal population (R^2 = 0.52).

In conclusion, lower limb lymphatic flow can account for over 50% of the variability in femoral neck BMD, consistent with the hypothesis that interstitial fluid flow is a critical factor in mediating bone formation and resorption processes. That therapies such as plantar vibration can significantly enhance interstitial flow in the lower limbs potentially opens the door for preventing and treating bone loss through relatively simple interventions.

Cortical Bone Density Increases with Resistance and Agility Training: A Six-Month RCT. T. Liu-Ambrose[1], K. M. Khan[2], J. J. Eng*[3], A. Heinonen[4], H. A. McKay[5]. [1]Orthopaedics, University of British Columbia, Vancouver, BC, Canada, [2]Family Practice, Human Kinetics, University of British Columbia, Vancouver, BC, Canada, [3]Rehab Sciences, University of British Columbia, Vancouver, BC, Canada, [4]Health Sciences, University of Jyväskylä, Jyväskylä, Finland, [5]Orthopaedics, Family Practice, University of British Columbia, Vancouver, BC, Canada.

A randomized, controlled, single-blinded 25-week prospective study was conducted to compare the effects of group-based resistance and agility training on bone, as measured by both DXA and pQCT, in older women with low bone mass. The study was approved by the University of British Columbia Clinical Research Ethics Board and the Research Committee of the Children's and Women's Hospital of British Columbia. All participants provided written informed consent. Ninety-eight community-dwelling women aged 75-85 years were randomized to one of three groups: Resistance Training (n = 32), Agility Training (n = 34), or Stretching (sham exercise) (n = 32). Total hip, femoral neck, and trochanteric BMD were measured by a Hologic 4500 DXA. All the DXA scans were analyzed using standard Hologic analysis protocol. Peripheral QCT measurements were performed at the tibia and radius using the Norland/Stratec XCT 540 densitometer. Single 2.5 mm slices were obtained of the left lower leg at (i) the 50% site (i.e., 50% of the tibial length proximal to the distal endplate of the tibia) and (ii) the 10% site. Similar slices were obtained of the left forearm at the 30% and 10% sites of the radius. A voxel size of 0.5 mm was used for all scans. The pQCT outcome measures at the shaft regions were cortical bone content, cortical bone cross-sectional area, cortical bone density, and density-weighted polar section modulus (SSI). The pQCT outcome measures at the distal sites were total bone content, total bone cross-sectional area, and total bone density. An analysis mask was created specifically for each measured site. Different tissues within each slice were separated according to different density thresholds. At trial completion, the Agility Training group significantly increased cortical bone density by 0.5 ± 0.2% (SE) at the tibial shaft compared with a 0.4 ± 0.3% loss in the Stretching group (p = 0.02). The Resistance Training group significantly increased cortical bone density (1.4 ± 0.6%) at the radial shaft compared with a 0.4 ± 0.5% loss in the Agility Training group (p = 0.03). There were no significant differences among the three groups in any of the DXA outcome measures. Future research is needed to determine the mechanism(s) responsible for the observed adaptation of cortical bone to mechanical loading in older adults with low bone mass.

Multiexercise Program Reduce Risk Factors for Fractures in 70- to 78-Year Old Women: A Randomized Controlled Trial. A. Heinonen[1], S. Karinkanta*[2], H. Sievänen*[2], K. Uusi-Rasi[2], M. Pasanen*[2], P. Kannus*[2]. [1]Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, [2]UKK Institute for Health Promotion Research, Tampere, Finland.

The purpose of this one-year randomized, controlled exercise intervention trial was to evaluate the effects of strength training, balance & agility-jumping training, and combination of strength and balance & agility-jumping training on postural control, muscle strength, and bone mineral mass and geometry in 149 home-dwelling 70 -78-year--old women. The inclusion criteria were no regular exercise or previous bone fractures, no current or previous use of drugs or illness affecting bone metabolism or balance, no contraindication to exercise, and femoral neck T-score ≥ -2.5. The final data could be obtained from 144 women. Femoral neck bone mineral density (BMD) was measured by DXA (Norland XR-26). BMD, total area (TotA), cortical area (CoA) and polar section modulus (SSI) of the shaft and distal part of the tibia were measured with peripheral computed tomography (Stratec XCT 3000). Dynamic balance (agility) was tested by a figure-of-8 running test. Maximal isometric strength of the leg extensors was measured with a leg press dynamometer. All training sessions were supervised and were given 3 times a week for 12 months. Between-group differences were estimated by analysis of covariance using baseline values as covariates. The leg extension strength change was significantly (p<0.05) higher in the strength group (effect: 13%, 95% CI: 3% to 24%) and in the combination group (12%; 2% to 23%) than that in the control group. In addition, the dynamic balance was improved significantly (p<0.05) more in the agility-jumping group (5%; 2% to 7%) and in the combination group (7%; 2% to 11%). In the bone variables, there were no statistically significant differences between the exercise groups and the control group. However,

there was a trend that at the tibial shaft CoA area decreased less in the strength group compared with the control group. This study suggests that 12-month exercise program including muscle strength, balance and jumping training is able to reduce risk factors for fractures among home-dwelling elderly women..Because fluent performance of daily activities and steady postural control require good muscle strength and power, strength training combined with balance & agility-jumping exercises are included in elderly women ´s exercise programs.

Multiexercise Program to Improve Muscle Strength and Dynamic Balance in Home-dwelling Elderly Women. S. Karinkanta*, A. Heinonen, H. Sievänen*, K. Uusi-Rasi, P. Kannus*. UKK Institute, Tampere, Finland.

Decline in neural and musculoskeletal functions in older adults is associated with the ability to respond abruptly to a loss of balance. Balance and lower limb muscle strength are connected to functional ability. The purpose of this randomized controlled exercise intervention trial was to evaluate the effect of six months strength training, agility-jumping training, and combination of strength and agility-jumping training, on lower limb muscle strength, and dynamic balance and agility in home-dwelling elderly women.

The subjects, 149, elderly women aged 70 to 79 years were randomly assigned into four groups: 1) strength training group (SG) (n=37), 2) agility-jumping training group (AG) (n=37), 3) combination of strength and agility-jumping training group (SAG) (n=38) and 4) control group (CG) (n=37). Progressive, supervised training sessions were given 3 times per week. The maximal isometric strength of the leg extensors was measured with a leg press dynamometer. The dynamic muscle strength of lower limbs was assessed by measuring ground reaction forces with a force platform during common daily activities (sit-to-stand and step-on-a-stair tests). Dynamic balance and agility was assessed by a figure-of-eight running test. The between-group differences were analyzed by analysis of covariance using baseline values as covariates.

The mean increase (95% CI) in the leg extension strength was 11% (2% to 20%) greater both in the SG and SAG than in CG. Further, in the step-on-a-stair test, the mean increase in ground reaction forces (N/kg) improved 13% (1% to 27%) more in the SAG than in the CG. In a sit-to-stand test, improvement in the ground reaction forces were 22% (7% to 40%) greater in the AG compared to the CG and 18% (3% to 35%) greater compared to the SG group. In addition, the agility estimated by the figure-of-eight running time improved by 5% (1% to 9%) in the SAG compared to the CG.

According to this data combined strength and agility-jumping training seems to be an effective way to improve muscle strength of the lower limbs, as well as dynamic balance and agility in home-dwelling elderly women. In these respects, strength or agility-jumping training alone was less effective.

Safe Landing During a Fall: Response Time Affects Ability to Avoid Hip Impact During a Sideways Fall. F. Feldman*, S. N. Robinovitch*. Kinesiology, Simon Fraser University, Burnaby, BC, Canada.

Ninety percent of hip fractures are due to falls, and fall severity is at least as important as bone density in determining fracture risk. Of particular importance is whether impact occurs to the hip, which increases fracture risk 30-fold. Previous studies indicate that individuals can avoid hip impact during a sideways fall by rotating the trunk forward or backward during descent. In the present study, we tested whether a critical time window exists for initiating this response after the onset of the fall, in order for it to be effective in preventing hip impact.

Fifteen women participated (mean age=23±4(SD) yrs). In all trials, a sideways fall was initiated by releasing a tether which supported the subject at a 10 deg lean angle. This caused the subject to fall suddenly on a gym mat (average descent time approx. 900 ms). Subjects were instructed to avoid hip impact by rotating backward (BR) or forward (FR) during descent. The instruction was provided as a visual cue (a 1.1x1.6 m image projected in front of them, showing the desired landing configuration) presented either before tether release (by 300, 200, or 100 ms) or after tether release (by 0, 100, 200, or 300 ms). In each trial, we used a 3D motion measurement system to determine the pelvis impact angle. A value of zero deg indicated direct impact to the hip, while 90 deg indicated impact to the anterior or posterior aspect of the pelvis.

From repeated measures ANOVA, we found that the absolute value of pelvis impact angle depended strongly on the time of cue delivery ($p<0.001$; Fig.1), but did not associate with the direction of rotation ($p=0.62$). When the cue was provided 200 ms before release, pelvis impact angles averaged 61.9±22.3 deg for BR and 66.8±12.6 deg for FR. When the cue was provided 200 ms after release, average angles were 19.9±16.0 deg for BR and 13.9±11.9 deg for FR.

Our results indicate that trunk rotation must be initiated early during descent (within 100 ms after loss of balance) to prevent hip impact during a sideways fall. Future studies should examine the sensorimotor and cognitive determinants of response speed, and fracture prevention programs should incorporate safe techniques for enhancing fall protective responses.

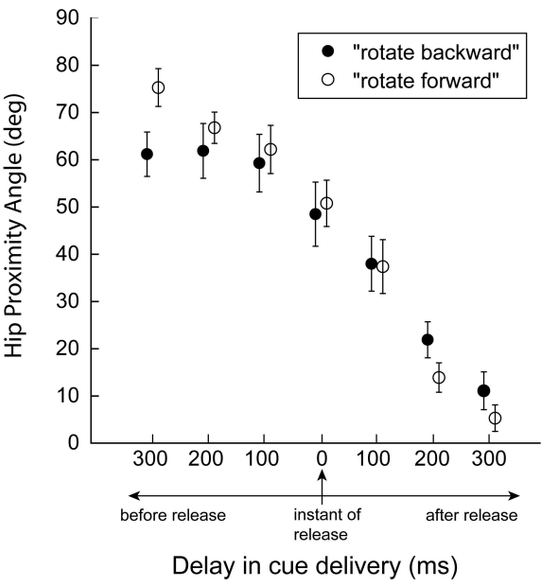

Figure 1: Mean ± S.E. values of pelvis impact angle.

Can Tai Chi Exercise As a Primary Treatment Prevent Osteoporosis And Improve Health Fitness in Seniors? W. Jin*. Shenyang Physical Education University of China, Shenyang, China.

Tai Chi, as a weight bearing form exercise, widely practiced among Chinese, has beneficial effects on cardiorespiratory and musculoskeletal function, posture control capacity, and the reduction of falls experience by elders. However, there have not been enough studies covering the effects of Tai Chi exercise on both preventing bone loss and improving health fitness in seniors. Our objective was to compare the changes of Bone Mineral Density (BMD) and health fitness after six months of Tai Chi exercise in twenty-five healthy seniors (mean age, 65.3+/-5.2y). BMD in the lumbar spine (LS) and femur neck (FN) were measured at baseline and at follow-up by using dual energy x-ray absorptiometry (DXA). Single-stance postural balance, strength, blood pressure and heart rate were also evaluated pre- and post-test. The results showed that there were no significant changes of BMD at LS and FN. Foot COP displacement during stance with eyes open and closed improved +15% ($P<0.01$) and 11% ($P<0.01$). The increases of abdominal muscle and knee muscle strength were +6.4% ($P<0.05$), +22% ($P<0.01$), respectively. The blood pressure (SBP, -11.3%; DBP, -8.8%) decreased significantly but not heart rate (HR, -2.6%). The results indicate Tai Chi exercise as age-appropriate and cost-effective moderate intensity program has benefits on balance, muscle strength, blood pressure in seniors. No significant changes of BMD in this study might be connected with the senior age group and short-term program length. The long term Tai Chi exercise intervention as a primary treatment for preventing osteoporosis should be investigated in further study.

Influence of HMG-CoA Reductase Inhibitors on Bone Mass in Postmenopausal Women. Y. J. Kim, S. Y. Lee*, Y. J. Kim*. Family Medicine, Pusan National University Hospital, Busan, Republic of Korea.

Introduction: It is controversial whether use of HMG-CoA reductase inhibitors(statins) is associated with an increased bone mineral density (BMD) in human or not. The purpose of this study was to assess the influence of statins on BMD of postmenopausal women.

Methods: Forty-four postmenopausal women(mean aged 54.3 ± 5.8 years) were included. The statins users(n=24) were adminstered with simvastatin, atorvastatin, pravastatin or lovastatin. The control group (n=20) did not take statins. BMD of the spine was measured by dual energy X-ray absorptiometry. Alkaline phosphatase(ALP) was tested as a bone turnover marker. The data was analysed with two-sample t-test and paired t-test.

Results: The mean annual spinal BMD changes of the study groups were -1.5± 5.6% for statins users and -0.2±4.2% for control group ($P>0.05$ and $P>0.05$). The mean annual ALP changes of the study groups were - 5.6±18.1% for statins users and -0.4±13.9% for the control group($P>0.05$ and $P>0.05$). In each group, the spinal BMD did not change significantly after 1 year($P>0.05$).

Conclusions: Our results suggest that statins do not protect women from postmenopausal bone loss.

Vertebroplasty Alters the Structural Behavior of Osteoporotic Vertebrae. R. N. Alkalay*, D. von Stechow*, M. L. Bouxsein. Dept. of Orthopedics, Beth Israel Deaconess Medical Center & Harvard Medical School, Boston, MA, USA.

Percutaneous vertebroplasty and kyphoplasty are gaining acceptance for surgical treatment of vertebral fractures (VF), as they have been shown to alleviate protracted back pain with few complications (1, 2). Yet, several reports suggest a high rate of incident VF following these procedures (3, 4, 5). We hypothesized that this increased rate of VF may be partly attributable to altered mechanical behavior of cement-augmented vertebrae. Our goal was to compare the structural behavior of intact, fractured and cement-augmented osteoporotic vertebrae. We used a multi-axial load cell to measure the strength and stiffness of 19 human thoracic and lumbar vertebrae under combined compression and anterior flexion loading. Each vertebrae was tested to failure (50% reduction in anterior height), allowed to recover unloaded for 30 minutes, retested, then augmented with PMMA cement (3 to 10 cc), and tested again. As expected, fractured vertebrae had a reduced ability to resist loading in compression and anterior bending (Table). Cement augmentation not only increased the load-bearing capacity compared to fractured vertebrae (86 to 489%), but also increased compressive (+125%, $p<0.0001$) and anterior bending strengths (+71%, $p<0.01$) compared to intact vertebrae (Table). In summary, vertebroplasty significantly increased the structural competance of fractured vertebrae. However, the mechanical behavior of cement-augmented vertebrae under combined compression and forward bending loads was markedly altered relative to that of intact vertebrae. Our data indicate that vertebroplasty may change the load transfer pattern between adjacent vertebrae, perhaps increasing their risk of fracture. These findings underscore the need for randomized controlled trials to determine the long-term efficacy and safety of vertebroplasty and kyphoplasty.

	Intact	Fractured	Augmented

Does a Distal Forearm Fracture Lead to Evaluation for Osteoporosis? A Retrospective Cohort Study in 147 Danish Women. B. Rud[1], R. Greibe*[2], L. Hyldstrup[1], H. A. Sørensen*[2]. [1]The Osteoporosis Unit, Department of Endocrinology, Hvidovre University Hospital, Copenhagen, Denmark, [2]Department of Internal Medicine, Amager University Hospital, Copenhagen, Denmark.

In postmenopausal women a low trauma distal forearm fracture is a risk factor for osteoporosis and future fracture, which indicates osteoporosis follow-up according to prevailing guidelines. Unfortunately, reports from several countries suggest low compliance with these guidelines.

We decided to determine how often women over 45 years, presenting with a low trauma distal forearm fracture to a Danish emergency department during a one-year period were followed-up for osteoporosis. We excluded women with: 1) dementia or cancer with bone metastases, and 2) avulsion of the styloid process of the ulna.

We performed a retrospective review of hospital records, and we sent the women and their general practitioners pre-tested questionnaires regarding the follow-up undertaken in primary care. Finally, we invited the women for a densitometry of the lumbar spine and the femoral neck. The densitometries were performed on a Norland XR26. T-scores were calculated using a Danish reference material of 103 women aged 20-35 years. We calculated the prevalence of three levels of low BMD using the lowest T-scores measured ($T \leq -2.5$, $T \leq -2.0$, $T \leq -1.5$).

From May 1st, 2001 to April 30th, 2002, 147 women presented with a low trauma distal forearm fracture. According to the review of hospital records none of the women was referred for bone densitometry or spine X-rays. One woman had calcium and vitamin D prescribed and two were recommended to consult their general practitioner for osteoporosis follow-up. As regards primary care we had replies from the women or the GPs for 134 (91%) women. Twelve women were referred for densitometry or spine X-rays and 11 started calcium and vitamin D after the fracture. Women with risk factors for osteoporosis beside the forearm fracture were not more likely to be referred for densitometry or spine X-rays (Fischer's test, $p = 0.10$). Three women started antiresorptive treatment (bisphosponates) following the fracture. The prevalence of $T \leq -2.5$, $T \leq -2.0$ and $T \leq -1.5$ was 24%, 53% and 69%, respectively among the 79 women, who underwent densitometry. Women, who had a densitometry were significantly younger than women, who did not (mean ages 67 and 77 years, respectively) (two sample T-test, $p= 0.0005$).Our study demonstrated a low use of available measures to reduce the risk of future fracture in women with a low trauma distal forearm fracture, and it emphasizes the need to decide on a local level, how to provide osteoporosis follow-up for women with fragility fractures.

A Multi-faceted Post-fracture care Model: The Fracture? Think Osteoporosis! Program. A. Papaioannou[1], E. Coker*[1], C. C. Kennedy*[1], J. DeBeer*[2], J. D. Adachi[1]. [1]Medicine, McMaster University, Hamilton, ON, Canada, [2]Orthopaedics, McMaster University, Hamilton, ON, Canada.

Osteoporotic fractures are a significant burden on our health care system. In Ontario alone, the projected number for 2003 was 10,000 wrist fractures and 8700 hip fractures. While it is unknown how many of these fractures were preventable with proper post-fracture care, part of the fracture burden can be attributed to clinicians, patients and health care systems alike not linking fractures to osteoporosis. Canadian studies show that 50-98% of individuals who experience a fragility fracture do not receive treatment for osteoporosis, despite therapeutic options that decrease future fracture risk. The Fracture? Think Osteoporosis! program is a comprehensive, interdisciplinary strategy that will target the entire spectrum of post-fracture care in the Hamilton region and will provide a model for closing the osteoporosis care gap that exists in Canada today. A multi-faceted approach targeting multiple stakeholders, including providers, patients and the overall health system, has been chosen based on knowledge transfer models of dissemination. The primary objective of the *Fracture? Think Osteoporosis* program is to improve diagnosis and treatment of osteoporosis in patients with fragility fractures and to decrease the rate of subsequent fractures by at least 20% in those individuals > 50 who have experienced a fracture. The intervention will span the spectrum of acute care (fracture clinic, orthopedic units and rehabilitation, radiology), primary care and the community (including BMD clinics, community falls prevention clinics). Planned interventions include predisposing strategies to improve practitioner behavior including needs assessment, CME, patient self- assessment and educational materials; enabling strategies such as care maps on orthopedic and rehabilitation units, reminders, and patient-mediated interventions; reinforcing strategies such as practitioner audit and feedback. In addition strategies at the Health Care System Level will include: guidelines and care maps, hospital committees, development of quality indicators, and working across jurisdictions. Over the course of 5-years, these initiatives will be implemented within a continuous feedback model overseen by an advisory board with scheduled evaluations of process and outcome indictors. Partners in the program include all the acute care hospitals in the region, the Public Health Department, and the Osteoporosis Society of Canada and Fitness Centres.

Ballon-kyphoplasty in the Treatment of Osteoporotic Vertrebral Compression Fractures (VCF) - Our First Experiences. C. Guenther[1], J. Borgulya*[2], A. Kapner*[1], O. Guenther*[1]. [1]Deutsches Zentrum für Osteoporose, Johannesbad Reha-Kliniken AG & Co. KG, Bad Füssing, Germany, [2]Wirbelsäulenchirurgie, Chriurgisch-Orthopädische Fachklinik Lorsch GmbH & Co. KG, Lorsch, Germany.

To look for pain relief and correction of spinal deformity after ballon-kyphoplasty. In addition to this we were interested in new fractures nearby the operated segments.

All together 85 vertebras were treated in 54 patients (48 women, 6 man, age 72 years). This 85 vertebra can be devided in 49 with acute fractures (AF, operation shorter than four weeks after fracture) and 20 subacute fractures (SAF, four to eight weeks). From this 54 patients had 11 adequate trauma, 15 a non-adequate accident and 28 spontaneous fractures. For pain-estimation we used the VAS-scale, for measurement of kyphosis angle the lateral X-ray of the spine.

AF- group (n=49) showed a improvement kyphosis angle of 11.5 grad postoperative (p.o.). and 10.7grad after four weeks. In the SAF -group we could see an improvement of 1.8/ 1.7grad. Looking to the pain-score the AF showed following VAS- values: 8.8 preoperative, 4.1 postoperative and 3.2 after four weeks. SAF- showed: 8.3, 4.7 and 4.2. In no case we have seen any disturbance wound-heeling. Leakage of cement occured in 12 cases (14% of 85), only in one case a radiculopathy (1.2% from 85 vertebras,1.85% from 54 patients).

1. Fresh osteoporotic vertebral fractures can be good restored within the first 4 weeks after fracture. 2. Subacute fractures don't allow a such good improvement of the kyphosis angle. 3. In both cases a good pain relief is possible. 4. The complications happened within the first month of using of this method, that means within the learning phase. Therefore a good training is necessary. 5. In some cases new fractures happened in the vertebras nearby the operated segment. 6. Our two years experiences show that endangered.

adjacent segments should be treated also. 7. The ballon-kyphoplasty is a very safe therapy option in the treatment of the acute vertrebral fracture. 8. Furthermore, osteoporotic patients, with fractures must also be treated with changes in nutritional behaviour, movement therapy, evidenced bases medical therapy (modern bisphosphonates, serms, parathormon, Calcium and Vitamin D) as well as psychological care.

Disclosures: ***C. Guenther****, None.*

A Structured Educational Program Improves the Compliance to Osteoporosis Treatment of Patients with Recent Low-trauma Fracture. T. Chevalley[1], M. Schaad*[1], P. Hoffmeyer*[2], R. Rizzoli[1]. [1]Department of Rehabilitation and Geriatrics, Division of Bone Diseases, University Hospitals Geneva, Switzerland, [2]Department of Surgery, Service of Orthopaedic Surgery, University Hospitals Geneva, Switzerland.

Patients with osteoporotic fracture have a 2 to 4-fold higher risk, according to the skeletal sites, to undergo another fracture. These patients represent high risk patients and

deserve high priority diagnostic and prevention procedures for osteoporosis. After acute management by the orthopaedic team, patients with a low-trauma fracture were enrolled in a medical management pathway. A half a day interactive educational program led by a multidisciplinary team was proposed 8 to 12 weeks after fracture and followed by 35% of the patients. Group discussions concern physical activity, fall prevention and available treatments of osteoporosis, nutritional workshops are held, a series of information brochures are made available, ending into the elaboration of a personal habits modifications program. By considering as controls, patients who did not participate to this educational program, we measured its impact on compliance after 6 to 9 months, as evaluated as the percentage of specific anti-osteoporotic drugs still taken on the number of prescribed medications. During a 55-month period, 264 patients (217F/47M, mean age 72.5±10.7 yrs) were evaluated among the 392 (313F/79M, 70.8±12.3yrs) included in this clinical pathway (hip fracture 45%, ankle/tibia 24%, proximal humerus 9%, wrist 7%, spine 6%, pelvis 3% et other sites 13%). A DXA measurement, performed in 80% of the 264 patients, revealed either osteoporosis (55%) or osteopenia (40%) at spine or hip. Among all patients who attended the educational program, compliance was higher (88% vs 71%, $p<0.05$). Among patients who recognized that their fracture was related to bone fragility at the time of the fracture (32%), compliance was also higher among patients who attended the educational program (94% vs 67%, $p<0.05$). Among the patients with a DXA diagnosis of osteoporosis, the educational program increased the compliance (94% vs 74%, $p<0.05$). Likewise, among patients with DXA diagnosis of osteoporosis and who recognized that their fracture was related to bone fragility (32%), compliance was even better among those who participated to the educational program (100% vs 68%, $p<0.05$). By considering the importance of compliance in the treatment of osteoporosis, we conclude that our educational program may improve the long term management of the disease, and possibly contribute to prevent subsequent osteoporotic fracture.

Disclosures: ***T. Chevalley****, None.*

Targeting Fragility Fractures in an Orthopaedic Treatment Unit: Cost Effectiveness of a Dedicated Coordinator. A. Maetzel*[1], B. Sander*[1], V. I. M. Elliot-Gibson*[2], D. E. Beaton*[2], E. R. Bogoch[3]. [1]Division of Clinical Decision Making and Health Care Research, University Health Network, University of Toronto, Toronto, ON, Canada, [2]Mobility Program Clinical Research Unit, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada, [3]Department of Surgery, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada.

The orthopaedic unit at a university teaching hospital hired an osteoporosis (OP) coordinator to manage a collaborative program to identify fragility fracture patients and arrange for investigation and treatment of OP, and patient education. This analysis evaluates the cost-effectiveness of a coordinator in avoiding inpatient hospitalizations due to further hip fractures from the hospital perspective. A 1-year decision analytic model was developed combining data from the literature and patient-level data from the first year of the program, during which 430 patients entered the study: age 71 years, +/- 14, female n = 333 (77%), index fracture hip (n = 185, 43%), wrist (n = 124, 29%), humerus (n = 72, 17%) and other (n = 49, 11%); OP most likely cause of fracture n = 349 (81%). The decision analysis model calculates the annual incidence of a further hip fracture dependent on type of index fracture (hip, wrist, humerus, other), attribution to OP, age and gender. Referral uptake, initiation of OP treatment and compliance modified the incidence of further hip fractures in the presence of a coordinator. The relative risk of further hip fracture varied from 3.2 to 9.8 depending on the index fracture. Average direct hospital cost of $21,800 for the subset of patients with an index hip fracture were used as a surrogate for the cost of a potential further hip fracture; the cost of a coordinator was $60,000 + 30% benefits. Baseline cost-effectiveness analysis showed that a coordinator who manages 500 patients yearly would reduce further hip fractures from 30 to 21, saving the hospital $104,000. A coordinator was cost-saving: 1) over reasonable cost ranges, 2) if only half of patients initiated treatment and only half complied, 3) if treatment efficacy reduced fractures by as low as 20% and 4) if only 220 patients were seen annually. Employment of a coordinator to manage fragility fracture patients may reduce further hip fractures and is cost-effective from the hospital's perspective. This analysis did not estimate the full benefit of a coordinator on the prevention of other fractures. The results may change, when expanding the model to include all relevant costs from a societal perspective.

Research Participants' Satisfaction Questionnaire. D. E. Conn*, L. M. Rushforth*, E. E. Steffens*, P. M. Workman*, C. E. Schile*, K. M. Hill*, E. A. Mossman, M. R. McClung. Oregon Osteoporosis Center, Portland, OR, USA.

Research subjects prematurely withdrawing from a clinical trial may substantially impair the quality of data and may even jeopardize the ability to assess the study outcomes. The purpose of this study was to determine which services and activities provided by the Oregon Osteoporosis Center affect the satisfaction of the research participants.

Local institutional review board approval was obtained. In April 2004 a 24-item questionnaire was sent to all current participants in research trials at the Oregon Osteoporosis Center. Participants were asked to rate each item as "not important", "somewhat important", "neutral", "important", "very important" and "not applicable" as it related to influencing their satisfaction with being a research participant. In addition, they were asked to rate their overall study experience satisfaction. Quantitative descriptive statistics were used to analyze the questionnaire responses.

74% of questionnaires were returned (193/260). 93% of respondents rated their overall satisfaction with the study experience as 4 or 5, on a 1 to 5 scale with 5 being extremely satisfied. A skilled phlebotomist, explanation of bone density results by a clinician, and professional staff were all rated as very important (68%, 67% and 57% respectively). In contrast, greeting cards and tote bags/other gifts were rarely rated as very important (8% and 5% respectively). Age of respondents (40-90) and type of trial (prevention versus treatment) did not appear to effect the results.

The vast majority of respondents were very satisfied with their overall experience. In general, the overall services provided by staff were perceived as more important than material items and amenities. Whether or not concentrating on these services would help retention in clinical trials remains to be answered in future studies.

The Osteoporosis Self-Assessment Tool (OST) Leads to Increased Osteoporosis Evaluation and Therapy in Men. M. I. Williams*[1], V. I. Petkov*[2], D. M. Biskobing[2], R. A. Adler[3]. [1]Endocrinology, McGuire Veterans Affairs Medical Center/Virginia Commonwealth University School of Pharmacy, Richmond, VA, USA, [2]Endocrinology, McGuire Veterans Affairs Medical Center/Virginia Commonwealth University School of Medicine, Richmond, VA, USA, [3]Endocrinology, McGuire Veterams Affairs Medical Center/Virginia Commonwealth University School of Medicine, Richmond, VA, USA.

Osteoporosis (OP) is a silent disorder which, when left untreated, leads to fracture. OP is under-diagnosed, particularly in men. OST, a simple screening tool for stratifying OP risk, is calculated based on age and weight. We tested different modalities using OST over a 12 month period in 3 primary care group practices (GP) at a single VA Medical Center. Through OST, we identified over 5,000 men at high or moderate risk for OP and over 500 were referred for BMD testing (Williams, MI et al. 2003, ASBMR abstract SA 314.) Although no change from baseline was noted in GP1 or 2, GP 3 demonstrated a marked increase (>500%) in the number of DXAs ordered as a result of OST. We hypothesized that OP specific medications and metabolic bone clinic referrals would also increase as a result of the OST implementation.

Specifically, GPs were randomly assigned and providers received: GP1 Education about OST and an OST pocket nomogram only; GP2 Education/nomogram plus a computer desktop OST-index calculator; GP3 Education/nomogram plus an automatic clinical reminder in the electronic patient medical record. GPs assigned to the two interventions were compared to the GP that received education/nomogram only as well as to their baseline.

Metabolic bone clinic referrals increased by 37%, 16% and 275% for GP 1, 2, and 3, respectively. Bisphosphonate prescriptions increased significantly only in GP3 compared to the one-year baseline period. The percent change in calcium prescriptions issued by GP providers was 16%, -3% and 70%, respectively. In conclusion, electronic record reminders for OST resulted not only in an increased number of DXAs ordered but also in an increased number of men referred to a specialized clinic for OP treatment and in prescriptions for OP specific medications. The combination of a simple screening tool (OST) plus an electronic reminder leads to improved patient care through an increase in diagnosis and treatment of osteoporosis.

The Influence of Bone Mineral Density Testing on the Initiation of an Osteoporosis-related Pharmacotherapy: A Population-based Analysis. P. A. Caetano[1], W. D. Leslie[2], C. J. Metge*[1]. [1]Faculty of Pharmacy, University of Manitoba, Winnipeg, MB, Canada, [2]Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada.

The influence of bone mineral density (BMD) assessment on a woman's decision to initiate an osteoporosis-related pharamcotherapy has not been analyzed at the population-level through the use of administrative databases. Through linkage of a BMD database (containing the results of nearly all BMD measurements performed in the province of Manitoba since 1990), we measured the influence of such testing on the likelihood of initiating an osteoporosis-related pharmacotherapy (OSRx) in post-menopausal women. Hospital, physician, pharmaceutical, clinical (bone mineral density results) and demographic data for women continuously residing in Manitoba from 1997 through 2002 were obtained from provincial administrative databases. Outcome variable: Initiation of an OSRx (including hormone replacement therapy [HRT], bisphosphonates, selective estrogen receptor modulators[SERM], and calcitonin). Women with a prescription claim for an OSRx between 1997-1998 were excluded to restrict the analysis to incident users. Explanatory variables: BMD test (yes/no), prior osteoporotic fracture (hip, spine, rib, or vertebral) after age 50, age, income quintile, and urban vs. rural residence. Likelihood of initiating an OSRx was analyzed using the Cox proportional hazards regression. 112,464 women satisfied the inclusion criteria, of which, 7.5% received at least one BMD test and 12.5%(14,031 women) initiated at least one OSRx within the study period (39.8% HRT; 51.9% bisphosphonates; 5.8% SERM; and 2.5% calcitonin). Multivariate-adjusted predictors of OSRx initiation included (but are not limited to): a BMD assessment [RR 9.08 (95%CL: 8.39-9.88)] and, long-term glucocorticoid steroid use [RR 3.77 (95%CI:2.98,4.79)]. Women with BMD results indicating osteoporosis at *either* the spine or hip were more likely to initiate an OSRx [RR 3.89 (95%CI: 3.33,4.55)]. Women with BMD results indicating osteoporosis at *both* the spine and hip were even more likely to initiate an OSRx [RR 15.11 (10.59,21.56)]. Receipt of a BMD assessment drastically increases the likelihood a woman will initiate an OSRx, particularly in those women diagnosed with osteopenia and/or osteoporosis according to their BMD test results.

SU484

Measuring the Impact of Hip Protector Pads in Mobile Demented Seniors: A Controlled Cohort Study. A. G. Juby*. Medicine, Division of Geriatrics, University of Alberta, Edmonton, AB, Canada.

The prevalence of osteoporosis rises with age, as does the risk of fracture. Hip fractures result in significant morbidity and mortality, and are more frequent in those with increased risk of falls. Mobile, demented nursing home residents are thus at high risk of hip fracture. Hip protector pads have been shown to be efficaceous in preventing hip fracture, but compliance can be an issue.

The purpose of the study was to evaluate the acceptability and efficacy of hip protector pads in preventing hip fracture in mobile, demented, nursing home residents.

Two identical dementia nursing home facilities were chosen within the Capital Care Group in Edmonton, Canada. All residents were independently mobile at baseline. All consenting residents in one facility were provided with hip protector pads (Safehip). All participants (in both facilities) were monitored for cognition (Mini Mental Status Examination), balance (Berg), timed up-and-go and calcaneal ultrasound measurement at baseline. They were followed for three years, and significant falls and fractures recorded.

There were 58 participants (12 men). All had a diagnosis of dementia. The average age was 85 (64-98). At baseline: the average MMSE score was 10/30 (range 0-25); average calcaneal bone mineral density was 0.341g/cm^2 (0.164-0.812gcm^2). 26 participants wore hip protector pads (in a single facility). Over the three year study period, 24 participants died (41%), 12 in each cohort. Multiple falls occurred in 12 participants (>20), 33 participants had falls resulting in injuries. There were 20 fractures in 13 participants 5 of which were hip fractures. 2 of the hip fractures occurred in the hip pad group. In 1 of these the hip pad was on at the time of the fall.

In conclusion, the total number of hip fractures was lower in this high risk cohort than would have been expected. The compliance with pad wearing was high over the three year period. The highly motivated nursing home staff may have accounted for the low fracture rate and high compliance. In those wearing hip pads at the time of the fall, the prevalence of fracture was 20% versus 80% in those without pads.

Effect of Transdermal vs. Oral Estradiol Treatment on Growth Factors and Markers of Bone Turn-over in Young Adults with Turner Syndrome: A Pilot Study. S. Yigit, M. Onyirimba*, P. Gendreau*, T. Lerer*, K. Rubin. Pediatric Endocrinology, Connecticut Children's Medical Center, Hartford, CT, USA.

Gonadal dysgenesis and subsequent chronic estrogen deficiency is a well-described feature of Turner syndrome(TS) where estrogen replacement is accomplished most commonly using oral estrogen. Recent studies report an increased prevalence of symptomatic osteoporosis in TS. In previous studies comparing transdermal (TD) to oral estradiol (E_2) in postmenopausal women, TD E_2 was shown to stimulate IGF-1 production and increase bone formation markers. This study was designed to compare the short term effects of oral vs. TD E_2 on growth factors and markers of bone turnover in young TS adults.10 young adults with TS , ages 16.6-27.9 years were randomized to receive E_2 patch 100 mcg applied twice weekly(n=5) or oral micronized E_2 (n=5) following a 12 week estrogen wash-out. Duration of treatment was 12 weeks with Provera 5 mg daily instituted during weeks 5,6,11, and 12. E_2, estrone, IGF-1, IGFBP-3, bone specific (bs)-alkaline phosphatase, osteocalcin, PINP, and urine NTx were measured at baseline, 6, and 12 weeks. Changes in levels over time in each group, comparisons between groups, and correlations between growth factors, estrogen levels and bone turn-over markers were analyzed. Higher levels of E_2 were achieved with oral vs TD E_2 reaching significance at 6 weeks(p=0.05). Estrone / E_2 ratio was significantly higher in oral E_2 vs. TD E_2 at 6 and 12 weeks (p=0.002 ,p=0.0007 respectively). An upward trend in IGF-1 in TD E_2 group vs a downward trend in IGF1 in oral E_2 group occurred, although non-significant. IGFBP-3 levels decreased over time with TD E_2 (p=0.01) with no change in the oral E_2 group. NTx levels decreased in both groups, significantly in the oral E_2 group (p=0.02). PINP significantly increased over time in TD E_2 group whereas there was a non-significant decrease in PINP in the oral E_2 group. In the TD E_2 group only, significantly positive correlations were observed between all bone formation markers (Osteocalcin, bs-ALP, PINP) with positive albeit non-significant correlations between IGF-1 and all these markers. These pilot data suggest route-specific effects of TD vs. oral E_2 on IGF-1/ IGFBP3 which impact favorably on markers of bone formation. Similar studies with larger numbers of TS adults are warranted.

Comparison between Testosterone, Biphosphonate and Combination of Both in Males with Decreased BMD. U. Gruntmanis[1], M. Denke*[1], A. Kermani*[1], A. Mello*[2], N. M. Gazmen*[2], B. Welch*[1]. [1]Endocrinology, UT Southwestern and Dallas VA Medical Center, Dallas, TX, USA, [2]Radiology, Dallas VA Medical Center, Dallas, TX, USA.

Both, biphosphonates and testosterone are known to improve BMD in males. To our knowledge, there have been no publications comparing efficacy of testosterone and biphosphonates used separately or in combination. In this study our goal is to evaluate effectiveness of each of three treatment regimens in males with decreased BMD.

We analyzed data on 100 men in retrospective manner. The number of men was predetermined by statistical analysis to have power of .8 and experiment-wise type I error of .05, to find difference in BMD between groups. 40 men were on one of the biphosphonates, 40 men were on testosterone and 20 men on combination of testosterone and biphosphonate. To minimize selection bias, all patients were chosen alphabetically from medical records. The 25-hydroxyvitamin D, PTH, calcium, 24-hour urine calcium and creatinine and AM pooled testosterone were measured in all patients. All patients had two BMDs at least one year apart to be included in analysis. Only patients with hypogonadism were treated with testosterone or combination regimen. All patients were prescribed calcium 500mg and 800 IU vitamin D twice a day. Primary outcome was change in BMD in each of the groups.

At baseline, BMD of the lumbar spine and total hip were 0.837±0.11 and 0.749±0.18 (mean SD) g/cm^2 in biphosphonate, 0.923±0.16 and 0.891±0.13 (mean SD) g/cm^2 in testosterone and 0.827±0.12 and 0.81±0.14 (mean SD) g/cm^2 in combination groups. The mean BMD at the lumbar spine and total hip were statistically different between, testosterone and biphosphonate groups (p=0.04 and p=0.001), and testosterone and combination groups (p=0.03 and p=0.02) at baseline. There were no statistical difference between baseline BMDs in the biphosphonate and combination groups. The baseline median testosterone levels were 3.7ng/ml, 1.55ng/ml and 2.4ng/ml in biphosphonate, testosterone and combination groups respectively (p<0.001). The median percentage per year change in lumbar spine and total hip was 2.6% and 0.97% in biphosphonate, 3.3% and 0.46% in testosterone and 2.3% and 1.27% in combination groups (NS).

We conclude that testosterone has similar efficacy with biphosphonates in increasing BMD in men with hypogonadism. The combination of testosterone and biphosphonate does not appear to be superior to single drug therapy

Effect of Food on the Pharmacokinetics of Lasofoxifene, in Healthy Postmenopausal Women. R. Moller*[1], J. Fisher*[2], A. Taylor*[2], S. Kolluri*[2], M. Gardner*[2]. [1]Worldwide Clinical Development, Pfizer, New York, NY, USA, [2]Global Research and Development, Pfizer, Groton, CT, USA.

The purpose of this study was to determine the effects of food on the bioavailability of lasofoxifene (LASO), a next generation selective estrogen receptor modulator (SERM), in late stage development for the prevention and treatment of osteoporosis, in postmenopausal women.

Sixty-four, postmenopausal women were randomized into this four-armed, parallel design, IRB approved study. Following a 10-hour fast, half the women remained in the fasting state while the other half received a standard high fat breakfast. One fed/fasted group received LASO (0.25 mg) while the other fed/fasted group received 0.5 mg of LASO. Blood samples for LASO pharmacokinetic determinations were collected prior to dosing and at various times during the 96 hours following dosing.

These results indicate that food did not affect the bioavailability of a single 0.25 mg or 0.50 mg dose of LASO relative to the fasting state. The ratio of AUC $_{0\text{-}96}$ for the fed/fasted groups was 98.6% (CI: 90.8-107.1%) and 104.7% (CI: 95.8-114.4%) for the 0.25 and 0.5 mg doses respectively. The ratio of Cmax for the fed/fasted groups were 104.5% (CI: 93.1-117.3%) and 100.5% (CI: 91.6-110.2%) for the 0.25 and 0.5 mg doses respectively. Tmax showed a slight difference between the fed and fasted groups, with the fasted group, reaching peak faster than the fed group.

Food does not affect the relative bioavailability of either the 0.25 or 0.5 mg doses of LASO. Therefore, LASO can be dosed without regard to meals.

PSK3471 Restores Long Bone Biomechanical Properties in Ovariectomized Mice with Established Osteopenia. P. Clément-Lacroix[1], P. Ammann[2], R. Galien*[1], D. Minet*[1], C. Belleville*[1], N. Bruyniks*[1], M. Resche-Rigon[1], R. Rizzoli[2], R. Baron[1]. [1]ProSkelia, Romainville, France, [2]Univ. Hosp., Geneva, Switzerland.

Among the first generation of selective estrogen receptor modulators (SERMs), Raloxifene (RAL) has proven efficacy in clinic, reducing the risk of vertebral fracture. However, RAL does not significantly prevent non-vertebral fractures. Thus, there is a need for alternative therapy like SERMs, which could prevent bone loss and decrease bone fragility, while preventing breast cancer and lacking side effects on genital tract. PSK3471 displays good safety profile on breast and uterus and efficiently prevents bone loss in ovariectomized (OVX) mice and rat. The present study was conducted to evaluate the effects of PSK3471 on bone strength in OVX mice with established osteopenia. Eight weeks post-ovx osteopenic mice were orally administered PSK3471 (0.03, 0.1, 0.3 mg/kg/d) or RAL (10 mg/kg/d) for 8 weeks or sc injected with PTH (80 µg/kg/d). After 8 weeks treatment, the doses of 1 and 3mg, of PSK3471 not only fully restored OVX-associated bone loss, but also elicited an increase in trabecular bone mass compared to sham mice (+23% and +50% vs. OVX; p<0.001, for PSK3471 0.1 and 0.3 mg/kg/d respectively). RAL (10 mg/kg/d) only partially restored OVX-induced bone loss. MicroCT analysis confirmed that PSK3471 increased cancellous bone volume (+52% to +68% vs. OVX; p<0.01). Again

RAL exhibited only a partial effect (+14% vs. OVX, ns). In terms of micro-architecture, PSK3471 but not RAL, increased trabecular number, but did not change trabecular thickness. PSK3471, and again unlike RAL, also dose-dependently increased cortical BMD of tibia (+2.7% to +3.8% vs. OVX; p=0.031, PSK3471 0.1 and 0.3 mg/kg). Tibia and femur were then evaluated for ultimate strength, stiffness and energy in compression or/and flexion tests, respectively. Ovariectomy significantly decreased ultimate strength at the level of the proximal tibia and of midshaft femora. At the same skeletal site PSK3471 dose-dependently increased ultimate strength and energy, significantly better than RAL and PTH. At cortical site, PSK3471 and PTH treatment increased ultimate strength, but only PTH reached significance. RAL did not exhibit any protection at the level of the midshaft femur. Thus, after 8 weeks of treatment, PSK3471 is able to restore bone mass in mice with established osteopenia, acting at both trabecular and cortical bone, whereas RAL was only acting at trabecular bone. In addition PSK3471 increased dose-dependently bone strength at the level of the proximal tibia.

Oxandrolone Acts on Human Osteoblasts by Androgen Receptor. L. X. Bi[1], G. V. Oliveira*[2], G. L. Klein[3], W. L. Buford*[1], E. G. Mainous[4], D. N. Herndon*[2]. [1]Dpts. of Surgery and Orthopaedics & rehabilitation, UTMB, Galveston, TX, USA, [2]Dpt. of Surgery, Shriners Hospitals for Children, Galveston, TX, USA, [3]Dpt. of Pediatrics, UTMB, Galveston, TX, USA, [4]Dpt. of Surgery, UTMB, Galveston, TX, USA.

Use of the anabolic agent oxandrolone in severely burned children has been shown to increase lean body mass at 6 mo and bone mineral content at 1 yr post-burn (Murphy KD et al, Surgery 2004, in press). The mechanism of action of oxandrolone is uncertain. The aim of this study was to determine whether oxandrolone acts directly on the androgen receptor (AR) in bone by stimulating type I collagen synthesis. We examined nuclear translocation of androgen receptor (AR) and expression of type I collagen after treatment of cells with oxandrolone. Human osteoblast cells were cultured in a-minimum essential medium [a-MEM] and 10% fetal bovine serum without or with oxandrolone (15ng, 15ug and 30 ug/ml) for 24 hr, respectively. Immunohistochemistry for Androgen Receptor (Neomarkers, Freemont, CA) and collagen type I (RDI, Flanders, NJ) were performed using indirect immunofluorescence. And images were captured using Confocal Scanning Laser Microscopy. Expression of type I collagen was also confirmed using immunoquantitative assay. AR translocation to the nuclei was observed in stimulated cells compared to control group, suggesting the oxandrolone targets osteoblasts through AR. Increased staining for type I collagen was also observed in osteoblasts stimulated with oxandrolone in higher doses (15 and 30ug/ml) but not in lower doses (15ng/ml). Immunoquantitative assay showed that expression of type I collagen was increased (29%, $P<0.01$) in oxandrolone-treated group (30ug/ml), compared to control group. Conclusion: Thus it appears as if oxandrolone at a dose of 15 and 30ug/ml in cultured human osteoblasts results in nuclear translocation of AR and a subsequent increase of type I collagen immunostaining as well as an increase in cellular production of type I collagen by immunoquantitative assay.

Raloxifene Prevents Bone Loss Associated with GnRH Agonist Administration in Mice Through a Potentially Different Mechanism of Action from That of Estrogen. Y. Onoe, Y. Miyabara*, R. Yoshikata*, H. Okano, H. Ohta. Obstetrics and Gynecology, Tokyo Wemen's University, Tokyo, Japan.

Marked bone loss due to estrogen deficiency can be prevented by estrogen replacement therapy (HRT). However, HRT has estrogenic effects on the uterus. In contrast, raloxifene, a selective estrogen receptor modulator, has been reported to reduce bone loss without exerting estrogenic effects on the uterus. Likewise, GnRH agonists (GnRHa) decrease the pulsatile gonadotropin secretion and are useful for the treatment estrogen-dependent disease; long-term treatment with GnRHa can lead, however, to bone loss due to associated increased bone resorption. We therefore examined secondary bone loss associated with the use of GnRHa in mice and studied the effect of raloxifene on such bone loss as compared with estrogen.

8 week-old female ddy mice were given an injection of GnRHa (5 mg/kg) every 4 weeks for 4 to 12 weeks. Some of the GnRHa-treated mice also received concurrent raloxifene (1 mg/kg/day) or 17β-estrdiol (1 μg/kg/day) given subcutaneously via an Alzet pump). Control mice underwent ovariectomy (OVX) and received raloxifene or 17β-estradiol.

OVX mice showed a marked decrease in uterine weight due to uterine atrophy. Likewise, GnRHa-treated mice showed a decrease in uterine weight but not to the same degree as in OVX mice. However, serum FSH levels were markedly lower in GnRHa-treated than in OVX mice, suggesting that uterine atrophy was caused by GnRHa administration. Femoral bone mineral density (BMD) levels in GnRHa-treated mice were significantly reduced, and were similar to those in OVX mice. Raloxifene reduced bone loss in GnRHa-treated mice, while it had no effect on uterine weight; in contrast, 17β-estradiol reduced both bone loss and uterine weight. Raloxifene and 17β-estradiol had similar effects on OVX mice. Bone marrow supernatant OPG levels in GnRHa-treated mice were similar to those seen in OVX mice. Both raloxifene and 17β-estradiol decreased OPG levels in GnRHa-treated mice. 17β-estradiol treatment decreased GnRHa-associated increases in bone marrow supernatant sRANKL levels, while raloxifene led to further increases in sRANKL levels. Furthermore, OPG and sRANKL mRNA levels were not changed by GnRHa, raloxifene or 17β-estradiol.

Our results indicate that raloxifene can prevent the bone loss associated with GnRHa treatment without exerting estrogenic actions on the uterus in female mice through a mechanism of action that differs from estrogen.

Estrens Protect Bone against Ovariectomy-induced Bone Loss in Mice but Fail to be Selective on Reproductive Organs and/or Breast Cancer Cell Lines. R. Galien*[1], S. Windahl[2], P. Clément-Lacroix[1], R. Chiusarolli[2], F. Marsais*[1], D. Minet*[1], L. Lepescheux*[1], C. Jagerschmidt*[1], F. Nique*[1], M. Resche-Rigon[1], R. Baron[1]. [1]ProSkelia Pharmaceuticals, Romainville, France, [2]Orthopaedics and Cell Biology, Yale University School of Medicine, New Haven, CT, USA.

The mechanisms by which androgens and estrogens protect bone are still controversial. Estren α has been reported to act on both receptors and to protect bone while having no effect on reproductive organs in male and female mice. The present study was designed to compare the ability of 4-estren3α-17β-diol (Estrenα) and its isomer 4-estren3β-17β-diol (Estrenβ) to prevent bone loss in adult gonadectomized (GDX) male and female mice and their respective safety profiles on reproductive organs, compared to a classical SERM, PSK3471.

Twelve week-old GDX male and female mice were implanted with slow release pellets delivering either 1/ PSK3471 (30μg/kg/d); 2/ Estrenα (5mg/kg/d); 3/ 17-β-Estradiol (E2; 50μg/kg/d), 4/ DHT (2.5mg/kg/d), or were daily injected with Estrenβ (5mg/kg/d) for 4 weeks. In this model, E2, DHT and PSK3471 not only prevented GDX-induced bone loss, but also elicited an anabolic increase in bone mass compared to sham. In contrast, Estrenα and β, although given at a dose more than 150-fold that of PSK3471, only maintained bone mass at control levels.To assess the safety profile of these compounds, we then measured their impact on uterus and seminal vesicles. As expected from a SERM, PSK3471, but also Estren β, induced very moderate increases in seminal vesicle and uterus weights compared to GDX controls. In contrast, Estrenα had deleterious effects on both uterus and seminal vesicles, similar to E2 and DHT, suggesting that this compound is not selective in its effect on bone versus reproductive organs. We consequently measured the relative binding affinities of Estrenα and β for steroid receptors: unlike PSK3471, these compounds are ligands of both ERs and AR. Both Estrens can stimulate transcription from several estrogen-responsive promoters, and more importantly very efficiently stimulated proliferation of MCF7 cells, whereas PSK3471 did not display agonist activity in these assays but was instead an E2 antagonist. Finally, and again in contrast to PSK3471 or E2, Estrenα and β displayed full agonist activity on the AR, and stimulated strongly ARE-dependent transcription. Given the high concentrations of Estren required *in vivo*, genotropic effects are difficult to exclude. In conclusion, although SERMs and Estrens efficiently prevent bone loss in GDX males and females, the SERM PSK3471 is more efficient on bone and exhibited, in contrast to Estrenα and Estrenβ, a good safety profile on reproductive organs, and breast tissue

Psoraleae Semen Prevents Bone Loss in Ovariectomized Rats. H. Ha[1], J. S. Choi*[1], H. Y. Lee*[1], D. Y. Jung*[1], H. Y. Jeong*[1], K. Y. Song*[2], J. H. Lee*[3], C. Kim[1]. [1]Drug Research and Development Team, Korea Institute of Oriental Medicine, Daejeon, Republic of Korea, [2]College of Medicine, Chung-Ang University, Seoul, Republic of Korea, [3]College of Pharmacy, Kyunghee University, Seoul, Republic of Korea.

Psoralease Semen (PS) is the seed of *Psoralea corylifolia* L. (Leguminosae), which has been used in traditional medicine as a tonic and to treat backache and knee pain, *etc.* This study was focused on development of new drug from PS and its ingredients to prevent and treat osteoporosis after menopause without any side effects. The proliferations of osteoblast like cell (Saos-2) induced by PS and its ingredients were analyzed using a tetrazolim salt (MTT) and alkaline phosphatase (ALP) activity. Gene expressions, such as Runx-2, BSP, and OCN were screened by RT-PCR in MC3T3-E1. The inhibition on osteoclast was also studied using the coculture method of mouse bone marrow cells and ST-2 cells. Adult OVX SD rats (10 weeks old) were administrated EtOH extract of PS (5 g herb/kg/day) during 9 weeks. After administration, complete blood cells counted and biomarkers in plasma analyzed biochemical analysis method. Trabecular bone areas (TBAs) of tibia and lumbar were measured by bone histomorphometry. In results, PS increased ALP activity (139.8% of control) on Saos-2. The TBAs of tibia and lumbar in PS group were increased to 141.1% and 135.1% of the control. PS did not induce estrogenic side effects in uterus. In conclusions, PS prevents OVX-induced cancellous bone loss without any adverse estrogenic effects for 9 weeks in OVX rats. (Supported partially by a grant, #03-PJ9-PG6-SO01-0002, from Health Technology Planning & Evaluation Board, Korea)

A 12-Month Dose-Response Study of Atorvastatin Effects on Bone in Postmenopausal Women. M. McClung[1], D. Kiel[2], R. Lindsay[3], E. M. Lewiecki[4], M. Bolognese[5], E. Leary[6], H. Bone[7]. [1]Oregon Osteoporosis Center, Portland, OR, USA, [2]Beth Israel Deaconess Medical Center, Boston, MA, USA, [3]Regional Bone Center Helen Hayes Hospital, West Haverstraw, NY, USA, [4]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA, [5]Bethesda Health Research, Bethesda, MD, USA, [6]Pacific Biometrics Inc, Seattle, WA, USA, [7]Michigan Bone and Mineral Clinic, Detroit, MI, USA.

Preclinical studies indicate that HMG-CoA reductase inhibitors (statins) may stimulate bone formation and/or inhibit bone resorption. However, this has not heretofore been evaluated prospectively in humans treated with conventional systemic doses. Observational studies and secondary analyses from lipid-lowering trials have yielded inconsistent results regarding the effect of statins on bone mineral density (BMD) and fracture risk.This multicenter, randomized, double-blind placebo-controlled study was designed to determine the effects of a range of doses of atorvastatin on BMD in postmenopausal women. Postmenopausal women (N=626), aged 40-75 yrs, with LDL-cholesterol ≥130 mg/dL and <190 mg/dL, and lumbar spine (LS) BMD -2.5<T-score<0, were randomized to atorvastatin 10 mg, 20 mg, 40 mg, or 80 mg daily or placebo for 52 weeks. All subjects were provided calcium and vitamin D supplements. The primary endpoint was % change from baseline in LS BMD assessed by DXA. Secondary endpoints included additional BMD measurements and changes in biochemical markers of bone turnover (sNTX, sCTX, osteocalcin, BSAP, P1NP and urinary DPD).

On a modified intent-to-treat basis, 482 participants were evaluable. At baseline, the mean age was 59 yrs and mean LS T-score was -1.16. At 52 weeks, there was no significant change from baseline in LS BMD on any dose of atorvastatin or on placebo, and no there was no significant change on any dose vs. placebo. Similar results were obtained for secondary BMD measurements. Changes in biochemical markers of bone turnover did not differ significantly between treatment groups or from baseline within any group. Similar results were observed when the analysis was confined to only the subjects who completed the full 12 months of study. The expected dose-related changes in total cholesterol and LDL-cholesterol were observed. Adverse events across all dose groups were similar to placebo.

Atorvastatin, administered over the range of approved systemic doses, did not affect bone density or turnover in mildly hypercholesterolemic postmenopausal women.

Osteopontin Antagonizes Against Bone Formation Induced by EP4 Agonist in vivo Via Specific Suppression of Osteoblastic Activity. N. Kato[1], K. Kitahara[1], K. Tsuji[1], S. R. Rittling[2], H. Kurosawa[3], A. Nifuji[1], D. T.Denhardt[2], M. Noda[1]. [1]Dept of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Rutgers University, Piscataway, NJ, USA, [3]Juntendo University, Tokyo, Japan.

Bone mass reduction due to osteoporosis increases fracture risk and therefore measures to increase bone formation is to be developed. EP4 agonist (EP4A) has possibility to increase bone in vivo. However, EP4A still is not sufficient since EP4A fails to increase bone mass depending on the background strain of animals due to as yet unidentified reasons. Since osteopontin (OPN) is a molecule which is produced by osteoblasts in response to cytokines and mechanical signals to modulate osteoblastic function as well as osteoclastic function, we examined whether OPN is involved in regulation of bone in response to EP4A (ONO-AE1-329). EP4A was injected three times per day for 5 days a week for 4 weeks subcutaneously into the back of wild type (WT) or OPN deficient (OPN-KO) mice. EP4A significantly enhanced BMD in the distal one fifth of femora in OPN-KO but not in WT. EP4A increased cancellous BV/TV in vertebrae in OPN-KO but not in WT. Subcutaneous EP4A injection in the back did not affect the thickness of calvaria in WT but it was increased significantly in OPN-KO. Mineral apposition rate (MAR) as well as bone formation rate (BFR) were not altered by EP4A in WT but these parameters were both enhanced by EP4A in OPN-KO. In contrast to bone formation parameters, bone resorption parameters were not altered by EP4A in both WT and OPN-KO. Bone marrow cells (BMC) from the femur of OPN-KO treated with EP4A for 4 weeks in vivo significantly increased nodule formation (NF) levels compared to the cells from untreated OPN-KO cells while EP4A treatment in vivo did not alter the NF levels in case of WT. Interestingly, BMC taken from the bone of EP4A-treated OPN-KO but not WT mice showed reduction of osteoclast formation. Systemic injection of EP4A for 4 weeks resulted in increase in alkaline phosphatase (ALP) activity in the cells outgown from the calvaria of these mice. In the EP4A treated OPN-KO-derived cells, there were further increase in ALP activities. OPN-KO enhances ALP activity in the serum of the mice treated with EP4A more than the levels of enhancement of ALP in WT treated with EP4A. Finally, direct EP4A injection onto the calvaria increased new bone formation in WT. However, direct injection of EP4A further enhanced in vivo bone formation on the calvaria in OPN-KO. These data indicated that OPN antagonizes against bone formation induced by EP4A.

Inhibin Prevents Orchidectomy-Induced Bone Loss and Is Anabolic in Intact Mice by Increasing Osteoblast Activity. D. S. Perrien, N. S. Akel, M. Bendre, R. A. Skinner*, F. L. Swain*, D. C. Montague, L. J. Suva, D. Gaddy. Physiology and Biophysics and Orthopaedic Surgery, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Hypogonadism causes a rapid decline in bone mass and strength associated with an increase in turnover favoring resorption over formation. We have previously demonstrated that Inhibin A (InhA) suppresses osteoblast and osteoclast differentiation in primary bone marrow cultures. This led to the hypothesis that Inhibins may suppress bone turnover and maintain bone mass *in vivo* by inhibiting osteoblast and osteoclast development. To test this hypothesis in male mice, the GeneSwitch system of inducible human InhA overexpression was utilized. This system combines liver-specific expression of a mifepristone (MFP)-activated chimeric nuclear receptor (Glvp) and a second Glvp-responsive target transgene encoding linked sequences of the alpha- and beta A-subunits of human InhA. When treated with MFP, mice harboring both transgenes (Glvp/InhA) selectively overexpress InhA from the liver. After reaching peak bone mass (5-6 months), mice underwent either sham operation (Sham) or orchidectomy (Orch) and subcutaneous placement of a time-release pellet containing MFP or vehicle (Veh). All mice were injected with calcein and tetracycline on days 20 and 26, respectively, and were sacrificed on day 28. The mean serum concentration of human InhA in MFP-treated Glvp/InhA mice at the time of sacrifice was 662 pg/ml in Sham-MFP, 808 pg/ml in Orch-MFP, and was undetectable in all Veh treated mice. Treatment of non-InhA expressing Glvp/- mice with MFP had no effect on any measured parameters regardless of gonadal status. Using *ex vivo* microCT and finite element modeling, it was determined that MFP-driven overexpression of InhA prevented Orch-induced loss of trabecular bone volume, microarchitectural parameters, and strength (all $p<0.05$) in the proximal tibia. In addition, InhA improved these measures in intact Sham mice (all $p<0.05$). Systemic bone resorption, measured by serum collagen C-telopeptide crosslinks, was significantly increased by Orch ($p<0.05$ vs Sham) but unaffected by InhA, regardless of gondal status. Histomorphometric analysis of tibial trabecular bone revealed that InhA did not affect the number of osteoclasts or osteoblasts, osteoid thickness, eroded perimeter, osteoclast perimeter, or osteoblast perimeter. In contrast, InhA significantly increased the mineral apposition and bone formation rates in both Sham and Orch mice (all $p<0.05$). Collectively, these data are the first to demonstrate a novel effect of Inhibin A as a potent anabolic agent in intact mice that prevents orchidectomy induced bone loss by increasing bone formation of mature osteoblasts.

The Effect Of Oral Dehydroepiandrosterone (DHEA) on Bone in Premenopausal Women Treated with a GnRH Agonist. N. Glass*[1], S. Hurwitz*[1], M. Hornstein*[1], M. Delaney[2], C. Rosen[3], J. Glowacki[1], M. S. LeBoff[1]. [1]Brigham and Women's Hospital, Boston, MA, USA, [2]The Cleveland Clinic Foundation, Cleveland, OH, USA, [3]St. Joseph's Hospital, Bangor, ME, USA.

Use of Gonadotropin Releasing Hormone Agonist (GnRHa) therapy for endometriosis in premenopausal women leads to accelerated bone loss that may not be completely reversible and may compromise peak bone mass. Low-dose estrogen and/or progestin add-back therapy is often used in conjunction with GnRHa to prevent bone loss. The adrenal androgen, DHEA may have an anabolic and antiresorptive effect on bone, and circulating levels may decrease with use of a GnRHa. Using this model of bone loss, we investigated the effects of oral DHEA vs. placebo in women with endometriosis.

Thirty-two women between the ages of 18-40 yrs with endometriosis who elected to undergo a 6-month course of GnRHa were randomized to receive oral, micronized DHEA (12.5 mg/d or 25 mg/d) or placebo in this IRB approved, double-blind study. Lab evaluations included longitudinal tests for bone markers, hormones, and safety parameters. Bone mineral density (BMD) and body composition was measured by Dual X-ray Absorptiometry (DXA) every 3 months.

Baseline data showed normal, mean serum 25-hydroxyvitamin D (26.14 ± 7.62 ng/ml) and PTH levels (28.63 ± 9.92 pg/ml). DHEA sulfate (DHEAS) levels were at the low end of normal range for premenopausal women; 120.48 ± 54.43 µg/dl (normal range 65-380 µg/dl.) Because of no differences between the 12.5 mg and 25 mg DHEA doses, these data were pooled.

Absolute Changes between Baseline and Month 3

Variable	DHEA (mean)	Placebo (mean)	p value
Estrone (pg/ml)	+5.262	-47.374	0.009
Androstendione (ng/ml)	+1.626	-0.448	0.002
DHEAS (µg/dl)	+246.063	-18.000	0.001
SHBG (nmol/L)	-20.375	+5.800	0.012
Osteocalcin (OC) (ng/ml)	-0.854	+3.380	0.010
N-telopeptides (NTX)	+10.286	+12.200	0.611
IGF-1 (ng/ml)	+1.400	-65.200	0.040
BMD Whole Body (g/cm^2)	+0.007	-0.007	0.090

There were no differences in total testosterone, body fat, or weight changes at 3 months. In women treated with DHEA vs. placebo, the positive change in androstendione and DHEAS and reduction in SHBG, indicate predominant androgenic effects of DHEA in estrogen deficient women treated with GnRHa. The positive effect of oral DHEA on IGF-1 compared with placebo suggests an anabolic effect on bone. The positive change in OC in the placebo group may indicate increased bone turnover that was attenuated by DHEA. Although there was a trend for a positive change in the total body BMD with DHEA vs.

placebo, changes in spine or hip BMD were not observed at 3 months. Further studies with long term follow-up or higher doses of DHEA may be necessary to show a skeletal effect in the setting of acute estrogen deficiency.

Disclosures: ***N. Glass****, None.*

1α,25-dihydroxy-2β-(3-hydroxypropoxy)vitamin D_3 (ED-71) does not Disturb Fracture Healing Process in Rat's Femoral Fracture Model. S. Mori, Y. Cao*, K. Miyamoto*, K. Iwata*, T. Mahiba, T. Akiyama*, S. Komatsubara*, T. Manabe*, H. Norimatsu. Orthopedic Surgery, Kagawa University, Faculty of Medicine, Kagawa, Japan.

While many therapeutic agents are used for the treatment of osteoporosis, osteoporotic patients are prone to fracture. So the question arises whether the drugs should stop or continue when fracture occurred. This study aimed to test whether ED-71 treatment disturb the fracture healing process using rat's femoral fracture model.

160 female SD rats of 6week old were treated either by ED-71 0.025(EDL), 0.05(EDH)) μg/kg, MCT(CNT1) p.o, or alendronate 5(ALL), 10(ALH) μg/kg or saline vehicle (CNT2)s.c. 5 times a week. Four weeks later right femur was fractured and fixed with intramedullary wire. Drug administration was continued and the animals were sacrificed at 6 and 16 weeks post-surgery after double labeling. Fractured femur was assessed by microradiograph, pQCT, 3point bending test and bone histomorphometry. Because no difference was observed, CNT1 and CNT2 were pooled and assumed as CONT for statistical analysis.

At 16weeks after fracture, fracture line disappeared in CNT, ED groups, while it remained in alendronate(ALN)groups. ALN groups showed significantly larger callus area, higher BMC compared to ED groups and CONT. Mechanical test revealed significantly higher ultimate load in ALN groups compared to ED groups and CONT. However % lamellar/callus area was significantly lower in ALN groups (ALL48%,, ALH53%) compared to CONT(99%) and ED groups (EDL99%, EDH98%) at 16 weeks. OC.S/BS was significantly lower in ED and ALN groups compared to CONT. BFR/BS was reduced in ED and ALN groups compared to CONT, while BFR/BS in ALH was the lowest among the groups.

It is considered that the highest mechanical strength of fractured femur in ALN was caused by large callus. However, ALN callus remodeling was delayed as evidenced by lower lamellar bone ratio in the callus. It suggests that strong antiresorptive effect of ALN disturbed the remodeling process of fracture healing. In contrast, ED-71, mild anti-resorptive agent, did not delay callus remodeling, nor disturbed restoration of mechanical strength of the fracture compared to the control. Our results suggest that mild anti-resorptive effect of ED does not disturb fracture healing process.

Comparison of Therapeutic Effects on Bone Mineral Metabolism and Soft Tissue Composition between Alfacalcidol and Alendronate. S. Takata[1], M. Takahashi*[1], H. Yonezu*[2], N. Yasui*[1]. [1]Orthopedic Surgery, The University of Tokushima, Tokushima, Japan, [2]Orthopedic Surgery, Shikoku Chuo Hospital, Kawanoe, Japan.

We demonstrated the difference in therapeutic effects of a one-year treatment between alfacalcidol and alendronate on bone mineral metabolism and soft tissue composition in Japanese osteoporotic women. Ninety-two women suffering from primary osteoporosis without osteoporotic fractures, aged 55 to 81 years, were divided into two groups: women treated with alfacalcidol (0.5 microgram/day; alfacalcidol group, n=57) and women treated with alendronate (5 mg/day; alendronate group, n=35). Bone mineral density (BMD) and soft tissue composition were measured using dual energy X-ray absorptiometry. The percentage change in total lean mass of the alendronate and alfacalcidol groups were 98.6±4.0% and 100.0±4.7%, respectively, which was significantly different (p=0.0357). The total fat mass of the alendronate group increased to 106.8±13.7% of the pre-treatment level, whereas that of the alfacalcidol group decreased to 98.1±14.4%. There was a significant difference in total fat mass between these two groups (p=0.0054). The regional lean mass of the alfacalcidol group except for the trunk lean mass was significantly greater than that of the alendronate group. In contrast, the regional fat mass of the alfacalcidol group was significantly smaller than that of the alendronate group. The mean BMD of the 2nd to 4th lumbar vertebrae (L2-4BMD), and regional and total body BMD of the alendronate group were increased after the one-year treatment, whereas those of the alfacalcidol group were maintained at the respective pre-treatment levels. The results showed the difference in therapeutic effects on soft tissue composition and bone mineral metabolism between alfacalcidol and alendronate. These results suggest that one-year treatment by alfacalcidol has extraskeletal effects on the skeletal muscle, maintaining regional and total lean mass, compared with that by alendronate.

Does Vitamin D Supplementation to Healthy Danish Caucasian Girls Affect Bone Mineralization? C. Molgaard*[1], C. Lamberg-Allardt*[2], K. Cashman[3], J. Jakobsen*[4], K. F. Michaelsen*[1]. [1]Department of Human Nutrition, The Royal Veterinary and Agricultural University, LMC, Frederiksberg C, Denmark, [2]Department of Applied Chemistry and Microbiology, University of Helsinki, Helsinki, Finland, [3]Nutritional Science, Department of Food Science, Food Technology and Nutrition, University College, Cork, Ireland, [4]Department of Nutrition, Danish Institute for Food and Veterinary Research, Søborg, Denmark.

A few observational studies have shown a relation between serum 25 hydroxy vitamin D (s-25OHD) levels and bone growth. In Scandinavia many pubertal girls have low levels of s-25 OHD during winter time. However, it is not known whether a supplement of vitamin D will affect bone metabolism and result in higher bone accretion during puberty. The purpose of this randomised one-year double-blinded, placebo-controlled study was to examine whether a vitamin D supplement could increase s-25OHD status and furthermore increase bone accretion. From the Danish Central Person Register 11-12 year old healthy Caucasian girls living in a certain area of Copenhagen were selected. About 25 percentage corresponding to 225 healthy girls mean (SD) age 11.4 (0.2) y agreed to participate. The girls were randomised to: group A (n=75): placebo, group B (n=75): 5 μg vitamin D_3 daily or group C (n=75): 10 μg vitamin D_3 daily for one year. The inclusions were evenly distributed over one year. 220 completed the one-year study. The following were registered at baseline and after one year: Weight, height, tanner stages, s-25OHD, whole body and lumbar BMC and BMD (Hologic 1000/W). Vitamin D and calcium intake were recorded at baseline by food frequency questionnaire. Mean (SD) s-25OHD, vitamin D and calcium intake were 43.2 (17.1) nmol/l; 2.6 (1.4) μg/d and 1029 (617) mg/d respectively. 8 percent had s-25OHD below 20 nmol/l. There were no significant differences between groups at baseline (ANOVA, all p>0.15). After one year s-25OHD increased significantly in the supplemented groups compared to placebo. A: -3.1 (9.8) nmol/l; B: +11.0 (10.2) nmol/l and C: +13.3 (10.8) nmol/l (p<0.001 for both B and C vs. A), but the difference between B and C was not significant (p=0.19). However, there were no differences between the three intervention groups in changes in whole body or lumbar BMC or BMD. In conclusion: Vitamin D supplementation to pubertal Danish girls results in higher s-25OHD. However there was no difference in s-25OHD increments between the groups supplemented with 5 and 10 μg vitamin D daily. Vitamin D supplementation did not have an effect on bone accretion in these healthy girls without severe vitamin D deficiency.

ED-71, 1α,25-dihydroxy-2ß-(3-hydroxypropoxy)vitamin D_3, Is a Potent Inhibitor of Bone Resorption in Aged Estrogen-deficient Rats. S. Takeda*[1], Y. Uchiyama[1], Y. Higuchi*[1], A. Shiraishi*[1], K. Tsunemi*[1], N. Kubota*[1], K. Sato*[1], H. Saito[1], F. Takahashi[1], F. Makishima*[1], N. Kubodera*[1], K. Ikeda*[2], E. Ogata*[3]. [1]Chugai Pharmaceutical Co.,Ltd., Shizuoka, Japan, [2]National Institute for Longevity Science, Aichi, Japan, [3]Cancer Institute Hospital, Tokyo, Japan.

Nutritional vitamin D supplementation is widely accepted to improve intestinal calcium intake as well as to suppress parathyroid hormone (PTH) via normalizing serum 25-hydroxyvitamin D3 in elderly patients with osteoporosis. However, our previous studies suggested that, in addition to the effects above, the main therapeutic effect of active vitamin D was a direct inhibition of bone resorption, which was enhanced by estrogen deficiency.

In the present study, we compared effects of a novel vitamin D analog, ED-71 (1α,25-dihydroxy-2ß-(3-hydroxypropoxy)vitamin D_3) with 1α-hydroxyvitamin D_3 (alfacalcidol) on bone and mineral metabolism of aged ovariectomized rats.

Eight-month-old female Wistar rats were subjected to ovariectomy (OVX) and then treated with ED-71 (0.05-0.2 μg/kg BW) or alfacalcidol (0.1-0.4 μg/kg BW) for 12 weeks. ED-71 increased lumber vertebral bone mineral density (BMD) greater than alfacalcidol, while ED-71 has activities in enhancing calcium absorption and suppressing serum PTH only comparable to those of alfacalcidol. In bone metabolism markers, ED-71 suppressed urinary deoxypyridinoline (DPD) excretion stronger than alfacalcidol, however, both ED-71 and alfacalcidol did not suppress serum osteocalcin. Bone histomorphometry at lumber vertebrae revealed that ED-71 decreased the osteoclast surface (Oc.S/BS), greater than alfacalcidol, while both agents had a same activity in increasing the bone formation rate (BFR/BS). We also observed only four weeks treatment of ED-71 prevented bone loss in aged ovariectomized rats by suppressing bone resorption, however, alfacalcidol did not show its efficacy after four weeks treatment. Reduction of osteoclast surface (Oc.S/BS) became evident within two weeks of ED-71 treatment. These results suggested that both ED-71 and alfacalcidol prevented bone loss, mainly due to suppressing enhanced bone resorption after ovariectomy. And also, ED-71 is a more rapid and strong inhibitor of bone resorption than alfacalcidol *in vivo.* ED-71 may be an attractive candidate for an orally active anti-osteoporosis agent.

Treatment with ED-71,1α,25-dihydroxy-2ß-(3-hydroxypropoxy) vitamin D_3, for 6 Months Increases Bone Mass in Ovariectomized Cynomolgus Monkey. H. Saito[1], F. Takahashi[1], K. Tsunemi*[1], S. Y. Smith[2], N. Doyle*[2], L. Chouinard*[2], A. Varela*[2], F. Makishima*[1]. [1]Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, [2]CTBR Bio-Research Inc., Senneville, PQ, Canada.

ED-71 (1α,25-dihydroxy-2ß-(3-hydroxypropoxy)vitamin D_3) is a novel vitamin D_3 analog for the treatment of osteoporosis, under Phase 3 clinical trials in Japan. Late Phase 2 clinical trial revealed that 0.5-1.0µg of ED-71 treatment for 48-weeks increased lumber spine bone mineral density (BMD) by 3% as well as femur BMD by 0.62% in patient with osteoporosis. Also, we previously reported that ED-71 dose-dependently increased both BMD and bone strength in vertebrae and femur of ovariectomized rats. The aim of this study is to determine the skeletal effects of ED-71 in ovariectomized (OVX) monkeys, a commonly used bone-remodeling animal model for the osteoporosis drug evaluation.

Adult female cynomolgus monkeys were divided into ovariectomized group (n=9) or ED-71 treated group (n=10). Each animal was orally given either vehicle or 0.3µg/kg of ED-71, daily for 24 weeks. Lumber spine and femur bone mass were measured by dual-energy X-ray absorptiometry, and tibia bone mass was determined by peripheral quantitative computed tomography at 0, 12 and 24 weeks. Serum markers of bone turnover, including bone-specific alkaline phosphatase, osteocalcin, collagen C-telopeptide and urinary collagen N-telopeptide as well as calcitropic hormones, PTH and 1α,25-dihydroxyvitamin D_3 were measured at 0, 12 and 24 weeks. Histomorphometry was carried out in bone sections of lumber vertebrae and proximal femur.

Treatment with ED-71 increased BMD, at lumber spine (OVX: -0.6%; ED-71: 10.2%), femoral neck (OVX: -0.4%; ED-71: 15.5%) and trochanter (OVX: 0.2%; ED-71: 11.8%) following ovariectomy in comparison with vehicle-treated animals. ED-71 significantly increased cortical bone mineral content (OVX: 2.3%; ED-71: 11.9%) and cortical thickness (OVX: 7.1%; ED-71: 13.7%) and also decreased cortical circumferences in tibia diaphysis. Bone histomorphometry revealed that ED-71 decreased bone resorption parameters such as osteoclast surface (Oc.S/BS) and eroded surface (ES/BS) as well as bone formation parameters, mineral apposition rate (MAR) and bone formation rate (BFR/BS) in cancellous bone compared to OVX control, whereas, ED-71 did not affect both periosteal (Ps.BFR/BS) and endocortical (Ec.BFR/BS) bone formation in cortical bone. These results suggested ED-71 increased trabecular bone mass mainly through inhibition of bone resorption, however did not interfere cortical bone formation, which both were enhanced by ovariectomy.

Oral Vitamin D3 Supplementation In Postmenopausal African American Women. S. A. Talwar, J. F. Aloia, S. Pollack*, J. Yeh. Bone Mineral Research Center, Winthrop-University Hospital, Mineola, United States, Winthrop University Hospital, Mineola, NY, USA.

BACKGROUND: Vitamin D insufficiency is a major problem among African American (AA)women living at higher latitudes in North America. We conducted a randomized, placebo controlled, double-masked study to test the hypothesis that vitamin D3 supplementation would prevent bone loss in calcium-replete, postmenopausal AA women.

AIM: We hypothesize that Vitamin D supplementation (intended to increase serum 25-OHD to "optimal" levels) would decrease postmenopausal bone loss in calcium-sufficient AA women.

METHODS: 208 healthy black postmenopausal women 50-75 of age, were randomly assigned to receive either placebo or 20 mcg daily of vitamin D3.Calcium supplements were provided to ensure a total calcium intake of 1200-1500mg/d in both groups. After 2 years, the vitamin D3 dose was raised to 50mcg/d in the active group and the study continued for an additional year. Bone mineral density (BMD) of the total body, spine, total hip, and mid radius were measured every 6 months by DXA. Markers of bone turnover, vitamin D metabolites and parathyroid hormone levels were measured in serum.

RESULTS: There were no significant differences in bone mineral density between the active and control groups throughout the study. There was a transient increase in total body, femur, and radial BMD at 6 months in both groups.Over the 3 years, BMD declined at these sites by .26 to .55%/ year. The BMD of the lumbar spine increased slightly in the placebo group and active group, respectively. Serum 25-OHD increased from 47nmol/L to 71 nmol/L at 3 months in the active group and by an additional 20 nmol/L 3 months after the increase in dose to 50 mcg/d. The mean serum 25-OHD levels at the end of the study in Ca+D group was 73.8nmo1/L with about 40% participants still under 80 nmo1/L in spite of supplementation. There were no persistent changes in serum PTH levels or the markers of bone turnover, although there was a transient decline in PTH in both groups at 3 months. No significant adverse events were attributed to vitamin D supplementation.

CONCLUSIONS: There was no effect of vitamin D3 supplementation on bone loss in calcium-replete African-American, postmenopausal women. Further studies are needed to determine if these findings are applicable to other ethnic groups or if higher amounts of vitamin D would have an effect.

BMD changes over 3 years with vitamin D supplementation

BMD site	Ca group (n=104)	Ca+D group (n=104)
Baseline Total Body (TBBMD) (g/m2)	.94(.074)	.934(.095)
Absolute change in TBBMD (g/m2)	-.018(.026)	-.018(.025)
Baseline Total Hip BMD (g/m2)	.946(.116)	.932(.146)
Absolute change in Hip BMD (g/m2)	-.014(.033)	-.012(.036)
Baseline spine BMD (g/m2)	1.005(.142)	.984(.155)
Absolute change in spine BMD (g/m2)	.007(.04)	.006(.039)

The Use of Alendronate in the Treatment of Osteonecrosis of the Femoral Head to Reduce Degenerative Osteoarthritis of the Hip. J. G. Hofstaetter*, J. Wang*, M. J. Glimcher. Orthopedic Surgery, Children's Hospital Boston, Boston, MA, USA.

Osteonecrosis (ON) of the femoral head can lead to structural failure and secondary osteoarthritis (OA) of the hip. We evaluated the effects of Alendronate (ALN), a potent bone resorption inhibitor, on microarchitecture and mineralization of trabecular and compact bone during the repair of the osteonecrotic femoral head and subsequent OA of the hip using micro-Quantitative Computer Tomography (16 microns), radiography and histology. ON of the left femoral head was surgically induced in 60 adult male NZW rabbits. Animals were randomized into four groups of 15 each and treated either with ALN (150µg/kg/day, s.c., 3x per wk) or saline, starting one month post-surgery. Rabbits were sacrificed 6 and 12 month post-surgery and contra-lateral hips of the saline groups served as controls. Two osteonecrotic femoral heads from the saline-group were collapsed at 12 months, whereas no collapse was observed in either ALN group. Repair of necrotic trabecular bone resulted in significant increases in volumetric bone mineral density (vBMD) and bone volume fraction (BVF) when compared to controls. Inhibition of resorption of necrotic trabecular bone by ALN led to marked increases in vBMD and BVF when compared to the saline-treated ON groups. Resorption of the necrotic subchondral bone was inhibited by ALN. In the saline-treated OA acetabulum, subchondral bone resorption was markedly increased at 6 and 12 month post-surgery, which was almost completely inhibited by ALN. The subchondral bone of the saline-treated OA acetabulum had a significantly higher porosity, lower vBMD and lower degree of mineralization than healthy controls. The OA subchondral bone of the ALN group was found to have an even higher vBMD and degree of mineralization than controls, and no change in porosity was observed. Bone volume and vBMD was significantly increased, but mineralization was decreased in the subchondral trabecular region of the OA acetabulum when compared to controls. In the ALN treated OA-group the increase of subchondral trabecular bone volume was less, but the bone had an even higher degree of mineralization than normal bone, which resulted in an overall increase in vBMD in this region. ALN reduced the histological Mankin score ($p<0.05$) of cartilage damage during OA progression in the acetabulum. These results strongly suggest that ALN effectively inhibits resorption of trabecular and subchondral compact bone in the ON femoral head without impairing new bone formation and thus preventing structural failure. Furthermore, this demonstrates that ALN reduces subchondral bone resorption in OA, and slows down the progression of OA.

Coumadin Therapy Is Associated with Bone Formation in Aortic Valves Excised for Aortic Valve Stenosis. S. W. Ing[1], E. R. Mohler*[2], M. Putt*[3], M. Leonard[4]. [1]Internal Medicine, Geisinger Health System, Wilkes-Barre, PA, USA, [2]Internal Medicine, University of Pennsylvania, Philadelphia, PA, USA, [3]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania, Philadlelphia, PA, USA, [4]Pediatrics, Childrens Hospital of Philadelphia, Philadelphia, PA, USA.

Ossification has been described in a number of vascular areas, including cardiac valves, and attributed to an inflammatory endochondral pathway of osteogenesis. The objective of this study was to identify determinants of aortic valve ossification in a series of 207 valves; 30 contained ossification. Medical records were reviewed for (1) factors associated with skeletal bone: age, sex, race, age, height, weight, BMI, cigarette smoking, serum creatinine, calcium, phosphate, and use of statins, warfarin, bisphosphonate, systemic glucocorticoids, estrogen, calcium, and multivitamin; and (2) additional factors associated with the development of aortic valve calcification or stenosis: hypertension, diabetes mellitus, elevated cholesterol, mitral regurgitation and left ventricular hypertrophy. Univariate analysis was performed using chi-square tests for dichotomous variables, and Student t-test or Wilcoxin rank-sum test for continuous variables. Multivariate analysis was performed using step wise logistic regression. Five variables were associated with valvular ossification (using a higher p-value cutoff of <0.1) for inclusion into multivariable analysis. The univariate odds ratios (OR, 95% C.I.) for these factors were: warfarin use- OR 5.3 (1.59, 17.72), p = 0.004; African American race (vs. Caucasian) - OR of 6.1 (1.56, 23.7), p = 0.006; female gender - OR 0.46 (0.2, P=1.07), p = 0.07, taller stature (taller median height) - OR 2.43 (1.09, 5.43), p = 0.03; and diabetes - OR=0.4, p=0.07. Warfarin use was not associated with race, sex, or diabetes. Inclusion of these factors in a step-wise logistic regression model revealed that warfarin use and African America race were independently associated with valvular ossification while female gender and diabetes were marginally associated with valvular ossification: warfarin use- OR 5.7 (1.5, 21.1), p=0.010; p=0.009; African Americans- OR=8.3 (1.8, 38.8), p=0.007; female gender- OR 0.39 (0.15, 0.98), p=0.044; and diabetes- OR=0.34 (0.11, 1.00), p=0.049. Further studies are needed to explore these associations, and the role of warfarin-induced inhibition of matrix Gla protein function in the development of valvular ossification.

The Effect of Growth Hormone Replacement on Serum FGF-23 and Various Phosphate Indices in Adult GH Deficiency. B. H. Durham[1], H. D. White*[2], A. M. Ahmad*[2], J. P. Vora*[2], W. D. Fraser[1]. [1]Clinical Biochemistry & Metabolic Medicine, Royal Liverpool University Hospital, Liverpool, United Kingdom, [2]Endocrinology, Royal Liverpool University Hospital, Liverpool, United Kingdom.

We have measured FGF-23 in fasting serum from growth hormone deficient adults [GHD] 12 male, 8 female, average age 55 yr [range 24-72] prior to, and at 1,3,6 and 12 months of GH replacement [GHR]. We also measured phosphate [PO4] and creatinine in serum and a 24 hour urine; from these we calculated the ratio of PO4 clearance to creatinine [PCl], PO4 excretion index [PEI] and the percentage of tubular reabsorbed PO4 [TRP]. After one month GHR, FGF-23 increased by > 25% in 15/20 [75%] and >50% in 10/20 [50%]. Maximum concentration was reached at 3 months in 6 [3m, 3f] and at 6 months in 5 [3m, 2f], in the remaining 9 [6m,3f] the concentration FGF-23 was still increasing 12 months after the commencement of GHR. The PO4 indices were calculated in the samples from the month when FGF-23 reached a maximum [or in the case of the nine who did not reach a maximum, the 12month sample]. Prior to GHR the median [range] values were: FGF-23 121 RU/L [49 to 324], serum PO4 1.08 mmol/L [0.73 to 1.33], total 24 hr urinary PO4 excretion [TuPO4] 23.8 mmol/24hr [7.7 to 46.1], PCl 0.22 [0.08 to 0.37], TRP 78.2 [63.2 to 91.6] and PEI 0.11 [-0.09 to 0.31]. Post GHR the values were: FGF-23 289 [82 to 1925], serum PO4 1.23 [0.71 to 1.38], TuPO4 26.9 [11.0 to 67.5], PCl 0.19 [0.12 to 0.41], TRP 80.6 [58.6 to 88.0], PEI 0.11 [-0.04 to 0.27]. The increases in FGF-23 and serum PO4 were significant [p= 0.05] and the percentage change in FGF-23 correlated significantly [p= 0.05] with those for serum PO4 and TRP. Although there was no significant correlation between the change in FGF-23 and that for TuPO4 the percentage change in TuPO4 correlated positively with the percentage change of PCl [p=0.05] and PEI [p=0.01] and negatively with that for TRP [p=0.01]. Therefore the increase in FGF-23 in GHR could be a mechanism to counteract the increase in circulating PO4 which occurs during GHR by altering the renal handling of PO4 and increasing phosphaturia.

A Vanadium-based Anti-diabetic Drug Affects Bone Cells and Bone Mineral In a Rat Model of Diabetes. D. Facchini*[1], V. Yuen*[2], M. Battell*[2], J. McNeill*[2], M. Grynpas[1]. [1]Mount Sinai Hospital & University of Toronto, Toronto, ON, Canada, [2]University of British Columbia, Vancouver, BC, Canada.

Vanadium-based drugs have an insulin-like glucose lowering ability, and oral vanadium drugs are being tested as alternatives to insulin injections for diabetes. Vanadium accumulates in bone where, in the form of vanadate, it replaces phosphate in the apatite lattice of bone mineral. The purpose of this study is to determine if incorporated vanadium affects bone quality in normal and diabetic bone. Nine to 12 month old, sham-operated and streptozotocin-induced diabetic Wistar rats were given BEOV, a vanadium-based anti-diabetic drug, in drinking water for 12 weeks. Non-diabetic rats were divided into groups of 10 to receive 0, 0.25 or 0.75 mg/mL BEOV. Groups of diabetic rats were either left untreated (n=12) or treated with 0.25-0.75 mg/mL BEOV as necessary to lower blood glucose in each rat (n=22). In diabetic rats, this treatment resulted in 2 groups: 1) a controlled glucose group (n=10), simulating well-managed diabetes, and 2) an uncontrolled glucose group (n=12), simulating poorly managed diabetes. BMD was assessed by DEXA. Mechanical properties were determined by femoral bending, vertebral compression and femoral neck fracture. Degree of mineralization was determined by density fractionation, mineral crystal size by x-ray diffraction and mineral chemistry by instrumental neutron activation analysis. Trabecular architecture and connectivity were assessed by image analysis and bone remodeling parameters by static and dynamic histomorphometry. In non-diabetic bone, BEOV increased vanadium content, degree of mineralization, osteoid volume (>+55% for both doses) and bone formation rate (>+140% for both doses). Diabetes decreased BMD (-16% in femurs, -21% in vertebrae) and mechanical strength (-16% in bending, -38% in compression, -22% in femoral neck). The diabetic bone was less mineralized, and this bone mineral had shorter crystals (-8%). Diabetes also decreased bone volume (-45%) and connectivity (-56% Number of Nodes). Controlling glucose with BEOV increased vanadium content, and improved bone properties. Increases in BMD of femurs (+10%), mechanical strength (+12% in bending, +19% in compression) and degree of mineralization were observed. There were also increases in osteoid volume (+91%) and bone formation rate (+220%), but no changes in bone volume or connectivity. The uncontrolled glucose state increased vanadium content, but did not improve bone properties. The results suggest that BEOV improves diabetes-related bone dysfunction. This may be due to a direct action of BEOV on bone cells, the incorporation of vanadate into bone mineral and the improvement by BEOV of the diabetic state.

Tobacco Smoking Effects on Bone Biomechanical Properties. M. P. Akhter, A. D. Lund*, S. Morgan*, D. J. Wells*, D. M. Cullen. Medicine, Creighton University, Omaha, NE, USA.

Tobacco use is associated with decreased bone mass and increased fracture risk. Based on a study of twin pairs discordant for cigarette use, women who smoke one pack of cigarettes per day throughout life will have 5 to 8% less bone than nonsmokers. The purpose of the current study was to evaluate the effects of high concentration tobacco smoke on bone strength in estrogen-replete (intact) and estrogen-deplete (ovariectomized) rats. Adult (6-month-old) Sprague dawley female rats were divided into 4 groups. Intact rats (n=24) and ovariectomized (OVX, n=24) were subjected to either sham or tobacco/cigarette (1R4F University of Kentucky research) smoke exposure. A steady state concentration of 126±4mg (mean± sem) smoke TSP/m^3 was maintained in the chamber during exposure of the rats to smoke. Exposures were given for 2hrs each week day and 1 hr on weekends (total of 12hrs/week) for 12 weeks. At the time of necropsy, femurs were collected and frozen in saline for subsequent structural and biomechanical evaluations. Specimens were allowed to reach room temperature before structural and strength evaluation. Using a micro computed tomography device (μCT20, Scanco Medical AG, Bassersdorf, Switzerland), femoral necks were scanned (9 micron resolution with an integration time of 80 milliseconds) to determine cancellous/trabecular structural properties in terms of bone volume (BV/TV), trabecular thickness, and spacing. After scanning, the mid-shaft femur was subjected to a 3-point bending test (along anterior-posterior direction) and femoral neck tested in bending. All tests were performed at rate of 3mm/minute. Structural strength parameters (ultimate/yield load, stiffness) were obtained from the load-displacement diagram. The apparent material strength (ultimate/yield stress, modulus) was calculated. Tobacco smoke exposure- and ovariectomy-related differences in all the measured variables were tested using two-way ANOVA at a significance level of P<0.05, followed by a Tukey HSD post-hoc test. While tobacco exposure effects on biomechanical properties were not detected, the ovariectomy caused a significant decline in most of the structural and biomechanical properties in the femoral shaft and femoral neck (Table, only the affected variables are listed).

Table. Biomechanical Properties (Mean ± SD)	Intact Sham	Intact Smoke Exposed	OVX Sham	OVX Smoke Exposed
FS Ultimate Load (N)	160±11	168 ± 15	142 ± 14 [b]	144 ± 18 [b]

Changes in Biochemical Bone Markers and Bone Mineral Density after Parathyroidectomy in Primary Hyperparathyroidism: A Three-Year Follow-up Study. F. Debiais[1], J. Kraimps*[2], M. Bounaud*[3], R. Marechaud*[4], P. Ingrand*[5], I. Azais*[1], R. Brault*[1], M. Alcalay*[1]. [1]Departments of Rheumatology, La Miletrie Hospital, Poitiers, France, [2]Endocrine Surgery, La Miletrie Hospital, Poitiers, France, [3]Biophysic, La Miletrie Hospital, Poitiers, France, [4]Endocrinology, La Miletrie Hospital, Poitiers, France, [5]Biostatistics, Faculty of Medicine, Poitiers, France.

Primary hyperparathyroidism may be associated with bone involvement. The aim of this study was to determine the changes in biochemical bone markers and to investigate long-term bone mineral density (BMD) changes at both trabecular and cortical sites after parathyroidectomy.

Serum levels of osteocalcin and bone alkaline phosphatase as markers of bone formation and excretion of urinary deoxypyridinoline as a marker of bone resorption were measured at baseline, 3 days, 1 month, 6, 12, 24 and 36 months. Measurements of BMD of lumbar spine (L2-L4), hip (femoral neck, trochanteric region and total hip), distal radius (proximal third, Mid, ultradistral and total) and whole body were obtained by dual energy X-ray absorptiometry (Hologic QDR 2000). BMD was measured before and after parathyroidectomy at 6 months (42 patients), 12 months (40 patients), 24 months (31 patients) and 36 months (27 patients). Mean age of the patients (10 men, 10 premenopausal women, 22 postmenopausal) was 57.4 ± 12.9 years. Before surgery, patients had increased serum calcium concentrations (Mean : 2.83 ± 0.21 mmoles/l ; normal range : 2.20-2.60 mmoles/l) and parathormone levels (Mean : 126.7 ± 84.1 pg/ml ; normal range : 15-60 pg/ml), and 28 patients had a low BMD with a T-score <-2.5 at least at one of the studied sites.

Following parathyroidectomy, the three biochemical markers, compared to baseline, decreased significantly within 6 months, with no major changes during the following 2.5 years. Increases in BMD were significant within 6 months in the spine (p<0.0001), the total hip (p<0.0001), the trochanteric region (p<0.0001), the femoral neck (p<0.05), and the whole body (p<0.001). In the radius, bone density rose more slowly and increases were significant within 1 year (mid, ultradistal, total) or 2 years (proximal third). At 3 years, the more pronounced increases were in the spine (6.6% + 5.7%) and in the trochanteric region (7.6% + 5.1%)

These results show that, following parathyroidectomy, bone turnover decreases and BMD increases at both cancellous and cortical sites, but with a slower and more modest increase in the radius.

Vitamin D Replacement in Patients with Concomitant Primary Hyperparathyroidism and Vitamin D Deficiency - A Safe Option. V. Eshed[1], E. Segal*[2], G. Tsvetov[1], C. Benbasat*[1], S. Ish-Shalom[3]. [1]Endocrinology and Metabolism, Rabin medical center, PetahTikva, Israel, [2]Metabolic bone diseases, Rambam Medical Center, Haifa, Israel, [3]Bruce Rapaport Faculty of Medicine, Technion Israel Institute of Technology, Haifa, Israel.

The prevalence of vitamin D deficiency/insufficiency in patients with primary hyperparathyroidism is more than 50%. Data from the literature support the notion that vitamin D deficiency may contribute to the severity of primary hyperparathyroidism. The aim of our work was to asses the effect of vitamin D replacement on calcium metabolism, in such patients. We followed 20 consecutive patients with a combination of primary hyperparathyroidism and $25(OH)D_3$ levels below 15 ng/ml. Sixteen (80%) of the patients were women and 4 (20%) were men. The mean age was 60.3 ± 21.01. All patients were hypercalcemic at their baseline test. Baseline and post treatment levels of serum and urinary calcium, serum phosphorus, alkaline phosphatase, $25(OH)D_3$ and PTH are shown in the table. All patients had normal serum creatinine levels. Patients were treated with 400-1000 units/day of vitamin D. Serum level of $25(OH)D_3$ significantly increased, to a mean of 17.04 ng/ml ($p<0.0001$) after a mean time of 4.2 ± 2.3 months. No significant changes in serum calcium, phosphorus, alkaline phosphatase, PTH and 24 hours urine secretion of calcium were observed.

Mean levels	Vitamin D depleted	Vitamin D repleted
25 hydroxyvitamin D (ng/ml)	7.8 ± 3.5	17.04 ± 6.7
PTH (pg/ml)	104.4 ± 78	99.3 ± 49.9
Serum calcium (mg/dl)	10.6 ± 0.4	10.55 ± 0.6
24 hours urine calcium (mg)	298 ± 163.9	249 ± 100.5
Alkaline phosphatase (u/l)	99.99 ± 38.38	89.75 ± 31.32
Phosphorus (mg/dl)	3.06 ± 0.7	2.91 ± 0.48

We conclude that treatment of patients with concomitant primary hyperparathyroidism and vitamin D deficiency/insufficiency with 400-1000 IU of vitamin D daily is safe and leads to improvement of vitamin D status.

Impact of Autoimmune Polyendocrinopathy-Candidiasis-Ectodermal Dystrophy (APECED) on Bone Health: Findings in 25 Adult Patients. O. Mäkitie*[1], E. Sochett[2], S. Bondestam*[3], J. Perheentupa*[1]. [1]Pediatric Endocrinology, The Hospital for Children and Adolescents, Helsinki University Hospital, Helsinki, Finland, [2]Division of Endocrinology, The Hospital for Sick Children, Toronto, ON, Canada, [3]Department of Radiology, Helsinki University Hospital, Helsinki, Finland.

Autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) is an autosomal recessive disorder characterized by chronic mucocutaneous candidiasis and autoimmune destruction of endocrine organs. The resulting endocrinopathies and their treatment may impact bone health in patients with APECED.

The purpose of our study was to assess bone health and its correlates in adult patients with APECED.

Twenty-five adults (12 males) with APECED, followed at the Helsinki University Hospital, were prospectively assessed. Data on their previous medical history was collected from hospital records. Areal BMD (aBMD) for the lumbar spine (L1-L4) and femoral neck as well as volumetric BMD (vBMD) for the lumbar spine (L2-L4) were measured with dual-energy x-ray absoptiometry (DXA, Hologic Discovery A); the aBMDs were transformed into z-scores using age- and sex-specific reference data for the equipment.

Mean age at study assessment was 38 years (range 21-59 years). All patients had 1-4 autoimmune endocrinopathies (median 2) and other manifestations. The most common endocrinopathies were Addison's disease (AD, 20 patients), hypoparathyroidism (HPT, 18), hypogonadism (10) and diabetes mellitus (6). The mean age at the onset of AD was 13.2 years (5.5 - 28.1 years) and of HPT, 5.8 years (1.6 - 18.9 years). The median aBMD z-scores were for the lumbar spine -0.3 (-2.3 - +3.3) and for the femoral neck, -0.1 (-2.2 - +2.0). The median volumetric BMD was 0.23 g/cm^3 (0.17-0.31 g/cm^3). The patients with HPT had significantly higher BMDs than the patients with normal parathyroid function: the mean aBMD z-scores were for the lumbar spine +0.4 *vs* -1.2 (P=0.016) and for the femoral neck, +0.2 *vs* -0.6 (P=0.094), respectively, and the vBMD, 0.24 g/cm^3 *vs* 0.21 g/cm^3 (P=0.008), respectively. Of the four patients with a lumbar spine aBMD z-score >+1.5 all had HPT and only one had AD. In contrast, of the four patients with a z-score <-1.5 all had AD and only one had HPT. The prevalence of fractures was higher among those with normal parathyroid function (4/7) than among those with HPT (4/18).

Our study suggests that despite the complex endocrine problems the overall prevalence of osteopenia and osteoporosis is low among adults with APECED. Normal parathyroid function may have a positive and AD a negative impact on bone health in patients with APECED.

Gene Expression in Primary and Secondary Hyperparathyroidism : Phosphate-Induced Genes in Human Parathyroid Tissue in Organ Culture. K. Sato, K. Nakajima*, K. Takano*, T. Obara*. Insitute of Clinical Endocrinology, Tokyo Women's Medical University, Tokyo, Japan.

To investigate the mechanism of phosphate-induced parathyroid cell proliferation, human parathyroid tissues were cultured in low and high phosphate medium, and mRNAs induced by high phosphate medium were analyzed using DNA microarray (Agilent), which can analyze 17000 - 41000 genes in a single run.

Hyperplastic parathyroid glands obtained from patients with primary hyperparathyroidism (N = 4), secondary hyperparathyroidism (N =4), and parathyroid carcinoma (N=1) were cut into pieces (1x1x0.5mm), placed on collagen-coated nylon mesh, and cultured in 10cm dishes. Culture medium containing 10% bovine serum and various concentration of Ca (4 - 11mg/dl) was prepared so that final phosphate concentrations were 2.5mg/dl (low P) or 10mg/dl (high P). After 5 - 30 days of culture, the conditioned medium was taken for measurement for PTH. Data were expressed as ng intact PTH/microg DNA.

Intact PTH secretion continued for a prolonged period (>30 days). PTH secretion was inhibited in Ca concentration-dependent manner, particularly at total calcium concentration between 5.8 - 7.4mg/dl (Ca++ 1.2 - 1.4mmol/L). When parathyroid tissues were cultured in low and high P medium, intact PTH secretion (basal level 5-10ng/microg DNA/16h) nearly doubled in the high P medium. [3H]-thymidine incorporation also increased in the high P medium. This phenomenon was not observed in parathyroid carcinoma. Oligo-DNA microarray analysis revealed that mRNAs of PTH, chromogranin A, CaSR, and VDR were highly - moderately expressed. Among growth factors, TGFbeta1, FGF1, FGF2, and FGF3 were substantially expressed but not modulated by the high P medium. Little or no mRNA for FGF23 was detected. More than 30 genes (e.g. cytochrome P450 retinoid metabolizing protein, etc) were expressed more than 100% in the high P medium. In addition, a number of mRNAs for proteins with unknown function increased nearly by 100%, although they were different in primary and secondary hyperparathyroid tissues.

In summary, we have established parathyroid organ culture system in which human parathyroid tissue maintained its patho-physiological features for a prolonged period. Although genes expressed in primary and secondary hyperparathyroidism are substantially different, genes which constantly increased in high P medium are under investigation.

Human Chorionic Gonadotropin: A Potential Tumor Marker for Parathyroid Carcinoma. M. R. Rubin, S. Birken*, J. P. Bilezikian, S. J. Silverberg. Columbia University College of Physicians & Surgeons, New York, NY, USA.

Differentiating between parathyroid carcinoma (PTHCa) and severe non-malignant primary hyperparathyroidism prior to surgery is difficult. A tumor marker for PTHCa could identify the disease preoperatively and increase the likelihood of surgical cure. In patients with established PTHCa, it could also possibly quantify tumor burden and be useful in monitoring therapy. Human chorionic gonadotropin (hCG) is a glycoprotein hormone, well established as a tumor marker in trophoblastic cancers such as choriocarcinoma, germ cell tumors and non-trophoblastic malignancies. Moreover, a hyperglycosylated isoform of hCG that normally comprises 10% of total urinary hCG excreted by pregnant women is excreted at much higher levels in patients with hCG-secreting malignancies. We observed elevated serum hCG levels (72 ± 20; nl <25 mIU/mL) in 3 non-pregnant women with PTHCa who were being evaluated for treatment with the calcimimetic agent cinalcalcet HCl. We hypothesized that hCG could be a tumor marker in both men and women with PTHCa and that hCG levels might correlate with changes in tumor burden.

hCG was measured in a first morning urine specimen in 8 patients (5 men, 3 women) with PTHCa. Several immunometric two-site assays were used to measure urinary β core metabolites of hCG and hLH as well as a hyperglycosylated isoform of hCG and total hCG and β subunit. In 5 patients with the highest PTH values (1106 ± 274 pg/ml), 3 had markedly elevated levels of urinary hCG metabolite (621 ± 286, nl 10-50 fmol/mg Cr) with a predominance of the malignant-associated isoform of hCG, while 2 had normal levels of hCG metabolite (23 ± 7, nl 10-50 fmol/mg Cr), consistent with pituitary-derived hCG. However, 1 of the 2 with normal hCG metabolite levels had a subsequent rise of hCG with cinacalcet of 1400% (16 to 226 fmol/mg) with a predominance of the malignant isoform. This change in hCG was associated with a 45% increase in PTH after cinacalcet. In the patients with lowest PTH values (262 ± 49 pg/ml; n=3) urinary hCG metabolite levels (pituitary-derived hCG) were normal (7 ± 2, nl 10-50 fmol/mg Cr). hCG subsequently increased by 1900% (7 to 136 fmol/mg Cr) in 1 patient. The increase was due to the appearance of the malignant isoform and was associated with a post cinacalcet increase in PTH of 50%.

In summary, hCG levels (predominantly the malignant isoform) are elevated in men and women with PTHCa who have severe disease. The levels of hCG were associated with higher PTH concentrations. The post cinacalcet rise in hCG in some patients might signal the presence of a more aggressive form of PTHCa than those individuals whose hCG levels did not rise after cinacalcet. The results suggest that hCG might become a useful biochemical marker for PTHCa.

A Molecular Form of PTH Distinct from PTH (1-84) Is Produced in Parathyroid Carcinoma. M. R. Rubin[1], P. D'Amour[2], J. H. Brossard[2], T. Cantor[3], J. P. Bilezikian[1], S. J. Silverberg[1]. [1]Columbia University College of P& S, New York, NY, USA, [2]Centre de recherche du CHUM, Montreal, PQ, Canada, [3]Scantibodies Lab Inc, Santee, CA, USA.

Circulating PTH is composed of bioactive PTH (1-84) and fragments of varying lengths. In normal (nls), primary (PHPT) and secondary hyperparathyroid (SHPT) subjects, there are large C-terminal fragments (CTF) which arise from parathyroid gland secretion and peripheral metabolism . The "intact" PTH IRMA (iPTH) detects both PTH(1-84) and CTF. The newer Scantibodies assay (wPTH) uses an Ab which binds only if the first amino acid is present, making it specific for the complete molecule, PTH(1-84). Since the iPTH assay detects CTF and PTH(1-84), iPTH levels are generally higher in PHPT, SHPT, and nls than wPTH levels. An N-PTH molecular form has been reported in a minority of patients (pts) with PHPT. We observed that in pts with parathyroid carcinoma (PTHCa) treated with the calcimimetic cinacalcet HCl, serum calcium (S Ca) falls yet iPTH is unchanged or rises. We investigated the existence of different types of PTH species in PTHCa and how cinacalcet might alter these measurements.

We measured iPTH and wPTH in 5 pts with PTHCa at baseline and after cinacalcet. The mean S Ca concentration of the pts (50 ± 6 yr; 3 M, 2 F) was 15.8 ± 1 mg/dl. We found an unusually high amount of wPTH relative to iPTH in all pts. In 3 pts with the most severe disease (S Ca 17.3 ± 2 mg/dl) wPTH was 1.4 times higher than iPTH (wPTH 1047 ± 154, iPTH 755 ± 64 pg/ml), the reverse of the typical pattern. In 2 pts with less severe disease (S Ca 13.6 ± 1 mg/dl), iPTH was greater than wPTH, as is usual, but CTF made up only an average of 24% of circulating PTH (wPTH 225 ± 35, iPTH 302 ± 77 pg/ml), a lower percentage than is usually seen. The ratio of wPTH to iPTH did not change in any of the pts over time with cinacalcet treatment.

A serum HPLC profile was obtained in one patient with wPTH > iPTH. wPTH was made up of 2 immunoreactive peaks. The first 45% coeluted with standard PTH (1-84) and was recognized equally by both PTH assays. The other 55% of PTH immunoreactivity was detected only by the wPTH assay. It was less hydrophobic, and migrated in front of PTH(1-84). An additional peak of immunoreactivity corresponding to N-truncated fragments was detected by the iPTH assay.

In summary, a new form of PTH in PTHCa is detected by the wPTH assay but not the iPTH assay. This new PTH form is distinct from PTH(1-84) and contains the first amino acid of native PTH (1-84). Posttranslational modification in site(s) not detected by iPTH but detected by wPTH are consistent with these findings. More information about this molecular variant of PTH including its structure, bioactivity, source and regulation will give new insights about PTHCa and the PTH molecule itself.

Parathyroidectomy Improve Bone Mineral Density in Mild Asymptomatic Primary Hyperparathyroidism of Post-menopausal Women. E. Hagstrom*, E. Lundgren*, H. Mallmin, J. Rastad*, P. Hellman*. Dept. of Surgical Sciences, Uppsala, Sweden.

Bone mineral density (BMD) in truly mild primary hyperparathyroidism (pHPT) and controls, and the effects on BMD of surgery vs surveillance over five years of time is reported.

A population-based screening of 5202 post-menopausal women identified 87 overtly asymptomatic women with mild pHPT. The 5-year follow-up included 49 cases subjected to parathyroidectomy and 20 individuals who were only surveilled, each assigned an age-matched control. BMD of lumbar spine (L2-L4), femoral neck and total body was measured with DXA at inclusion and at follow-up. The pHPT diagnosis was confirmed in 98% of the cases.

At inclusion in the study cases had s-calcium of 2.57±0.12 mmol/l and s-PTH 53.6±22 ng/l (controls: 2.36±0.07 and 29.5±9.7, respectively). At study entry BMD was 5-6% lower in L2-L4 and femoral neck in cases compared to matched controls ($P<0.05$). During follow-up BMD increased in L2-L4 with 2.9% ($P<0.01$) in the parathyroidectomized cases and remained stable in the femoral neck. In contrast, BMD in surveilled cases decreased 3.9% in neck during follow-up ($P<0.01$), but had no change in L2-L4. Controls decreased in BMD in femoral neck with 2.5% ($P<0.05$), but not in L2-L4.

In accordance with recent NIH guidelines of pHPT treatment, the level of BMD per se in the investigated group of patients justifies parathyroidectomy in almost half of the cases with truly mild pHPT. Surgery could be expected to preserve femoral neck BMD and increase BMD in L2-L4 to the level of controls, while surveilled cases continues to decrease in BMD.

Inappropriate Levels of Parathyroid Hormone in Relation to Serum Calcium in a Pre-menopausal Population - an Indication of Early Primary HPT? H. Siilin*[1], Ö. Ljunggren[2], E. Lundgren*[1]. [1]Dep. of Surgery, University Hospital, Uppsala, Sweden, [2]Dep. of Internal Medicine, University Hospital, Uppsala, Sweden.

Primary hyperparathyroidism (pHPT) in elderly females, the individuals most prone to develop pHPT, have been explored in recent studies, while less is known of the disease in younger females. The progress of the disease is slow and although the estrogen deficiency after menopause might be one underlying cause, pHPT could exist years before this period. The prevalence of inappropriate high parathyroid hormone in relation to serum calcium, maybe in accordance with early pHPT, in a pre-menopausal population is reported.

Altogether 1888 pre-menopausal women, between the ages of 40 and 50 years, participating in a mammography health survey during one year, were included in the study. All subjects with total serum (s-) calcium at or above 2.50 mmol/L (n=553; 29 %) were invited for subsequent fasting tests of s-creatinine, intact parathyroid hormone (iPTH) and total s-calcium.

Mean age in the screening cohort was 44.9 years and mean s-calcium 2.45 mmol/L (2.08-2.89 mmol/L). In those 553 individuals, who were asked back for further investigations, mean age was 45 years and mean total s-calcium was 2.57 mmol/L (2.50-2.89 mmol/L). Altogether 548 women (five additional drop outs) had fasting values of mean s-calcium 2.48 mmol/L (2.22-2.79 mmol/L), and mean iPTH value of 47 ng/L (1.38-164 ng/L). Only one individual had slightly elevated s-creatinine (119µmol/L). The prevalence of assumed mild pHPT, or inappropriate iPTH value in relation to total s-calcium, was estimated to be 13% (n=245).

These data suggest that primary HPT is probably more prevalent in pre-menopausal females than previously suggested, but diagnostic criteria must be tested in each age interval separately. The significance of these biochemical criteria for premenopausal women must be investigated further in prospective studies.

Regulation of Plasma Fibroblast Growth Factor 23 Level by Calcium in Primary Hyperparathyroidism. K. Kobayashi*[1], Y. Imanishi[1], A. Miyauchi*[2], N. Onoda*[3], T. Kawata*[1], K. Nakatsuka[1], H. Tahara[1], T. Miki[4], E. Ishimura*[5], T. Sugimoto[6], T. Ishikawa*[7], M. Inaba[1], Y. Nishizawa[1]. [1]Department of Metabolism, Endocrinology and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan, [2]National Hyogo Chuo Hospital, Hyogo, Japan, [3]Department of Oncology, Osaka City University Graduate School of Medicine, Osaka, Japan, [4]Department of Geriatrics and Neurology, Osaka City University Graduate School of Medicine, Osaka, Japan, [5]Department of Nephrology, Osaka City University Graduate School of Medicine, Osaka, Japan, [6]Department of Clinical Molecular Medicine, Kobe University Graduate School of Medicine, Osaka, Japan, [7]Department of Surgical Oncology, Osaka City University Graduate School of Medicine, Osaka, Japan.

While the importance of FGF-23 is established in the pathogenesis of phosphate wasting disorders, little is known about the regulatory mechanism of its circulating level. To investigate the role of parathyroid hormone (PTH) in FGF-23 metabolism, we examined plasma FGF-23 levels on 50 patients of primary hyperparathyroidism (PHPT) and 52 controls. All subjects provided written informed consent before participation in this study, which were approved by institutional ethics committee and conducted in accordance with the principles endorsed by the Declaration of Helsinki. The FGF-23 was significantly elevated in PHPT compared with those in controls. When analyzed together with PHPT patients and healthy controls, log FGF-23 levels were significantly correlated in a positive manner with creatinine-clearance, serum corrected-calcium, inorganic phosphate, and log intact PTH levels, among which creatinine-clearance and corrected-calcium were factors independently associated. To assess the significance of corrected-calcium on FGF-23 levels, time course of changes were monitored in 5 PHPT patients after parathyroidectomy (PTX). Under minimum calcium loading, corrected-calcium levels were significantly decreased by 1 h after PTX, which was followed by a reduction in plasma FGF-23 levels. Serum phosphate levels increased and 1,25-dihydroxyvitamin D did not change appreciably after PTX. Under steady-state levels of these parameters which was attained by 6 h after PTX, FGF-23 level on next day morning on 15 PTX patients was significantly correlated positively with corrected-calcium, supporting serum calcium as one of major regulators of FGF-23. The absent expression of FGF-23 on surgically resected parathyroid glands by both RT-PCR and immunohistochemistry indicated that parathyroid glands were not major sources of circulating FGF-23.

In conclusion, serum calcium could regulate plasma FGF-23 levels in primary hyperparathyroidism.

HRPT2 Gene Alterations in Sporadic and Familial Primary Hyperparathyroidism. C. Marcocci, E. Pardi*, S. Borsari*, E. Ambrogini*, L. Cianferotti, E. Vignali, A. Pinchera*, F. Cetani. Endocrinology & Metabolism, University of Pisa, Pisa, Italy.

We investigated the involvement of *HRPT2* gene by loss of heterozygosity (LOH) analysis and direct sequencing in a kindred with hyperparathyroidism-jaw tumor syndrome (HPT-JT) and three kindreds with isolated primary hyperparathyroidism (FIHP). Seven patients with sporadic parathyroid cancers and 35 with parathyroid adenomas with no family history of primary hyperparathyroidism or HPT-JT were also studied. A novel germline heterozygous substitution G to A was found in the donor splice site of intron 1 in one of the three FIHP families. No mutations were identified in the HPT-JT kindred. A somatic *HRPT2* mutation was found in six of seven patients with parathyroid cancers, two of which were novel frame shift mutations (195insT and 195insA) in exon 2. Unexpectedly, two of the six mutations found in parathyroid cancer were germ-line mutations. Four adenomas showed LOH at 1q24-32, whereas a somatic *HRPT2* mutation was found in one. In conclusion, we provide further evidence for a strong association between *HRPT2* gene mutations and sporadic parathyroid cancer. The finding that two of the six patients with sporadic parathyroid cancer carried a *HRPT2* germ-line mutation suggests that they might have occult HPT-JT. Our results also confirm the need for testing *HRPT2* gene in FIHP families.

Continued Higher Secretion of PTH after Curative Parathyroidectomy (PTX) In Patients with Primary Hyperparathyroidism (PHPT): Implications for Pathogenesis and Treatment of Mild Asymptomatic PHPT. D. Rao[1], N. Parikh*[1], T. Eskridge*[1], E. Phillips*[1], G. B. Talpos*[2]. [1]Bone & Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA, [2]Surgery, Henry Ford Hospital, Detroit, MI, USA.

It is generally assumed that PTH secretion returns to normal after curative PTX in PHPT, but very little data exists to support this notion. Furthermore, it is well known that age related bone loss is attenuated after PTX, mild untreated PHPT does not cause continued bone loss and continued BMD gain occurs long after PTX. Collectively, these data imply that an anabolic stimulus is present in such patients. We hypothesized that serum PTH levels after PTX may remain mildly elevated because of change in set-point of the remaining apparently "normal" glands.

We studied 53 of the 237 well characterized patients who were "cured" by removal an adenoma. To reduce the influence of confounders the study was restricted to women with both pre and post-operative PTH levels measured by the same method. We excluded 110 patients without post PTX-PTH levels and 38 men. There were no systematic differences between the 53 included and the excluded patients. Mean duration after PTX was 24.4 ± 19.8 months. The relevant data are in the Table:

In comparison to healthy subjects the 53 patients had significantly higher PTH levels, 14 of whom had values above the 2SD for healthy controls. However, no differences in various pre-PTX variables between these two PHPT groups except for higher age and pre-PTX-PTH levels in the latter group. There was no correlation between post-PTX-PTH levels and the time after PTX, serum 25-OHD or age.

PHPT patients continue to secrete higher than normal PTH levels after "curative" PTX possibly due to altered set point. Because of very low parathyroid cell proliferation, a second adenoma (as could be predicted from our proposal) is uncommon in the remaining life expectancy of most patients. This continued higher PTH secretion might explain the observed anabolic effects on bone both of post-PTX and in untreated mild PHPT. We propose that a PTH level of <100 pg/ml is anabolic to bone and this cut off level should be used to recommend PTX in PHPT. Further studies of steady state and dynamic PTH levels are needed to confirm or refute our hypothesis.

VARIABLE	PATIENTS	CONTROLS	p VALUE
Age (Years)	63 ± 12	58 ± 9	0.017

Temporary Brittle Bone Disease (TBBD): Analysis of an Additional 39 Cases Associated with Fetal Immobilization. M. Miller*. Department of Pediatrics, Wright State University, Dayton, OH, USA.

TBBD was described in 1993 by Paterson as an intrinsic bone disorder with unexplained fractures in the first year of life. In 1999 the analysis of 26 cases of TBBD suggested fetal immobilization from intrauterine confinement (IUC) as a cause of this transient brittle bone state [Calcif Tissue Intl 64:137-143]. Most child abuse experts believe that TBBD does not exist and that it is a ruse for child abuse. Herein is the analysis of an additional 39 cases of TBBD associated with fetal immobilization in which allegations of child abuse were made against the parents. Cases of unexplained fractures in infants were considered TBBD associated with fetal immobilization if the following were found: (1) parents deny wrongdoing, (2) no significant bruising or internal organ injury, (3) no history of antecedent injury, (4) no radiographic or laboratory evidence of biochemical bone disease such as rickets or OI, and (5) history/clinical evidence of decreased fetal movement or IUC. The average age of presentation with the fractures was 9 weeks (1 sd = 5 weeks, range = 2-24 weeks). The average number of fractures was 12 (1 sd = 7 fractures, range = 3-26 fractures). The basis of the fetal immobilization was the following: (1) Cephalopelvic disproportion- 20 cases (2) Maternal use of drugs during pregnancy that cause fetal immobilization (opiates, beta-blockers)- 7 cases. (3) Twins- 7 cases (4) Breech presentation- 2 cases (5) Large maternal fibroids- 1 case. Umbilical cord length was available in 7 cases, and in all 7 it was extremely short, a finding consistent with decreased fetal movement. The striking, early presentation of TBBD is consistent with a prenatal onset etiology. The large number of fractures (average = 12) without bruising or other extraskeletal injury suggests this is not child abuse. The results confirm the previous association of TBBD with fetal immobilization with the new observation that the fetal immobilization can also result from maternal use of medications that cause decreased fetal movement. These overall findings support the concept that fetal bone loading is an important determinant of fetal bone strength, and that fetal immobilization is the primary risk factor for TBBD. This hypothesis is in accord with the contemporary model of bone physiology and bone strength as posited by Frost in the Utah paradigm (Anat Rec 262:398-419) and explains the transient nature of TBBD.

Ibandronate Decreases Femoral Head Deformity Following Ischemic Osteonecrosis of the Femoral Head in Immature Pigs. H. K. W. Kim[1], T. S. Randall[1], H. Bian[1], J. Jenkins*[1], A. Garces*[1], F. Bauss*[2]. [1]Shriners Hospital for Children, Tampa, FL, USA, [2]Roche Diagnostic GmbH, Penzberg, Germany.

Development of femoral head deformity (FHD) is the most serious sequela of Legg-Perthes disease, a juvenile form of osteonecrosis of the femoral head. The deformity can produce premature osteoarthritis. The predominance of bone resorption during repair of the osteonecrotic femoral head has been shown to contribute to the development of FHD. The purpose of this study was to test the hypothesis that inhibition of bone resorption during repair will preserve the trabecular framework and minimize FHD. To test this hypothesis, the effects of a potent anti-resorptive agent, ibandronate, was investigated in a well-established animal model of Legg-Perthes disease. The study was approved by the local institutional animal care and use committee. Ischemic osteonecrosis of the femoral head was produced in 24 piglets by surgically placing a ligature tightly around the femoral neck. Animals were divided into 3 groups; saline, prophylactic ibandronate treatment, and post-ischemia ibandronate treatment groups. At 8 weeks, the femoral heads were assessed for deformity using radiography and for trabecular bone indices (trabecular bone volume, trabecular number, and trabecular separation) using histomorphometry. Radiographic assessment showed that the saline group had the greatest deformity. The epiphyseal quotient, a ratio of the maximal femoral head height over diameter, was lowest in the saline group. The epiphyseal quotient was significantly better preserved in the prophylactic ($p<0.001$) and the post-ischemia ibandronate treatment ($p=0.02$) groups compared to the saline group. Histomorphometric assessment also showed that the trabecular bone indices were significantly better preserved in the prophylactic and the post-ischemia ibandronate treatment groups compared to the saline group ($p<0.01$). The total number of osteoclast per tissue area was significantly higher in the saline group compared to the ibandronate treatment groups. In conclusion, ibandronate preserves the trabecular framework and minimizes FHD during the study period in the piglet model. The results support the hypothesis that therapeutic strategies to inhibit bone resorption in the early phase of Legg-Perthes disease will prevent the development of FHD.

Ilial Histomorphometry in Children with Osteoporosis Secondary to Chronic Illness. L. M. Ward[1], F. T. Rauch[2], C. A. White*[1], F. H. Glorieux[2]. [1]Pediatrics, University of Ottawa, Ottawa, ON, Canada, [2]Pediatrics, McGill University, Montreal, PQ, Canada.

Osteoporosis is a potentially debilitating consequence of chronic illness among children and adolescents. In this study we characterized the bone tissue abnormalities of 16 children with symptomatic secondary osteoporosis. The study population comprised 8 patients with steroid-induced osteoporosis (S-O; mean age 13.3 yrs, range 7.4 to 17.6; 4 girls), and 8 patients with osteoporosis secondary to neuromuscular disorders (NM-O; mean age 13.8 yrs, range 10.2 to 17.3; 7 girls). Fracture distribution varied with diagnosis. Atraumatic lower limb fractures had occurred in 7 patients with NM-O, but in only 1 S-O patient, whereas vertebral compression fractures were present in 7 patients with S-O and only in 2 patients with NM-O. The age- and sex-matched z-score for volumetric bone mineral density of the lumbar spine averaged -1.8 (range -3.0 to 0.0) in the S-O group and -2.9 (range -5.0 to -1.9) in patients with NM-O. Results of iliac bone histomorphometry are given below as the median of the raw value for each parameter and as the percentage of the age-specific healthy average result.

	S-O	NM-O
Structural		
Core Width (mm)	6.8 (79%)	4.5 (56%)
Cortical Width (μm)	618.0 (62%)	598.0 (59%)
Bone Volume per Tissue Volume (%)	17.9 (70%)	14.1 (57%)
Formation		
Osteoid Thickness (μm)	4.5 (68%)	5.1 (79%)
Osteoid Surface per Bone Surface (%)	12.0(60%)	13.0 (53%)
Mineralizing Surface per Bone Surface (%)	8.7 (74%)	6.4 (64%)
Mineral Apposition Rate (μm/d)	0.9 (94%)	0.8 (93%)
Resorption		
Osteoclast Surface per Bone Surface (%)	0.5 (44%)	0.9 (78%)

These observations highlight the potential severity of osteoporosis in childhood due to steroid use and neuromuscular disorders. The bone mass deficit in S-O and NM-O is due to a combination of small bone size, thin cortices and a low amount of trabecular bone. Bone turnover tends to be low in both types of secondary osteoporosis.

The Effects of Type 1 Diabetes on the Metabolism and Density of Bone in Korean Children. K. Won[1], H. Lee*[1], H. Shon*[2], H. Yoon*[2], E. Jung*[3], I. Lee*[3]. [1]Internal Medicine, Yeungnam University, Daegu, Republic of Korea, [2]Internal Medicine, Catholic University of Daegu, Daegu, Republic of Korea, [3]Internal Medicine, Keimyung University, Daegu, Republic of Korea.

Background: The effects of type 1 diabetes mellitus on the metabolism and density of bone in children are still controversial. The aim of this study was to evaluate the effects of type 1 diabetes on markers of bone metaboism and BMD in children by analyzing BMI, HbAlc, biochemical markers, sex hormones, bone metabolism and BMD related factors. Methods: We compared 36 patients (15 males, 21 females) with type l diabetes mellitus to 167 healthy children (84 males, 83 females) who lived in South Korea. We measured FBS, serum calcium, phosphorus, HbAlc, osteocalcin, testosterone and estradiol for analyzing the factors which influence on bone metabolism and BMD. BMD was measured at lumbar spine, femur and total body by DEXA. Results: The BMI and serum level of osteocalcin were not different in both groups. Serum calcium level was significantly lower in the diabetic group than that of control group. BMD had no difference in both groups. There was no correlation between BMD and glycemic control (HbAlc) or duration of diabetes. There was good correlation (r=0.78, p<0.01) between serum testosterone level and BMD in male patient group. There was negative correlation (r=-0.4) between serum osteocalcin level and BMD. There was significant correlation (male: r=0.76, female: r=0.66) between lean body mass and BMD in both group. Conclusion: The BMD was not decreased significantly and bone turn-over was normal in children with noncomplicated type 1 diabetes mellitus, and BMD was not influenced by the duration or degree of metabolic control of diabetes. But, we need further study including other risk factors that have influences on BMD and bone metabolism in Korean type 1 diabetes mellitus.

Effect of Vitamin D and Calcium on Percent True Calcium Absorption and Bone Mineralization in Children with Cystic Fibrosis. L. S. Hillman[1], J. D. Robertson*[2], B. J. Higgins*[2], F. Chanetsa*[1], M. F. Popescu*[1]. [1]Child Health, U. of Mo., Columbia, MO, USA, [2]Chemistry, Mo Research Reactor, U. of Mo., Columbia, MO, USA.

Bone mineralization is documented to be reduced in children with Cystic Fibrosis (CF). Because of the known fat malabsorption in CF there is concern that both calcium and vitamin D absorption may be decreased but supporting data is limited.This study was designed to assess the effects of supplemental calcium and vitamin D on calcium absorption and bone mineralization in children with CF. The study was approved by the U.of Mo. Health Sciences IRB. Eighteen children age 9.1±2.3 years with CF not treated with steroids were randomized to four sequences of treatments with each child getting all four treatments: P, 400 IU vitamin D and placebo calcium; Ca, 400 IU vitamin D plus 1gm calcium; D, 2000 IU vitamin D and placebo calcium and D+Ca, 2000 IU vitamin D plus 1gm calcium. Each treatment lasted 6 months followed by a 3 month washout period. Biochemical assays at 6 months and DEXA measurements (Hologic QDR 1000) at 9 months (period plus washout) were analyzed for significant change from period baseline. Calcium absorption was measured at 6 months by a dual stable isotope method using IV ^{48}Ca and PO ^{46}Ca measured in a 24 hr urine referenced to ^{42}Ca by HR-ICP-MS. The Kruskal-Wallis Test saw no order effect so all results for each treatment were combined. Serum and urine Ca, Mg, and P were unchanged by any treatment with mean serum Ca (9.0±0.3 mg/dl) remaining below normal values (10.1±0.6 mg/dl). 2000 IU of vitamin D did not increase 25-OHD or 1,25$(OH)_2$D over the study period and there were no differences in 25-OHD or 1,25-(OH)2D between treatments in this vitamin D sufficient population (study baseline 25-OHD 38±13 ng/ml, 1,25$(OH)_2$D 49±10 pg/ml). BMC and BMD of the whole body, hip, spine, and arm significantly increased with age but there were no differences between treatments. Bone markers were unchanged and not different by treatment. Calcium absorption was within the normal range for prepubertal and early pubertal children. There were no differences in percent true calcium absorption by treatment: P, 37±14%; Ca, 38±23%; D, 36±11%; Ca+D, 46±26%. We conclude that percent true calcium absorption is normal in children with CF and not significantly altered by 1gm calcium and/or 2000 IU vitamin D. Oral absorption of vitamin D may be reduced due to fat malabsorption in children with CF and, in children who are already vitamin D sufficient, 2000 IU/day does not increase serum 25-OHD , serum calcium, BMC, or markers of bone turnover. Studies using higher doses of vitamin D are warranted in this population. However, factors other than calcium and vitamin D may play major roles in the decreased mineralization seen in children with CF.

Osteopenia in Children With Inflammatory Bowel Disease Is Due to Persistent Decrease in Bone Formation. F. A. Sylvester[1], J. S. Hyams*[1], P. M. Davis*[1], N. Wyzga*[1], T. Lerer*[2], A. M. Griffiths*[3]. [1]Digestive Diseases & Nutrition, Connecticut Children's Medical Center, Hartford, CT, USA, [2]Research, Connecticut Children's Medical Center, Hartford, CT, USA, [3]Gastroenterology & Nutrition, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.

Decreased BMD has been reported in patients with inflammatory bowel disease (IBD) due to increased bone resorption, but most studies examined corticosteroid-treated patients years after diagnosis and who may also have had age-related or post-menopausal bone loss. We hypothesized that children with IBD have decreased BMD secondary to decreased bone formation. Furthermore, we proposed that bone remodeling becomes activate in response to clinical improvement, with rapid accrual of bone calcium. To examine these questions, a 2-year prospective observational study was conducted in newly diagnosed children with IBD. We measured BMD in total body and lumbar spine by DXA, serum 25-hydroxyvitamin D (vit D), intact parathyroid hormone, interleukin (IL)-6, insulin growth factor (IGF)-1, sex steroids, and serum and urinary parameters of bone remodeling. BMD was performed yearly and laboratory evaluation every 6 months. BMD comparisons were adjusted for height-age and bone age in growth-retarded children. Disease severity was estimated using standard clinical scores. The control group consisted of age- and sex-matched healthy children from the same community. We studied 59 children with Crohn disease (CD) (20 F), 18 with ulcerative colitis (UC) (7 F), and 52 controls (CL) (23 F). Children with IBD had moderate-to-severe disease activity at diagnosis, and improved significantly with treatment. Age at diagnosis was (means ± SD, in yr), CD 12.8 ± 2.7, UC 11.8 ± 2.5, and CL 12.8 ± 2.7. Tanner stage and serum sex steroids were consistent with early puberty in all groups. BMD spine Z-score at diagnosis was -0.80 ± 1.02, -0.24 ± 1.14, -0.13 ± 1.12, respectively ($p < 0.01$, CD vs. CL); 10 CD children had Z-scores <-2. Patients with IBD exhibited low bone turnover at diagnosis that partially recovered with clinical improvement. However, Z-scores were stable over the course of the study. Calcium accretion by bone was lower than normal in IBD. At baseline, serum IL-6, IGF-1, vit D, and body mass index were significantly different in children with CD compared to CL, but no single parameter predicted decreased mineralization. We conclude that decreased BMD is common in newly diagnosed children with IBD, especially in the lumbar spine of CD children, and is probably due to decreased bone formation. Although clinical improvement is associated with increased bone remodeling, calcium incorporation into bone is slower than in healthy children up to 2 years after diagnosis.

SHP-2 Mutations in Noonan Syndrome Lead to Increased MAPK Activation: A Possible Mechanism of Short Stature. N. Namba[1], E. Ogura*[2], K. Ozono[1], Y. Seino[3], H. Tanaka[2]. [1]Pediatrics, Osaka University Graduate School of Medicine, Suita, Osaka, Japan, [2]Pediatrics, Okayama University Graduate School of Medicine and Dentistry, Okayama, Japan, [3]Pediatrics, Osaka Koseinenkin Hospital, Osaka, Japan.

Noonan syndrome (NS) is an autosomal dominant disorder characterized by unusual facial features, proportionate short stature, skeletal anomalies, and congenital heart defects. Though the molecular basis of this disease has been elusive, Tartaglia and coworkers have recently identified mutations in the PTPN11 gene, which encodes the protein tyrosine phosphatase SHP-2, in about 50% of the patients. Mutations have also been identified in LEOPARD syndrome and juvenile myelomonocytic leukemia (JMML).

SHP-2 is a ubiquitously expressed protein composed of two tandemly arranged SH2 domains at the amino-terminus (N-SH2 and C-SH2) followed by a protein tyrosine phosphatase (PTP) domain. Most of the known mutations cluster in the interacting portions of the N-SH2 domain and the PTP domain and are postulated as gain-of-function changes. Previous studies have also shown that SHP-2 is required for activation of the Ras/Erk cascade. However, despite intensive study, the underlying molecular mechanisms are not completely understood.

Since MAPK has been shown to influence chondrocyte proliferation and differentiation, we evaluated phosphatase activity, intracellular distribution, and EGF induced MAPK activity in SHP-2 mutants found in NS patients. COS-1 cells were transfected with wild type (WT) or mutated FLAG-tagged SHP-2. Cell lysates were subsequently immunoprecipitated and tested for phosphatase activity using phosphorylated poly(Glu, Tyr) random peptides as substrate. N58K SHP-2 exhibited a 3.2-fold increase in phosphatase activity compared to WT SHP-2, which was comparable to that of E76K, a mutation commonly found in JMML. In contrast, P491T SHP-2 had less phosphatase activity than that of WT SHP-2. This coincided with the observation that N58K and E76K were partially membrane associated while WT and P491T were distributed in the cytosol. However, when the cells were stimulated with EGF, both NS mutations and E76K displayed increased Erk1/2 activation compared to WT.

In conclusion, NS mutants show increased MAPK activation in response to EGF stimulation, while basal phosphatase activity is not necessarily elevated. Increased MAPK activation in chondrocytes could lead to the skeletal anomalies and short stature seen in NS.

Increased Early Resorption Activity and Alterations of Morphology in Osteoclasts Derived from the oim/oim Mouse Model of Osteogenesis Imperfecta (OI). H. Zhang[1], C. Hughes[2], C. Raggio*[1], D. W. Dempster[2], N. P. Camacho[1]. [1]Research Division, Hospital for Special Surgery, New York, NY, USA, [2]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

Histologic and histomorphometric studies have established that patients with the collagen-based disease osteogenesis imperfecta (OI) have increased bone turnover, which may be linked to abnormal osteoclast activity. To date, there have been no studies on isolated osteoclasts from either OI patients or animal models of OI. The goal of the current study is to determine if there are alterations in osteoclasts derived from oim/oim mice, an established animal model of moderate-to severe OI. Bone marrow cells from oim/oim and +/+ mice were cultured on bovine bone slices in the presence of macrophage colony-stimulating factor (M-CSF, 20ng/ml) and (RANKL, 60ng/ml), and studied at days 1, 4, and 7 of culture. Tartrate-resistant acid phosphatase (TRAP) staining was used to identify multinucleated osteoclast-like cells (MNCs). Confocal microscopy was used to evaluate formation of resorption pits and to study the cytoskeletal organization with fluorescein-labeled phalloidin staining for F-actin and Topro-3 staining for nuclei. At day 1 culture, only mononuclear cells were present on the bone slices, but the oim/oim slices had a greater percentage of those cells associated with resorption pits compared to +/+ bone slices (43.4$\pm$6.0 % vs 21.9$\pm$11.0%, $p<0.05$). Although a similar number of TRAP positive MNCs were present on both oim/oim and +/+ bone slices at days 4 and 7, the oim/oim MNCs had obvious cytoskeletal differences compared to the +/+ MNCs. The overall diameter and area of the oim/oim MNCs were larger compared to the +/+ MNCs (87.3$\pm$ 9.4 nm vs 61.8$\pm$7.4 nm, $p<0.05$, and 4399.0$\pm$558.6 nm^2 vs 2262.8 $\pm$ 746.1 nm^2, $p<0.05$). In addition, the number of nuclei per MNC were greater for the oim/oim vs +/+ derived cells (21.9 $\pm$3.0 vs 6.64 $\pm$ 1.57, $p<0.01$). Overall, this study demonstrates that there is an increase of early resorption activity in the oim/oim-derived osteoclasts, and that they are also morphologically different from wildtype osteoclasts in this in vitro culture system. These findings may yield insight into the basis of the increased bone turnover in OI patients and animal models of OI.

Bisphosphonate Binding in the Infarcted Piglet Femoral Head. T. S. Randall*[1], M. V. Sanders*[1], H. Bian[1], A. H. Garces*[1], F. Bauss[2], H. K. W. Kim[1]. [1]Shriners Hospitals for Children, Tampa, FL, USA, [2]Roche Diagnostics GmbH, Penzberg, Germany.

Recent studies have shown that bisphosphonate (BP) therapy may prevent the development of femoral head deformity following osteonecrosis by inhibiting bone loss during repair. These studies raise questions regarding the most appropriate time for commencement of BP treatment, and also regarding the delivery and distribution of systemically administered BPs into the infarcted femoral head. The purpose of this study was to investigate the optimal time to begin BP treatment following the induction of osteonecrosis and also the distribution of BP within the femoral head as it undergoes repair.

Sixteen piglets had ischemic necrosis surgically induced. One, 3 and 6 wks following the induction surgery the animals were injected with 14C labeled ibandronate. The animals were euthanatized 24 hrs after the injection and the level of radioactivity in the infarcted femoral heads was assayed by liquid scintillation. Autoradiographic assessment was performed on undecalcified sections to determine the distribution of ibandronate in the infarcted head in relation to the areas of revascularization and repair.

One-wk post surgery, the level of radioactivity was not increased above background in the infarcted femoral head either by liquid scintillation or by autoradiography. There was also no evidence of revascularization. In contrast, 6 wks following the induction of ischemia the level of radioactivity was significantly increased above background ($p<0.01$). Autoradiographic assessment of the infarcted femoral heads revealed a strong level of binding in areas with renewed bone growth. Within the areas of revascularization, ibandronate was bound to the necrotic bone, although not as heavily as on live bone. Areas of the head that were not revascularized at six weeks showed increased ibandronate binding compared to back ground, but less than was seen in revascularized areas. All femoral heads showed large areas of revascularization, with the presence of fibrovascular tissue and resorption of trabecular bone. Renewed endochondral ossification was also observed.

The findings from this study indicate that the most appropriate time to start BP treatment following osteonecrosis is when revascularization has begun in the infarcted head. Given this finding a bone scan or a perfusion MRI scan may be indicated to confirm blood flow, prior to initiating BP therapy in patients with osteonecrosis of the femoral head.

Disclosures: ***T.S. Randall****, None.*

Altered Bone Mineral Metabolism in Children at Time of Diagnosis of Inflammatory Bowel Disease. M. Harpavat*[1], D. J. Keljo*[1], D. Bowen*[2], S. L. Greenspan[3]. [1]Pediatrics, University of Pittsburgh, Pittsburgh, PA, USA, [2]Radiology, University of Pittsburgh, Pittsburgh, PA, USA, [3]Medicine, University of Pittsburgh, Pittsburgh, PA, USA.

Recent studies suggested that bone mineral metabolism is altered in children with Inflammatory Bowel Disease (IBD). The cause of these alterations is unclear, but often attributed to corticosteroid use. The purpose of this study was to examine biochemical markers of bone turnover in a cohort of children newly diagnosed with IBD before initiation of steroid therapy.

We studied 23 otherwise healthy, corticosteroid-naive children within 3 weeks of initiation of therapy for IBD. We assessed serum aminoterminal propeptide of type I collagen [(P1NP) a marker of bone formation] and urine N-telopeptide crosslinked collagen type 1 [(NTx) a marker of bone resorption]. Bone mineral content (BMC) and bone mineral density (BMD) were obtained by Dual Energy X-ray Absorptiometry (DXA, Lunar DPX-L). Z-scores were calculated based on age and gender. Data analysis was performed by Mann Whitney U and Spearman rank-order correlation.

Of the 23 newly diagnosed children (12 girls, 11 boys), 18 had Crohn's disease, 4 had ulcerative colitis, and 1 had indeterminate colitis. Mean age at diagnosis was 12.5 years with a range of 5.5 to 16.8 years. Five of the 23 patients (22%) had a total body BMD Z-score of less than -1, with 1 patient having a Z-score of less than -2. Twelve (52%) subjects had vertebral BMD Z-scores of less than -1, with 3 children having Z-scores of less than -2. IBD patients had significantly reduced mean lumbar spine BMD Z-scores (-0.90 ± 1.1, $p=0.001$). IBD patients also had significantly reduced mean serum P1NP Z-scores (-1.8 ± 1.2; $p=0.0006$). Mean urine NTx Z-scores were not altered. Correlation coefficients between P1NP Z-scores and DXA measurements ranged from 0.49-0.72 (see Table, *all $p<0.05$).

We conclude that children newly diagnosed with IBD have significantly reduced vertebral BMD and decreased bone formation, as reflected by significantly low P1NP Z-scores. P1NP Z-scores correlate positively with BMC and BMD. Bone resorption, as reflected by normal urine NTx Z-scores, does not appear to be altered. Low bone formation with normal bone resorption may explain alterations in bone mineral metabolism in steroid naïve children newly diagnosed with IBD.

Correlation Between BMD and BMC with P1NP Z Scores

DXA	P1NP
Whole body BMC (g)	0.63*
Whole body BMD (g/cm^2)	0.54*
Femoral neck BMC (g)	0.49*
Femoral neck BMD (g/cm^2)	0.51*
Trochanter BMC (g)	0.59*
Lumbar spine BMC (g)	0.70*
Lumbar spine BMD (g/cm^2)	0.72*

Disclosures: ***S.L. Greenspan****, None.*

A Phase 1, Single-Dose Study of ABX10241, a Fully Human Monoclonal Antibody to Parathyroid Hormone Secondary Hyperparathyroidism (SHPT) Patients. G. M. Bell*[1], S. Swan*[2], K. J. Martin[3], T. Shamp*[2], W. B. Smith*[4], M. Sack*[5], R. H. Arends*[1], M. R. Wyres*[1], L. Roskos*[1], A. Young*[2], N. Raie*[1], S. Huang*[1], D. Shoback[6]. [1]Abgenix, Inc., Fremont, CA, USA, [2]Hennepin County Medical Center and DaVita Clinical Research, Minneapolis, MN, USA, [3]Saint Louis University, St. Louis, MO, USA, [4]New Orleans Center for Clinical Research, New Orleans, LA, USA, [5]Radiant Research, Austin, TX, USA, [6]Endocrine Research Unit, VAMC, University of California - San Francisco, San Francisco, CA, USA.

ABX10241 is a high affinity monoclonal antibody directed against the 1-34 region of human parathyroid hormone (PTH). ABX10241 is specific for human and non-human primate PTH. In primate and rodent models of hyperparathyroidism induced by continuous administration of PTH, ABX10241 reverses the metabolic consequences of hyperparathyroidism in a dose-dependent manner. In the primate model, a single 4 mg/kg dose of ABX10241 produced a sustained reduction in plasma unbound PTH (non-antibody complexed PTH measured with the Nichols Intact Assay) and normalized serum Ca for up to two weeks relative to control animals. On the basis of these results, a randomized, double-blind, single-dose, dose-escalation study in hemodialysis patients with SHPT was initiated. Eligibility criteria include plasma PTH > 300 pg/mL (Nichols Intact Assay), serum corrected Ca $\geq$9 mg/dL, and a Kt/V $\geq$ 1.2. Vitamin D or vitamin D analogs, oral phosphate binders, and cinacalcet were permitted provided the doses were stable for at least 2 weeks prior to treatment. Planned dose cohorts include 30, 100, 200, and 300 mg of ABX10241; the starting dose of 30 mg was less than the no-effect level in preclinical studies. Within each cohort subjects are randomized 3:1 to ABX10241 or placebo. ABX10241 is administered by IV push after hemodialysis and patients are monitored in a Phase 1 unit for 3 days post treatment. Four patients were randomized in the 30 mg dose cohort. Mean baseline PTH was 442 pg/ml (range 319 - 632 pg/ml). Twenty-four hours post-dose the mean reduction in plasma unbound PTH was 45% in the ABX10241-treated group compared with a 12% reduction following placebo treatment. Consistent with the decrease in PTH, the ABX10241-treated group had an average 6.9% reduction in iCa compared with 0% change following placebo treatment 24 hours post-treatment. Both PTH and iCa returned to baseline within 72 hours post treatment. The transient (< 72 hour) PTH suppression following the 30 mg dose was consistent with in silico modeling simulations that predict higher doses of ABX10241 may suppress PTH to within the desired normal uremic range (100- 250 pg/ml) for up to 7 days after a single dose. Based on the safety of the 30 mg cohort, higher dose levels will be explored and reported.

Disclosures: ***M.R. Wyres****, None.*

SU531

OPG, RANK-L, Bone Metabolism and BMD in Patients on Haemodialysis and Continuous Ambulatory Peritoneal Dialysis. E. Wittersheim*[1], M. Mesquita*[2], A. Demulder[1], M. Guns*[1], O. Louis*[3], M. Dratwa*[2], P. Bergmann[4]. [1]Laboratory of Haematology, Brugmann University Hospital, Brussels, Belgium, [2]Nephrology Departement, Brugmann University Hospital, Brussels, Belgium, [3]Departement of Radiology, Brugmann University Hospital, Brussels, Belgium, [4]Laboratory of Experimental Medicine, Brugmann University Hospital, Brussels, Belgium.

Patients with end-stage renal failure (ESRF) on dialysis develop hyperparathyroid bone disease; PTH acts on bone resorption through the cytokines osteoprotegerin (OPG) and Receptor Activator of Nuclear κB-Ligand (RANK-L).

We evaluated serum OPG and RANK-L in 79 patients with ESRF undergoing hemodialysis (HD, n=58) or continuous ambulatory peritoneal dialysis (CAPD, n=21) and assessed their relation with hyperparathyroidism (circulating iPTH), bone turnover rate (βCrossLaps, CL, and the carboxyterminal extension peptide of type I procollagen, PICP), bone densitometry (BMD, Hologic QDR 4500) and hand radiography. A group of 65 healthy subjects matched for sex and age was used as control. Bone densitometry was performed at the lumbar spine, left and right hip and right forearm. An X-ray of the right hand was obtained.

In our control group, there was no sex difference for OPG nor RANK-L; OPG increased slightly with age, significantly for men; RANK-L and the RANK-L/OPG ratio did not change with age.

OPG and RANK-L were higher in patients with ESRF than in controls (3.7 vs 1.8 ng/ml, and 1.2 vs 0.14 pg/ml respectively), particularly in the HD group than in controls ($p<0.001$ and <0.05); RANK-L was higher in HD than in CAPD ($p<0.001$). None of the parameters varied with the duration of dialysis. OPG levels were higher in women undergoing HD ($p<0.001$) and increased significantly with age ($p<0.0001$), particularly in men. RANK-L and the ratio RANK-L/OPG did not change with age nor sex. Nor OPG neither RANK-L depended on iPTH levels. Serum CL and PICP were significantly higher in ESRF than in controls ($p<0.001$), but they did not correlate with OPG, RANK-L or RANK-L/OPG ratio. BMD did not differ significantly between HD and CAPD; as opposed to PTH and CL, nor OPG neither RANK-L correlated significantly with BMD. OPG was significantly higher in patients with cortical demineralization at X-Ray (3.0 vs 4.3 ng/ml); CL was lower in patients with calcifications (3.1 vs 3.9 ng/ml). Conclusions: 1) PICP and CL are significantly increased in ESRF and BMD is low. 2) BMD correlates negatively with serum iPTH and CL. 3) Serum OPG increases with age in control and ESRF subjects. OPG and RANK-L serum levels are significantly higher in ESRF. 4) Serum OPG, RANK-L or RANK-L/OPG ratio do not correlate with serum iPTH levels nor BMD. Thus, circulating OPG and RANK-L do not reflect bone status in ESRF.

Disclosures: ***E. Wittersheim****, None.*

SU532

Osteoprotegerin Is a Bone Protective Agent in a Rat Model of Chronic Renal Insufficiency and Hyperparathyroidism. V. Shalhoub, J. Padagas*, M. Colloton*, E. Shatzen*, S. Morony, P. Kostenuik, C. R. Dunstan, D. L. Lacey, D. Martin. Department of Metabolic Disorders, Amgen, Inc., Thousand Oaks, CA, USA.

Osteoprotegerin (OPG) is a novel antiresorptive agent that plays a critical role in the physiological regulation of bone resorption. OPG acts by neutralizing RANKL, the dominant mediator of osteoclast differentiation, activation and survival. OPG is non-toxic to kidney cells, and may thus represent a novel and safe approach to treating bone loss in patients with renal insufficiency. Renal insufficiency is also associated with hyperparathyroidism, which leads to significant cortical osteopenia. OPG effectively blocks the catabolic effects of PTH, so we examined whether OPG could prevent or reverse bone loss in a rodent model of secondary HPT. Secondary HPT was induced in young growing male SD rats (250-275 g) by performing 5/6 nephrectomy (Nx). One week post-surgery, sham and Nx rats (n=6-10) were fed a 1.2% P/ 0.6% Ca^{2+} diet, and treated with vehicle or OPG (3 mg/kg, IV), every 2 weeks for 9 weeks. Prior to treatment (baseline) and at 3, 6 and 9 weeks, BMD was assessed by DEXA and blood was taken for PTH and ionized calcium levels. Nx resulted in dramatic increases in serum PTH at all timepoints, reaching a maximum of 912 pg/ml at 9 weeks (vs. 123 pg/ml in shams at 9 weeks). Nx rats also had significant osteopenia at all skeletal sites compared to shams. Treatment of either Nx or sham rats with OPG-Fc caused rapid and progressive increases in BMD at all skeletal sites. At the earliest timepoint (3 weeks), the mean percent changes from baseline (±SEM) in Nx OPG compared with Nx vehicle are shown in the table below. OPG had no significant effect on serum PTH or blood ionized calcium levels in Nx or sham animals. Histologically, OPG augmented the thickness of trabeculae in both Nx and shams at 9 weeks in the primary spongiosa of the distal femur and/or proximal tibia. This study demonstrates that the RANKL antagonist OPG effectively restores BMD in a rat model of HPT and chronic renal insufficiency. The data also confirm that OPG is capable of blocking the catabolic effects of PTH on cortical and cancellous bone, even when PTH is continuously elevated for sustained periods. This suggests that RANKL may be an important therapeutic target for protecting bone in patients with HPT and/or chronic renal insufficiency.

PTH-Stimulated Signaling Molecules that Are Involved in the Endocytosis of NaPi-IIa Phosphate Transporter Are Compartmentalized and Activated in Caveolae-Like Microdomains. Y. Taketani, T. Takeichi*, K. Nashiki*, H. Yamamoto, N. Sawada*, M. Ichikawa*, H. Arai*, E. Takeda. Department of Clinical Nutrition, Institute of Health Biosciences, University of Tokushima Graduate School, Tokushima, Japan.

Phosphate homeostasis is maintained by regulating the renal type IIa sodium-dependent phosphate transporter (NaPi-IIa). Parathyroid hormone (PTH) is a potent inhibitor of NaPi-IIa activity by leading endocytosis from brash border membrane of renal proximal tubular cells. We have demonstrated caveolae-like microdomains (CM) and actin play an important role in the apical targeting and regulation of NaPi-IIa endocytosis in response to PTH, though their precise role has not been clarified. To clarify the role of CM in the translocational regulation of NaPi-IIa by PTH, we investigated the effect of PTH on the activation of PKA and PKC and their substrate phosphorylation in biochemically isolated CM fraction from opossum kidney cells. PTH activated both PKA and PKC-alpha in CM through PTH receptor also localized in CM. Inactive PKA is widely distributed in the cells, but was only strongly activated in CM by PTH. On the other hand, inactive PKC-alpha is localized in cytosol, and was translocate to CM in response to PTH. Both PKA and PKC activation increased the phosphorylation of 80 kDa and 250 kDa substrates observed by anti-phospho-PKA or PKC substrate antibody. Resulted from protein sequence analyses, 80 kDa substrate was identified as ezrin that is a ERM (ezrin-radixin-moesin) family protein, and is a linker protein between brash border membrane and actin cytoskeleton. Previous studies demonstrated that NaPi-IIa can bind to NHERF-1/EBP-50 that associates with ezrin-actin complex, and this interaction is necessary for apical targeting of NaPi-IIa in proximal tubular cells. Ezrin is also phosphorylated by many protein kinases to interact with target proteins. This study suggests that ezrin can be phosphorylated by PKA or/and PKC in response to PTH in proximal tubular cells, and the phosphoryation would also play an important role in the actin-dependent NaPi-IIa endocytosis, probably that may be involved in reorganization of actin directly or indirectly. CM appear to be important for the regulation of NaPi-IIa endocytosis in proximal tubular cells by compartmentalizing signal transduction and cytoskeletal molecules.

Impact of Parathyroidectomy for Renal Hyperparathyroidism on the Endocortical Surface, the Juxtaendocortical Resorption Spaces and Cancellous Bone. A. Yajima[1], Y. Ogawa*[2], Y. Tominaga*[3], T. Tominaga*[4], T. Inou*[1], O. Otsubo*[1], S. Yagi*[1]. [1]Nephrology, Towa Hospital, Tokyo, Japan, [2]Urology, University of the Ryukyus, Naha, Japan, [3]Surgery, Nagoya Second Red Cross Hospital, Nagoya, Japan, [4]Urology, Mitsui Memorial Hospital, Tokyo, Japan.

Purpose: Impact of parathyroidectomy (PTX) for renal hyperparathyroidism on the endocortical surface (A), and the juxtaendocortical resorption spaces (B) were compared with that on cancellous bone (C). Methods: Iliac bone biopsies were performed before and at 1 week after PTX in Group 1 (n=13), and before and at 4 week in Group 2 (n=10). Oc.S/BS and O.Th were measured in both Groups before and after PTX, and BFR/BS was also measured in Group 2 only after surgery Results: Group 1; Oc.S/BS significantly decreased after PTX in (A)-(C), but that in (B) was higher than that in (C) after surgery; 1.2 ± 1.3 vs 0.1 ± 0.5 % ($p<0.05$). Ob.S/BS increased from 18.1 ± 17.1 to 35.6 ± 20.8 % ($p<0.001$) in (C). O.Th increased from 13.4 ± 3.5 to 17.6 ± 6.0 µm ($p<0.005$) in (C), but these two values in (A) and (B) did not. Group 2; Oc.S/BS decreased to 0 after PTX in (C), but to 0.1 ± 0.2 in (A) and 0.9 ± 1.8 % in (B). BFR/BS in (B) tended to be higher than that in (C); 0.012 ± 0.0018 vs 0.003 ± 0.005 mm^3/mm^2/year ($p=0.06$).Conclusion: An increase in BMD of cortical bone was estimated to be smaller than that of cancellous bone because bone turnover was higher in cortical bone even after PTX.

Disassociation of the Anabolic, Catabolic and Fibrotic Response to Parathyroid Hormone. R. T. Turner, S. Lotinun. Orthopedic Research, Mayo Clinic, Rochester, MN, USA.

Intermittent increases in parathyroid hormone (iPTH) are highly anabolic in regards to bone formation, whereas continuous increases (cPTH) are generally considered to be catabolic. We tested this latter belief by performing detailed time course (1-7d) studies in which the effects of PTH administered continuously (40 µg/kg/d) using a s.c. implanted osmotic pump were compared to hormone given by daily s.c. injection. PTH induced impressive increases in osteoblast number and mRNA levels for bone matrix proteins. The response to the two treatments were virtually identical indicating that the method of PTH administration had little effect on the measured osteoblast parameters. However, iPTH resulted in an ~2 fold increase in osteoclast number with no change in serum calcium and no bone marrow fibrosis while cPTH resulted in an ~8 fold increase in osteoclast number, severe hypercalcemia and extensive peritrabecular fibrosis (~70% of trabecular surface covered by fibroblasts), changes similar to osteitis fibrosa seen in patients with parathyroid bone disease. These findings suggest that the effects of PTH on osteoblasts are mediated by signaling pathways that differ from the catabolic and fibrotic responses and that these differences are partially (bone resorption) or fully (fibrotic) disassociated by reducing the duration of exposure to elevated PTH levels. Over expression of platelet derived growth factor-A by mast cells has been implicated as having a causal role in the development of parathyroid bone disease. In this regard, cPTH treatment of mast cell deficient W/Wv mice increased bone formation but did not cause hypercalcemia, increase osteoclast number or induce peritrabecular bone marrow fibrosis. The importance of PDGF-A signaling is supported by additional studies in which we demonstrated that antagonism of receptor tyrosine kinase activity with gleevec greatly reduced peritrabecular bone marrow fibrosis in cPTH-treated rats but did not diminish the bone anabolic response to the hormone. Taken together, these results suggest that PDGF-A signaling mediates PTH-induced bone marrow fibrosis but not the PTH-induced increase in osteoblast number and activity.

Most Renal Transplant Patients have Primary or Active Secondary Hyperparathyroidism. A. Räkel*[1], J. H. Brossard[1], L. Rousseau*[1], G. St-Louis*[2], M. Pâquet*[2], T. Cantor[3], P. D'Amour[1]. [1]Hôpital Saint-Luc, Centre de recherche du CHUM, Montreal, PQ, Canada, [2]Hôpital Notre-Dame, Centre de recherche du CHUM, Montreal, PQ, Canada, [3]Scantibodies Laboratory Inc., Santee, CA, USA.

Carboxyl-terminal PTH/Total-PTH ratio values differ in various hyperparathyroid states. When the parathyroid function is stimulated, C-PTH/T-PTH ratio values are similar or lower than those observed in normal individuals but when the parathyroid function is suppressed, C-PTH/T-PTH values are usually increased. To see whether hyperparathyroidism after renal transplant reflects a stimulated parathyroid function or suppressed persistent hyperplasia, we have measured total (T) and carboxyl-terminal (C) PTH as well as total corrected calcium (Ca_{tc}), phosphate (PO_4), alkaline phosphatase (AP) and creatinine levels in 225 receivers of a renal graft (RTP) over a period of 30 years, 71 normals individuals (N) and 14 patients with primary hyperparathyroidism (PHP). The RTP were subdivided in 3 groups according to Ca_{tc} and T-PTH levels. Results are means ± SD and were compared with a non parametric ANOVA. Serum creatinine levels were similar in each RTP groups (110±33 to 119±36 mmol/L) and higher than in N or PHP (66±17 and 76±26 µmol/L, $p<0.05$). Phosphorus levels were higher in N (1.12±0.14 mmol/L, $p<0.05$) than in the four other groups. Group 1 included 61 RTP with normal Ca_{tc} (<2.55 mmol/L) and T-PTH levels (<6.5 pmol/L). Compared to N, these patients had slightly higher Ca_{tc} (2.37±0.10 vs 2.42±0.09 mmol/L, $p<0.05$), C-PTH (7.0±21.8 vs 12.9±4.5 pmol/L, $p<0.05$) and T-PTH levels (3.1±1.2 vs 5.1±1.2, $p<0.05$) and a similar C-PTH/T-PTH ratio (2.5±0.8 vs 2.7±1.1). The 102 RTP of group 2 had normal Ca_{tc} (2.42±0.08 mmol/L) but high T-PTH levels. Their C-PTH (21.6±10.4 pmol/L) and T-PTH levels (11.8±5.8 pmol/L) were higher than the two previous groups but similar to values observed in PHP or RTP group 3. Group 2 patients had a lower C-PTH/T-PTH ratio (1.9±0.5) than the four other groups ($p<0.05$). Group 3 was composed of 62 hypercalcemic RTP with similar characteristics to PHP patients: elevated Ca_{tc} (2.62±0.07 and 2.74±0.24 mmol/L), increased C-PTH (25.0±14.2 and 38.5±27.8 pmol/L) and T-PTH (11.1±6.8 and 16.9±14.7 pmol/L) but normal C-PTH/T-PTH ratio (2.5±0.9 and 2.6±0.8). Thus, 27% of RTP have a PTH profile typical of classical primary hyperparathyroidism with a set point defect, 45% have significant increase in PTH levels with low C-PTH/T-PTH ratio suggestive of an active secondary hyperparathyroidism, and the remaining 28% have slightly elevated PTH levels compatible with an ongoing state of PTH resistance. This work was supported by a grant from CIHR.

Low Prevalence of Osteoporosis Among Pediatric Patients With Juvenile Idiopathic Arthritis - Protective Influence of Anti-Rheumatic Drug Combinations? H. Valta*[1], P. Lahdenne*[1], K. Aalto*[1], O. Mäkitie[2]. [1]Pediatric Rheumatology, The Hospital for Children and Adolescents, Helsinki University Hospital, Helsinki, Finland, [2]Pediatric Endocrinology, The Hospital for Children and Adolescents, Helsinki University Hospital, Helsinki, Finland.

Patients with juvenile idiopathic arthritis (JIA) are at increased risk of secondary osteoporosis because of chronic inflammation and frequent use of glucocorticoids (GC). Previous studies have reported high prevalence of osteopenia and fractures even in pediatric patients with JIA.

The aim of this study was to assess bone health and its correlates in an unselected cohort of GC treated pediatric patients with JIA.

The study included 35 consecutive patients (24 females) followed at the Pediatric Rheumatology clinic, Helsinki University Hospital, with a history of systemic GC treatment for at least 3 months. Patients were assessed clinically and their charts reviewed for medical history. Blood biochemistry was obtained for S-Ca, Pi, PTH and 25-OH-Vitamin D (25-OHD). Bone mineral density (BMD) of the lumbar spine (L1-L4) and femoral neck was assessed with DXA (Hologic Discovery A); age- and sex adjusted z-scores were used for analysis.

The disease onset was polyarticular in 51%, oligoarticular in 43% and systemic type in 6% of the patients. The mean age at study assessment was 11.3 yrs (4.6-17.9 yrs) and the mean disease duration 6.3 yrs (2.4-14.8 yrs); 16 patients (46%) had an ongoing GC treatment. The median duration of GC treatment was 820 days (170-3920 days) and the median cumulative dose (as prednisolone) was 3.3 g (0.5-21.2 g). In addition to systemic GCs, all patients had been treated with methotrexate, 97% with intra-articular GCs, 63% with hydroxychloroquine and 40% with TNF-α antagonists. Other less frequently used medications included sulphasalazin, azathioprine and cyclosporin A. Two patients had a positive fracture history.

The median BMD z-score for the lumbar spine was -0.1 (-2.4 - +1.3) and for the femoral neck, -0.2 (-2.1-+1.4). Only four patients (11%) had a BMD z-score below -1.5. The BMD z-score tended to be lower in patients with longer disease duration ($P=0.001$) and higher absolute ($P=0.007$) and weight-adjusted ($P=0.07$) cumulative GC dose. None of the biochemical parameters correlated with the BMD z-scores; ten patients (29%) had vitamin D-deficiency (S-25-OHD <37 nmol/l).

We suggest that with the presently used anti-rheumatic drug combinations and increasing use of TNF-α antagonists resulting in reduced GC use, secondary osteoporosis is not as common as previously reported among pediatric patients with JIA. The high frequency of vitamin D deficiency suggests that preventive measures of osteoporosis are often neglected.

Selective COX-2 Inhibitor suppresses the Increased Bone Resorption Associated with Collagen-Induced Arthritis in Mice. T. Taketa*, A. Sakai, S. Akahoshi*, M. Nagashima*, T. Mori, K. Nakai*, T. Nakamura. Orthopeadic surgery, university of occupational and environmental health, Fukuoka, Japan.

Type II collagen-induced arthritis (CIA) has been established as a possible model of rheumatoid arthritis (RA). We have already demonstrated that trabecular bone mass of tibia is reduced as a result of increased bone resorption in CIA mice. And there is a study that celecoxib, selective cyclooxygenase-2 (COX-2) inhibitor, inhibited bone resorption which was elicited by the inflammatory cytokines in vitro. The aims of this study are to clarify whether selective COX-2 inhibitor (celecoxib) suppresses theincreased bone resorption associated with collagen-induced arthritis, and also to discriminate differences of actions on bone resorption among celecoxib, a selective COX-1 inhibitor (SC-58560) and indomethacin, which inhibits both COX-1 and -2. DBA/1J male mice, 8 weeks in age, were divided into 6 groups of 5 animals each as follows: no-treated (1 group) and collagen-induced (5 groups) mice. CIA mice were administered celecoxib orally at doses of 0 (vehicle control), 16, 75 mg/kg body weight in contrast to SC-58560 (1.0mg/kg) and indomethacin (0.5mg/kg). All mice were killed at 6 weeks after commencement of oral administration. At the end of the experiment, serum osteocalcin and urinary deoxypyridinoline (DPD) were measured. Histomorphometrical analyses were also performed on the undecalcified sections of the proximal tibia. The DPD values in CIA were significantly higher than those in vehicle control. Celecoxib suppressed the increased DPD in CIA to the control level. In bone histomorphometry, trabecular bone volume (BV/TV) in CIA mice decreased compared to that in vehicle control mice. BV/TV in high dose celecoxib group significantly increased compared to that in CIA mice. Osteoclast number (Oc.N/BS) in CIA mice increased compared to that in vehicle control. Oc.N/BS in celecoxib groups decreased compared to that in CIA mice. On the other hand, there were no significant differences in DPD and any parameters of bone histomorphometry among SC-58560, indomethacin and CIA mice. Celecoxib administration suppresses the increased bone

resorption and trabecular bone loss in collagen-induced arthritis mice. The inhibitory effect of celecoxib on bone resorption in arthritis miceis remarkable compared to that of SC-58560 or indomethacin.

Effect of Alendronate on Radiographic Progression in Rheumatoid Arthritis. T. Shuto, T. Kuwano*, Y. Nakashima*, H. Yamada*, K. Okazaki*, T. Mawatari*, T. Maeda*, Y. Iwamoto*. Orthopedics, Kyusyu university, Fukuoka, Japan.

Objective. Because bone erosion in patients with rheumatoid arthritis (RA) is mainly formed by accelarated osteoclastic bone resorption, it is possible that bisphosphonate retards the progression of bone destruction in RA patients. We previously reported that amino-bisphosphonate inhibits bone and joint destruction in established adjuvant arthritis (Matsuo et al, J Rheumatol, 30: 1280, 2003). The aim of this study is to examine if oral administration of alendronate retards the radiographic progression in RA patients.

Methods. Twenty five patients with RA who were administered alendronate (AL) for the treatment of osteoporosis were examined as AL group. The Sharp's score (erosion score, joint space narrowing score), serum C-reactive protein (CRP), RAHA, erythrocyte sedimentation rate (ESR), and the excretion of urinary deoxypyridinoline/creatinine (DPD/Cre) were measured before and after the AL treatment. We also evaluated yearly radiographic progression before (estimate-Sharp score) and after (delta-Sharp score) the treatment. As a control, 25 patients with RA who had not been administered bisphosphonate including alendronate were randamly selected (control group).

Results. The mean score of delta-Sharp with respect to erosion significantly decreased compared to that of estimate-Sharp in AL group. However, there was no significant difference between the mean erosion score of delta-Sharp and that of estimate-Sharp in control group. The mean of delta/estimate ratio of erosion was significantly lower in AL groups compared to control group. On the other hand, the delta-Sharp score with respect to joint space narrowing (JSN) was significantly lower than that of estimate-Sharp in both AL and control groups. There was no significant difference with respect to the delta/estimate ratio of JSN between both groups. In laboratory analysis, the urinary DPD/Cre value decreased significantly by AL treatment, however, significant change of the ESR and CRP level was not observed between before and after AL treatment.

Discussion & Conclusion. This is the first report demonstrating significant retardation of radiographic progression of bone erosion after alendronate treatment in RA patients. Although it is unclear if alendronate has benefical effect on either articular cartilage destruction or inflammatory reaction, alendronate could have the inhibitory effect on progressive bone destruction in RA patients.

Nurse-like Cells from Patients with Rheumatoid Arthritis Support Survival of Osteoclast Precursors via Macrophage-Colony Stimulating Factor Production. H. Tsuboi*[1], N. Udagawa[2], J. Hashimoto*[1], H. Yoshikawa[1], N. Takahashi[3], T. Ochi*[4]. [1]Orthopaedic surgery, Osaka University, Suita, Japan, [2]Department of Biochemistry, Matsumoto Dental University, Shiojiri, Japan, [3]Institute for Dental Science, Matsumoto Dental University, Shiojiri, Japan, [4]National Hospital Organization Sagamihara National Hospital, Sagamihara, Japan.

Osteoclasts play an important role in the bone destruction of rheumatoid arthritis (RA). In RA synovium, synovial fibroblasts are thought to support osteoclastogenesis. This study was performed to elucidate the role of nurse-like cells (NLCs), which were established from RA synovium, in bone destruction with progressive synovial expansion. CD14-positive monocytes (CD14+s) were cocultured with NLCs for 4 weeks and collected as NLC-supported CD14+s (NCD14+s). To determine the ability of NCD14+s to differentiate into osteoclasts, NCD14+s were further cultured with macrophage colony-stimulating factor (M-CSF) together with receptor activator of nuclear factor-kB ligand (RANKL) or tumor necrosis factor a (TNFa). NCD14+s were also cocultured with SaOS-4/3 cells, which were shown to support osteoclastogenesis in response to parathyroid hormone (PTH). Furthermore, CD14+s were cocultured with SaOS-4/3 cells to elucidate how SaOS-4/3 cells and NLCs supported CD14+s for a long period in the coculture. Synovial expansion adjacent to bone in RA patients was examined immunohistochemically to detect osteoclast precursors like NCD14+s. In results, NLCs supported the survival of CD14+s for 4 weeks. NCD14+s as well as CD14+s differentiated into osteoclasts in the presence of M-CSF together with RANKL or TNFa. NCD14+s also differentiated into osteoclasts in PTH-treated cocultures with SaOS-4/3 cells. SaOS-4/3 cells supported the survival of CD14+s for 4 weeks in the presence but not in the absence of PTH. Treatment of SaOS-4/3 cells with PTH up-regulated M-CSF mRNA expression. Neutralizing antibodies against M-CSF inhibited the NLC-supported survival of CD14+s. In immunohistochemical stains of tissue sections from RA patients, CD68-positive monocytes and M-CSF-positive fibroblast-like synoviocytes were co-localized in the regions adjacent to bone destruction with progressive synovial expansion. The present study suggests that NLCs are certainly involved in RA-induced bone destruction through maintaining osteoclast precursors via M-CSF production.

The Determinants of the Bone Mineral Density in Korean Patients with Rheumatoid Arthritis. The Focus on the Use of the Glucocorticoids. W. Park*, B. H. Park*, J. S. Song*, S. B. Hong. Medicine, Inha University Hospital, Incheon, Republic of Korea.

There are more risk factors of osteoporosis in rheumatoid arthritis (RA) than in general population including the use of the glucocorticoid(GC). We evaluated the effect of the daily and cumulated glucocorticoid dose, duration of the disease, markers of disease activity, and menopausal status on the bone mineral density (BMD), and markers of bone metabolism in RA patients.

Sixty-three patients with RA (disease duration of 4.9, range 0.5-32 years), aged 21~72 years (9 men, 26 premenopausal and 28 postmenopausal women) who met the American College of Rheumatology classification of RA were randomly enrolled in the study between 1999 and 2001. Depending on the daily prednisolone (PD) doses, patients were divided into D1 (5.0 mg or less, mean 3.7 mg) and D2 (7.5 - 15 mg, mean 8.3 mg) groups. According to cumulated PD doses, they were divided into C1 (less than 5.0 gm, mean 3.68 gm) and C2 (more than 5.0 gm, mean 10.30 gm) groups. They were also divided into 2 groups by the limit of 3 years disease duration, ESR 20mm/hr, and CRP 0.5mg/dL. BMD was measured at lumbar spine and femur neck by DEXA. Serum osteocalcin (OC) and urinary deoxypyridinoline (DPD) level were measured.

The results are 1) The BMD T-score in total patients were -1.85, -1.81 and -2.13 in L-spine, total femoral neck and Ward's triangle respectively. The femoral neck BMD was lower in postmenopausal female patients, the patients with more than 3 years of the disease duration, the patients with ESR more than 20mm/hr, and C2 group. The lumbar BMD were lower in postmenopausal female patients and patients with ESR more than 20mm/hr. 2) Urinary excretion of DPD tended to be higher, while serum OC level was within normal limit in most of the RA patients (normal, 3.0-7.4 nM/mM creatinine). 3) Urinary DPD was neither different between D1 and D2 groups(7.7 ± 4.78, and 9.4 ± 6.51 nM/mM creatinine, respectively, p=0.066) nor between CI and C2 groups(7.7 ± 5.55, and 8.9 ± 5.69 nM/mM creatinine, respectively, p=0.147). 4) Serum OC was neither different between D1 and D2 groups(7.68 ± 4.14, and 6.00 ± 2.74 ng/ml, respectively, p=0.152) nor between CI and C2 groups(7.49 ± 2.93, and 6.76 ± 4.25 ng/ml, respectively, p=0.259). 5) The independent predictors of bone mass by linear regression analysis were ESR, cumulated GC dose, disease duration, and menopausal state.

Conclusively, RA patients generally have an imbalance in bone metabolism markers. But the imbalance was not GC dose dependent in the low dose range(less than 15 mg PD daily). The BMD was lower in RA patients in postmenopausal state, with long disease duration, higher cumulated GC dose, and high ESR.

Positive Effects of Infliximab Therapy on Bone Metabolism in Patients with Rheumatoid Arthritis. T. Thomas[1], P. Garnero[2], A. le Henanff*[3], F. Debiais[4], X. Le Loet*[5], C. Roux[6], J. Sany*[7], D. Wendling[8], C. Zarnitsky*[9], P. Ravaux*[3]. [1]Rheumatology, INSERM 0366, Saint-Etienne, France, [2]SYNARC, Lyon, France, [3]Epidemiology, Biostatistics and Clinical Research, Hôpital Bichat, Paris, France, [4]Rheumatology, University Hospital of Poitiers, Poitiers, France, [5]Rheumatology, University Hospital of Rouen, Rouen, France, [6]Rheumatology, Hôpital Cochin, Paris, France, [7]Immuno-Rheumatology, Hôpital Lapeyronie, Montpellier, France, [8]Rheumatology, University Hospital of Besançon, Besançon, France, [9]Rheumatology, Groupe Hospitalier du Havre, Le Havre, France.

Rheumatoid arthritis (RA) is characterized by a progressive destruction of joint structures. The RA-related bone loss is mediated by cytokines, including TNFa, which are produced within the synovitis. Therefore we proposed the working hypothesis that administration of anti-TNFa drugs in the treatment of RA would also slow down bone remodeling. We present here a prospective study of a multicentric cohort of 48 women, mean age 54.2±12.1 years old, with a severe RA for 11.4±7.8 years, who started infliximab after failure of other disease-modifying antirheumatic drugs. The objective of the study was to evaluate bone metabolism under infliximab by measuring type I procollagen N-terminal propeptide (PINP), a marker of bone formation, and serum C-terminal cross-linked telopeptide of type I collagen (S-CTX), a marker of bone resorption at 0, 6 and 22 weeks. In addition, bone mineral density (BMD) was assessed at baseline and after 6 months by DEXA both at the lumbar spine and hip.

Only 12.5% of patients were current smokers, 62.5% were postmenopausal women and 77% were under oral glucocorticoids (mean daily dose: prednisone 10 mg/d). Two patients had a previous clinical vertebral fracture. No patient received bisphosphonates. Patients had a total dose of infliximab 1002.6±262.5 in 4.6±0.6 infusions during the course of the study.

The S-CTX levels rapidly and significantly decreased by 19% and 28% after 6 and 22 weeks, respectively ($p<0.001$) whereas PINP levels remained stable with -9% and -13% decrease after 6 and 22 weeks of infliximab, respectively (NS). Prior treatment, BMD values expressed in T-score, were -0.65±1.53 and -0.66±1.63 at the spine and total hip, respectively. After 6 months, BMD did not change at both sites.

In conclusion, the 20% improvement in the formation/resorption balance observed after 6 months of therapy demonstrated beneficial bone effects of infliximab in patients with RA. These effects could partly explain the prevention of structural joint lesions observed with anti-TNFa therapy. Moreover, these results suggest that modulating TNFa pathway could be a potential therapeutic avenue in the treatment of osteoporosis.

Serum from Children with Juvenile Rheumatoid Arthritis (JRA) Inhibits the Differentiation and Increases Apoptosis of Human Osteoblasts in Culture. V. F. Caparbo*, C. A. A. da Silva*, R. M. R. Pereira. Rheumatology Division, University of São Paulo, São Paulo, Brazil.

Background: Bone demineralization is common in Juvenile Rheumatoid Arthritis and it has been associated with activity and severity of disease. The decrease of bone mineral density has been related to decrease of bone turnover, mainly with low bone formation. Decrease of osteocalcin, alkaline phosphatase has been described in the serum of these patients suggesting that the bone formation is compromised in JRA patients.
Objective: To examine the effects of JRA serum on the proliferation, differentation, and fate of human osteoblast cells (hOb) culture up to 17 days after confluence.
Methods: The human osteoblast cells were cultured in presence of 10% serum from JRA patients (n=10) and from healthy controls (n=10), 100 ug/mL ascorbic acid and 5 mmol/L beta-glycerophosphate and the medium was changed every 3 or 4 days. No JRA patient were using glucocorticoid at least one month before the study or another drug that can affect bone mineral metabolism and all patients were on disease activity. DNA synthesis was assessed by measuring the incorporation of H^3 thymidine into acid-precipitable material. The osteoblast cells differentation was examined by alkaline phosphatase activity and ostecalcin secretion. Serum from each control and JRA patient was tested in 8 indepedent cultures for alkaline phosphatase, osteocalcin and DNA synthesis assays and in 3 hOb osteoblasts cultures for DNA fragmentation.
Results: There is a decrease of alkaline phosphatase activity and secretion of osteocalcin, boths markers of mature osteoblasts, in hOb cultured with the serum of JRA compared with controls. No effect statistically significant was observed in DNA proliferation in hOb cultured with JRA serum. Apoptosis of hOb was present in cells cultured with JRA serum, but not with controls sera, detected by DNA fragmentation.

	JRA	Healthy controls	p
1. Celular differentation			
Alkaline phosphatase activity, µmol	16.93 ± 4.54	22.75 ± 5.08	0.015*
Osteocalcin synthesis, ng/well	1.30 ± 0.023	1.33 ± 0.022	0.023*
2. Celular proliferation			
DNA synthesis, dpm/well	955.3 ± 155.63	1078.6 ± 310.8	NS
3. DNA quantification, µg/culture	10.7 ± 7.4	27.8 ± 4.0	0.002*

Conclusion: JRA serum decrease the differentiation of human osteoblast cells but not the DNA proliferation. There is also an increase of apoptosis in human Osteoblasts cultured with JRA serum. A lot of cytokines has be implied in physiopathology of JRA bone loss that can explain these results. Understanding better the role of these cytokines in bone formation is fundamental to find a drug to prevent and treat the osteoporosis and fractures that occur in JRA patients.

Catabolic Effects of Continuous Infusion of Human PTH1-34 Fragment in C57BL/J6 Mice. A. Iida-Klein[1], S. S. Lu[1], R. Kapadia[2], M. Burkhart*[2], D. W. Dempster[1], R. Lindsay[3]. [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Scanco Inc., USA, Wayne, PA, USA, [3]Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

Parathyroid hormone (PTH) stimulates bone resorption as well as bone formation in vivo and in organ culture. Catabolic actions of PTH have been recognized in patients with hyperparathyroidism, whose serum PTH levels are continuously elevated. However, it is often difficult to create a condition of hyperparathyroidism in mice. The goal of the present study was to determine whether continuous infusion of N-terminal human PTH1-34 fragment (hPTH1-34) could be catabolic in mice, and whether its catabolic action could be confirmed by biochemical markers, and by changes in bone mineral density (BMD) and microarchitecture. Ten-week-old female C57BL/J6 mice were continuously treated with hPTH1-34 for 2 weeks, using the Alzet osmotic pumps containing either hPTH1-34 (8.1 pmoles/0.25 µl/hr, equivalent to 40µg/kg/day, n=7) or vehicle (n=9). BMD was measured weekly, and bone and blood samples were collected at euthanasia. Serum levels of total calcium, hPTH1-34, mouse intact PTH1-84 (mPTH1-84) and mouse tartrate acid phosphatase activity (mTRAP) were measured. As expected, hPTH1-34 was undetectable in control mice, while the hPTH1-34 level was significantly elevated in the PTH-infused mice (79.79 $\pm$ 20.31 pM, $p<0.02$). Infusion of hPTH1-34 markedly suppressed endogenous intact mPTH1-84 (0.73 $\pm$ 0.25 pM for infused vs. 2.40 $\pm$ 0.55 pM for control, $p<0.02$), and significantly increased total calcium (2.64 $\pm$ 0.13 mM vs. 2.04 $\pm$ 0.07 mM, $p<0.005$). In one of two pilot experiments, infusion of hPTH1-34 increased serum TRAP activity (28.26 $\pm$ 0.78 vs. 10.78 $\pm$ 3.8 U/L, $p<0.002$) by ~3 fold. Finally, µCT analysis of the right femur revealed that infusion of hPTH1-34 decreased trabecular connectivity density by 40% ($p<0.05$, n=4 for vehicle and n=5 for PTH) as compared to vehicle infusion. This pilot study clearly showed that infusion of hPTH1-34 induces catabolic effects on bone with increased serum calcium and TRAP activity accompanied by decreased trabecular connectivity density. Infusion of hPTH1-34 in mice may be a good model to study the catabolic actions of PTH on the mammalian skeleton and to contrast these from a mechanistic standpoint with the anabolic effect seen with daily PTH injections

Survival After Parathyroidectomy In Patients With End-stage Renal Disease And Severe Hyperparathyroidism. A. Trombetti*[1], F. Herrmann*[1], C. Stoermann*[2], J. Robert*[3], P. Pennisi*[1], P. Y. Martin*[2], A. Spiliopoulos*[3], R. Rizzoli[1]. [1]Department of Rehabilitation and Geriatrics, University Hospital, Geneva, Switzerland, [2]Department of Internal Medicine, University Hospital, Geneva, Switzerland, [3]Department of Surgery, University Hospital, Geneva, Switzerland.

Patients with end-stage renal disease (ESRD) are at high risk of cardiovascular morbidity and mortality. Secondary hyperparathyroidism (SHPT) is considered as a contributing factor. Whether parathyroidectomy (PTX) influences long-term survival of patients with ESRD and severe SHPT is not known.
Between 1977 and 2002, 63 patients (mean age ± SD, 46.7 ± 13.7 years) with ESRD and severe SHPT underwent PTX. Their survival was compared to those of 752 ESRD patients treated at the same institution during the same period. Follow-up began either at the date of the first dialysis, at birth or at PTX, and continued until death or censoring (March 1st 2003). The observed survival curves were compared using a log-rank test. A Cox proportional hazards model was used to estimate the influence of patients' characteristics on mortality rate. Independent variables evaluated were gender, age at first dialysis, time on dialysis, and the presence of functioning renal graft.
Because of secondary or tertiary HPT, PTX was performed in 3% before onset of dialysis, in 68% during dialysis, and in 29% after kidney transplantation. The mean time between the first dialysis and PTX was 6.6 ± 5.0 years. Three PTX patients (4.8%) and 24 ESRD controls (3.2%) were lost to follow up (not significant). Taking into consideration the follow-up since time of first dialysis, PTX was associated with a significantly lower mortality rate than in non-operated ESRD controls (hazard ratio (HR): 0.33, 95% CI 0.22-0.50). However, the age at first dialysis (40.3 ± 14.6 vs 57.5 ± 16.6, $p < 0.001$), the proportion of patients with renal transplants (54.0 vs 32.1%, $p < 0.0001$) and the time on dialysis (8.6 ± 6.7 vs 3.9 ± 5.0 years, $p< 0.001$) markedly differed between PTX patients and controls. Adjustment for these factors negated the difference (HR: 0.98, 95% CI 0.64-1.52). Life expectancy at birth was not different between the two groups. Finally, to compare survival after PTX, we randomly selected 3 controls for each PTX case within the same 5-year age strata at time of first dialysis and who had the mean duration between first dialysis and PTX. Survival tended to be longer in PTX patients in the first 8 years after surgery (not significant). Censoring at time of first renal transplantation did not change the results. In conclusion, although patients who underwent PTX seemed to be very different from non-operated controls, PTX may protect against early death in patients with ESRD and severe SHPT.

Signaling and Transcriptional Regulation of Matrix Gla Protein by Parathyroid Hormone in MC3T3-E1 Osteoblast-like Cells. S. Suttamanatwong*[1], R. T. Franceschi[2], R. Gopalakrishnan[1]. [1]Oral Sciences, University of Minnesota, Minneapolis, MN, USA, [2]Periodontics/Prevention/Geriatrics, University of Michigan, Ann Arbor, MI, USA.

The inhibition of osteoblast-mediated mineralization is one of the major catabolic effects of parathyroid hormone (PTH). We have previously shown that matrix gla protein (MGP) is a key regulator of PTH-mediated inhibition of mineralization (*Endocrinology,* 142:4379-4388, 2001). To further understand the mechanism of this regulation, we investigated the effect of PTH on the 748 bp murine *Mgp* promoter activity in MC3T3-E1 osteoblast-like cells. Transient transfection of *Mgp*-luciferase reporter construct (pMGP-luc) in MC3T3-E1 cells showed that PTH (10^{-7} M) induced Mgp promoter activity in a time-dependent manner. Induction was noted as early as 3 hours, with maximal induction at 6 hours (~ 3 to 4-fold) and a return to baseline levels 24 hours after PTH treatment. The time course of pMGP-luc activation by PTH correlated with earlier published results for MGP mRNA induction. Using activators and inhibitors of various signaling pathways, we determined that protein kinase A (PKA) is one of the major pathways required for regulation of MGP by PTH. A specific PKA inhibitor, H-89, suppressed both PTH-induced pMGP-luc activity and MGP mRNA levels in a dose-dependant manner. Promoter deletion analysis of the pMGP-luc promoter revealed that PTH activation dramatically decreased when the region between position -173 and -49 was deleted, suggesting that a PTH-responsive element lies in this region of the promoter. We are currently investigating the transcriptional element/s contained between -173 to -49 of the promoter, which may be necessary for PTH responsiveness. The results described here indicate that PTH transcriptionally regulates MGP in MC3T3-E1 cells and this regulation, at least in part, requires a PKA-dependent mechanism.

Continuous And Intermittent Treatment Of Zebrafish With Recombinant Human Parathyroid Hormone (1-34) Have Opposite Effects On The Growing Fish Skeleton. A. Fleming*[1], M. Sato[2]. [1]DanioLabs, Cambridge, United Kingdom, [2]Bone and Inflammation, Lilly Research Labs, Indianapolis, IN, USA.

Skeletal effects of continuous and intermittent rhPTH (1-34) were evaluated in zebrafish (Danio rerio). Zebrafish larvae in embryo media were incubated in a 96 well plate format from 3 to 9 days d.p.f., either in the continuous presence of PTH or for 2 hr every other day. Viability of zebrafish was unaffected by the continuous presence of the highest dose of PTH (100 ng/ml) evaluated. PTH had no effect on the length of zebrafish, as evaluated up to 30 ng/ml, whether administered continuously or intermittently. Mineralization was measured by image processing of the head after alizarin red staining at 10 d.p.f., and evaluated as pixel number above a threshold and analysis of the pixel histogram

(integrated optical density, IOD). A dose dependent inhibition of bone formation activity was observed with continuous PTH, leading to a significant, dose-dependent 40% reduction in mineralization (pixel number) at 30 ng/ml, after 6 days treatment. Image processing showed that not all mineralized structures in the head respond equally to PTH treatment. Specifically, otoliths did not respond reproducibly to PTH; so exclusion of otoliths from mineralization analyses improved the coefficient of variation to about 8%. IOD analysis by the latter method showed up to 83% suppression with 30 ng/ml, that was significant at all doses. By contrast, intermittent PTH induced a significant, dose-dependent 16% and 17% increase in mineralization for 10 and 30 ng/ml, respectively. These data show that PTH has effects on the growing zebrafish skeleton, not unlike the catabolic and anabolic skeletal effects described previously for continuous and intermittent PTH treatment in rats and primates. However, not all of the effects may be identical, as intermittent PTH did not significantly enhance longitudinal growth, as has been observed for the growing rat skeleton.

Time-course of PTH-Regulated RANKL and OPG Expression in SaOS-2 Cells. J. L. Glover*, A. B. Hodsman, L. J. Fraher, P. H. Watson. Medicine, Lawson Health Research Institute, University of Western Ontario, London, ON, Canada.

Receptor activator of NF-kappaB ligand (RANKL) and osteoprotegerin (OPG) are important factors in the regulation of osteoblast to osteoclast communication during bone remodelling. Parathyroid hormone (PTH) is a key regulator of bone remodelling and affects osteoblastic expression of these molecules. It is well known that clinical use of PTH (1-34) in daily intermittent doses is highly anabolic while continuous exposure is catabolic to bone. Recently, PTH (1-31) and its derivatives have also shown promise as selective bone anabolic agents. Understanding the time course involved in PTH analogue regulation of OPG and RANKL protein expression should aid us to better understand the actions of PTH. SaOS-2 cells were grown to 70% confluence on cover slips and serum starved for 24 hours prior to treatment. The cells were treated with 10nM PTH 1-34 or PTH 1-31 and thereafter fixed at 0, 1, 2, 4, 8 and 24hours. Control cells for each time period were incubated with serum free media. Expression of OPG and RANKL protein was studied by immunofluorescence. Initial experiments have shown that after treatment with either PTH analogue there is an overall decrease in the apparent fluorescence for OPG. Treatment of SaOS-2 cells with 10 nM PTH 1-34 resulted in increased RANKL fluorescence localizing to the cell surface and in the golgi after 8 hrs. Treatment with 10 nM PTH 1-31 resulted in RANKL accumulation around the nucleus after 8 hrs. In time-course experiments with PTH 1-34, RANKL immunofluorescence was seen to change over a 24hour period. RANKL fluorescence was limited to the golgi after 1 and 2 hours of treatment. At 4 hours, most RANKL immunofluorescence was seen on the surface of the cell. RANKL fluorescence was uniformly dispersed throughout the cytoplasm at the later time points and was negligible after 24 hours. These studies demonstrate a clear pattern of RANKL subcellular localization throughout a 24 hour period in the presence of 10 nM PTH 1-34. Maximal presentation of RANKL on the cell membrane was seen after 4-8 hrs of PTH 1-34 exposure which may, in part, explain the catabolic action of this analogue. Although increased immunofluorescence for RANKL was seen in SaOS-2 cells after treatment with PTH 1-31, this fluorescence was limited to the perinuclear region. No RANKL was seen on the cell membrane which is a necessary step for osteoclast activation, providing a possible explanation for the more selectively anabolic activity of the PTH 1-31 analogue.

Serum Parathyroid Hormone (PTH) Levels Obtained with an "Intact" In House Monoclonal-Antibody Based Assay that Shows a 50% Cross-Reactivity with PTH-(7-84). Comparison with Two Commercial Assays. J. G. Vieira[1], S. K. Nishida*[1], M. T. Camargo*[1], L. H. Obara*[1], I. S. Kunii*[2], M. N. Ohe*[2], O. M. Hauache*[1]. [1]Endocrinology, Laboratório Fleury, São Paulo, Brazil, [2]Endocrinology, EPM/UNIFESP, São Paulo, Brazil.

Immunometric assays for serum PTH supposedly measure only the intact PTH-(1-84) circulating form. A series of studies published in recent years showed that some long carboxyl terminal forms, as PTH-(7-84), were also present in serum and were measured by these assays "intact" PTh assays (2nd generation). New assays (3rd generation), based on amino-terminal antibodies directed against the first amino acids, provide serum values that are significantly lower. We developed a monoclonal-antibody based immunofluorometric assay (IFMA) that presents a 50% cross-reaction with PTH-(7-84). The analytical sensitivity is 2.7 ng/dL, and the interassay CV <10%. The two commercial assays used were an electrochemiluminescent assay (ECLIA, Roche Diagnostics) and an immunochemiluminometric assay (ILMA, Nichols Institute). Both assays show 100% cross-reactivity with PTH-(7-84). Two sets of serum samples from our diagnostic service were used for the study. One comprising 135 samples was measured with the IFMA and the ECLIA; a second set of 252 samples were measured using the IFMA and the ILMA. In the first set, the results using the IFMA showed a median of 35.0 ng/L, with a range from 4.0 to 1579.0 ng/L, and the results using the ECLIA a median of 51.0, with a range from 6.0 to 1900.0 ng/L, values that were significantly higher (P<0.0001, Wilcoxon). Spearman correlation (rs) was 0.961 (P<0.0001). In the second set of samples, the IFMA showed a median of 36.0 ng/L, with a range from 3.0 to 1524.0 ng/L, and the ILMA a median of 45.5 ng/L, with a range from 5.0 to 1795.0 ng/L, values that were significantly higher (P<0.0001, Wilcoxon). Spearman correlation (rs) was 0.883 (P<0.0001). In both sets of samples the results obtained with our in house assay were significantly lower, as expected by the specificity of the amino-terminal antibody employed. Our data support the need of a precise description of the specificity of the amino-terminal antibodies employed in "intact" PTH assays (2nd generation) in order to better compare results and define normal ranges.

IL-6 Is Not Required for Parathyroid Hormone Stimulation of RANKL Expression, Osteoclast Formation, and Bone Loss in Mice. C. A. O'Brien, R. L. Jilka, Q. Fu, S. Stewart*, R. S. Weinstein, S. C. Manolagas. Internal Medicine/Endocrinology, Univ. Arkansas for Medical Sciences, Little Rock, AR, USA.

Sustained elevation of parathyroid hormone (PTH) stimulates osteoclast formation and net bone loss; and PTH regulation of the RANKL/OPG ratio is thought to play an important role in this process. However, previous studies have shown that PTH also stimulates the production of IL-6 and the increased bone resorption caused by PTH infusion was blunted in IL-6-deficient mice. The goal of these studies was to determine whether chronic elevation of endogenous PTH alters IL-6 gene expression in vivo and whether IL-6 is required for bone loss associated with this condition. To allow accurate quantitation of IL-6 gene activity in vivo, we generated transgenic mice harboring a luciferase reporter gene under the control of IL-6 gene regulatory regions. Serum PTH was elevated by feeding adult mice a calcium-deficient diet for 7 days. Secondary hyperparathyroidism did not alter IL-6-luciferase transgene expression in bone or any of the other tissues examined. However, RANKL mRNA expression was elevated in bone tissue from these mice. These results suggested that IL-6 gene expression was not altered by chronic elevation of endogenous PTH. However, it remained possible that elevation of IL-6 expression in a tissue that we did not examine is nonetheless required for PTH-induced osteoclast differentiation and bone loss. Alternatively, a tonic level of IL-6 expression may be required for PTH actions on bone. To address these issues, bone loss and compression strength were compared in 6 month old wild type and IL-6-deficient C57Bl/6 mice after 7 days of dietary calcium deficiency. Dietary calcium deficiency induced significant bone loss in the hind limbs and spine of both wild type and IL-6-deficient mice. Consistent with the loss of spinal BMD, loss of vertebral compression strength and increase in cancellous osteoclast perimeter were similar in wild type and IL-6-deficient mice. We, therefore, compared the ability of PTH to regulate RANKL and OPG mRNA in bone marrow cultures from wild type and IL-6-deficient mice. Consistent with the loss of bone mass in vivo, there was no difference in the stimulation of RANKL, or suppression of OPG, mRNA by PTH in bone marrow cultures from wild type and IL-6-deficient mice. This was reflected in equivalent osteoclast formation in response to PTH in cultures from wild type and IL-6-deficient mice. These results demonstrate that chronic elevation of endogenous PTH stimulates osteoclast formation and bone loss via a mechanism that does not require IL-6; instead it requires changes in the RANKL/OPG ratio.

Parathyroid Hormone Injection Induces Cyclooxygenase-2 in Bone, Kidney and Muscle *In Vivo*. M. Xu, O. S. Voznesensky*, L. G. Raisz, C. C. Pilbeam. Dept. of Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Intermittent parathyroid hormone (PTH) is used as an anabolic agent to treat patients with osteoporosis. Since PTH is a potent inducer of cyclooxygenase-2 (COX-2) in osteoblastic cells in vitro, we examined the PTH induction of COX-2 in vivo. We used CD-1 mice transgenic for 371 bp of the murine COX-2 promoter fused to a luciferase reporter. Total RNA was extracted from freshly isolated tissues and COX-2 mRNA and GAPDH mRNA were measured by Northern analysis. Cell lysates from the same tissues were analyzed for luciferase activity, normalized to total protein. COX-2 is a transiently inducible gene and little COX-2 mRNA is detectable by Northern analysis in freshly isolated bone under basal conditions. After injection of PTH (human PTH 1-34) 30 μg/kg subcutaneously bilaterally above each calvaria, COX-2 mRNA in the calvariae peaked at 1 h and returned to basal levels at 6 h. Because multiple tissues have been reported to express PTH/PTHrP receptors, we injected PTH (160 μg/kg) intraperitoneally and examined tissue samples from femur, tibia, kidney, muscle, brain, lung, heart, spleen and liver at 1 and 3 h after injection. Basal luciferase activity was highest in brain (brain > femur, tibia, muscle > heart, lung > kidney, spleen, liver). PTH increased luciferase activity 7-fold in tibia, 5-fold in femur, 3.5-fold in kidney, and 1.6-fold in muscle (all P<0.01) at 3 h. There was no increase in luciferase activity in the other tissues. PTH induced COX-2 mRNA, normalized to GAPDH mRNA, in femoral and tibial bone by 5 to 6-fold at 1 h with levels decreasing at 3 h. Smaller increases were seen in kidney (2-fold) and muscle (1.6-fold). At 3 h but not 1 h, serum calcium was significantly increased in PTH injected mice compared to controls (10.3 ± 0.2 *vs.* 9.3 ± 0.1, P<0.01) and serum phosphorus was decreased (10.6 ± 0.3 *vs.* 12.3 ± 0.2, P<0.01). Since increased extracellular calcium can induce COX-2, some of the effects of PTH might be due to increased serum calcium. However, the increase in calcium occurred later than the peak in COX-2 mRNA levels. This study suggests that exogenous PTH induces COX-2 mRNA rapidly and transiently in vivo, and that the induction is transcriptionally mediated. Bone has the greatest COX-2 response to PTH, but other tissues can also respond.

Connexins and PTH Regulation of the Osteocalcin Promoter. A. De Marzo, J. P. Stains, R. Civitelli. Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA.

It has been previously shown that the effect of PTH on cAMP production and in vitro mineralization are curtailed when gap junctional communication is disrupted. We have demonstrated that expression of chick connexin45 (cCx45) in ROS 17/2.8 and MC3T3-E1 cells, which express abundant endogenous connexin43 (Cx43), decreases the permeability of gap junctional channels and down-regulates osteocalcin (OC) and collagen α1 (I) promoters. We tested whether PTH regulation of OC gene transcription is altered by dominant negative inhibition (cCx45 expression) of Cx43 mediated gap junctional communication. Different fragments of the rat OC proximal promoter were used in a luciferase (LUC) reporter system and transiently co-transfected with cCx45 into ROS 17/2.8 or MC3T3 cells. Incubation (16-24 h) of either cell line with 10^{-8}M rat PTH (1-34) induced circa 1.8-fold increase of -637OCLUC (containing -637 to +32 promoter fragment) and -199OCLUC (containing -199 to +32 promoter fragment) reporter activities. Co-transfection with cCx45 reduced both basal and PTH stimulated luciferase activities, although the degree of PTH stimulation relative to basal activity was similar in the presence or in the absence of cCx45 for either reporter. A shorter, 5' truncated promoter fragment, -92OCLUC was minimally responsive to PTH and yet retained sensitivity to Cx45 overexpression. Since the OC promoter fragments tested encompass both a cAMP response region (ROCRR) and a connexin response element (CxRE), these data argue against a role of these regulatory regions in connexin sensitivity of PTH responsiveness observed in osteoblastic cells. Consistent with this hypothesis, cCx45 did not alter PTH stimulation of a heterologous promoter-luciferase construct containing 2 copies of ROCRR; and PTH did not stimulate a CxRE-LUC reporter. Further, while forskolin (10^{-5}M) did not affect OC gene transcription in ROS 17/2.8 cells, it did induce on average a 3-fold activation of -637OCLUC in MC3T3-E1 cells, as did 8Br-cAMP (10^{-3}M). This stimulation was not altered by co-expression of cCx45, arguing against a role of cAMP in cCx45 modulation of the OC promoter's responsiveness to PTH. In fact, cCx45 consistently exhibited synergistic activation of a canonical cAMP response element (CRE) when co-transfeted with a CRE-LUC reporter in either ROS 17/2.8 or MC3T3-E1 cells. These data suggest that interference with gap junctional communication by cCx45 expression reduces basal OC promoter activity, but does not abolish PTH activation of the promoter. Modulation of cAMP mediated responses does not seem to be involved in the mechanism by which gap junctional communication modulates OC gene transcription.

Receptor Structural Determinants for Extracellular Signal-Regulated Kinases (ERK) Activation by PTH. A. Rey*, D. Manen*, J. Caversazio, R. Rizzoli, S. L. Ferrari. Division of Bone Diseases, Geneva University Hospital, Geneva, Switzerland.

PTH/PTHrP receptor (PTH1R) activation by cognate agonists triggers intracellular signaling through the adenylate cyclase (AC)-cAMP and phospholipase C (PLC)-IP3/Ca pathways. In addition, PTH has been reported to activate ERK1/2 (ERK) through PTH1R, but the signal transduction mechanisms responsible for this activation remain uncertain. Moreover, it is currently unknown whether activation of the PTH receptor type 2 (PTH2R) by cognate agonists, PTH and TIP39, triggers ERK signaling. We investigated PTH1R and PTH2R structural requirements for ERK activation by evaluating ERK phosphorylation using immuno-western blotting in HEK293 cells transiently expressing wild type (WT), mutant or chimeric receptors.

In PTH1R expressing cells, ERK activation increased 60 fold over baseline (by ImageQuant analysis) 5 min. after exposure to PTH(1-34) (100nM), and quickly declined thereafter. In cells expressing the Jansen's PTH1R mutant H223R, which constitutively activates cAMP but is deficient for PLC-IP3 signaling, ERK activation by PTH was similar to WT. In contrast, AC-cAMP activation by forskolin did not activate ERK. In PTH2R expressing cells, ERK was activated by TIP39 (100nM), but not by PTH. Moreover, a PTH2R chimeric receptor carrying the N-term and 3rd extracellular loop of PTH1R, which we had previously shown to improve PTH-stimulated Gq-mediated signaling compared to WT PTH2R, did not mediate PTH activation of ERK. Altogether, these data indicated that cAMP is not sufficient whereas PLC signaling is not required for ERK activation by PTH. To further investigate the PTH1R determinants for ERK activation, sequential PTH1R C-terminus deletions were carried out. A juxta-membrane deletion of PTH1R C-term (aa472) abolished PTH activation of ERK . On the opposite, with a more distal C-term deletion (aa501), ERK activation was 2 fold higher after 5min. and was sustained at 15min. compared to WT PTH1R. Moreover, compared to WT PTH1R , PTH-mediated ERK activation was significantly increased in cells expressing a chimeric PTH1R carrying the distal C-term of PTH2R.

In summary, ERK is selectively activated by PTH through PTH1R and by TIP39 through PTH2R. Distinct structural determinants in PTH1R C-term, rather than Gs- or Gq-mediated signaling, appear to mediate PTH-stimulation of ERK. Indeed, PTH1R proximal C-term harbors activating sequences whereas the distal C-term, which shares the least homology with PTH2R C-term, harbors inhibitory sequences for ERK activation. These findings suggest that PTH-stimulated MAPK signaling is regulated by interactions of PTH1R C-term with cytoplasmic molecules, which remain to be identified.

Role of Angiogenesis in the Anabolic Effect of Parathyroid Hormone. Y. Rhee[1], Y. Kim[2], S. Lee*[1], J. Lee*[1], S. Kim*[1], J. Byoun*[1], R. Hwang*[1], S. Jun*[1], J. An*[1], S. Lim[1]. [1]Brain Korea 21 Project of Medical Science, Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea, [2]Internal Medicine, NHIC Ilsan Hospital (National Health Insurance Corporation Ilsan Hospital), Seoul, Republic of Korea.

In vivo osteogenic responses to anabolic stimuli are expected to be accompanied by angiogenesis as well as in the process of development of bone. One of the strongest pharamacologic osteogenic stimuli take place with the administration of parathyroid hormone(PTH). Consequently, angiogenesis might play an important role in mediating this bone forming stimulating effect of PTH. To investigate this relationship, actively growing young Sprague-Dawley rat were used. All animals were treated in accordance with the guidelines and regulations for the use and care of animals of Yonsei University, Seoul, Korea. The analogue of TNP-470 inhibitor, one of the angiogenesis inhibitor(AI) was administered concomitatntly to show the role of angiogenesis in the effect of PTH. The groups(n=7, each) were divided as (1) vehicle(VEH), (2) recombinant human PTH(1-84) (PTH84) [80 mcg/kg, sc, 5 days a week], (3) angiogenesis inhibitor alone (AI) [1 mg/kg, sc, 5 days a week] (4) PTH(1-84) + AI concomitatntly with same dosage as group 2 and 3(AI84). The duration of the treatment took 5 weeks. The dual x-ray absorptiometry(Hologic QDR 4500 A, small animal program) of right femur were taken. The bone mineral density(BMD) of PTH84 was higher than VEH by 6.3% ($p<0.05$) and the gain of bone mass was attenuated by 2.5% in AI84($p<0.05$). However more significant attenuation by concomitant use of AI was shown in the 3-point bending test. The maximal failure load was increased as much as 14.8%($p<0.05$) in PTH85 than VEH, but it was diminished by 24.3%($p<0.05$) by concurrent use of AI. Moreover, the toughness showed similar significant changes($p<0.05$). The BMD or the biomechanic data of AI group were similar with the VEH suggesting the minimal effect on the normally modeling phase of the growing rat. In contrast, the angiogenesis seemed to be quite important in completing the anabolic effect of PTH.

Protein Profiling in the Parathyroid Hormone-treated Bone Marrow Cell by Proteomics. S. Jun*, E. Lee*, R. Hwang*, S. Kim*, J. An*, S. Lee*, Y. Rhee, S. Lim. Brain Korea 21 Project of Medical Science, Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea.

Parathyroid hormone (PTH) plays a major role in the balance between bone formation and bone resorption. While prolonged exposure to PTH cause increased bone resorption, intermittent injections of PTH have an anabolic effect on bone. The ability of PTH to enhance bone formation has recently been exploited in the treatment of osteoporosis. However, despite the large body of evidence that intermittent administration of PTH is strongly anabolic and increases bone mass in humans, little is known of the mechanism by which it stimulates bone formation. Therefore, in this study, protein profiling in the intermittent PTH-treated bone marrow cells were evaluated by using proteomics. Daily treatment for 5 days consisting of subcutaneous (sc) injection of either 150 μg/kg per day of mouse PTH (1-84) or vehicle (0.9% normal saline) was performed to the ICR mouse. At the end of the treatment period, the animals were killed 6 hour after last treatment and bone marrow cells were extracted from mouse tibiae and femur. Bone marrow cells were separated with marrow plasma by centrifugation, and red blood cells were removed. Bone marrow cells were washed with PBS 2 times and homogenized by urea lysis buffer. Proteins were separated in 2-dimensional-electrophoresis and visualized by clumsier blue staining. Gel images were analyzed by PDquest software and a total of 7 known proteins and 1 unknown protein were found to have at least 2-fold expression changes after PTH treatment. Four known proteins were newly synthesized and 4 known proteins and 2 unknown proteins disappeared after PTH treatment. Newly expressed or increased proteins in PTH-treated cell are related to signaling, cell cycle proteins and Ca2+ ion regulation. Structural proteins like vimentin and putative beta-actin decreased or disappeared in PTH-treated cell. Proteins related in energy metabolism eg, mitochondrial or endoplasmic reticulum ATPase were down regulated. These results could be helpful to understand the physiological function of PTH in bone marrow cells.

The Effects of Intermittent but not Continuous Parathyroid Hormone (PTH) on Mineralation are Mediated through Hemichannels. P. Cherian[1], X. Wang*[1], L. F. Bonewald[2], J. X. Jiang[1]. [1]Biochemistry, University of Texas Health Science Center, San Antonio, TX, USA, [2]Oral Biology, School of Dentistry, University of Missouri, Kansas City, MO, USA.

Sustained elevation of PTH as in hyperparathyroidism, stimulates bone resorption, whereas intermittent administration stimulates bone formation. Even though $PTH_{(1-34)}$ is now used clinically for the treatment of osteoporosis, the mechanism whereby PTH mediates these opposing effects depending on timing of administration is not understood. Intermittent, but not continuous, treatment by $PTH_{(1-34)}$ has been demonstrated to stimulate osteoblast proliferation and differentiation. It has also been shown that inhibitors of gap junction function can block PTH induced osteoblast differentiation. We sought to determine the role that Cx43 as a component of gap junctions plays in the effect of $PTH_{(1-34)}$ on osteoblast mineralization. The cell line MLO-A5 that rapidly mineralizes in culture within 3-6 days was used. Intermittent PTH enhances mineralization of MLO-A5 cells, whereas continuous PTH inhibits this process. The stimulation of mineralization by intermittent PTH was significantly inhibited by the gap junction inhibitor 18 β-glycyrrhetinic acid

which is also known to block hemichannels. Cx43 is abundantly expressed intracellulary in MLO-A5 cells with minor expression on the cell surface. When the cells are treated with 10^{-8} M $PTH_{(1-34)}$ continuously for 48 h, the expression level of Cx43 mRNA increased significantly; however, there was no obvious change in the cell surface expression. In contrast, when the cells are subjected to intermittent treatment (4 h-treatment per 24 h culture) of 10^{-8} M $PTH_{(1-34)}$ for a total of 48 hrs, the majority of the intracellular Cx43 migrates to the cell surface even though overall total protein expression of Cx43 is unchanged. Interestingly, gap junction function was stimulated to the similar extent by both intermittent as well as continuous $PTH_{(1-34)}$. This work emphasizes the importance of not only examining the regulation of mRNA and protein expression, but also protein migration and localization. We propose that Cx43 in the form of hemichannels, instead of gap junctional channels, is likely to modulate the effect of intermittent PTH on the mineralization process.

Differential Short Term Responses of the Mouse Skeleton to the Same Daily Amount of hPTH1-34 Delivered Either Intermittently or Continuously: Effects of Bone Density and Biochemical Markers. S. S. Lu, D. W. Dempster, R. Lindsay, A. Iida-Klein. Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

Intermittent parathyroid hormone (PTH) treatment has an anabolic action on the skeleton, but PTH can also be catabolic when administered continuously. The mechanisms underlying those diverse actions are poorly understood. We investigated the response of mouse bone to the same daily amount of human PTH1-34 fragment (hPTH1-34) given either intermittently(iPTH)or continuously (cPTH). Female C57BL/6J mice at 10 weeks of age were treated with hPTH1-34 (40μg/kg/day, n=6) or vehicle (n=6) by subcutaneous injection, or were implanted with osmotic pumps releasing hPTH1-34 (33.3 ng/hr/0.25 μL, equivalent to 40μg/kg/day,n=6) or vehicle (n=6) for 14 days. Another 6 mice were sacrificed on day 0 as a basal group. Bone mineral density (BMD) was measured by PIXImus at 0, 7 and 14 days. Serum was obtained at autopsy for the measurement of hPTH1-34, mouse intact PTH (mPTH1-84), mouse tartrate resistant acid phosphatase (mTRAP) and total calcium. iPTH treatment induced a 9% increase in femoral BMD (from 0.0581 to 0.0636 g/ cm^2, $p<0.01$); an 80% increase in mTRAP (from 9.0 to 16.2 U/L, $p< 0.01$); but no change in serum calcium. cPTH treatment for 2 weeks reduced femoral BMD by 5% (from 0.0570 to 0.0547 g/ cm^2, $p<0.01$); increased mTRAP (from 8.5 to15.2 U/L, $p<0.05$) and calcium (from 9.4 to14.6 mg/dl, $p<0.01$) by 80% and 57%, respectively. Neither treatment changed BMD in tibia or vertebrae ($p>0.05$), but compared to cPTH treatment, iPTH treatment had both higher femoral BMD (0.0636 *vs* 0.0547 g/cm^2, 16%, $p<0.01$) and tibial BMD (0.0449 *vs* 0.0414 g/cm^2, 9%, $p<0.05$). Serum mTRAP was increased, and endogenous mPTH1-84 was reduced to the same extent by both treatments. However, exogenous hPTH1-34 was only detected with cPTH administration. Although both modes of administration increased a resorption marker, only cPTH induced hypercalcemia without increased bone mass, while iPTH increased BMD with no change in serum calcium. We conclude that 1) the two modes of administration of the same daily amount of hPTH1-34 produce distinctly different outcomes in serum total calcium and long bone BMD , 2) exogenous hPTH1-34 stays high when infused continuously but is metabolized rapidly when injected daily , and 3) short-term intermittent or continuous treatment of mice with hPTH1-34 represents a good model to study the dual actions of PTH on the skeleton .

SU558

Overexpression of G Protein-coupled Receptor Kinase 2 (GRK2) in Osteoblasts Decreases Bone Mass and Reduced the Anabolic Effects of PTH(1-34). L. Wang*, P. Flannery*, R. F. Spurney. Medicine, Duke Medical Center, Durham, NC, USA.

G-protein coupled receptor (GPCR) systems are important regulators of bone remodeling. The osseous effects of GPCR systems are likely to be modulated by the rate of receptor desensitization in osteoblasts. GPCR desensitization is largely mediated by phosphorylation of GPCR proteins by a family of enzymes termed GRKs. To investigate the role of GRKs in regulating bone formation in vivo, we overexpressed the potent GPCR regulator GRK2 in bone using the osteocalcin gene 2 (OG2) promoter to target expression to osteoblasts. Previous studies (JBMR 8(suppl 2):S38, 2003) found that GRK2 transgenic (TG) mice demonstrated a significant reduction in whole body bone mineral density (BMD) compared to non-TG littermate controls at 6 weeks of age. To investigate the age-dependent effects of GRK inhibition, we monitored BMD in TG mice and in controls at 6-week, 3-month and 6-month time points. Consistent with our previous findings, whole body BMD was decreased in TG mice compared to controls at the 6-week time point. The decrease in BMD was most prominent in trabecular rich lumbar spine and was less pronounced in cortical bone of the femoral shaft. A similar pattern was seen in animals at the 3 and 6 months time points although the difference decreased over time and remained statistically significant only in lumbar spine at 6 months of age (64.3 ± 1.2 mg/cm2 [non-TG] vs. 59.2 ± 0.9 mg/cm2 [TG]; P=0.003). To determine if the GRK2 transgene inhibited the effects of an anabolic GPCR agonist, 6-month-old mice were treated with PTH (1-34) for 4 weeks. Data was expressed as a percent increase in BMD above baseline to reduce the effect of the difference in baseline BMD. We found that PTH(1-34) increased whole body BMD to a greater extent in non-TG mice compared to TG animals (8.0 ± 0.9% [non-TG] vs. 3.4 ± 1.7% [TG]; P=0.025). A more pronounced effect of the GRK2 transgene on PTH(1-34) responsiveness was seen in trabecular rich lumbar spine (14.6 ± 3.2% [non-TG] vs. 6.9 ± 1.8% [TG]; P=0.038). PTH(1-34) treatment increased femoral shaft BMD to a similar extent in TG mice and non-TG controls (7.5 ± 1.9% [non-TG] vs. 7.4 ± 2.0% [TG]; P=NS). Taken together, these data suggest that enhancing GRK activity in osteoblasts causes a decrease in bone mass and reduction in the anabolic response to the bone-forming GPCR agonist PTH(1-34). We conclude that GRKs play a key role in regulating PTH responsiveness in bone.

PTH Receptor Activation but not Internalization Is Required for MAPK Stimulation. P. A. Friedman[1], J. Ba*[2]. [1]Depts. of Pharmacology and of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [2]Dept. of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

The Type 1 PTH receptor (PTH1R) activates multiple signaling pathways, including mitogen-activated protein kinase (MAPK, ERK), in a cell- and ligand-specific manner. In previous work we showed that PTH stimulated ERK1 and ERK2 in kidney distal tubule cells. Blockade of MAPK inhibited PTH-stimulated calcium transport. Emerging evidence points to a requirement for internalization of some G protein-coupled receptors, such as the ß2 adrenergic receptor, for induction of MAPK activity. In the present work we determined the role of PTH1R endocytosis in MAPK stimulation by taking advantage of PTH peptide fragments that are either capable of activating the PTH1R without internalizing it, or internalizing the PTH1R without antecedent activation. PTH(1-34) activated the PTH1R with 20x cAMP formation and 2x inositol phosphate accumulation, and promoted receptor desensitization and internalization. MAPK activation was measured by phosphospecific immunoblotting. Results were normalized to total MAPK. In distal tubule kidney cells harboring 10^6 PTH receptors/cell, PTH(1-34) stimulated ERK2 in a time-dependent manner, with maximal 3-fold activation at 10 min. Therefore, the effects of other PTH peptide fragments were examined after a 10-min stimulation. PTH(1-31) stimulated adenylyl cyclase and PLC caused receptor desensitization. However, PTH(1-31) does not internalize the PTH1R. PTH(1-31) stimulated 2.5-fold activation of ERK2. PTH(7-34) does not activate or desensitize the PTH1R but promotes efficient PTH1R internalization in these cells. PTH(7-34) had no effect on ERK2. We conclude that MAPK activation in distal kidney cells requires PTH1R activation but not internalization.

Functional Studies of the Nuclear Localization Sequence of the PTH Receptor. E. K. Patterson*[1], P. H. Watson[1], A. B. Hodsman[1], G. N. Hendy[2], F. R. Bringhurst[3], L. J. Fraher[1]. [1]Medicine, Lawson Health Research Institute, University of Western Ontario, London, ON, Canada, [2]Medicine, McGill University, Montreal, PQ, Canada, [3]Medicine, Harvard University, Boston, MA, USA.

In previous studies presented to this society, we attempted to demonstrate the function of the putative nuclear localization sequence (NLS) we identified in the PTH receptor. Initial immunocytochemical studies demonstrated the unexpected result that the PTH1R is apparently able to localize to the nucleus of cells in the gut, ovary, testes, liver and kidney in rat. Further studies in the monoclonal cell line MC3T3-E1, demonstrated that this localization to the nucleus occurs in a cell-cycle dependent manner, moving into the nucleus just before S-phase. An analysis of the amino acid sequence of all available PTH1Rs revealed a putative NLS of the bipartite type first described in nucleoplasmin. We began studies using green fluorescent protein (GFP) tagged constructs of the PTH1R, as a whole, lacking the NLS or the NLS alone to determine the function of the putative NLS. The PTH1R-GFP constructs showed the receptor on the plasma membrane as would be expected, but the NLS deletion construct, collected in a ring around the nucleus, possibly due to an inability to be transported away from the endoplasmic reticulum. The construct with the putative NLS alone tagged with GFP, collected in the cytoplasm, but did not enter the nucleus. This suggested the 18 amino acid sequence identified as the NLS was not able on its own to direct GFP to the nucleus. Since phosphorylation has been shown to be important for the import of other proteins into the nucleus and we have identified probable phosphorylation sites surrounding the NLS, we decided to create a construct including regions surrounding the NLS. A construct was produced including 15 amino acids upstream of the NLS down to the C-terminus of the PTH receptor, which was tagged on the N-terminus with the FLAG epitope, and on the C-terminus with the c-myc epitope. LLC-PK1 cells were transiently transfected with this construct and the fusion protein was detected with immunofluorescence. Nuclear localization of the fusion protein was detected in a large number of cells using an anti-C-myc primary antibody, as compared to untransfected controls. These results suggest that sequences in the C-terminal cytoplasmic tail of the PTH1R are capable of targeting proteins to the nucleus and support the concept of PTH1R translocation to the nucleus.

Loss-of-function Mutations in Exons 2 through 13 of GNAS Impair Signalling through both Human Gs-alpha and XL-alpha Proteins. A. Linglart*, H. Jüppner, M. Bastepe. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

The α-subunit of stimulatory G-protein ($G\alpha_s$) and its variant $XL\alpha_s$ share identical C-terminal domains encoded by exons 2-13 of *GNAS,* but both differ in their N-termini. $G\alpha_s$ is ubiquitously and mostly biallelically expressed, whereas $XL\alpha_s$ expression seems to be restricted to neuroendocrine tissues and occurs only from the paternal allele. Rat-$XL\alpha_s$ couples to typical $G\alpha_s$-coupled receptors in transfected cells that endogenously lack $G\alpha_s$ and $XL\alpha_s$ ($Gnas^{E2-/-}$ cells). To investigate the putative signalling function of human-$XL\alpha_s$ ($hXL\alpha_s$), which diverges from its rat homolog in the N-terminal domain, we transfected $Gnas^{E2-/-}$ cells with cDNAs encoding both wild-type and mutant forms of $hXL\alpha_s$ and $G\alpha_s$. In $hXL\alpha_s$ transfected $Gnas^{E2-/-}$ cells, cholera toxin treatment (inhibiting the intrinsic GTPase activity) and stimulation of the endogenous β-adrenergic receptor by Isoproterenol (Iso) raised cAMP levels from 6.5±5.2 to 36±11.5 pmol/well and 75.5±12.1 pmol/well, respectively, indicating that $hXL\alpha_s$ can function as a signalling protein. Mutations (Y391X, and H362P) identified in patients with pseudohypoparathyroidism (PHP) Ia and Ic were introduced into $hXL\alpha_s$ and $G\alpha_s$ cDNAs. These $hXL\alpha_s$ and $G\alpha_s$ mutants showed diminished basal cAMP accumulation and no evidence for Iso-stimulated second messenger formation. Compared to our previous study of wild-type $XL\alpha_s$ and $G\alpha_s$ that increase cAMP accumulation after PTH(1-34) or TSH treatment, the Y391X and the H362P mutant failed to increase the agonist-stimulated cAMP formation when $Gnas^{E2-/-}$ cells were co-transfected with cDNAs encoding the PTH/PTHrP or the TSH receptor (table).

cAMP (pmol/well); n= 4 to18; mean±SEM

	Y391X-$G\alpha_s$	**Y391X-$XL\alpha_s$**	**H362P-$G\alpha_s$**	**H362P-$XL\alpha_s$**
Basal	1.6±0.7	0.8±0.2	0.6±0.2	0.5±0.3
Isoproterenol	1.7±0.4	0.4±0.0	1±0.3	2.4±0.3
PTH	0.8±0.1	0.7±0.3	1.1±0.0	0.5±0.1
TSH	1.8±0.2	0.6±0.1	1.1±0.6	0.5±0.3
Cholera Toxin	6.3±3.2	31±15.5	1±0.5	0.8±0.4

Cholera toxin treatment of $hXL\alpha_s$ or $G\alpha_s$ with the Y391X mutation, but not with the H362P mutation yielded cAMP accumulation similar to that observed with wild-type $G\alpha_s$ and $hXL\alpha_s$. In summary, $hXL\alpha_s$ mediated ligand-dependent cAMP accumulation is indistinguishable from that of $G\alpha_s$ when expressed in $Gnas^{E2-/-}$ cells. These data suggest that 1) defective $hXL\alpha_s$ signaling may contribute to the phenotypes of diseases associated with *GNAS* mutations in exons 2-13, especially when inherited paternally; 2) the Y391X mutation affects coupling of $G\alpha_s$ and $hXL\alpha_s$ to different G protein-coupled receptors, likely explaining the PHP-Ic phenotype of the patient in whom this mutation was identified.

A Specific High-Affinity Carboxy-Terminal Parathyroid Hormone Receptor Is Present In Vascular Endothelial Cells And Utilizes a Calcium-Dependent Signaling Pathway. C. M. Isales[1], K. H. Ding[1], P. Divieti*[2], F. R. Bringhurst[3]. [1]Medicine, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA, [2]Medicine, Massachusets General Hospital, Boston, MA, USA, [3]Medicine, Massachussets General Hospital, Boston, MA, USA.

We previously reported that human umbilical vein endothelial cells (HUVEC) contain PTH1R and respond to PTH 1-84(intact) with increased cellular proliferation. However, we found that carboxy-terminal PTH (C-PTH) fragments 53-84, 70-84 and 73-84 increased intracellular calcium and proliferation to the same extent as intact PTH, while PTH 1-34 and 28-48 had no effect on either response. To define the specificity and signaling pathways utilized by intact vs. C-PTH molecules we used the intracellular calcium chelator BAPTA. BAPTA at concentrations of 1 μM and above was more effective in abolishing thymidine incorporation in PTH 1-84 stimulated cells PTH1-84(10-12M)+BAPTA(10-6M): 183+11 vs. 108+2.2; PTH73-84(10-12M)+BAPTA(10-6M): 185+10 vs. 139+8.3 %change/control+SEM. There was no effect of PKC inhibition on C-PTH stimulated proliferation, PTH1-84(10-12M)+Go6850(10-6M): 184+4.9 vs. 177+5; PTH73-84(10-12M)+ Go6850(10-6M): 186+8.5 vs. 182+6.5 %change/control+SEM. However, C-PTH stimulated proliferation was much more sensitive to inhibition by CAM kinase II inhibitor (KN93) compared to intact PTH: PTH 1-84(10-12M)+KN93(10-7M): 183+1.8 vs. 197+15.4; PTH 73-84+KN93(10-7M):188+3.5 vs. 153+0.5 10-12M: %change/control+SEM, p<0.01 PTH 1-84+KN93 vs. PTH 73-84+KN93. To assess the specificity of C-PTH fragment binding to the HUVEC we utilized alanine substituted PTH analogs (PTH53-84) in which the EDN sequence at 55-57 is replaced with alanine(s), the single alanine substituted analog (M9.1) binds CPTHR with equal affinity as PTH53-84 while the triple alanine substituted analog (M9) does not bind to the C-PTH receptor. We found that the triple alanine substituted PTH M9 (in contrast to the M9.1 analog) does not significantly stimulate HUVEC proliferation PTH53-84 M9(10-12M) vs. PTH53-84M9.1(10-12M): 116+3.5 vs. 156+8.7 %change/control+SEM.

In an effort to assess the downstream effects of the C-PTH fragments on HUVEC function we performed gene microarray studies. PTH 1-84 (10-11M) altered the expression of 222 genes of which 166 genes were upregulated and 56 down-regulated. In contrast PTH 73-84 (10-11M) altered the expression of 1621 genes of which 922 genes were upregulated and 699 down-regulated.

Taken together, these data demonstrate the existence of a specific high-affinity C-PTH receptor in endothelial cells that preferentially uses a calcium-CAM kinase II signaling pathway to stimulate endothelial cell proliferation.

PTH Receptor Activates Wnt/β-catenin Signaling Pathway in Growth Plate Chondrocytes ex vivo. J. Guo, F. R. Bringhurst, H. M. Kronenberg. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Wnt/β-catenin-signaling pathway plays an important role in many processes of development. Activation of the Wnt family of proteins leads to translocation of β-catenin into the nucleus and the formation of transactivation-competent Lef/Tcf-β-catenin complexes. To examine whether the canonical Wnt/β-catenin signaling pathway is regulated by the PTH/PTHrP receptor (PTHR) in chondrocytes, we treated cultured E14.5 tibia and femur isolated from mice expressing the TOPGAL transgene, and then assessed reporter β-galactosidase activity by in situ staining using X-gal. In TOPGAL transgenic mice the LacZ gene is expressed under the control of regulatory sequence consisting of three consensus Lef/Tcf-binding motifs upstream of a minimal c-fos promoter. The transgene expression is dependent upon stabilized β-catenin and is comparably responsive to Tcf3 and Lef1 in vitro. Here we show that TOPGAL is weakly active mostly at the boundary of proliferative and prehypertrophic chondrocytes after treatment with vehicle for three days, whereas treatment with hPTH (100 nM) dramatically induced transgene expression in chondrocytes at the center of the rudiments. At the same time, PTH treatment greatly suppressed chondrocyte hypertrophy, as assessed histologically and by in situ hybridization for type X collagen mRNA. These observations raise the question of the role of PTHrP-induced Wnt signaling in the growth plate.

Signaling Characteristics of the PTH Type-1 Receptor can not be Transferred to the Type-2 Receptor by Mimicking the Type-1 Cytosolic Interface Using Receptor Chimeras. E. Blind, U. Heindel*, T. Wobbe*. Medicine - Endocrinology, University of Wuerzburg, Wuerzburg, Germany.

Activation of the phospholipase C (PLC) pathway upon stimulation with PTH is unique to the PTH-1 receptor (P1R) and is virtually absent in the PTH-2 receptor (P2R). The sites of P1R mutations known to reduce PLC signaling may achieve this indirectly by disturbing coupling at other sites. We therefore chose a more stringent approach and attempt to reestablish PLC signaling in the closely (70%) related P2R by gradually adapting the P2Rs cytosolic interface to a P1R-like sequence by engineering hybrid P1R/P2R constructs. Key differing regions of the P1R´s second loop (DT272-273:EK), third loop (IW344-345:LR), and C-terminal tail (T440-end: K-end) were put into the P2R. A fourth chimeric P1R/P2R receptor, combining all these changes, thus had a > 90% sequence identity with the cytosolic interface of the P1R. All mutants were expressed on the cell surface of stably transfected HEK 293 cells, using a radioreceptor assay with [125I]-Nle8,21-Tyr34-rat PTH(1-34), with a similar density of 1.1 to 2.5 mio receptors/cell. Activation of the PLC pathway was assessed by: 1) accumulation of total inositol phosphates in myo[3H]-inositol-prelabeled cells. No increase was detectable in the P2R or any of the receptor chimeras, even after enhancing the possible response by blockade of protein kinases A and C, despite an up to 13-fold increase with the P1R upon PTH stimulation. 2) Similarly, a PTH-induced increase in intracellular calcium (detected by fluo-3) of the wildtype P1R with as little as 1 nM hPTH(1-34) was completely absent in all mutants as well as in the P2R. The PTH-induced max. response of the cyclic AMP pathway was virtually identical for the P1R and P2R. However, the max. response of the mutant with the P1R tail sequence was reduced to only 35% (PTH) and 26% (TIP39) of the P2R response. Surprisingly, this signaling loss could be overcome by introducing more P1R sequence into the second and third cytoplasmic loop of this P1R/P2R hybrid receptor thus regaining a max. cAMP response of 64% (PTH) and 85% (TIP39). Presumably, an interaction of P1R sequences seems to result in a more effective coupling to the cAMP signaling pathway. In conclusion, these results suggest that the activation of the IP / intracellular calcium signaling pathway by the P1R is highly dependent on a P1R-like intracellular contact interface, which can not be mimicked easily even in the presence of > 90% of P1R sequence in the cytosolic interface of the P2R.

Expression, Purification and Characterization of Human Parathyroid Hormone Receptor 1 from a Stable HEK293S Cell Line. L. Gan*, J. M. Alexander, M. Rosenblatt. Department of Physiology, School of Medicine, Tufts University, Boston, MA, USA.

In order to further explore the structural basis of the interaction between human parathyroid hormone (hPTH) and human parathyroid hormone receptor 1 (hPTHR1) by comparative methods such as photoaffinity crosslinking, X-ray crystallography or NMR, we aimed to purify milligram quantities of receptor. To accomplish this, a HEK293S GnTI$^-$ cell line stably expressing recombinant hPTHR1 with a 9 amino acid rhodopsin tag at its C-terminus has been constructed. The inactivity of N-acetylglucosaminyltransferase I in this cell line is hypothesized to enable the production of receptor with homogeneous N-glycan at its four N-glycosylation sites. Transfection of the stable HEK293S GnTI$^-$ cell lines with CRE-luc plasmid resulted in robust increase in luciferase activity in response to hPTH(1-34), indicating the expressed hPTHR1_rho is fully functional (EC_{50} = 2.4 nM). The receptor was expressed in large-scale cell culture grown in a bioreactor. It was solubilized with dodecyl maltoside and subsequently purified to homogeneity by affinity and gel filtration chromatography. The purified receptor will allow us to accurately identify the contact sites in the ligand-receptor complex by structural analysis.

G protein Dependent Binding of a PTH(1-15) Analog Radioligand to the Juxtamembrane Portion of the PTH/PTHrP Receptor. T. Dean*, A. Linglart, M. Bastepe, M. Mahon, J. T. Potts, H. Jueppner, T. J. Gardella. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

PTH(1-34) is thought to bind to the PTH/PTHrP receptor (PTHR) via a two-site mechanism that involves high-affinity interactions between the ligand's C-terminal domain and the receptor's amino-terminal extracellular (N) domain, and lower-affinity interactions between the ligand's amino-terminal domain and the receptor's juxtamembrane (J) region, comprised of the extracellular loops and seven transmembrane helices. It is further hypothesized that the J domain interactions promote G protein coupling, and, reciprocally, that G protein coupling stabilizes the ligand/J domain complex. We explored this hypothesis using ^{125}I-PTH(1-34) as a radioligand that binds to both N and J domains, and ^{125}I-PTH(1-15) (^{125}I-[Aib^{1,3},Gln^{10},Har^{11},Ala^{12},Trp^{14},Tyr^{15}]ratPTH(1-15)NH$_2$) as a radioligand that binds selectively to the J domain. In membranes prepared from LLC-PK1 (HKRK-B7) cells that stably express the hPTHR, ^{125}I-PTH(1-34) and ^{125}I-PTH(1-15) exhibited similarly high binding affinities (K_ds ~1 nM) and maximum binding values (B_{max}s ~ 5 picomoles/mg protein). The binding of ^{125}I-PTH(1-34) was only marginally (~10%) inhibited by GTPγS (IC_{50} > 100,000 nM), whereas, in contrast, the binding of ^{125}I-PTH(1-15) was nearly completely (~95%) inhibited by GTPγS (IC_{50} = 10 nM). The rates of dissociation of both the ^{125}I-PTH(1-34)/ and ^{125}I-PTH(1-15)/PTHR complexes formed in HKRK-B7 cell membranes were slow ($t_{1/2}$s ~ 100 minutes). In the presence of GTPγS, most (~75 %) of the bound ^{125}I-PTH(1-34) remained in a slowly dissociating form, while a minor fraction (~25%) dissociated rapidly ($t_{1/2}$ ~3 min.). In contrast, nearly all (~95%) of the bound ^{125}I-PTH(1-15) dissociated rapidly ($t_{1/2}$ < 3 min.) in the presence of GTPγS. Since the PTHR signals most strongly via the cAMP pathway, we tested the hypothesis that Gαs might be the principal G protein determinant of ^{125}I-PTH(1-15) binding affinity. To test this, we used a line of fibroblast cells (Gnas$^{E2-/-}$ cells) derived from Gαs gene-knock-out mouse embryos, and transduced these, via an adenovirus/shuttle vector system, to transiently express the hPTHR. ^{125}I-PTH(1-34) bound to these cells as well as it did to HKRK-B7 cells; in sharp contrast, ^{125}I-PTH(1-15) bound only poorly. The overall results show that the binding of PTH(1-15) to the PTHR, but not that of PTH(1-34), is strongly dependent on coupling of the receptor to G protein, and that the G protein modulates specifically the affinity of the J domain ligand-binding site.

The Skeletal Response to Estrogen Is Impaired in Female but not in Male Steroid Receptor Coactivator-1 Knock Out Mice. U. I. Moedder[1], A. Sanyal[1], J. Xu*[2], B. W. O'Malley*[2], T. C. Spelsberg[1], B. L. Riggs[1], S. Khosla[1]. [1]Mayo Clinic, Rochester, MN, USA, [2]Baylor University, Houston, TX, USA.

Steroid Receptor Coactivator (SRC)-1 is an important nuclear receptor coactivator that enhances estrogen (E) action in a number of tissues. We previously demonstrated (Endocrinol 145:913, 2004) that SRC-1 knock out (KO) female mice have a defect in E action in cancellous, but not in cortical bone. Here we report findings in the 3 month old male littermates of the female mice that were treated concurrently either with sham surgery, orchiectomy (orch) plus vehicle (V), or orch plus estradiol (E_2) replacement (0.25 μg/d) (n = 10/group) by slow release pellets for 60 days. The Figure below shows, for reference, our previous data on changes in the spine (which contains predominantly cancellous bone) BMD, measured by DXA, in the wild type (WT) and SRC-1 KO female mice (panel A) as well as the comparable new data on spine BMD changes in the male WT and SRC-1 KO mice (panel B). While the 0.25 μg/d dose of E_2 was entirely ineffective in preventing spine bone loss following ovariectomy in the female SRC-1 KO mice (Panel A; overall P-values are for within strain ANOVAs), the same dose of E_2 was equally effective in the male WT and SRC-1 KO mice in preventing spine bone loss following orch (Panel B).

We have previously also demonstrated (J Endocrinol 176:349, 2003) that in osteoblastic cells, SRC-1 potentiates the activity of co-expressed ER-α/β or ER-β alone, with little or no potentiation of ER-α. Based on this, we hypothesized that the defect in E action in cancellous bone in the female SRC-1 KO mice could be due to the presence of both ER-α and -β in cancellous bone versus the predominant expression of ER-α in cortical bone (Endocrinol 145:913, 2004; JCEM 86:2309, 2001). Of interest, using ER-α KO mice, Sims et al. (JCI 111:1319, 2003) have recently demonstrated that whereas ER-β plays no role in E action on bone in male mice, it does partially mediate E effects on bone in female mice. Thus, our current findings of a lack of a defect in E action in male SRC-1 KO mice are consistent with this gender difference in ER-β action on bone in male versus female mice. These findings also provide further support for our hypothesis that the defect in E action predominantly in cancellous bone in the SRC-1 KO female mice may be due to differential interactions of SRC-1 with ER-β versus ER-α in cancellous and cortical bone.

Loss of Signaling Through Classical EREs Leads to Osteopenia and Paradoxical Responses to Estrogen in Cortical Bone. F. A. Syed*[1], A. Sanyal[1], D. Fraser*[1], A. Krust*[2], P. Chambon*[2], L. Jameson*[3], T. C. Spelsberg[1], B. L. Riggs[1], S. Khosla*[1]. [1]Mayo Clinic, Rochester, MN, USA, [2]Institut de Genetique et de Biologie Moleculaire et Cellulaire (IGBMC), Illkirch, France, [3]Northwestern University, Chicago, IL, USA.

The ER can act either via classical EREs or through non-classical pathways that do not require binding to an ERE (eg AP-1 sites). Generation of mice with a wild type ERα allele (ERα+) and an ERα allele with a knock-in mutation abolishing ERE binding [non-classical ER knock-in, NERKI (Mol Endo 16:2188, 2002)] presents a unique opportunity to unravel the roles of classical vs non-classical pathways of E signaling in bone. However, while heterozygous male NERKI mice are fertile, heterozygous females are infertile, making it difficult to generate homozygous NERKI/NERKI mice. To circumvent this problem, we crossed heterozygous ERα+/NERKI male with ERα+/ERαKO (-) female mice and compared skeletal phenotypes and E action in ERα+/ERα+ mice versus littermates with one deleted ERα and one NERKI allele (NERKI/ERα-). Due to the presence of only the NERKI receptor in the NERKI/ERα- mice, they can transduce E signals solely through non-classical pathways. Trabecular BMD (tibial metaphysis) was similar in ERα+/ERα+ and NERKI/ERα- mice; however, cortical BMD at the tibial mid-shaft was reduced by 6.2% in the NERKI/ERα- mice (P < 0.001). To further assess E signaling in the NERKI/ERα- mice, 3 month old ERα+/ERα+ and NERKI/ERα- mice underwent sham surgery, ovx plus vehicle (V) pellet, ovx plus a 0.25 μg/d E_2 pellet ($E_{0.25}$), or ovx plus a 1 μg/d E_2 pellet ($E_{1.0}$) (n = 10-12/group). All treatments were for 2 months. As shown in the Figure, the pattern of changes in tibial cortical BMD was the exact opposite in the NERKI/ERα- as compared to the ERα+/ERα+ mice (P < 0.001 for a treatment/genotype interaction). Thus, relative to the sham mice, ovx'd NERKI/ERα- mice gained more bone (not less, as in the ERα+/ERα+ mice), and E dose-dependently suppressed this increase (while augmenting it in the ERα+/ERα+ mice).

These data thus demonstrate that E signaling solely through non-classical pathways results in osteopenia and paradoxical responses to E in cortical bone. Defining the molecular mechanisms responsible for these changes in the NERKI/ERα- mice may provide fundamental, novel insights into the role of classical vs non-classical signaling pathways in transducing E effects on bone.

Estrogen regulation of TNF-α -induced expression of cytokine mRNA in U2OS human osteosarcoma cells transfected with estrogen receptor α. T. Guo*[1], E. Lamminen*[2], K. Väänänen*[2], P. Härkönen*[2], T. Hentunen[2]. [1]Institute of Hematology, Union Hospital, Huazhong University of Science and Technology, Wu han, Hubei, China, [2]Medicity Research Laboratory and Department of Anatomy, Institute of Biomedicine, University of Turku, Tykistökatu 6, 20520, Turku, Finland.

Osteoblasts are capable of producing a wide array of cytokines and growth factors that can potentially act as autocrine and paracrine regulators of bone cell function. To investigate the action of estrogen on TNF-α induced cytokine production in osteoblast-derived cells we first stably transfected estrogen receptor -negative U2OS human osteosarcoma cells with human estrogen receptor α or an empty control vector. Expression of estrogen receptor α in transfected U2OS cells was confirmed by RT-PCR, western blotting and immunocytochemistry. Reporter gene assays were further used to confirm that estrogen receptor α was functional in these cells. We then used these cell lines to study the effect of TNF-α on expression of TNF-α and IL-6 mRNA using RT-PCR analysis of the cells treated with or without estrogen. Treatment of U2OS cells with TNF-α for one hour led to a strong induction of IL-6 and TNF-α mRNA in both estrogen receptor a expressing and non-expressing cells. Pretreatment of the cells with 17-β-estradiol for 24 hours before a one-hour incubation with TNF-α blocked the TNF-α induction of IL-6 and TNF-α mRNA in estrogen receptor α expressing U2OS cells but had no effects on the increase of IL-6 and TNF-α mRNA levels in estrogen receptor α -negative control cells. - Our results demonstrate that ectopic expression of estrogen receptor α in estrogen receptor -negative U2OS human osteosarcoma cells can render them estrogen responsive. The results further show that in these osteoblast-derived cells 17-β-estradiol represses expression of IL-6 and TNF-α mRNA by interacting with estrogen receptor α.

Creation of Estrogen-Resistance in vivo by Transgenic Overexpression of the Heterogeneous Nuclear Ribonucleoprotein (hnRNP)-Related Estrogen Responsive Element Binding Protein. H. Chen[1], W. D. Stuart*[2], L. Nguyen*[1], B. Hu*[3], G. Huang*[1], T. L. Clemens[4], J. S. Adams[1]. [1]Division of Endocrinology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]Surgery, University of Cincinnati, Cincinnati, OH, USA, [3]Pathology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [4]Pathology, University of Alabama, Birmingham, AL, USA.

Trans dominant-negative-acting proteins in the hnRNP family are now thought to be a proximal cause of steroid/sterol hormone resistance in both non-human and human primates. Estrogen resistant New World primate cells demonstrate constitutive overexpression of an hnRNPC-like protein that competes with the estrogen receptor (ER) for binding to the estrogen responsive element (ERE). In order to verify that it is this hnRNPC-like protein, coined the ERE-binding protein or ERE-BP, that legislates estrogen-resistance in vivo, we generated five transgenic mouse lines that overexpressed ERE-BP only in breast tissue under the control of whey acidic protein (WAP) gene promoter. Despite the detection of equivalent levels of transgene in the breast of male and female ERE-BP +/- mice, there was distinct sexual dimorphism at the level of expression of the product of the transgene. At the protein level, ERE-BP was encountered only in breast of female transgenic mice. Low-to-high ERE-BP overexpression did not alter expression of ER in the breast of transgenic mice. Both male and female founder mice were viable and fertile. Female transgenics in all lines gave birth to pups, but the ability to nurse offspring was variable. Mothers with low or intermediate levels of ERE-BP expression in the breast were able to lactate and nurse pups to weaning in a fashion similar to that observed for wild-type pups. Mothers from the high ERE-BP-overexpressing line were unable to lactate, and none of their pups survived to weaning unless were fostered to a normally-lactating mother. This maternal nursing phenotype were recapitulated in all subsequent generations of the "high" ERE-BP line. Mice with a low ERE-BP transgene expression had a mammary phenotype similar to wild-type. However, mice expressing the high level of ERE-BP demonstrated both impaired mammary gland differentiation and lactation; whole-mount and histological analyses showed only rudimentary duct formation, aborted alveolar generation and near absence of milk-containing lumina. In summary, relatively high overexpression of ERE-BP leads to the development of a lactation-deficient mouse incapable of undergoing adolescent "estrogen priming" of mammary tissue. It is our plan to employ this animal model of estrogen resistance to antagonize estradiol-ERalpha-ERE directed breast cancer growth and development in vivo.

From Non-genomic Androgen Action to phosphatidylinositol 3-Kinase/Akt Signaling Pathway in Osteoblasts. H. Kang*[1], K. Huang*[2], K. Huang*[1]. [1]Graduate Institute of Clinical Medical Sciences, Chang Gung University, Kaohsiung, Taiwan Republic of China, [2]Department of Biological Science, National Sun Yat-sen University, Kaohsiung, Taiwan Republic of China.

Androgens have important effects on the human skeleton in both males and females. However, the mechanism of androgen action on bone cell growth remains unclear. The aims of this current study were to determine the effect and mechanism of androgen action on the osteoblast cells. Here we demonstrated that 5α-dihydrotestosterone (DHT) accelerates cell growth of MC3T3-E1 cell line in a time and dose dependent manner. The specific phosphatidylinositol 3-kinase (PI 3-kinase) inhibitor LY294002 and kinase-deficient Akt mutant can repress the androgen effect on MC3T3-E1 cells. Western blot analysis showed that DHT, 17β-estradiol and testosterone (T) induce a rapid and transient phosphorylation of Akt in MC3T3-E1 cells. This activation reached to a plateau after 15 min and gradually diminished after 60 min of DHT treatment. Fluorescence microscopy showed a distinct increase in immunostaining intensity in the nuclear interior after androgen treatment but no change in the subcellular distribution of Akt when the cells were pretreated with hydroxyflutamide (HF) or LY294002. In addition, small interfering RNA against androgen receptor (siRNA-AR) prevented DHT-induced Akt phosphorylation and cell growth. In addition, G-proteins, phospholipase C (PLC), Src kinase and intracellular calcium mobilization are essential for androgen-mediated Akt activation. These findings strongly suggest that this androgen non-genomic action mediated by AR and androgen-induced Akt activation represents the first physiological finding to indicate how steroid hormones such as androgens can mediate the nuclear localization of Akt/PKB in osteoblasts that has previously mainly been linked to growth factor-induced events occurring at the plasma membrane level.

Effects of Phytoestrogens and Their Metabolites on estrogenic activity and Osteoclast Formation. C. Hwang*[1], Y. Kang[1], I. Moon*[1], C. Yim*[2], H. Yoon[2], I. Han*[2], H. Hur*[3], K. Han[2]. [1]Laboratory of Endocrinology, Samsung Cheil Hospital and Women's Healthcare Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Medicine, Samsung Cheil Hospital and Women's Healthcare Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Department of Environmental Science and Engineering, Gwangju Institute of Science and Technology, Gwangju, Republic of Korea.

Phytoestrogens are plant-derived compounds with estrogen-like biological activity. Although there are many convincing data on the bone-sparing effects of soy isoflavonoes such as genistein and daidzein, the exact effects and mechanisms of phytoestrogen action remain elusive. In this study, we investigated the estrogenic activity of phytoestrogens and their metabolites in competition binding assays with ERα or ERβ protein, and in a transient gene expression assay by co-transfection of ERα or ERβ cDNA with estrogen dependent reporter plasmid. Also, we examined the effect of phytoestrogens on the $1,25(OH)_2D_3$-induced osteoclast formation. phytoestrogens and metabiltes; GTN(genistein), DIH-GTN(dihydrogenistein), DDZ(daidzein), DIH-DDZ(dihydrodaidzein), T-DDZ(tetrahydrodaidzein), Eqoul, O-DMA(O-desmethyl-angolensin). Saturation ligand-binding analysis of hERα and β protein for [^{3}H]-17β-estradiol(E_2) revealed a K_d of 0.054nM for ERα and 0.078nM for ERβ. Relative binding affinities(RBA) of phytoestrogen metabolites are 100-1000-fold lower than that of E_2 and they bound more stronger to ERβ than to ERα. The phytoestrogens and their metabolites stimulated the transcriptional activity of both ER subtypes in co-transfection analysis using MCF-7, MC3T3E1 and 293 embryonic kidney cells. The ranking of binding affinity is, E2>RAL>>GTN>EQOUL>>DDZ>T-DDZ>O-DMA>DIH-GTN>DIH-DDZ for ERα, and E2>RAL>>GTN>EQOUL>>T-DDZ>DDZ=O-DMA>DIH-GTN>DIH-DDZ for ERβ. Transactivation assay using cells showed similar degrees to the binding affinities. The phytoestrogens and metabolites induced cell proliferation 2-6-fold higher in MCF-7 than control, but not in MC3T3E1 cell line. E_2(10^{-8}M-10^{-5}M), raloxifene(10^{-8}M-10^{-5}M), tamoxifen(10^{-6}M-10^{-5}M) and genistein(10^{-6}M-10^{-5}M) clearly inhibited the $1,25(OH)_2D_3$-induced osteoclast formation, but not with others metabolites. In transactivation analysis using 293 cell and $1,25(OH)_2D_3$-induced osteoclast formation in the presence of E_2 or raloxifene, genistein did not enhance the activity of E_2 or raloxifene. These results demonstrate that the estrogenic activity of phytoestrogens is substantially weak compared to E_2, and phytoestrogens did not show a synergistic action on the activity of E_2

Ginsenoside Rg1 Induce Human Breast Cancer Cell Proliferation and IGF-I Receptor Expression via Tyrosine Kinase- and MEK-Dependent Pathways. W. Lau*, W. Chen*, R. Y. Chan*, M. Wong. Department of Applied Biology and Chemical Technology, Central Laboratory of the Institute of Molecular Technology for Drug Discovery and Synthesis,The Hong Kong Polytechnic University, Hong Kong, Hong Kong Special Administrative Region of China.

Ginsenoside Rg1, an active ingredient commonly found in ginseng root, was previously demonstrated to be a novel class of phytoestrogen as it can stimulate the growth of human breast cancer (MCF-7) cell as well as to activate the estrogen response element-luciferase activity in HeLa cells. Interestingly, the action of Rg1 is estrogen receptor alpha (ERa)-dependent but it does not interact directly with this receptor. Therefore, we hypothesize that Rg1 may mediate its estrogen-like actions in MCF-7 cell via its cross-talk with IGF-I receptor (IGF-IR) mediated pathway. The present study aims to investigate if Rg1 alter signaling proteins expressions in the IGF-IR mediated pathway and to determine if tyrosine kinase and the downstream signaling molecule MEK are involved. In order to investigate the roles of tyrosine kinase and MEK in the action of Rg1, MCF-7 cells treated with 1 pM Rg1 were cotreated with either 50 μM genistein (tyrosine kinase inhibitor) or 50 μM PD98059 (MEK inhibitor). After treatment of MCF-7 cells for 48h, their effects on cell proliferation was determined by MTS assay and their effects on protein expression of IGF-IR, src-homology-collagen (Shc) and ERa were measured by western blotting analysis. Our results showed that Rg1 could increase the expression of IGF-1R protein significantly ($p<0.05$) but did not alter the expression of Shc and ERa. When MCF-7 cells were cotreated with 50 μM genistein, the proliferative effects of Rg1 and its induction of IGF-1R protein expression were completely abolished. Similarly, the effects of Rg1 on MCF-7 cells could also be abolished by 50 μM PD98059. These results showed that the proliferative effect of Rg1 in MCF-7 cells is at least in part mediated by the induction of IGF-I receptor expression and its action involved both tyrosine kinase- and MEK- dependent pathways. These data provide new evidence to support our hypothesis that Rg1 may mediate its estrogen-like actions in MCF-7 cell via the cross-talk with IGF-I receptor mediated pathway.

Proteome Analysis for the Identification of Estrogen Regulated Proteins in Bone. R. Pastorelli*[1], D. Carpi*[1], L. Airoldi*[1], C. Chiabrando*[1], R. Bagnati*[1], R. Fanelli*[1], S. Moverare[2], C. Ohlsson[2]. [1]Department of Environmental Health Sciences, Institute of Pharmacological Research, Milan, Italy, [2]Department of Internal Medicine, Centre for Bone Research at the Sahlgrenska Academy, Gotenburg, Sweden.

Estrogen deficiency results in a reduced bone mass, which can be prevented by treatment with estrogen. However, the detailed cellular and molecular mechanisms underlying these effects remain poorly understood.

In this study, the *in vivo* effects of estrogens on global bone protein expression have been investigated by comprehensive differential display analysis and mass spectrometry, in a murine model of osteoporosis induced by ovariectomy followed by treatment with 17-beta estradiol (E2).

To our knowledge, this is the first report of a proteomic analysis of bone *in vivo*. Humerus proteome profiles were examined in three experimental mice groups: (i) sham-operated with normal ovarian functions (sham), (ii) ovariectomized with osteoporosis induced by ovariectomy (ovx), and (iii) ovx mice treated with 17-beta estradiol. (ovx+E2). Bone proteins were separated by 2-D electrophoresis and visualized by the Coomassie colloidal staining. Approximately 300 spots in each averaged (n=3) gel image were detected and quantitated using the Progenesis Workstation software (Nonlinear Dynamics, UK). Differential expression analysis among the three experimental groups showed statistically significant changes for fourteen proteins, which were subsequently identified by mass spectrometry (MALDI-TOF-MS and LC-MS/MS). Our results indicate that ovariectomy causes a broad spectrum of metabolic perturbations in a nonreproductive tissue like bone,

and suggest possible interactions among various proteins in estrogen depletion. Our data also suggest that some proteins, related to cytoskeleton and to energy pathways, are involved in the mechanism behind the bone sparing effect of estrogens.
In conclusion, the identification of several differential expressed proteins, as described in this study, might represent an important starting point for the search of novel aspects of the pleiotropic effects of estrogens on bone.

Estrogen Receptor α and β Heterodimers Have Unique Effects on Estrogen- and Tamoxifen-Dependent Gene Expression. D. G. Monroe[1], F. J. Secreto[1], B. J. Getz*[1], B. L. Riggs[2], S. Khosla[2], T. C. Spelsberg[1]. [1]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Estrogen (E) exerts its genomic effects largely through two distinct estrogen receptor (ER) isoforms, ERα and ERβ, which function as dimers and are found individually or in combination. The presence of both isoforms in osteoblasts (OBs) can potentially lead to either homodimer formation or ERα heterodimer formation in response to ligand binding. Virtually no information exists in the literature concerning the functions of the ERα heterodimer on gene expression. Therefore, we have developed osteoblastic U2OS cell lines, stably expressing ERα, ERβ or both ERα and ERβ. Western blot analysis demonstrates that the U2OS-ERα line expresses the receptors in a 1:4 ratio (ERα :ERβ). Using a combination of CoIP and an ERα-specific agonist (PPT), we have identified functional ERα heterodimers. To understand the contribution of ERα in ligand-dependent gene expression, we first performed duplicate microarray analysis in the ERα which were treated with E2 for 24 hrs using the U2OS-ERα and -ERβ lines as controls. Microarray analysis identified 270 genes regulated by E2 (< > 2-fold) in the ERα line with 90 (33 %) regulated exclusively in the ERα line (compared to the ERα and ERβ lines). These results indicate that ERα heterodimers specifically regulate the expression of a unique pattern of genes. Since the SERM, 4OH-tamoxifen (4HT) has effects on osteoblasts and is clinically relevant, we performed identical microarray analysis using 4HT as the ligand. Significantly less genes (140), when compared to E2, were 4HT-regulated (< > 2-fold) in the ERα line. Interestingly, 95 (68 %) were regulated exclusively in the ERα line, again demonstrating that 4HT bound to the ERα heterodimer generates specific patterns of gene regulation. Relatively few genes are commonly regulated in the ERα, ERβ and ERα by both E2 and 4HT (9 %, 12 %, 10 %, respectively), citing important differences that the actions of the ER isoforms and the SERMs have on ER-dependent gene expression. To more stringently examine the genes specifically regulated by 4HT, we identified those genes regulated by 4HT (< > 2-fold) that were unaffected by E2 treatment (within 20 % of control). We found 23, 24, and 31 genes (in ERα, ERβ, ERα) that fit this stringent criteria, demonstrating that 4HT can effect gene expression on a unique set of genes not affected by E2. Collectively our data clearly show that the ERα heterodimer, as well as ERα and ERβ homodimers, have specific and unique effects on ligand-dependent transcription in OBs. Furthermore, E2 and 4HT also have unique effects on gene expression through each of these isoforms.

Comparative Analysis of Bone Tissue Histomorphotherapy in the Ovariectomized (OVX) Rats under Replacement Hormonal Therapy and a Phytoestrogen. A. Kandilyotu, F. Gafurova*, L. Nugmanova*, V. Vorojeikin*. Institution of Endocrinology, Tashkent, Uzbekistan.

Aim- to study effect of a phytoestrogen (ferutinin) on the ovariectomized rat bone tissue and to compare the effect with the one of a replacement hormonal therapy (estradiol valerat+levonorgestrel). 3-month old white rats-virgins with body mass of 120-150g were divided into 5 groups. The 1st control group (n=10)-intact animals, the 2nd one - sham OVX rats (n=10), the 3rd one - OVX untreated rats (n=20), 4th - 10 OVX rats receiving estradiol valerat + levonorgesterl (*per os* 0.5 mg)and 5th - 10 OVX rats receiving ferutinin (*per os* 1,2 mg). The 3rd group was subdivided into two subgroups, 10 rats decapitated a month after castration and 10 rats- two month after castration, respectively. Ferutinin is an ester of terpenoid alcohols obtained from a Central Asian plant *Ferula L* possessing estrogenic activity. Thighbones were prepared; their proximal metaphyses underwent histomorphometry. Histomorphometry of sham OVX rats was similar to the one in the control structure. The 3rd group rat bone histomorphometry "a month after castration" showed marked signs of osteoporosis. Thighbone mass reduction in female rats by 24% is the leading sign. The process is caused by both cortical layer and trabeculae thickness reduction. In the 3rd group rat bones "2 months after castration" revealed reduction in mass of non-calcified thighbone by 32% of the initial one, decrease of cortical layer area by 30%, the highest (35%) reduction being observed in trabecular area. The trabeculae are thin and "trabecular nodes", their connection zones, are practically absent. Histomorphometry of the 4th group rat bones showed: the bone resorption intensity decrease. Though thighbone mass is 0.9% lower than the one in the condition "a month after castration", it is 10.7% higher than that in the condition "two months after castration". The increase of cortical layer area by 6.5% in the average and the one of trabecular apparatus by 15.7%, are the evidence for the fact. Thinning of the trabeculae is less marked; they have few connective nodes. In the5th group rats:highbone mass reduction by 5.4% as compared with the one under condition "a month after castration" and its increase by 5.6% as compared with the one under condition "two months after castration". Cortical layer area increased by 3.7% in the average, the one of trabecular apparatus by 9%. Hormonal therapy stimulated osteogenesis, stabilized resorption and sustained it on the level of "a month after castration" condition. Ferutinin caused poor stimulation of osteogenesis, the cortical layer and trabecular resorption continuing with less speed and not reaching "a month after castration" condition.

Transcriptional Profiling of Cell-type and Tissue Selective Agonism of an Osteoanabolic SARM. S. Harada[1], W. J. Ray[1], D. B. Kimmel[1], C. Bai*[1], F. Chen*[1], P. V. Nantermet*[1], V. Kasparcova*[1], H. Zhang*[1], R. L. Vogel*[1], S. Rutledge*[1], M. E. Duggan*[2], S. P. Sahoo*[2], R. L. Phillips*[3], G. A. Rodan[1], L. P. Freedman[1], A. Schmidt[1]. [1]Molecular Endocrinology/Bone Biology, Merck Research Laboratories, West Point, PA, USA, [2]Medicinal Chemistry, Merck Research Laboratories, West Point, PA, USA, [3]Molecular Profiling, Merck Research Laboratories, West Point, PA, USA.

Tissue and cell-type agonisms have been documented for nuclear receptor ligands. We have identified a selective androgen receptor modulator (SARM), SA-766, that is anabolic to bone and muscle with limited effects on prostate and uterus. In osteopenic OVX rats, SA-766 (10 mg/kg/day) stimulates periosteal bone formation and increases cortical bone and lean body mass similar to the effects of 5α-dihydro-testosterone (DHT, 3 mg/kg/day). In the same animals, SA-766 had no effects on uterus while DHT treatment induced significant enlargement. In castrated rats, SA-766 exhibited minimal effects on prostate weight and antagonized the effects of testosterone, confirming the tissue selective androgen receptor (AR) partial agonism of SA-766. In cell-based transcription assays, SA-766 exhibits context-dependent AR agonism by repressing the MMP-1 promoter, while having no effects on AR-AF2 activity in 22RV1 prostate cancer cells where DHT acts as an AF2 agonist. To gain additional insight into the molecular mechanisms underlying tissue-selective AR agonism by SA-766, transcriptional profiles of uterus and bone were analyzed by microarray using DNA chips containing 25,000 rat genes. Analysis of RNA isolated from uterus identified strong DHT specific gene signatures, including IGF-I and uterocalin that were also induced by estrogens but not by SA-766. In addition, significant but less prominent signatures were induced by both DHT and SA-766 in uterus, supporting the notion that differential effects of DHT and SA-766 on uterus are mediated by tissue-selective and promoter-specific AR agonism. Aalysis of RNA from tibia identified rather weak signatures induced modestly by both DHT and SA-766. These signatures are distinct from known androgen-responsive signatures found in uterus and prostate, suggesting that androgen effects on bone are mechanistically distinct. Accordingly, DHT pellets implanted in tibia failed to document the local stimulatory effects on bone, suggesting that anabolic action of androgens could be mediated at least in part via AR expressed in extra-skeletal tissues. Taken together, transcriptional profiling of androgen target tissues uncovered the distinct mode of action of androgens in reproductive tissues versus bone that could account for tissue-selective AR agonism of SARMs.

Bone Density and Body Composition in Mice with Defective Classical Signaling through the Estrogen Receptor Alpha. O. K. Oz[1], A. Thomas*[1], J. L. Jameson*[2]. [1]Radiology, UT Southwestern Medical Center at Dallas, Dallas, TX, USA, [2]Medicine, Northwestern University Medical School, Chicago, IL, USA.

Estrogens regulate accrual of peak bone mass and bone remodeling by acting through estrogen receptor (ER) α or β. The signaling may occur through the classical pathway in which the ER bound to an agonist regulates gene transcription by binding directly to DNA. The ER also regulates gene transcription through protein-protein interactions, a pathway known as the nonclassical pathway. Recent studies have shown that ERα is the major mediator of estradiol's protective effects on trabecular bone mass but that signaling through ERβ is partially protective in females only (1). Recently a nonclassical estrogen receptor knock-in mouse (NERKI) model has been created (2). Homozygous NERKI females are infertile. The phenotypes of the reproductive tissues from heterozygous females have been described (2) but the bone phenotype of neither gender has been reported. The purposes of this study were to determine if the NERKI mice have abnormalities in bone mass, body composition, and skeletal response to estradiol after ovariectomy. Heterozygous NERKI males were mated to WT 129 females to produce NERKI heterozygotes and WT littermates. The whole body bone mineral density (BMD) and body composition of WT and NERKI mice, aged 8-12 months, were compared by DEXA (GE Lunar PIXImus). Following ovariectomy female mice were treated with a water soluble form of estradiol (20μg/mouse) 3 times per week for 1 month. DEXA was performed weekly. NERKI males had significantly lower BMD than WT males (52.7±2.3, n=9 vs. 58.9±3.4, n=10, p<0.001). The BMD of NERKI females was also significantly lower (54.5±3.8, n=7 vs. 61±3.4, n-15, p=0.003). There was no significant difference in percentage body fat between NERKI and WT mice. Estradiol was less protective of spinal BMD in NERKI females following ovariectomy. There was a13% decrease compared to baseline for NERKI versus 3% for WT. Therefore, an imbalance in classical and non-classical signaling is sufficient to decrease bone mass in both genders. In contrast to other models of estrogen resistance or deficiency body composition does not seem to be affected.

Androgen Responsive Genes Identified in Orchidectomized Mice through Affymetrix Microarray Analysis. A. Jackson*, P. Clément-Lacroix, T. Garcia*, W. Newell*, R. Galien*, M. Resche-Rigon, C. Robin-Jagerschmidt*, R. Baron. Proskelia, Romainville, France.

Despite limited clinical data on the role of androgens in bone mass maintenance, several studies have shown that DHT prevents the increase in bone turnover and the decrease in bone mass in orchidectomized (ORX) rats and mice, thereby demonstrating direct effect of androgens mediated via androgen receptor. However little is known regarding the mechanisms of action of androgens on bone cells and androgen regulated genes. The present experiment was therefore designed to determine the genes that are modulated by androgens in bone marrow cells of C57Bl/6 mice. Bone marrow cells were collected from twelve week-old sham and ORX mice which had been treated with vehicle and DHT 2.5 mg/kg/d (pellet) for 7, 10 and 14 days. Total RNA from 3 animals in each group were pooled, labeled by *in vitro* transcription and hybridized to Affymetrix Murine Genome MU74Av2 arrays, which interrogate 12488 full-length genes and EST clusters. Analysis has been completed to discover genes differentially regulated between sham or DHT treated-ORX groups and ORX mice (2-fold regulation with pvalue < 0.05). In addition, Chi2 statistical filtering of the data was performed to determine the genes most significantly regulated based on their profiles. Comparing expression profiles allowed identification of four clusters of differentially regulated genes. Among those clusters were found genes involved in the Wnt-signaling pathway such as Lef-1. In addition, Inpp5d (SHIP) is strongly repressed by ORX at d10 and its repression is prevented by DHT. Inpp5d is known to negatively regulate osteoclast formation and function. Another example is Wdr5 (BIG-3) that is induced by ORX at d14, an effect prevented by DHT treatment. Wdr5 is known to be induced by BMP-2 treatment and to increase osteoblast differentiation. These results are consistent with *in vivo* results since ORX in mice induces an increase of bone turnover, indicated by increased osteoclast number, osteoblast surface and mineral apposition rate as well as elevated urinary deoxypyridinolin and serum osteocalcin levels. It therefore appears that androgens normally maintain the expression of a number of genes capable of down regulating bone turnover. ORX suppresses this regulation and allows a marked increase in turnover with a negative balance.

Vitamin D Insufficiency Is Common in Obese Patients Prior to Bariatric Surgery. J. Fleischer[1], M. Bessler*[2], N. Restuccia*[2], L. Olivero-Rivera*[2], D. J. McMahon*[1], S. J. Silverberg[1]. [1]Medicine, Columbia University, New York, NY, USA, [2]Surgery, Columbia University, New York, NY, USA.

Bariatric surgery has become one of the most effective means to treat and prevent the complications of morbid obesity. Several procedures are available, some of which greatly alter the gastrointestinal tract and its absorptive capacity. While there are limited data regarding the effects of bariatric surgery on skeletal health, there is growing recognition that these procedures may be associated with the development of metabolic bone disease. One of the main concerns and a proposed mechanism of post-operative bone disease is vitamin D malabsorption. Obesity itself has also been associated with lower serum 25-hydroxyvitamin D (25D) levels, which has been attributed to both decreased sun exposure and decreased bioavailability of vitamin D_3 from its deposits in body fat. Since obesity itself and the surgical procedures available for its treatment may be associated with altered vitamin D metabolism, it is essential to know the vitamin D status of obese patients prior to bariatric surgery.

We conducted a retrospective chart review study of 120 patients (21 men, 99 women; (mean ± SD) age: 41.4 ± 11.5 yrs, BMI: 49.6 ± 8.2 kg/m^2) evaluated by a single bariatric surgeon over a 3-month period. Mean serum calcium (Ca) was 9.3 ± 0.4 mg/L; albumin 4.1 ± 0.3 g/dL; BUN 15 ± 4 g/dL and creatinine (Cr) 0.8 ± 0.2 mg/dL. Severe vitamin D deficiency (25D <10 ng/mL) was present in 31 patients (26%). Fifty-three patients (44%) had 25D levels between 10-20 ng/dL, 27 (22%) had 25D levels between 20-30 ng/dL and only 9 (8%) had 25D levels >30 ng/mL. Parathyroid hormone (PTH) concentration was 39 ± 17 pg/mL (normal range: 10-65 pg/ml). 25-Hydroxyvitamin D levels were negatively correlated with both BMI (R= -0.18, <0.05) and PTH concentration (R= -0.55, p=0.006). No association was observed between 25D and serum Ca or Cr.

In summary, vitamin D deficiency or insufficiency (25D ≤ 20 ng/ml) was documented in 70% of young obese individuals evaluated prior to bariatric surgery. Serum 25D levels were negatively correlated with BMI and PTH. These data suggest that post-operative vitamin D insufficiency, often attributed to the malabsorptive effects of the surgery itself, may in fact be a reflection of poor pre-existing vitamin D stores. We conclude that standard of care should include assessment of 25D levels in patients prior to bariatric surgery, so that appropriate treatment can be initiated.

Vitamin D Deficiency Is Associated with Diminished Quality of Life: Insights from Qualeffo-41 Questionnaire Analysis. P. Sapountzi*, P. M. Camacho. Endocrinology and Metabolism, Loyola University of Chicago, Maywood, IL, USA.

Vitamin D deficiency leads to accelerated bone loss, fractures, bone pain, and muscle weakness . Vitamin D deficient individuals who are treated with vitamin D frequently report an improvement in the general feeling of well-being and mood, however, the impact of vitamin D deficiency on patients' quality of life has not been systematically analyzed and quantified. We describe the partial results of an ongoing prospective study that aims to determine the effect of vitamin D deficiency on health-related quality of life based on the Qualeffo-41 questionnaire. Qualeffo-41 is a quality of life questionnaire designed by the International Osteoporosis Foundation specifically for patients with osteoporosis. It contains questions in five domains: pain, physical function, social function, general health perception, and mental function. Each domain score and Qualeffo total scores are expressed on a 100-point scale, with 0 corresponding to the best health related quality of life.

Individuals being evaluated for low bone mineral density at the Loyola Osteoporosis and Metabolic Bone Disease Center were screened for vitamin D deficiency. Patients with 25 OH Vitamin D level < 20 ng/ml were asked to participate in the study.

The study group was composed of 24 individuals with vitamin D deficiency (21 females and 3 males). The mean age was 60 years +/-, 25 OH Vitamin D level was 14 ng/ml +/- 4.97, and intact PTH level was 65.5 pg/ml +/-32.28. The mean lumbar spine T score was -1.1+/-2.06 and the femoral neck T score was -1.7 +/-1.14.

The mean Qualeffo-41 score of the cohort was 39.8 +/-15.8. These scores showed a negative correlation with 25OH Vitamin D levels (r=-0.25). No correlation was seen with the severity of osteoporosis or parathyroid hormone levels.

The total score seen in our cohort is higher than the score previously reported in osteoporotic patients with and without vertebral fractures (36 +/- 17 and 26 +/- 14) . Our scores will further be compared to age-matched controls and will be presented at the meeting.

Thus, it appears that Vitamin D deficient individuals suffer from diminished quality of life. Future results of this ongoing study will determine if correction of the deficiency will lead to an improvement in these patients' quality of life.

Prevalence of Vitamin D Insufficiency in an Osteoporosis Population in Southern California. E. M. Blau*[1], S. K. Brenneman[2], A. L. Bruning*[1], Y. Chen[2]. [1]Kaiser Permanente, Southern California, San Diego, CA, USA, [2]Merck & Co., Inc., West Point, PA, USA.

Vitamin D is an important factor for bone mineralization, prevention of osteomalacia, muscle strength and balance. The reported ideal level of vitamin D is 30 ng/mL or greater as measured by serum 25-hydroxyvitamin D (25 (OH)D). A primary source of Vitamin D is conversion in the skin through sun exposure; therefore, vitamin D deficiency/insufficiency may be perceived as less of an issue in southern latitudes. However, few data have described the vitamin D distribution in the sunnier latitudes, and among those who are osteoporotic. We report the prevalence of vitamin D insufficiency/deficiency in an osteoporosis population living in Southern California. Study sample were consecutive community-dwelling women referred to an osteoporosis clinic in Southern California from November 2003 to April 2004 following fragility fracture (37%) or with a bone mineral density T-score less than -2.5 (63%). Vitamin D levels were assessed by measuring serum 25 (OH)D levels at a central laboratory (Quest Diagnostic Lab: Diasorin radioimmunoassay [RIA]). Blood specimen was collected at the time of assessment, prior to any treatment for osteoporosis. Demographics were obtained by patient self-report. Results of 25(OH)D levels were available for 252 women and are included in the current analysis. Patients were Caucasian (78%), Asian (8%), Hispanic (4%) and African American (2%) with mean age 71 (range 45 - 91). The mean 25 (OH)D level was 29 ng/mL (SD 13) with a range of 5 - 70 ng/mL. 53% of the patients had 25 OHD levels <30 ng/mL: 42% ≤ 25 ng/mL, 29% ≤ 20 ng/mL, 13% ≤ 15 ng/mL, and 4% ≤ 9 ng/mL. Mean 25 OHD levels were not significantly different between women under 65 years (mean 29.0, SD 12.7) and women 65 years and older (mean 29.4, SD 13.1) or between Caucasian (mean 29.9, SD 13.4) and non-Caucasian (mean 27.3, SD 11.5) women. About one-half of the osteoporotic women in this study located in southern California were vitamin D insufficient (< 30 ng/mL), including 4% with deficiency (≤ 9 ng/mL). Women with osteoporosis warrant special attention to ensure adequate and persistent vitamin D intake to prevent further bone loss and fractures.

Vitamin D Insufficiency Is Highly Prevalent among North American Women Treated For Osteoporosis. M. F. Holick*[1], E. Siris*[2], N. Binkley*[3], M. K. Beard*[4], A. A. Khan*[5], J. Sackarowitz*[6], E. Chen*[6], A. E. de Papp[6]. [1]Boston University, Boston, MA, USA, [2]Columbia University, New York, NY, USA, [3]University of Wisconsin, Madison, WI, USA, [4]University of Utah, Salt Lake City, UT, USA, [5]McMaster University, Oakville, ON, Canada, [6]Merck & Co., Inc., West Point, PA, USA.

Vitamin D (D) is an essential component of osteoporosis therapy. However, D insufficiency may be overlooked by clinicians, leading to inadequate D supplementation in patients diagnosed with osteoporosis. Serum 25-hydroxyvitamin D (25(OH)D) levels greater than 30 ng/mL have been recommended to maximize intestinal calcium absorption and prevent secondary hyperparathyroidism. This cross-sectional observational study was designed to measure the distribution of serum 25(OH)D levels in postmenopausal women currently receiving antiresorptive or anabolic therapies to treat or prevent osteoporosis.

We enrolled 1554 postmenopausal women from 61 North American sites between November 2003 and March 2004. A serum 25(OH)D and biointact PTH (both using the Nichols Advantage System) and blood chemistry panel were obtained. A patient questionnaire was administered to obtain fall and fracture history, and information on factors that influence 25(OH)D.

1536 subjects, mean age 71 years (range 47-103), 92% Caucasian, completed the study. 35% resided at a latitude ≥ 42° N (Boston, Massachusetts) and 24% resided below 35° N (Memphis, Tennessee). The majority were ambulatory, community dwelling women seen in primary care offices. 84% reported good to excellent health. 51% had either some college education or a post-graduate degree. 66% reported previously discussing the importance of vitamin D for bone health with their physician and 59% reported taking at least 400 IU of vitamin D supplementation daily. 18.7% reported a low trauma fracture since

age 45 and 18.5% reported a fall resulting in a fracture within the past 5 years. The mean (SD) serum 25(OH)D was 30.4 (13.2) ng/mL, median 29 ng/mL (range 7-212 ng/mL). 1.1% had 25(OH)D <9 ng/mL, 8.1% < 15 ng/mL, 18% < 20 ng/mL, 36% < 25 ng/mL and 52% < 30 ng/mL. 16.5% had evidence of secondary hyperparathyroidism as defined by a normal serum calcium and an elevated PTH. The prevalence of D insufficiency (25(OH)D < 25 ng/mL) was significantly higher in subjects who took less than 400 IU of D supplementation daily compared with those who took at least 400 IU daily (47% vs 28% respectively, p<0.001).

This study demonstrates that approximately 50% of North American women currently receiving treatment for osteoporosis have suboptimal 25(OH)D levels. Despite routine recommendations for OTC vitamin D supplementation by physicians, D insufficiency is highly prevalent even among women diagnosed and treated for osteoporosis.

Clinical Assessment of Vitamin D Status: An Imposing Dilemma. D. M. Gemar*, N. Binkley, D. Krueger, J. Engelke*, M. K. Drezner. University of Wisconsin, Madison, WI, USA.

Recent studies suggest that vitamin D (D) inadequacy is common in patients with osteoporosis and contributes to bone loss and fracture. Thus, adequate D supplementation is critical to assure optimal osteoporosis treatment and, appropriately, clinicians have focused on developing strategies for accurate assessment of D stores. These attempts include assay of serum 25OHD levels by commercially available methods and theoretically, use of elevated serum parathyroid hormone (PTH) levels to confirm the presence of inadequate D reserves. However, our previous studies suggest that commercially available chemiluminescent 25OHD assays do not define D status similarly to HPLC. Thus, radioimmunoassay (Diasorin) or HPLC techniques appear essential for accurate clinical 25OHD measurement. Unfortunately, use of radioisotopic assays in clinical laboratories has become less frequent and few commercial laboratories are equipped for high volume HPLC assays. Thus, the necessary means for accurate clinical evaluation of 25OHD status are limited. In the present study, we examined if a newly available chemiluminescent technology, the Diasorin Liaison, provides accurate assessment of serum 25OHD and if PTH measurement confirms a D insufficiency state. We obtained blood from 183 healthy young (mean age 23.8, range 18.1-39.5 years) male and female subjects having normal serum calcium and creatinine. Measurements of Liason-determined 25OHD were compared with that obtained by Diasorin RIA. Additionally, assays of whole and intact PTH by Scantibodies, Diasorin and Liaison methodology were performed. Liason determined serum 25OHD significantly correlated with that determined by RIA (r^2=0.78; p < 0.001). However, the Liason-determined values had a consistent bias, systematically underestimating serum 25OHD by an average of 9.8 ng/ml. As the mean 25OHD measured by RIA was 34.4 ng/ml, this under read is ~30% of the observed concentration. Moreover, whole and intact PTH measurements did not reveal a trend to elevated levels at concentrations of 25OHD <30 ng/ml. Indeed, in all cases correlation between the serum 25OHD and PTH levels was not significant. These observations reaffirm that currently available assays do not produce interchangeable serum 25OHD values. Thus, a single value cannot be widely utilized to define D insufficiency. Moreover, clinical reliance on serum PTH measurement to confirm suboptimal D status has no factual basis. Hence, the clinically attractive approach of a single 25OHD value to define D status is not currently feasible. As such, given the apparent epidemic of D insufficiency, standardization of 25OHD assays is essential unless definitions of insufficiency/deficiency are established for each assay.

Evaluation of Precision and Accuracy of Nichols Advantage 25-Hydroxyvitamin D Assay for 25-Hydroxyvitamin D_2 and 25-Hydroxyvitamin D_3: Comparison to Four Other Assay Methods Including Liquid Chromatography-Mass Spectrometry. M. F. Holick[1], T. C. Chen[2], D. Jamieson*[2], Z. Lu*[2], J. Mathieu*[2]. [1]Department of Medicine, Boston University School of Medicine, Boston, MA, USA, [2]Medicine, Boston University School of Medicine, Boston, MA, USA.

The serum assay for 25-hydroxyvitamin D [25(OH)D] is used to determine the vitamin D status of patients. The serum 25(OH)D assay measures both $25(OH)D_2$ and $25(OH)D_3$. The automated Nichols Advantage 25(OH)D assay is based on chemiluminescence detection and vitamin D binding protein (DBP) for competitive displacement. To determine how efficient and accurate the Nichols Advantage chemiluminescence assay was for detecting both $25(OH)D_2$ and $25(OH)D_3$, as compared to other methods, serum samples were obtained from healthy adults and from patients who were treated for several months with pharmacologic doses of vitamin D_2. The serum was divided into aliquots and numbered. Frozen samples were provided in a blinded fashion for analysis by five different methods including: (1) high performance liquid chromatography (HPLC), (2) liquid chromatography-mass spectrometry (LC-MS), (3) DBP binding assay, (4) radioimmunoassay, and (5) the Nichols Advantage System. These samples were tested at several independent laboratories. The amount of $25(OH)D_2$ and $25(OH)D_3$, was determined from results obtained by LC-MS and HPLC. A comparison of all the assays suggests that there are precision and accuracy differences among the various methods. The DBP binding assay, radioimmunoassay and the Nichols Advantage assay were able to detect $25(OH)D_2$ and $25(OH)D_3$.

Prevalence of Vitamin D in Post Menopausal Women and its Relevance to i-PTH in the Central Jersey. G. Kulkarni*, C. Guerard*, A. Wilson*, S. J. Wimalawansa. Dept. Medicine, Div. Endocrinology, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Introduction: The incidence of osteoporosis is rising in the US due to aging of the population. More than 90% of all the fractures in the elderly are associated with osteoporosis. Osteoporosis lead to spine and hip fractures, which is a major source of morbidity and mortality. Treatment options available are although effective, are costly and associated with significant adverse effects.

Methods: In the present study on prevention of postmenopausal bone loss, using Nitroglycerine as an Option: Value in Early Bone Loss (NOVEL study), a baseline data obtained from 123 postmenopausal women (ages ranging from 40- 60 years) who qualified out of 248 pre-screened for the study were analyzed. Several biochemical tests were performed and the data from serum 25(OH) Vitamin D, i-PTH, and spine and hip BMD data presented.

Results: The results obtained were analyzed by ANOVA. Depend on the age, women were classified into (i) 40 - 55 years (n=57), (ii) > 55 years (n=66). The overall correlation between i-PTH vs. vitamin D showed a statistically significance inverse relation as observed in previous studies (r = -0.31 and P = 0.0005). Serum i-PTH levels were higher in the age group >55, compared to the age group 40-55 years (Fig 1). Spine and hip BMD showed a strong correlation with each other [r = 0.478 and p = >0.001]. The body surface area (BSA) strongly correlated with height and weight as expected (height: r =0.525 and P = >0.0001; weight: r = 0.981 and p = >0.0001), while the spine and hip BMD values correlated well with BSA p <0.05 level (spine BMD: r = 0.192; p = 0.034 and hip BMD: r = 0.184; p = 0.041).Conclusion: We can conclude that serum i-PTH increases with age and strongly correlated with vitamin D status inversely. Vitamin D insufficiency is common, and needs to be identified (incidence of ~12% in this population) and corrected to avoid secondary hyperparathyroidism in postmenopausal women, especially in the elderly, prior to embark on any anti-osteoporosis therapy.

The Effect of Physical Activity on Bone Mass After Puberty in Men: A Eight-year Longitudinal Study. A. Nordstrom*[1], P. Nordstrom[2]. [1]Department of Surgical and Perioperative Sciences, Sports Medicine, Umeå, Sweden, [2]Department of Community Medicine and Rehabilitation, Geriatric Medicine, Umeå, Sweden.

Background: A high peak bone mass from physical activity could reduce the risk of osteoporosis if the benefits are retained with reduced activity. The long term effect of physical activity on bone mass after puberty to peak bone mass has not been studied.

Material and Methods: At baseline, bone mineral density (BMD, g/cm^2) of the total body, total hip, femoral neck, and spine were measured in 63 athletes (mean age 17.2 years) and 27 controls (mean age 17.1 years). Follow ups were made after a mean of 27, 68, and 94 months. The aim was to investigate the effect of physical activity on BMD after puberty in men, and evaluate whether a high BMD from physical activity is sustained with reduced activity.

Results: At baseline, the athletes were found to have significantly higher BMD at all sites compared to controls (total body 2.5%, femoral neck 7.7%, total hip 9.0%, spine 2.6%, p<0.05 for all). During the whole study period the 23 athletes that remained active increased significantly more at all BMD sites compared to controls (total body 3.6%, femoral neck 10.2%, total hip 7.8%, spine 5.2%, p<0.05 for all). Between the first and second follow up 27 athletes stopped their active career. During the same time period these athletes lost significantly more BMD compared to the still active athletes in the femoral neck (7.8%, p<0.001) and total hip (5.5%, p=0.009), but not compared to the control group. From the second to the third follow up period the former athletes did not loose BMD compared to any other group. At the final follow up the former athletes still had higher BMD compared to the controls at the femoral neck (10.6%, p=0.007) and total hip (9.1%, p=0.02).

Conclusion: The results of the present study suggest a high sensitivity to physical loading after puberty in men. Reduced activity is associated with bone mass losses only the first three years, and a sustained benefit from previous physical activity is seen five years after cessation of active career. Thus, previous physical activity up to the time of peak bone mass may decrease the risk of osteoporosis.

Comparison of Two DXA Software Versions for Assessment of Whole Body Bone Mineral Density and Body Composition in Pediatric Population. B. Fan[1], M. Sherman*[1], L. Borrud*[2], A. Looker*[2], J. Shepherd[1]. [1]Radiology, University of California San Francisco, San Francisco, CA, USA, [2]National Center for Health and Statistics/CDC, Washington DC, WA, USA.

Objective: To compare three Hologic software versions for assessment of BMD and body composition analysis of whole body scans in children. Dual-energy X-ray absorptiometry (DXA) has been widely used in pediatric populations for assessment of bone density as well as body composition. However, when using an adult algorithm to assess pediatric bone density, it often fails to recognize small bones . To address this issue, the manufacturer (Hologic Inc., Bedford, MA) offers a pediatric analysis option (QDR Pediatric Whole Body, version 8.26a) for whole body scans. Recently, Hologic updated its pediatric analysis software (Discovery Software, version 12.1). Which has a variable bone density threshold that automatically adjusts for differing body sizes.

Methods: We compared the QDR Adult, QDR Pediatric, and Discovery whole body algorithms, using106 pediatric subjects aged 7 to 21 years old (mean = 14 ± 4 yrs) who participated in the NHANES 1999-2004 pilot study. The children were measured on one of three QDR-4500A DXA densitometers. Scans were analyzed by a single operator using all three analysis options. To evaluate how well each algorithm identified true bone area, we developed the Bone Area Score and applied it to each region of interest as follows: 0 = too little bone (< 50% true area) identified, 1 = accurate bone (50% < bone area < 100%) identified, and 2 = too much bone (>100% of true bone area) identified.

Results: The results of BMD and body composition from the three analysis options were highly correlated, with R square values ranging from 0.923 to 0.997. The table below shows the percentage of scores in different body parts for each algorithm.

	QDR Adult Analysis			QDR Pediatric Analysis			Discovery Analysis		
	0 (low)	1 (accurate)	2 (too high)	0 (low)	1 (accurate)	2 (too high)	0 (low)	1 (accurate)	2 (too high)

Our data shows that the adult algorithm failed to identify the bone area in small bones half of the time. The pediatric algorithm increased sensitivity in finding lower density small bones; however, in the axial region and large bones it often defined lean mass.

The Discovery algorithm identified more of the bone area in small bones than the adult algorithm without the tendency to identify lean tissue as bone in the axial and large bones.

Conclusions: The Discovery software was more accurate in identifying bone area than either the adult or pediatric options.

Osteoporosis Resulting From Deficient Acquisition of Peak Bone Mass: the SAMP6 Mouse Model. J. Ophoff*, S. Boonen, E. Van Herck*, R. Bouillon, D. Vanderschueren. K.U.Leuven, Leuven, Belgium.

The SAMP6 (P6) mouse model is characterized by spontaneous fractures and is considered an animal model of senile osteoporosis. In line with human findings in hip fracture patients, P6 mice show thinner but wider bone cortices. Presently, it is unclear when and how these structural abnormalities of the bone cortex develop.

This *in vivo* study was designed to monitor acquisition of peak bone mass longitudinally in (male and female) P6 and control SAMR1 (R1) mice. To this end, serial peripheral computed tomography (pQCT) and dual-energy X-ray absorptiometry (DEXA) measurements were performed from 4 weeks till 20 weeks of age. At week 4 also urinary deoxypyridinoline (DPD) and serum osteocalcin (oc) levels were determined.

Peak bone mass acquisition in the tibia of R1 was characterized by greater cortical thickness in males than females. Male R1 showed 39% periosteal expansion, compared to only 18% at the endocortical site; females had less periosteal (24%) and no endocortical expansion. In both genders, total-body bone mineral content (tBMC) and polar moment of inertia (pCSMI) correlated with body weight (r^2= 0.59 and r^2=0.74 respectively, p<0.0001). Even after adjusting for differences in body weight, males had a higher pCSMI compared to females. Adjusting for lean body mass gave similar results.

Compared to R1 mice, P6 mice showed evidence of impaired cortical bone mass acquisition due to an early acceleration of endocortical expansion. It was observed in both genders (22% endocortical expansion in P6 females, 28% in P6 males), was already present at 4 weeks and reached its maximum around 8 weeks. This was confirmed by higher DPD (a marker for bone resorption) and lower oc (marker for bone formation) levels at week 4 in SAMP6 mice compared to R1 mice. In female P6 mice, endocortical expansion was partly compensated by additional periosteal bone apposition (7% more than in female R1 mice). Male P6, however, did not show such extra periosteal bone expansion and, consequently, experienced excessive cortical thinning. As a result, a decrease in pCSMI and lower pCSMI/weight and tBMC/weight ratios were observed in both genders of P6, but particularly in male animals.

In conclusion, SAMP6 mice show deficient peak bone mass acquisition as a result of an early, gender-neutral acceleration of endocortical bone expansion. Additional periosteal apposition compensates for the endocortical bone expansion in female P6 mice but not in male P6 mice. These findings support the concept that osteoporosis and osteoporotic fracture may partly result from deficient peak bone mass acquisition during skeletal development.

Bone Mass has Reached its Peak in the Spine and Hip but Continues to Increase in the Cortices of the Long Bones in 18-20-Year-Old Men. M. Lorentzon[1], D. Mellström[2], C. Ohlsson[1]. [1]Dept. of Internal Medicine, Center for Bone Research at the Sahlgrenska Academy (CBS), Gothenburg University, Gothenburg, Sweden, [2]Department of Geriatric Medicine, Gothenburg University, Gothenburg, Sweden.

In men, peak bone mass is believed to be achieved by the end of the second decade in life. The aim of the present study was to determine if the peak bone mass, at different localities, is reached in 18-20-year-old men. The *G*othenburg *O*steoporosis and *O*besity *D*eterminants (*GOOD*) study consists of 1075 men, age 18.9±0.6 yrs, and was initiated with the aim to find environmental and genetic determinants for bone and fat mass. Questionnaires were used to collect information about physical activity, dairy product intake and smoking. Bone parameters were measured using DXA and pQCT.

DXA measurements demonstrated that age was correlated to areal BMD of the radius (r=0.16; p<0.001) and the ulna (r=0.15; p<0.001) but not to the total body, femoral neck, or lumbar spine. pQCT measurements revealed that age was correlated to cortical BMC in both the radius and tibia (p<0.05). Age was found to be an independent predictor (in a multiple linear regression analysis including height, weight, physical activity, and smoking) of both the cortical volumetric BMD (radius β=0.29, p<0.001; tibia β=0.14, p<0.001) and the cortical thickness (radius β=0.15, p<0.001; tibia β=0.08, p<0.01) in the long bones. Trabecular volumetric BMD of the radius (β=0.08, p<0.05) but not of the tibia was associated with age.

These results demonstrate that in 18-20-year-old men peak bone mass has been attained in the femoral neck and lumbar spine, but not yet in the cortical bone of the long bones.

Bone Mineral Density in Healthy School Children in North India. N. Tandon*[1], R. K. Marwaha*[2], H. K. Reddy*[1], R. Aggarwal*[2], B. Saluja*[3], M. A. Ganie*[1]. [1]Endocrinology, All India Institute of Medical Sciences, New Delhi, India, [2]Endocrinology, Institute of Nuclear Medicine and Allied Sciences, Delhi, India, [3]Dentistry, Instiute of Nuclear Medicine and Allied Sciences, Delhi, India.

Preliminary studies suggest that ethnic Asian Indians have a lower bone mass compared with white Caucasians. Clinical observations also suggest that osteoporosis is more prevalent in this ethnic group, occurs at an earlier age and affects males more frequently than that described in whites. One possible mechanism could be poor accrual of peak bone mass. In this study we have measured bone mineral density of apparently healthy school children from North India.

Bone mineral density of forearm and calcaneum was measured by pDXA in a total of 745 school children, aged 10-18 years, hailing from lower (Group 1; N=443) and higher (Group 2; N = 302) socio-economic groups. Dental fluorosis was observed in 213 children from Group 1 and 38 children from Group 2. Serum concentrations of calcium, phosphorus, alkaline phosphatase, 25 hydroxy vitamin D and iPTH were measured in fasting blood samples.

The mean BMD at the forearm and calcaneum in the total cohort was 0.373 ± 0.07 g/cm^2 and 0.482 ± 0.09 g/cm^2. There was a significant positive correlation between BMD at both forearm and calcaneum with BMI. There was a significant negative correlation between BMD at both sites with serum alkaline phosphatase. Children from Group 1 had a significantly lower BMD than Group 2 at both forearm and calcaneum. Males had significantly higher BMD at both forearm and calcaneum than females in both socio-economic groups. There was a progressive increment in the mean BMD at both sites with age. Interestingly, the mean BMD at both sites was significantly lower in children with dental fluorosis than those without fluorosis.

The significantly lower BMD in children belonging to the lower socio-economic group suggests that nutrition plays an important role in the accrual of bone mass and could be contributory in the lower bone mass in Asian Indians compared with other ethnic groups.

This study will also help establish norms for bone mineral density in the age group 10-18 years in North India.

M006

Physical Activity Level and Peak Bone Mass in 737 Young Adult Women. M. Callréus*, K. Ringsberg*, K. Akesson*. Malmö University Hospital, Dept of Orthopedics, Malmö, Sweden.

Introduction: The level of peak bone mass is most likely one of the key factors for later risk of osteoporosis. Peak bone mass is largely genetically determined and reached between age 20-30. External factors, such as physical activity, are contributing, but the relative significance is not evaluated in young adult women at the age of peak.

Materials and methods: 737 women, all 25 yrs (25.0-25.9), were included in this population-based study to evaluate factors of importance for peak bone mass.

Bone mineral density (BMD) was measured at the total body (TB), femoral neck (FN), trochanter (Troch) and spine (LS). Muscle strength was measured with isokinetic, concentric peak torque of the hamstrings and quadriceps together with handgrip strength. A questionnaire was completed for different variables of physical activity and lifestyle.

Physical activity was assessed by the subjects own scoring, recreational activity level (RAL) and objectively for impact load by the peak strain activity (PSA) score, a model based on ground reaction forces related to the type of activity. A combination of the RAL and PSA scores (COMB-RP) was also constructed. The scores were dichotomized into high and moderate/low.

Results: Young adult women reporting higher physical activity level, had significantly higher peak BMD at most sites, compared to those with lower physical activity. This was most pronounced for those (n=229) scoring high in both domains (COMB-RP), with also an increase in TB BMD 1.1% ($p<0.05$). Body weight, height and BMI were similar between groups.

High vs Low	Troch	FN	LS	p-levels
RAL (recreational activity)	3.6 %	2.9 %	1.8 %	0.044-0.007
PSA score (peak strain activity)	2.6 %	1.7 %	2.0 %	0.027-0.0002
COMB-RP (combined scores)	4.0 %	3.0 %	2.5 %	0.008-0.0002

Knee flexion and extension strength correlated with hip BMD (r^2=0.22-0.27, $p<0.0001$) and COMB-RP ($p<0.0001$), but not with handgrip strength. Women with high COMB-RP enjoyed to a greater extent scheduled physical exercise already in school (36% vs 23%) and were less likely to decrease their activity level compared to those with low combined activity.

Conclusion: This is the first study demonstrating the effect of physical activity on peak bone mass in the average 25-year-old woman. Physically active young women, particularly those involved in recreational activities with high impact, have a significantly higher peak bone mass at the hip, spine and total body. It also indicates that in order to achieve the beneficial effect, it is important to establish a behavioral pattern where physical activity is enjoyed already in the early school years.

The Effect of Ethnicity and Gender on the Growth of the Axial and Appendicular Skeleton in Children. L. H. Nyati*[1], S. A. Norris[1], N. Cameron*[2], J. M. Pettifor[1]. [1]MRC Mineral Metabolism Research Unit, Department of Paediatrics, University of the Witwatersrand, Johannesburg, South Africa, [2]Department of Human Biology, University of Loughborough, Loughborough, United Kingdom.

Ethnic and gender variations in the growth of the axial and appendicular skeleton have been explored to determine their effects on bone mass. The heterogeneity in growth of one region in relation to another and the disparity in the size and mass of the same region are suggested to predispose to differential susceptibility to bone fracture. However, the influence of the differential axial and appendicular growth on the expression of bone mineral content is not yet established. Data assessing axial and appendicular growth and bone mass is largely drawn from the developed world and there is paucity of data describing these trends in the developing world where patterns may differ. Hence the aim of this study was to investigate (i) ethnic and gender differences in axial and appendicular dimensions of South African prepubertal children (ii) and the influence of regional bone length on the expression of site-specific bone mass. Anthropometric measurements of stature, weight, sitting height and limb lengths were taken on 369 black and white, male and female 9 yr old children. DXA scans of the ulna; radius; hip and spine were also obtained. An ANCOVA was performed to assess stature independent differences of limb lengths. A multiple regression was also performed to assess significant predictors of site-specific bone mass.

White children of both sexes were significantly taller than black children. Similarly sitting height was significantly greater in white children than black children of both sexes. However sub-ischial, humerus, ulna and calf lengths were similar between the ethnic and gender groups. Black girls had longer thighs than black boys. White boys were also heavier than black boys but no gender difference was observed.

Stature adjusted means of limb lengths show that black boys have longer legs and humerus but shorter trunks than white boys. In addition, black children have longer forearms than white children and girls have longer thighs than boys. This pattern is similar to those observed in the African American and Caucasian American populations. Bone mineral content at all sites with the exception of the hip, was predicted better by regional bone length than stature. However, using regional bone length as compared to stature to adjust for the effect of size on bone mass only had a marginal effect on the significance level of ethnic and gender differences.

Association Between Central Bone Mineral Density and Biochemical Bone Markers in Japanese Young Women. H. Ohta[1], Y. Onoe[1], Y. Miyabara*[1], R. Yoshikata*[1], H. Okano[1], T. Kuroda*[2]. [1]Obstetrics and Gynecology, Tokyo Wemen's University, Tokyo, Japan, [2]Public Health Research Foundation, Tokyo, Japan.

The relationship between the status of central bone mineral density (BMD) and bone metabolism in young Japanese women remains unclear. To establish the status of peak bone mass in these women, we investigated BMD and biochemical bone markers.

The study subjects comprised healthy 139 women aged between 19 to 25 years of age (mean, 21.1 years), and those receiving treatment for any disease affecting bone mass or on diet and/or exercise therapy were excluded from the study. Subject background data surveyed included age, weight at birth, age at menarche, and current menstrual status. Measurements included height, body weight, lumbar vertebrae 2-4 BMD (L 2-4 BMD), and total BMD of the proximal femur (QDR 4500). Biochemical variables examined included serum levels of calcium, phosphorus, and albumin. To investigate the bone metabolism milieu in these women, serum levels of intact-osteocalcin, cross-linked N-telopeptides (NTX), bone specific alkaline phosphatase (BAP), osteoprotegerin (OPG) and soluble RANKL (sRANKL) were also measured.

The mean BMD at the lumbar spine (L2-4) and the total of proximal femur was 0.99 ± 0.10 and 0.90 ± 0.10 g/cm^2, respectively. There were no statistically significant differences in BMD (peak bone mass) in the subjects aged between 19-25 years of age. Furthermore, the mean BMD was lower than the YAM established previously by the JSBMR. The mean serum levels of NTX and BAP were 13.5 + 4.14 nmol BCE/L and 22.1 + 7.1 U/L, respectively. These levels were higher than the mean previously reported for those aged 30-44 years old, and were similar to those seen in older women. Serum BAP levels showed a significant (r = -0.22, p = 0.01) negative correlation with age, and serum NTX levels also indicated a negative correlation with age. Moreover, there was a significantly (r = 0.39, p = 0.0001) positive correlation between serum OPG and sRANKL levels.

In Japanese young women between 19-25 years of age, bone metabolism was shown to be of high turnover type where bone resorption exceeded bone formation. However, during these ages, the BMD at the lumbar spine and the total BMD of the proximal femur was not shown to peak. Further investigation in subjects in a wider age range is required to determine the age at which bone mass peaks in these women, as well as their peak BMD values.

Proximal Femur Bone Bending Strength Is Appropriately Adapted to Muscle Mass in Overweight Children and Adolescents. M. A. Petit[1], T. J. Beck[2], J. Shults*[3], B. Zemel[4], B. J. Foster*[4], M. B. Leonard[5]. [1]Health Evaluation Sciences, Penn State University, Hershey, PA, USA, [2]Dept. of Radiology, Johns Hopkins University, Baltimore, MD, USA, [3]Biostatistics and Epidemiology, Univeristy of Pennsylvania School of Medicine, Philadelphia, PA, USA, [4]Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, [5]Pediatrics; Biostatics and Epidemology, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

It is unclear whether bones of overweight children are appropriately adapted to their skeletal loads. The objective of this study was to compare cross-sectional bone geometry and strength in 40 overweight (body mass index [BMI] > 85th percentile) and 94 normal weight (BMI ≤ 85th percentile) subjects, aged 4-20 yr. Proximal femur, dual energy x-ray absorptiometry (DXA, Hologic QDR 4500) scans were analyzed at the femoral shaft (FS) and narrow neck (NN) by the Hip Structure Analysis Program. Subperiosteal width and indices of axial and bending strength (bone cross sectional area - CSA - and section modulus - Z) were measured from bone mass profiles and cortical thickness was estimated using models. Log transformed regressions were used to determine percent differences in bone parameters in overweight compared with controls. After adjusting for height, maturation and gender, Z was 11 [95% C.I. 5, 19] and 13 [7, 20] % higher at the FS and NN, respectively, in overweight subjects ($p \leq 0.001$). At the NN, higher Z was due to greater subperiosteal diameter (4% [2, 7]) bone CSA (10% [5, 16]) and thicker cortices (9% [3, 15]) and at the FS, to higher bone CSA (10% [5, 16]). Differences for all bone variables became non-significant ($P > 0.22$) after adjusting for lean mass, with the exception of NN subperiosteal width (+3%, [0, 6], $p = 0.04$). Fat mass did not contribute significantly to any model. In summary, proximal femur bone strength in overweight children is appropriately adapted to their lean body mass and height, but greater weight in the form of fat mass does not have an independent effect on bone bending strength. These geometric adaptations are consistent with the mechanostat hypothesis where bone strength adapts to skeletal loads dominated by muscle forces, but not to static loads represented by body weight.

Disclosures: ***M.A. Petit****, None.*

The Relationship Between Continued Periosteal Apposition and Bone Fragility. J. E. Bird*[1], P. Nasser*[1], S. M. Tommasini[2], D. Casagrande[1], K. J. Jepsen[1]. [1]Mt Sinai School of Medicine, New York, NY, USA, [2]CUNY Graduate School, New York, NY, USA.

Continued periosteal apposition (CPA) has the benefit of maintaining bone strength during age-related endocortical bone loss. Recent cross-sectional data segregating Caucasian females based on fracture history revealed evidence of CPA at the distal radius of females without a history of fracture but not in those with a history of fracture [1]. Because Lazenby [2] showed that the degree of CPA varies with bone size, we tested whether differences in CPA between the fracture (fx) and non-fracture (n-fx) groups could be explained by differences in initial bone size.

Morphological parameters of the distal radius were obtained for Caucasian females (age < 50 yrs) with and without a history of fracture in an IRB approved clinical evaluation using plain film radiographs. All data were age-corrected. To determine the degree of periosteal apposition needed to maintain a constant moment of inertia or strength throughout life, we derived an equation for CPA or periosteal apposition rate (dR/dt) as a function of endocortical resorption rate (dr/dt) assuming the radial diaphysis has a circular cross-section (R = periosteal radius, r = endosteal radius): $CPA = dR/dt = (r/R)^3 * dr/dt$.

For both fracture groups, r/R increased linearly with R. This means that individuals with small bones (small R) have a small r/R ratio or proportionally thicker cortices. Based on our equation, individuals with small bones would need a much smaller dR/dt to maintain bone strength when compared to individuals with large bones (note: r/R is raised to the 3rd power). No differences in any morphological traits were observed between the two groups ($r = 3.0 \pm 0.6$ mm n-fx, 3.2 ± 0.9 mm fx; $R = 6.2 \pm 0.8$ mm n-fx, 6.3 ± 0.7 mm fx; $r/R = 0.48 \pm 0.06$ n-fx, 0.5 ± 0.11 fx). In addition, no difference in endosteal resorption rate (dr/dt) was observed between the two groups (0.017 mm/yr n-fx and 0.019 mm/yr fx). Given these parameters, the predicted degree of CPA was similar for the two fracture groups (dR/dt = 0.0031mm/yr n-fx, 0.0036 mm/yr fx). However, this was not observed clinically; dR/dt had a positive slope in the non-fracture group and zero slope in the fracture group. Thus, the difference in CPA (dR/dt) between the two groups could not be explained on the basis of initial bone size. This data indicated that the fracture group failed to add the appropriate amount of bone to maintain bone strength.

The derived equation may be used prospectively to predict the amount of CPA necessary to maintain bone strength on an individual basis. These findings have important clinical implications for providing novel diagnostic measures for the prevention of fragility fractures. [1] Bird et al, Trans.ORS 2004 [2] Lazenby, 1990 Amer J Phys Anthr 82.

Demineralized Bone Promotes Chondrocyte or Osteoblast Differentiation of Human Marrow Stromal Cells Cultured in Collagen Sponges. S. Zhou, K. E. Yates, K. Eid*, J. Glowacki. Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

Demineralized bone implants are used for many osseous reconstruction procedures. Demineralized bone powder (DBP) induces chondrogenesis of human dermal fibroblasts (hDFs) in a DBP/collagen culture system. Here, we test the hypothesis that human marrow stromal cells (hMSCs) can be stimulated by DBP to differentiate to chondrocytes or to osteoblasts, depending upon the culture conditions. First, we confirmed that hMSCs became chondrocytes when treated with TGFß. Second, we found that DBP induced chondrogenesis in hMSCs in 3-D sponges (serum-free MEM-a with 1% ITS^{+1}, 10^{-8} M dexamethasone, 50 µg/ml ascorbate-phosphate), assessed by metachromasia and induction of chondrocyte-specific genes *COL II and COL X*. Third, hDFs were used to define mechanisms of chondroinduction because unlike hMSCs they have no inherent chondrogenic potential. *In situ* hybridization revealed that hDFs vicinal to DBPs express chondrocyte-specific genes *Aggrecan* or *Col II*. Macroarray analysis showed that there was convergence and divergence in DBP and rhBMP-2 regulation of genes in the TGFß/BMP signaling pathway in 3-D hDFs cultures. Smad target genes were the predominant group of DBP or rhBMP-2 regulated genes. Several genes (*IGF-BP3*, *ID2*, and *ID3*) responded similarly to DBP and rhBMP-2. In contrast, many genes that were greatly upregulated by DBP, such as *TGFBI/ßig-h3* (1260% vs collagen sponges), *Col3A1* (1400%), *Col1A2* (1770%), *TIMP1* (250%), *p21/Waf1/Cip1* (260%) etc., were barely affected by rhBMP-2. On basis of Smad target gene changes, we conclude that DBP acts through both AR and BR Smads. Although BMP-2 was originally isolated as a putative inductive factor in DBP, rhBMP-2 alone and DBP do not affect all the same genes or in the same ways. Finally, DBP induced hMSCs to express osteoblast genes *Alkaline Phosphatase* and *Osteocalcin* when cultured in MEM-a with 10% FBS-HI, 10^{-8} M dexamethasone, 5 mM ß-glycerophosphate, 50 µg/ml ascorbate-phosphate. In summary, we show that culture conditions influence the differentiation pathway that human marrow stromal cells follow when stimulated by DBP. Second, our results show that DBP activates TGFß/BMP signaling pathway genes. The mechanism of induction by DBP is very complex and is not mimicked by TGFß or by rhBMP-2. Understanding the interactions of the various growth and differentiation factors in bone matrix will be important to determine the mechanisms of DBP's action and its effects on chondroinduction or osteoinduction.

Mechanisms of Osteoblast Differentiation by BMP-7 in Human Bone Marrow Osteoprogenitor Cells. L. R. Chaudhary, K. A. Hruska. Pediatrics, Washington University School of Medicine, St. Louis, MO, USA.

Bone remodeling is complex biological process which involves osteoprogenitor commitment, differentiation, expression of osteogenic genes, synthesis of matrix proteins and mineralization resulting in new bone formation. Although BMP-7 is a potent stimulator of human osteoprogenitor differentiation and mineralization accompanied by induction of alkaline phosphatase (ALKP) activity and BSP gene expression, its mechanism of action remains unknown. Human bone marrow stromal (HBMS) progenitors although positive for CBFA1 do not progress to osteoblast differentiation without positive stimulation suggest that the processes of osteoblast commitment and differentiation require additional osteoblast specific factors. Here this hypothesis was tested in HBMS treated with BMP-7 (40 ng/ml), FGF-2 (20 ng/ml), dexamethasone (DEX, 10-7 M) or PTH (10-7 M) for 1, 2, 3, and 4 weeks in the alpha-MEM medium containing 50 µg/ml ascorbic acid and 10 mM β-glycerophosphate. RNA was analyzed by conventional and Real-Time RT-PCR. BMP-7 stimulated alkaline phosphatase activity and hydroxyapatite crystal deposition. CBFA1 expression was observed throughout the osteoblast differentiation without significant change in response to BMP-7 and other factors. Osterix gene expression was stimulated only by BMP-7 as the cells were undergoing differentiation program, and only stimulation of Osterix correlated with osteoprogenitor differentiation. PTH had no effect on ALKP activity, osterix gene expression and biomineralization. DEX did not affect osterix or OPGL gene expression. Interestingly, FGF-2 increased the expression of OPGL at 2, 3, and 4 weeks indicating a role in osteoclastogenesis. FGF-2 did not stimulate ALKP activity and inhibited BMP-7 stimulated ALKP and biomineralization. Results suggested that CBFA1 might be important in early commitment to the osteoblast phenotype, but osterix is a key regulatory factor in the differentiation of osteoprogenitor cells and biomineralization. Our results demonstrate that BMP-7 acts as a potent stimulator of osteoprogenitor cell differentiation and this process is mediated by osterix.

Autoregulation of Endogenous BMP Expression Mediates Osteogenic Differentiation of Murine Marrow Stromal Cells in Culture. C. M. Edgar, V. Chakarvarthy*, G. L. Barnes, L. C. Gerstenfeld, T. A. Einhorn. Orthopaedic Surgery Research Laboratory, Boston University Medical Center, Boston, MA, USA.

Bone Morphogenetic Proteins (BMPs) are key morphogenetic regulators of skeletal tissue development and are necessary proteins in both the developmental and post-developmental regulation of stem cell differentiation. Previous studies show a temporal expression pattern for multiple BMPs during fracture repair and pre-natal bone development, suggesting that skeletal tissue development and repair is regulated through the coordinated actions of multiple BMPs. The goals of these experiments were to determine if the osteogenic differentiation of adherent murine MSCs, in an *ex vivo* system is dependent on the endogenous expression of multiple BMPs, characterize their interactions within this network, and determine if the network is autonomously regulated by specific BMP expression. Murine bone marrow stromal cells (MSCs) were prepared from 10 week old male mice and grown in osteogenic media for 21 days. Osteogenic differentiation was characterized by development of mineralizing nodules, AlkPase activity, and the assessment of mRNA expression. During the normal differentiation of MSCs in culture, increased expression of Dlx5 and Runx2 was accompanied by commensurate decreases in the expression of specific AP1 transcription factor family members. These changes were associated with sequential temporal increases in Col1α1, OPN, BSP and OC expression, and the unique up-regulation the expression of BMPs 2, 4, 5, 6, 8A and 3. Noggin treatment inhibited nodule counts by 50%-70% with an accompanied reduction in the expression of osteo-inductive transcription factors, matrix gene mRNA expression and the expression of BMPs 8A, 2, 5, and 3, in contrast BMP-4 and 6 demonstrated an increased expression. The addition of rhBMP-7, or 2 increased nodule counts by 30%-50% and the expression of osteogenic extracellular matrix markers and at 21 days, transcription factors Dlx5 and Runx2 expression was twice that of control cultures. Interestingly, the addition of rhBMP-7 or 2 inhibited the endogenous expression of BMP-4, 6, and 3b while enhancing the expression of BMP-8a,and 3. Culture treatment with a specific blocking antibody to BMP-2 had identical effects to noggin, and the inhibition of differentiation could be rescued by competitive addition of BMP-2 back to the media. In conclusion, these data suggest that the *ex vivo* MSCs system relies on the expression of certain endogenous BMPs during osteogenic differentiation which is regulated in a dynamic network which appears to be largely controlled through the action of BMP-2.

The Comparison of Lentiviral- and Adenoviral-mediated BMP-2 Gene Transfer in the Repair of Segmental Femoral Defects in Rats. W. Hsu*, O. Sugiyama*, B. Feeley*, N. Liu*, L. Krenek*, J. Lieberman*. UCLA Medical Center, Los Angeles, CA, USA.

Our laboratory has previously demonstrated that lentivirus-mediated gene transfer into rat bone marrow stromal cells (RBMSC) induced BMP-2 production *in vitro* for up to 12 weeks after transduction. We have also shown through previous studies that adenoviral-mediated BMP-2 gene transfer is capable of robust bone formation *in vivo*. This study compares the bone repair potential of lentiviral and adenoviral vectors in an immunocompetent rat femoral defect model.

Lentiviral-mediated gene transfer (LGT) via Lenti-RhMLV-BMP2 and adenoviral-mediated transfer (AGT) using Adv-cmyc-BMP2 vectors were used. A total of 50 8-mm femoral defects were created in five groups of Lewis rats: Group 1 - 5 x 10^6 BMP-2-producing RBMSC generated through LGT; Group 2 - 5 x 10^6 BMP-2-producing RBMSC created through LGT implanted 8 weeks after transduction; Group 3 - 5 x 10^6 GFP-producing RBMSC created through LGT; Group 4 - 5 x 10^6 BMP-2-producing RBMSC generated through AGT; Group 5 - 5 x 10^6 RBMSC alone. A compression resistant matrix comprised of both calcium phosphate ceramic and type I bovine collagen was used as a carrier for all groups. All specimens were harvested 8 weeks after surgical implantation and underwent plain radiographs, manual palpation, histological evaluation, and biomechanical testing.Table 1 summarizes results seen 8 weeks after treatment based on plain radiographs and manual palpation. ELISA results for BMP2 production *in vitro* for the following groups were measured: Group 1: 131 ng BMP-2/day/mg cell protein, Group 2: 84.5 ng BMP-2/day/mg cell protein, and Group 4: 29.2 ng/mL.

BMP2-producing RBMSC from LGT can heal a segmental rat femoral defect *in vivo*. Furthermore, we concluded that in an immunocompetent rat model, the use of LGT offers superior results in the induction of bone formation of a segmental defect when compared to AGT. The safety profile of lentiviruses has been recently improved by genetic alterations allowing study in experimental animal models. All animals in our study survived until the 8-week endpoint without observed side effects. Furthermore, because lentiviral vectors are less immunogenic, provide a high rate of transduction efficiency, and offer stable, long-term production of BMP2, they show promise in the future treatment of orthopaedic conditions which require bone repair.

Group	Treatment	N	N Fused
1	Lentiviral-BMP2-transduced 5 mil RBMSC	9	9
2	Lentiviral-BMP2-transduced 5 mil RBMSC 8-wk old	8	4
3	Lentiviral-GFP-transduced 5 mil RBMSC	13	0
4	Adenoviral-BMP2-transduced 5 mil RBMSC	8	4
5	5 mil RBMSC alone	12	0

Repair of Intercalated Long Bone Defect with Biodegradable β-Tricalcium Phosphate Added by a New Delivery System for Recombinant Human Bone Morphogenetic Protein-2. M. Yoneda*, H. Terai, S. Miyamoto, K. Takaoka. Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan.

To create a new absorbable biomaterial with osteo-inducing capacity equivalent to autogenous bone-graft, we combined recombinant human bone morphogenetic protein (rhBMP-2, Yamanouchi Pharmaceutical. Co., Ltd.) with its delivery system and absorbable osteo-conductive biomaterial. In this study, porous β-tricalcium phosphate (β-TCP, Olympus. Co., Ltd.) cylinder blocks were coated with a block copolymer composed of poly-D,L-lactic acid with random insertion of p-dioxanone and polyethylene glycol (PLA-DX-PEG, Taki Chemical. Co., Ltd.) containing rhBMP-2 at the concentration of 0.02%. Twenty Japanese white rabbits were used for this study A longitudinal critical bone defect (15 mm in length) were filled with three β-TCP cylinder blocks coated with PLA-DX-PEG containing rhBMP-2 in the experimental group (n=10). Five rabbits recieved the same implants without rhBMP-2 as a control group. The critical defects left empty in 5 rabbits as another control. All critical defects were fixed with external fixators until 8 weeks after surgery. The animals were examined every two weeks by radiographs. At 8 weeks after surgery, half of the experimental group (n=5) and both control groups (n=5 each) were sacrificed and the both femurs were harvested for histological and mechanical examinations. The rests of experimental group (n=5) were fed up to 24 weeks.

On radiological examination of the femurs in the experimental group, the calcified image became more evident at 4 weeks and the newly formed bone connected both ends of the defect, appeared to be remodeled into the cortical bone with bone marrow cavity at 8 weeks. Image analysis and mechanical testing performed at 24 weeks revealed the complete anatomical restoration of defects with cortical bone and marrow space without the residual of β-TCP blocks.

On histological sections of the femurs in the experimental group, the newly formed bone in the defect was remodeled and cortical bone was clearly recognized with regenerated hematopoietic marrow like tissue. In 24 weeks, cortical bones were remodeled into the original anatomical shape with marrow like tissue without the the residual of β-TCP.

Our experimental results indicated that porous β-TCP combined with rhBMP-2 with its delivery system have osteogenic capacity equivalent to autogenous bone grafts. This newly developed material is effective for the repair of large bone defects without leaving implants in the defects.

A Combinatorial Approach to Craniofacial Regeneration in Wounds Compromised by Radiation Therapy. Z. Wang*, B. Nussenbaum*, P. H. Krebsbach. School of Dentistry, University of Michigan, Ann Arbor, MI, USA.

Functional and aesthetic restoration of craniofacial defects is challenging. One practical obstacle is the exposure to radiation that is characteristic of patients with head and neck malignancies. A potential strategy for overcoming the negative effects of radiation includes the use of anabolic dosing of parathyroid hormone (PTH), which effectively augments bone formation during stem cell directed osteogenesis. We hypothesized that a combination of molecular medicine and gene therapy could successfully overcome the negative effects of radiation in skeletal regeneration. Two weeks prior to surgery, 200 gm rats received no radiation or a single 12 Gray radiation dose delivered to the calvarium. The radiated (n=32) and non-radiated (n=32) rats were divided into 4 groups of 8 animals: inlay calvarial bone graft, non-transduced dermal fibroblasts, transduced dermal fibroblasts plus vehicle injections, and transduced dermal fibroblasts plus PTH injections. For the gene therapy treated groups, fibroblasts were transduced ex vivo with an adenoviral vector containing the BMP-7 cDNA. Transduced cells were loaded into a gelatin scaffold and were placed into 9 mm critical-sized calvarial defects. PTH treated groups were given daily injections of rhPTH [1-34] (80 mg/kg) and the controls received 0.9% sodium chloride. Bone regeneration was evaluated by micro-computed tomography (μCT) and histomorphometry. Non-transduced dermal fibroblast groups revealed fibrous union without any bone formation independent of radiation exposure. Micro-CT analysis in the non-radiated rats demonstrated significantly increased percent bone volume/total defect volume when comparing gene therapy plus anabolic-PTH to gene therapy plus vehicle (75 ±12.7 versus 63.0 ± 12.1, $p< 0.05$). Radiation therapy significantly limited tissue regeneration by transduced cells. This was demonstrated by comparing bone growth for the gene therapy plus vehicle treated rats that did or did not receive radiation (63.0 ± 12.1 versus 37.7 ± 15.6, $p< 0.05$). However, bone regeneration was significantly enhanced in the radiated defects by the combination of gene therapy plus anabolic-PTH compared to gene therapy plus vehicle (54.9 ± 13.9 versus 37.7 ± 15.6, $p< 0.05$). In fact, there was no significant difference when comparing the non-radiated gene therapy plus vehicle treated group to the radiated gene therapy plus anabolic-PTH group (63.0 ± 12.1 versus 54.9 ± 13.9, $p=0.67$). Bone mineral density was also significantly increased by the addition of PTH treatment. Anabolic dosing of PTH can augment bone regeneration induced by BMP-7 ex vivo gene therapy and overcome the negative effects of radiation therapy in cranial defects.

Role of ERK Activation in the Osteogenic Actions of BMP-2. S. Fukayama, J. M. Owens, J. M. Wozney. Women's Health and Bone, Wyeth Research, Cambridge, MA, USA.

BMP-2 is a well-known osteogenic factor and is used clinically as a bone-inductive agent. It has been shown that BMP-2 signals not only via Smad activation but also via activation of a variety of kinases such as extracellular signal-regulated kinase (ERK) and p38. BMP-2 activates these kinases either in Smad-dependent or -independent fashion. For example, recent evidence suggests that BMP-2 activates ERK and p38 via activation of Ras. Using a neonatal mouse (ICR) calvaria organ culture assay, we have explored the role of activation of these kinases in the action of BMP-2. In this assay model, incubation with 500 ng/ml BMP-2 for 7 days did not increase total bone area although the same treatment resulted in an increase in the number of osteoblasts by up to 100%. Continued incubation with BMP-2 stimulated bone resorption as well, as assessed by measuring calcium release from calvaria into the medium. However, withdrawal of BMP-2 from culture after a brief treatment (~3 days) resulted in an increase in total bone area by up to 30% after 7 days incubation (brief exposure model). In contrast, the stimulatory effect of BMP-2 on the number of osteoblasts often was reduced in the brief exposure model. In the brief exposure model, BMP2-induced bone resorption was no longer evident at the end of organ culture (day 7) although it was still enhanced on day 4. Using this brief exposure model, we examined the roles of ERK and p38 kinase in the osteogenic action of BMP-2. The stimulatory effect of 500 ng/ml BMP-2 on total bone area was almost completely blunted in the presence of 1 μM U-0126 (MEK inhibitor). Incubation with 1 μM SB-203580 (p38 kinase inhibitor) did not alter the stimulatory effect of BMP-2 on total bone area. Incubation with either U-0126 or SB-203580 alone was without effect on total bone area. This argues against nonspecific inhibitory effects of U-0126 on bone formation. Similar results were obtained when calvaria were incubated with 30 μM PD-98059, another MEK inhibitor. In contrast, bone resorption stimulated by BMP-2 was not altered either by MEK or p38 inhibitors when examined on day 4, suggesting differences in BMP2-induced signaling pathways responsible for bone formation and resorption. We conclude that ERK activation, but not p38 activation, is involved in BMP2-induced bone formation but not resorption in this organ culture model.

Role of SFRP-1 in the Osteogenic Effects of BMP-2. S. Fukayama[1], J. M. Owens[1], P. V. N. Bodine[2], J. M. Wozney[1]. [1]Women's Health and Bone, Wyeth Research, Cambridge, MA, USA, [2]Women's Health and Bone, Wyeth Research, Collegeville, PA, USA.

Several recent lines of evidence suggest that Wnt(s) are involved in the action of bone morphogenetic protein (BMP)-2. Secreted frizzled-related protein (SFRP)-1, a secreted receptor for Wnt(s), binds Wnt(s) and modulates their action. In immortalized human osteoblastic HOB cells, BMP-2 down-regulates expression of SFRP-1. SFRP-1 knockout (KO) mice (C57B/6J) exhibit increased trabecular bone density, increased osteoblast differentiation and mineralization, and decreased apoptosis of osteoblasts and osteocytes. Deletion of the SFRP-1 gene also stimulates osteoclast (OC) differentiation from bone marrow progenitor cells *in vitro*. Using a neonatal mouse calvaria organ culture assay, we have examined the possible functional role of SFRP-1 in the action of BMP-2. We used calvaria harvested from 32 littermates [14 wild-type (WT) and 18 KO]. In control (WT) calvaria, treatment with 500 ng/ml BMP-2 significantly increased the total bone area and number of osteoblasts in 9 of 14 littermates by up to 30-40% and 100%, respectively. BMP-2 also stimulated cartilage formation in the peripheral region of the calvaria in all the littermates examined. Total bone area in the control groups was not significantly different between WT and SFRP-1 KO. In calvaria harvested from SFRP-1 KO mice, the increase in total bone area by BMP-2 was largely blunted in 17 of 18 littermates, although the stimulatory effect on the number of osteoblasts in 14 of 18 littermates and cartilage formation in all littermates were not altered. However, histological analysis revealed that bone remodeling (both bone formation and resorption) stimulated by BMP-2 was enhanced in SFRP-1 KO calvaria. This suggests that the lack of a stimulatory effect of BMP-2 on total bone area may be due to accentuation (rather than loss) of the BMP-2 effects in SFRP-1 KO calvaria since bone remodeling was increased. Finally, there was no significant effect of BMP-2 on OC differentiation or activation in either WT or SFRP-1 KO bone marrow cells. Our findings are most consistent with the hypothesis that the osteogenic effect of BMP-2 involves, at least in part, up-regulation of Wnt(s) signaling, via down-regulation of SFRP-1.

δEF1 Represses BMP-2-induced Osteoblast Differentiation of C2C12 Cells. S. Yang*[1], M. Petrey*[2], P. Stevens*[2], N. Jaiswal*[2], D. Chai*[1], H. Yang*[1], T. Zhu*[1], X. Ji[2], G. Sabatakos[2]. [1]Nankai University Medical College, Tianjin, China, [2]Skeletal Research, Procter and Gamble Pharmaceuticals, Mason, OH, USA.

Osteoblasts are derived from mesenchymal precursor cells which acquire their phenotype following distinct stages of proliferation, maturation and mineralization. In an attempt to identify novel regulators of osteoblast differentiation, human mesenchymal stromal cells were subjected to osteoblastic differentiation in the presence of BMP-2 and the expression profile of regulated genes was analyzed by READS analysis. δEF1, a member of the zinc finger-homeodomain family was identified in this manner as a repressor of osteoblast differentiation as its expression was downregulated in time courses in response to BMP-2. Since deletion of δEF1 in vivo resulted in profound skeletal effects, we sought to elucidate the molecular mechanism by which δEF1 regulates osteoblast differentiation. For this purpose, δEF1 or mutants lacking the C- or N-terminal zinc finger domains were stably transfected in C2C12 cells and their effect was analyzed in response to BMP-2. Overexpression of δEF1 or the truncated mutants resulted in a decrease in the mRNA levels of early osteoblast marker genes including osterix and collagen type I. This inhibitory effect was further confirmed by decreased alkaline phosphatase activity levels in cells overexpressing all δEF1 proteins, suggesting that neither of the zinc finger domains is critical for δEF1 function in osteoblast differentiation. In an effort to determine whether the repressive function of δEF1 was mediated via interactions with the Smad transcriptions factors, we performed co-immunoprecipitation studies with Smad1, Smad6 and Smad4 in the presence of BMPRIA. Neither δEF1 nor the zinc finger domain mutants were able to interact with any of the Smad factors analyzed. However, it was observed that Smad1 protein levels were downregulated in cells co-transfected with δEF1. In order to identify additional pathways that are regulated by δEF1, stable cell lines overexpressing δEF1 were co-transfected with constructs containing a variety of promoter elements and their responses were analyzed using the Mercury Pathway Profiling System. Consistent with its role as an inhibitor of osteoblast differentiation, δEF1 overexpression resulted in the downregulation of AP-1 responses in response to BMP-2. In contrast, in similar time courses the NFkB, NFAT and HSE pathway responses were significantly increased, suggesting that the effect of δEF1 in osteoblast differentiation could be mediated via these pathways. In conclusion δEF1 is a potent inhibitor of osteoblast differentiation that functions by differentially regulating a variety of essential signaling pathways.

Plasma Amino-Terminal proCNP: A Putative Marker of Growth Plate Activity. T. C. R. Prickett*[1], G. K. Barrell*[2], M. Wellby*[2], A. M. Lynn*[3], R. J. Kaaja*[4], V. A. Cameron*[1], E. A. Espiner*[1], A. M. Richards*[1], T. G. Yandle*[1]. [1]Department of Medicine, Christchurch School of Medicine & Health Sciences, Christchurch, New Zealand, [2]Animal & Food Sciences Division, Lincoln University, Canterbury, New Zealand, [3]Department of Pediatrics, Christchurch Hospital, Christchurch, New Zealand, [4]Department of Obstetrics and Gynecology, Helsinki University, Helsinki, Finland.

Recent evidence from rodents and humans shows that C-type natriuretic peptide (CNP) plays an essential role in endochondral bone growth. Like other members of the natriuretic peptide family, the biologically active (carboxy-terminal) forms of CNP are processed from a precursor (proCNP), and are subject to rapid degradation by clearance receptors (NPR-C) and enzyme hydrolysis. We have recently identified a stable product of proCNP, amino-terminal proCNP (NT-proCNP), which unlike CNP is readily measurable in human and ovine plasma. Further, despite reports of low CNP gene expression (and peptide levels) in growth plates, we have identified NT-proCNP in growth plate tissues of lambs at concentrations exceeding those in plasma. Hypothesising that plasma NT-proCNP concentrations reflect in part CNP synthesis within growth plates of rapidly growing cartilage, we have studied levels of CNP forms in both children and growing lambs and related these to age, growth velocity and biochemical markers of bone turnover.

NT-proCNP concentration (RIA) in umbilical venous plasma (246 ± 17 pmol/L, mean ± sem, n=13) greatly exceeded levels in children aged 5-18y (46.6 ± 1.7 pmol/L, n=58) and fully mature adults aged 20-80y (19.2 ± 0.4 pmol/L, n=117). Highly significant positive associations were found in children between plasma NT-proCNP and height velocity ($r=0.57$, $p<0.005$), alkaline phosphatase (ALP) ($r=0.55$, $p<0.001$) and Type 1 collagen C telopeptide ($r=0.33$, $p<0.013$). Plasma NT-proCNP concentrations were 10-50 fold those of CNP irrespective of age. In longitudinal animal studies, elevated plasma concentration of NT-proCNP in 1 week old lambs (61.7 ± 1.9 pmol/L, n=24) fell progressively to mature adult levels (26.7 ± 0.9 pmol/L, $p<0.001$) at age 27 weeks. Plasma NT-proCNP showed a highly significant positive association with ALP ($r=0.94$, $p<0.001$) and metacarpal growth velocity ($r=0.55$, $p<0.001$). Glucocorticoids (dexamethasone 0.25mg/kg/d for 15 days) - a treatment known to inhibit cartilage proliferation - reduced metacarpal growth elongation ($P<0.001$) in 4 week old lambs and markedly lowered circulating NT-proCNP levels ($p<0.001$).

In summary, NT-proCNP levels in blood show a strong association with growth velocity and markers of bone formation and may well serve as a useful marker of growth plate activity in humans and other mammals.

Canonical Wnt Signaling Promotes Chondrogenic Differentiation and Hypertrophy. F. Yano*[1], S. Ohba*[1], F. Kugimiya*[1], T. Ikeda[1], N. Ogata[1], T. Ogasawara[1], T. Takato*[1], K. Nakamura[2], H. Kawaguchi[2], U. Chung[1]. [1]Tissue Engineering, University of Tokyo, Tokyo, Japan, [2]Orthopaedic Surgery, University of Tokyo, Tokyo, Japan.

Although several pieces of evidence in mouse genomics have implicated the involvement of Wnt signaling pathways in cartilage development, its direct action remains unknown. To better understand the role of the canonical Wnt pathway in cartilage development, we constructed adenoviral vectors expressing a constitutively active form (ca) and a dominant negative form (dn) of T-cell factor/lymphoid enhancer factor-1 (TCF/LEF-1), the main nuclear effecter of the pathway. To analyze its effect on chondrogenic differentiation, we transfected undifferentiated mesenchymal cell line C3H10T1/2 with caTCF/LEF-1 or dnTCF/LEF-1, and examined early differentiation markers of cartilage such as type II collagen, aggrecan and chondromodulin-1 by real-time RT-PCR analysis. caTCF/LEF-1 induced expression of these markers, and treatment with LiCl, an activator of the canonical Wnt pathway by inhibiting GSK3ß, also up-regulated them. In contrast, dnTCF/LEF-1 down-regulated the markers, and silencing of ß-catenin, an essential signaling molecule of the canonical Wnt pathway, through RNA interference also suppressed them. We further investigated the role of the pathway in hypertrophic differentiation of chondrocytes using a three-dimensional culture of mouse embryo rib chondrocytes. caTCF/LEF-1 induced expression of type X collagen, a marker of hypertrophy, whereas dnTCF/LEF-1 suppressed it. These results suggest that the canonical Wnt pathway promotes cartilage development at both early and late stages.

Growth Factors Capable of Suppressing Chondrocyte Hypertrophy Arrest Collagen Cleavage in Human Osteoarthritic Cartilage. E. V. Tchetina*, A. R. Poole. Joint Diseases Laboratory, Shriners Hospitals for Children, McGill University, Departments of Surgery and Medicine, Montreal, PQ, Canada.

Articular cartilage degeneration in idiopathic osteoarthritis (OA) involves excessive degradation of extracellular matrix, including type II collagen and aggrecan. It is also characterized by chondrocyte differentiation (hypertrophy). We hypothesised that destruction of the collagen network in OA involves mechanisms that include chondrocyte terminal dif-

ferentiation. If this hypothesis is correct, collagen degradation in OA may be inhibitable by agents that suppress hypertrophy. We show in cultured explants of human OA articular cartilage that collagenase-mediated collagen cleavage measured by ELISA is downregulated in about half the cases by the combined action of the growth factors TGFbeta2, FGF-2 and insulin. These have previously been shown to suppress hypertrophy, maintaining a prehypertrophic phenotype. Examination by semi-quantitative RT-PCR of the expression profiles of genes involved in chondrocyte differentiation revealed that the decrease in collagen cleavage induced by these growth factors was accompanied by the downregulation of terminal differentiation related genes namely, COL10A1, MMP-13, MMP-9, Indian hedgehog, caspase 3, as well downregulation of genes related to early chondrocyte differentiation (proliferation) such as TGFbeta2, PTHrP, FGF-2, cyclin B2. Downregulation of the cytokines IL-1beta and TNFalpha was also observed. In contrast the expression of aggrecan and TGFbeta1 was upregulated. The analysis of the effect of individual growth factors on collagen cleavage showed two types of response. In some OA articular cartilage explants FGF-2 or insulin did not downregulate collagen cleavage activity. In contrast TGFbeta2 downregulated collagen cleavage activity in all OA cartilage explants tested and is likely to be most potent molecule that can suppress type II collagen cleavage. These observations suggest that chondrocyte differentiation may play a role in cartilage collagen resorption in OA and that a combination of growth factors described above or TGFbeta2 alone can suppress cartilage matrix damage.

Estrogen Receptor-Related Receptor Alpha, ERRa, Regulates Cartilage Formation and Is dysregulated in Inflammatory Arthritis. E. Bonnelye[1], N. Laurin*[1], P. Jurdic[2], D. Hart*[3], J. Aubin[1]. [1]Department of Molecular and Medical Genetics, University of Toronto, Toronto, ON, Canada, [2]Laboratoire de Biologie Moleculaire et cellulaire, Ecole Normale Superieure de Lyon, Lyon, France, [3]Department of Surgery, McCaig Center for Joint Injury and Arthritis Research, University of Calgary, Calgary, AB, Canada.

The estrogen receptor related receptor alpha, ERRa, has been shown to be expressed by osteoblasts and play a functional role in bone formation. We now report the expression of ERRa in fetal and adult rat chondrocytes in growth plate and articular cartilage and the rat chondrogenic cell line C5.18 cells in vitro. ERRa mRNA and protein were expressed from proliferating chondrocytes to mature chondrocytes with the exception of fetal hypertrophic chondrocytes. To assess a functional role for ERRa in chondrocyte proliferation and differentiation, we blocked its expression by antisense oligonucleotides in C5.18 cell cultures and found significant inhibition of cell growth with concomitant downregulation of Sox9 and Ihh (Indian Hedgehog), both master genes in cartilage formation and cyclinD1, a cell cycle marker. We also found a proliferation-independant inhibition of cartilage formation and accelerated maturation of proliferating chondrocytes into hypertrophic chondrocytes in vitro. Semi-quantification of expression of cartilage markers showed a dramatic decrease in expression of Sox9, Ihh, Aggrecan, Link, and Col2a1 compared to control. Consistent with the decrease of Sox9 and Ihh, the hypertrophic chondrocyte markers Col10a1 and PTHrP receptor increased and the anti-apoptotic marker Bcl2 decreased. We therefore next asked whether ERRa dysregulation may play a role in conditions in which cartilage integrity is lost such as joints undergoing destruction as seen in inflammatory arthritis. Erosive arthritis was induced by injection of type II collagen into the joints of DBA-1 mice. Semi-quantitative RT-PCR of RNA from joints 7 weeks after injection revealed a dramatic decrease in expression of ERRa and mature chondrocyte markers; the decreases were even more striking when mice were boosted 5 weeks after the first injection. Notably, expression of ERRa and markers of bone formation was also decreased in the subchondral bone of the same treated mice. Taken together, these results suggest that ERRa plays a role in cartilage formation and integrity with a functional role in maturation of proliferating chondrocytes into hypertrophic chondrocytes. They also suggest that agonists and antagonists of ERRa may be useful as therapeutic agents in a wide variety of bone and cartilage metabolic and other diseases affecting these two tissues.

M025

ATF-2 Directs BCL-2 Expression in the Growth Plate. Q. Ma*[1], M. L. Brown*[1], Y. Li*[2], F. Beier*[3], P. LuValle[1]. [1]Anatomy and Cell Biology, University of Florida, Gainesville, FL, USA, [2]University of Calgary, Calgary, AB, Canada, [3]University of Western Ontario, London, ON, Canada.

Activating transcription factor-2 (ATF-2) is expressed ubiquitously, but in the endochondral growth plate it is restricted to chondrocytes in the resting and proliferating zones. Mice that are deficient in ATF-2 demonstrate ataxia, hyperactivity, diminished hearing and a hypochondroplasia-like dwarfism characterized by shortened limbs and disorganized growth plates. ATF-2 targets the cyclic AMP response element (CRE) in several genes in growth plate chondrocytes, including cyclin D1, cyclin A, pRb, p107, p130, c-fos, and c-jun in order to activate their expression. Bcl-2, an inhibitor of cell death that functions in the regulation of apoptosis, is also targeted by ATF-2. The bcl-2 promoter contains a CRE at approximately 1550bp upstream of the translation start. Bcl-2 is expressed within the growth plate in proliferative and prehypertrophic chondrocytes, but its expression is decreased in hypertrophic chondrocytes (Amling; et al. J Cell Biol. 134: 205-213, 1997). We employed western blot analyses, transient transfection assay, immunohistochemistry, in situ hybridization and apoptosis assay (TUNEL) to determine the consequences of ATF-2 deficiency on bcl-2 expression and activity. Bcl-2 protein levels and promoter activity are significantly reduced (~ 50%) in growth plate chondrocytes from ATF-2 deficient mice. Bax/Bcl-2 ratios in growth plate chondrocytes are increased in the absence of ATF-2. The growth plates themselves display a severely truncated hypertrophic zone, consisting of only one or two layers of hypertrophic chondrocytes. The number of hypertrphic chondrocytes expressing type X collagen in ATF-2 deficient mice growth plates is less than in wild type mice. Apoptotic activity is significantly increased in the few hypertrophic-appearing chondrocytes of these mice. One possibility for this interesting phenotype is that the hypertrophic chondrocytes are undergoing apoptosis prior to their complete maturation. These results suggest that bcl-2 expression and activity in the growth plate requires optimal ATF-2 expression and activation, in order to provide adequate longitudinal growth and endochondral ossification.

EphrinB2, an Arterial Endothelial Cell Marker, Is Expressed in Avascular Chondrocyte and Is Regulated by Sp1. N. Hosogane*[1], T. Miyamoto[2], M. Yagi*[1], N. Fujita*[1], Y. Toyama*[1], T. Suda*[2]. [1]Orthopaedics, Keio University School of Medicie, Shinjuku-ku, Japan, [2]Department of Cell Differentiation The Sakaguchi Laboratory, Keio University School of Medicie, Shinjuku-ku, Japan.

EphrinB2 is a transmembrane ligand for Eph receptor tyrosine kinases. They are presumed to regulate cell-cell interactions, and the major consequence of activation of Eph receptors and ephrin ligands is cell repulsion. EphrinB2 is specifically expressed in arterial endothelial cells and is known to be involved in angiogenesis. Mice deficient for ephrinB2 die at E9.5 with severe cardiovascular defect. Recently, by using ephrinB2 LacZ knock-in mice, we found that ephrinB2 is expressed in proliferating chondrocyte in the developing stage, where vascularization does not occur. EphrinB2 expression is promoted by Notch1 in arterial endothelial cells, however, the constitutive active Notch1 and adeno-Notch1-IC did not stimulate ephrinB2 expression in chondrogenic cell line ATDC5. Thus, we analyzed the regulatory elements of its promoter by luciferase assay to elucidate the regulatory mechanisms of ephrinB2 expression using ATDC5. First, the transcriptional start site was determined by primer extension method, and it was located at 628bp up-stream of ATG start codon and 31bp down-stream of TATA box.

Deletion mutants of the promoter containing 5'UTR region were fused to promoter-less firefly luciferase gene. The -107/+629 fragment was required for maximum promoter activity which contained two CCAAT boxes and a specificity protein 1(Sp1) site. The luciferase activity reduced to 40% when two CCAAT boxes were deleted(-56/+629), and to basal level by further deleting Sp1 site(-42/+629). Also, we found that the co-localized expression of ephrinB2 and Sp1 in chondrocytes of E17.5 embryo by immunohistochemical studies. These results indicate that Sp1 is involved in the expression of ephrinB2 in chondrocytes.

Nuclear factor Y(NFY), which can also bind to CCAAT box, up-regulated the promoter activity when three isoforms(A, B and C) were co-transfected together. Moreover, NFYs and Sp1 synergistically up-regulated the promoter activity. Thus, NFY and Sp1 coordinately regulate the expression of ephrinB2 in chondrocytes.

To elucidate the function of ephrinB2 in chondrocytes in vivo, we are now generating chondrocyte specific deletion mice using typeXI collagen-Cre transgenic mice and ephrinB2 loxP mice. This chondrocyte specific ephrinB2 deficient mice will clarify the function of ephrinB2 on the regulation of angiogenesis in chondrocytes.

Characterization of Growth Plate Abnormalities in Rachitic Mouse Models. Y. Sabbagh[1], T. O. Carpenter[2], M. Demay[1]. [1]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, [2]Department of Pediatrics, Yale University, New Haven, CT, USA.

Rickets is seen in association with vitamin D deficiency and vitamin D receptor (VDR) mutations, suggesting that the actions of vitamin D are required for a normal growth plate. Studies in VDR null mice have demonstrated that the expansion of the late hypertrophic chondrocyte layer, characteristic of rickets, is secondary to impaired apoptosis of these cells. Since mutations in the VDR or vitamin D deficiency lead to hypocalcemia, hypophosphatemia and secondary hyperparathyroidism, the underlying pathogenesis of the impaired apoptosis and subsequent rachitic changes is uncertain. The observation that normalization of mineral ion homeostasis in VDR null mice normalizes PTH levels and prevents rachitic changes, suggests that rickets is secondary to hypocalcemia, hypophosphatemia or hyperparathyroidism, rather than impaired VDR action. To determine which of these abnormalities leads to impaired chondrocyte apoptosis and subsequent rachitic changes, two additional models were examined: diet induced hypophosphatemia and hypophosphatemia secondary to mutations in the Phex gene. The former model is associated with hypercalcemia and suppressed PTH levels as a consequence of elevated levels of 1,25-dihydroxyvitamin D. The latter model demonstrates normal calcium and PTH levels, but 1,25-dihydroxyvitamin D levels that are inappropriately low for the degree of hypophosphatemia.

Histological sections of the tibial growth plate were examined in mice fed chow and littermates fed a phosphorus restricted (0.02%) diet from day 18 to 24, as well as from 24 day old mice with mutations in the Phex gene (Hyp mice) and their wild type littermates. For evaluation of chondrocyte apoptosis, TUNEL staining was performed on adjacent tissue sections. Our studies demonstrate that hypophosphatemia, regardless of circulating PTH, 1,25-dihydroxyvitamin D, or calcium levels, leads to a rachitic growth plate secondary to impaired apoptosis of the hypertrophic chondrocytes. These data demonstrate that normal phosphorus levels are required for growth plate maturation and implicate a critical role for a phosphorus regulated apoptotic signaling pathway in endochondral bone formation.

Wnt Expression Induces Chondrocyte Maturation through β-Catenin-mediated Signaling: Modulation by TGF-β. Y. Dong, M. Chen*, M. J. Zuscik, D. Chen, E. M. Schwarz, R. N. Rosier, H. Drissi, R. J. O'Keefe. Orthopeadics, University of Rochester, Rochester, NY, USA.

Wnt secreted factors are expressed during limb morphogenesis yet their role and mechanism of action remains unclear during cartilage development. We used a chick embryonic cell culture model to assess the role of Wnt expression and signaling and its interaction with TGF-β during chondrocyte differentiation. Several wnt transcripts, including *wnt4*, *wnt8* and *wnt9a* were upregulated during the spontaneous differentiation of chick embryonic sternal chondrocytes in cell culture, while *wnt5a*, expression was slightly increased. TGF-β, which blocks chondrocyte maturation, inhibited the increase in *wnt* expression. Over-expression of β-catenin, Wnt8 and Wnt9a stimulated the expression of the chondrocyte maturation specific genes, *colX* and *alkaline phosphatase*, while Wnt5a inhibited expression of these markers. We found that activation of the β-catenin pathway potently enhanced chondrocyte maturation while wnt-mediated activation of calcium pathways repressed differentiation. Over-expression of β-catenin and/or its nuclear co-factor TCF/LEF caused a 20-30 fold induction of transcription of the ABC-640 chick type X collagen promoter. Induction of this promoter by β-catenin signaling was dramatically repressed by TGF-β indicating a cross talk between TGF-β and the β-catenin-dependant Wnt signaling pathways. TGF-β also inhibited β-catenin mediated induction of *colX*. To further assess the effect of TGF-β on TCF/LEF-β-Catenin signaling transfection assays were performed using the β-catenin/TCF/LEF-responsive reporter, Topflash. TGF-β blocked Topflash induction in chondrocytes transfected with β-catenin and/or TCF/LEF, indicating a direct inhibition of the β-catenin transcriptional complex. Potential interactions between Smad signaling and -β-catenin was investigated by immunoprecipitation, which showed co-immunoprecipitation of β-catenin with Smad3, with an increase observed with activation of β-catenin or TGF-β signaling. Altogether we demonstrate that Wnt/β-catenin signaling induces chondrocyte maturation, but is modified by activation of TGF-β/Smad signaling.

High-Throughput Modelling Of Bone Disease In Zebrafish. A. Fleming*, P. Goldsmith*. DanioLabs Ltd, Cambridge, United Kingdom.

The optical clarity, speed of development, and fecundity of zebrafish have made them a popular vertebrate model for the study of developmental biology and more recently as an animal model to study disease processes. Larval stages are viable in 96-well plates for the first 10 days of life and the optical clarity of the tissue at these stages allows the use of vital dyes to mark discrete tissues and observe disease changes in the living animals and in post-mortem studies. The entire skeleton of the zebrafish larva can be visualized *in vivo* by the administration of a fluorescent dye such as calcein and tetracycline to the embryo medium or on fixed tissue using alizarin red. Staining not only provides a rapid method for visualizing the skeleton but also allows measurement of the labeled area or the intensity of staining in particular elements that can then be used to quantify bone size and density. Having optimized staining protocols for skeletal analysis in zebrafish larvae, we examined whether we could induce and detect bone loss in zebrafish larvae by administration of the glucocorticoid prednisolone. When exposed to 30 uM prednisolone from 5 d.p.f. to 10 d.p.f., staining in the head skeleton is markedly reduced compared to control (untreated) samples of the same age. Using digital image analysis, we have measured the amount of stained, mineralized tissue to quantify the OP-inducing effects of prednisolone at a range of doses. A dose-dependent decrease in the amount of stained tissue was observed with increasing doses of prednisolone, with statistically significant changes observed at 3, 10 and 30 uM (24%, 36% and 49% decrease in stained area, respectively). This bone loss is partially rescued in a dose-dependent manner by co-administration with etidronate. These staining and quantification methods can also be applied to anabolic bone agents to determine the relative anabolic effects of compounds. In the zebrafish larva, we have detected statistically significant anabolic bone effects with estradiol, PTH and calcitriol. We are now performing compound screens in 96 well plate format to identify novel compounds for both the rescue and prevention of bone loss.

Fibrin-sealant Thrombin Promotes Proliferation, Cytosolic Ca^{2+} Elevation and Survival of Human Chondrocytes via Activation of Protease-Activated Receptors. M. Zheng[1], R. Han*[2], L. Kirilak*[2], N. Asokananthan*[3], G. Stewart*[3], A. J. Bakker*[3], P. Henry*[4], D. Wood[1]. [1]Orthopaedic Surgery, University of Western Australia, Perth, Australia, [2]University of Western Australia, Perth, Australia, [3]Department of Microbiology, University of Western Australia, Perth, Australia, [4]Pharmacology, University of Western Australia, Perth, Australia.

Fibrin sealants have recently been recommended to be used as tissue glue for autologous chondrocyte implantation. However, it is not clear that the effect of fibrin sealants on the proliferation and migration of human chondrocytes. In this study, we investigated the possible inovlvement of protease-activated receptors in the effect of fibrin sealant thrombin on the proliferation and migration of human chondrocytes. Thrombin at a concentration ranged from 0.11 to U/ml to 1 U/ml was shown to signifigantly promote proliferation of human chonrocytes in vitro. The maximum effect on stimulating proliferation was achieved at a concentration of 0.5 U/ml of thrombin. Fibrin glue (thrombin) also promoted migration of human chondrocytes co-cultured with collagen membrane from the membrane to fibrin glue within two weeks. Many of thrombin effects have been attributed to activation of protease-activated receptors (PARS). In this study, we also found that PAR-1 through PAR-4 were expressed by human chondrocytes. Thrombin and PAR-1 agonist peptide induced a fast intracellular Ca2+ response in human condrocytes. Taken together, these data suggest thrombin promotes proliferation and migration of human chondrocytes at least in part by stimulating PAR-1

Repression of Glycogen Synthase Kinase Inhibits Chondrocyte and Perichondrial Osteoblast Differentiation. R. Kapadia*, M. C. Naski. Pathology, University of Texas Health Science San Antonio, San Antonio, TX, USA.

Glycogen synthase kinase 3 (GSK3) is an essential regulator of cell differentiation in diverse organisms and cell-types. Unlike many kinases, GSK3 has constitutive enzymic activity that is regulated by repressor pathways. To understand how the regulation of GSK3 influences osteoblast and chondrocyte differentiation, we inhibited GSK3 in mouse metatarsal bone rudiments using the specific inhibitors, lithium and SB216763. Repression of GSK3 caused a dramatic inhibition of both chondrocyte and perichondrial osteoblast differentiation. Chondrocyte differentiation was completely inhibited as evidenced, by 1) a histological absence of hypertrophic chondrocytes and 2) dramatic repression of chondrocyte-specific gene expression including type II collagen and aggrecan. The differentiation of perichondrial osteoblasts was also repressed as demonstrated by the absence osteoid synthesis and diminished assembly of a chain of terminally differentiated osteoblasts linked via adherens junctions. Interestingly, inhibition of GSK3 caused a reduction in chondrocyte proliferation, whereas perichondrial cell proliferation was increased. The effects of GSK inhibition were accompanied by an increase in the expression of fibroblast growth factors (FGFs). Significantly, the effects of GSK3 inhibition on chondrocytes and osteoblasts were phenocopied by treatment of metatarsals with FGF. These results indicate that GSK is an important regulator of FGF expression and that effects of GSK3 on bone and cartilage cells may be mediated by FGFs.

Maturation of the Epiphyseal Chondrocyte:Survival-Death Decisions at the HIF-PHD Axis. S. P. Terkhorn*, M. Ohashi*, C. S. Adams, I. M. Shapiro, V. Srinivas*. Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

During long bone growth, activated chondrocytes undergo a series of temporal and spatial changes that lead to hypertrophy and the induction of the terminally differentiated phenotype. Since the cartilage is avascular, it is hypothesized that the low pO_2 induces apoptosis of the hypertrophic chondrocytes. Indeed, previous studies have shown that the transcription factor, HIF-1 is required for cell survival in this oxygen limited microenvironment. The purpose of this study was to examine the impact of the environmental pO_2 on HIF expression and chondrocyte apoptosis. N1511 chondrocytes were cultured under hypoxic conditions and subsequently challenged with either staurosporin or FasL. Surprisingly, at low pO_2, the cells were refractory to staurosporin-mediated apoptosis. In contrast, almost 100% of the cells were killed when challenged with 50 nM FasL under hypoxic conditions. We noted that in 2% pO_2 there was upregulation of Fas receptor expression. To examine the mechanism of sensitization, we evaluated by Western blot and RT-PCR analysis the expression of both pro- and anti-apoptotic members of the Bcl-2 gene family. We noted enhanced Bcl2 and Nip3 expression was temporally correlated with the downregulation of survival signals in terminally differentiated chondrocytes. To further explore the O_2 sensitivity to apoptosis, we modulated the expression of the cellular PHD oxygen sensors using siRNA technology. Down regulation of the PHDs resulted in an increased resistance to staurosporin-mediated apoptosis. This observation lends support to our hypothesis that inhibition of apoptosis at low pO_2 is mediated by the HIF signaling pathway. Once growth plate cells are terminally differentiated, the hypoxic chondrocytes are highly sensitized to FasL mediated apoptosis. Based on these observations, we suggest that the rise in pO_2 that accompanies the invasion of vascular elements in the growth plate, serves to increase the sensitivity of terminally differentiated chondrocytes to apoptogens such as FasL.

Post-irradiation Recovery of Growth Plate Function Is Driven by Expansions of Regenerative Clones. J. A. Horton, B. S. Margulies*, J. A. Strauss*, T. A. Damron*, J. A. Spadaro. Orthopedic Surgery, SUNY Upstate Medical University, Syracuse, NY, USA.

Radiation therapy used to treat pediatric malignancies may result in a disruption in the progression of chondrocytes through proliferation and maturation in the growth plate, which can impact longitudinal growth. In the present study we compare growth plate cell-cycle kinetics between the normal and irradiated growth plates following their functional and morphologic nadir until the appearance of regenerative clones. We hypothesize that growth rate, while initially reduced in the irradiated limb, would partially recover, and correlates with the expansion in size and number of the regenerative clones.Under IACUC approval, the right knees of 27 weanling male rats were exposed to a 17.5 Gy X-ray exposure, with the left limb used as an internal control. Six days following treatment animals were injected with oxytetracycline (OTC). On day seven bromodeoxyuridine (BrdU) was injected. Proximal tibiae were sampled 1,2, 4, 12, 24, 48, 72, 96, and 120 hours following BrdU injections and prepared for histomorphometry. Indices of BrDU labeling, matrix area fraction (Aa), growth plate zonal height, and numeric density of clones (Nv) were calculated from digital images at 10x magnification. Analysis of BrdU indices revealed one mitotic cycle per 24-48 hours in the normal

growth plate. After irradiation there were fewer BrdU positive proliferative cells in irradiated tibiae; however, they were cycling at the same rate as the cells in unirradiated growth plates. The label progresses through the strata, peaking in the transitional and hypertrophic zones of both tibiae at 72 and 96 hours, respectively. Nv increased at a rate of $2x10^{-4}$ clones/mm^3/day (R^2=0.94), and Aa decreased in the proliferative, transitional, and hypertrophic zone during this period. Increases in Nv were correlated (R^2=0.92) to increases in daily growth by OTC labeling. Growth in the unirradiated limb proceeded at a constant rate within the period observed.

In previous work, irradiation of the growth plate lead to cell death and accelerated maturation of proliferative chondrocytes. In the present study proliferating cells were lost at a faster rate than they were replenished, thus fewer cells were available to progress into hypertrophy resulting in the observed growth arrest. The lack of differences in reserve zone BrDU labeling between normal and irradiated limbs suggests that this population of slowly cycling relatively radio-resistant cells may seed the proliferative zone with progenitor cells that expand to become regenerative clones. Thus, restoration of the proliferative pool via expansion of regenerative clones appears to initiate functional recovery in the irradiated growth plate.

Impaired Fracture Healing in Diabetes May Be Due To Enhanced Chondro/osteoclast Activity. D. V. Tsatsas*[1], K. Wang*[2], C. Edgar*[2], C. Leone*[1], L. C. Gerstenfeld*[2], D. T. Graves[1]. [1]Department of Periodontology and Oral Biology, Boston University School of Dental Medicine, Boston, MA, USA, [2]Orthopedic Surgery Research Laboratory, Boston University Medical Center, Boston, MA, USA.

Patients with diabetes type I exhibit significant problems with fracture healing due to delayed or inadequate bone formation. We investigated fracture repair in a mouse model examining several histomorphometric endpoints. The underlying hypothesis was that alterations in cartilage lead to subsequent deficits in bone formation associated with diabetes. In the experimental group mice were rendered diabetic by multiple low dose streptozotocin treatment, which induces diabetes via an autoimmune response in the pancreas. Results were compared to a control group that was treated with vehicle alone, citrate buffer. Closed simple standardized tibial fractures were generated by blunt trauma and mice were sacrificed at 12, 16 and 22 days post-fracture. Samples were prepared for histomorphometric analysis. The area of new bone and cartilage formation and number of chondro/osteoclasts were determined using Van Gieson, saffranin-O and TRAP staining, respectively. New bone formation in the diabetic group was significantly less on day 12 and 22 compared to non-diabetic controls ($p<0.05$). The area of cartilage was similar on day 12 but was reduced ~50% in the diabetic compared to normoglycemic group by day 16 and absent from both groups on day 22. This coincided with chondro/osteoclast numbers on days 12 and 16 that were significantly higher in the diabetic group ($p<0.05$). These results indicate that diabetes may affect fracture healing by increased formation of chondro/osteoclasts that cause more rapid removal of cartilage thereby impairing the ultimate formation of bone within the healing callus. Supported in part by DE11254 and AR47045.

Negative Regulation of TGF-β Signaling by Smurf2 in Growth Plate Chondrocytes. M. K. Mulcahey*, M. Pirri*, Y. Dong*, Q. Wu, E. M. Schwarz, J. E. Puzas, R. J. O'Keefe, H. Drissi, R. N. Rosier, M. J. Zuscik. Orthopaedics, University of Rochester, Rochester, NY, USA.

Growth plate chondrocyte (GPC) differentiation involves a series of maturational events that are tightly regulated by several factors including TGF-β, a potent suppressor of hypertrophic differentiation. The signaling mechanisms that facilitate this suppressive function of TGF-β include phosphorylation of Smad proteins (Smads 2 and 3) which directly, or in concert with other transcription factors, affect target gene expression. Negative regulation of these signaling events occurs via several mechanisms including the Smad ubiquitin regulatory factor-2 (Smurf2), an E3 ubiquitin ligase which is known to promote degradation of Smad2 by the proteasome. Based on the ability of Smurf2 to block Smad2/TGF-β signaling, we hypothesize that it acts to relieve the suppressive constraint of the TGF-β pathway on GPC maturation, thereby inducing progression of these cells toward terminal maturation. We tested this hypothesis by performing Smurf2 gain of function experiments in GPCs to assess the signaling and phenotypic impact of this gene. To establish that Smurf2 inhibits Smad2/TGF-β signaling, we performed Western analyses to measure ubiquitination of Smad2 along with P3TP promoter-luciferase reporter assays to assess TGF-β signaling. Western analyses of ubiquitinated Smad2 in empty vector- and Smurf2-transfected cells indicated that Smurf2 enhanced ubiquitination of endogenous Smad2. This degradative effect was even more pronounced in cells treated with 5 ng/ml TGF-β. Corellating with these findings, TGF-β signaling on the P3TP reporter was reduced in cells transfected with Smurf2. Having confirmed the function of this gene in GPCs from a signaling perspective, we proceeded to assess the effect of Smurf2 overexpression on chondrocyte phenotype. As expected, Smurf2-transfected cells displayed a more hypertropic phenotype based on increased expression of type X collagen and alkaline phosphatase, two markers of chondrocyte hypertrophy. Given the signaling and phenotypic effects of Smurf2 in GPCs, we next examined the regulation of Smurf2 expression by factors that are known to alter GPC phenotype. Of the factors tested, PTHrP, another potent inhibitor of chondrocyte maturation, strongly enhanced expression of Smurf2 mRNA and induced a concommittant decrease in TGF-β signaling on the P3TP reporter. These findings suggest a novel interaction between PTHrP and TGF-β signaling that involves Smurf2-induced degradation of Smad2. This novel interaction may represent an important regulatory mechanism in the progression of GPC maturation.

SP Transcription Factors and Histone Deacetylases Regulate Alpha 2 Type XI Collagen Gene Expression in Saos-2 Human Osteosarcoma-Derived Cells. T. Goto*[1], Y. Matsui*[1], K. Yukata*[1], T. Kubo*[1], H. A. Chansky*[2], L. Yang*[2], D. R. Eyre[2], N. Yasui*[1]. [1]Orthopaedics, The University of Tokushima, Tokushima, Japan, [2]Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, USA.

Type XI collagen, composed of three chains, alpha 1 (XI), alpha 2 (XI) and alpha 3 (XI), is crucial for collagen fibril formation and skeletal morphogenesis. It was previously reported that the mouse alpha 2 (XI) collagen gene (*Col11a2*) is regulated by modular arrangement of cartilage- and neural tissue-specific cis-elements in the promoter region. Several lines of evidence revealed that *Col11a2* is expressed by osteoblastic cells in mice, rats and humans. Although the mechanisms by which *Col11a2* is transactivated in chondroblastic cells have been well documented, those in osteoblastic cells remain unclear. We therefore analyzed Saos-2 cells, osteosarcoma-derived human osteoblastic cells, in which we found the alpha 2 (XI) collagen gene (*COL11A2*) expression. RT-PCR analysis showed that Saos-2 cells expressed a range of splicing variants of *COL11A2*. The mouse *Col11a2* promoter sequence from -742 bp to +380 bp, from the transcriptional start site, was activated in Saos-2 cells when transiently transfected and assayed for luciferase activity. Deletion of cartilage- and neural tissue-specific cis-elements did not affect promoter activity. Further deletion analysis identified a minimum sequence for promoter activity between +133 bp and +380 bp. The evolutionally conserved human *COL11A2* promoter construct H149, containing the sequence from -149 bp to +27 bp, from the transcriptional start site, showed activity in Saos-2 cells. Deletion and mutation analysis of H149 construct revealed that at least two SP1 sites were critical for the promoter activity. Electrophoretic mobility shift assay demonstrated physical interaction between the SP1 sites in the *COL11A2* promoter and SP1/3 proteins in the Saos-2 nuclear extract. Inhibition of the histone deacetylases (HDACs) using trichostatin A enhanced the *COL11A2* promoter activity in Saos-2 cells. This enhancement was abolished when the SP1 sites were mutated, suggesting that the binding of SP1/3 proteins to the *COL11A2* promoter mediated the action of HDACs. Together, our results indicate that *COL11A2* collagen gene is transactivated via functional interaction between SP transcription factors and HDACs in Saos-2 osteoblastic cells.

Temporal Gene Expression Profiles in Cartilage Development. C. James*[1], T. Appleton*[1], V. Ulici*[1], T. M. Underhill[2], F. Beier[1]. [1]Physiology and Pharmacology, CIHR Group in Skeletal Development and Remodeling, University of Western Ontario, London, ON, Canada, [2]Anatomy and Cell Biology, University of British Columbia, Vancouver, BC, Canada.

Endochondral ossification occurs through the coordinated expression of genes that regulate the formation of a cartilaginous template, which is ultimately replaced by bone. Microarray analysis of primary mouse mesenchymal cells undergoing chondrocyte differentiation in high-density micromass cultures was performed using Affymetrix MOE430A arrays containing 14 000 genes. Bioinformatics approaches were employed to characterize temporal gene regulation during cartilage differentiation. Data analysis using Microarray Suite 5.0 algorithms and GeneSpring 6.1® filtering parameters identified approximately 3300 expressed transcripts. Among the expressed probe sets, 1772, 481 and 249 demonstrated minimum two-fold, five-fold and 10-fold changes over a 15-day time course, respectively. The temporal expression patterns of selected markers identified in the array such as Cartilage link protein were confirmed with RT-PCR. Parallel filtering criteria employed in GeneTraffic 3.0® generated similar, albeit reduced numbers of differentially expressed genes. K-means clustering was used to identify pervasive gene expression patterns, namely genes that are either upregulated or downregulated towards the end of the culture period. Functional categorization of the probe sets used in this analysis according to GeneOntology terms revealed differentially expressed growth factors, receptors, transcription factors and extracellular matrix molecules among others.

Several genes identified in these microarray analyses were stably overexpressed in the mouse chondrogenic cell line ATDC5 for functional characterization. Specifically, overexpression of Activating Transcription Factor 3 (ATF-3), a transcriptional repressor that was shown to be upregulated in hypertrophic chondrocytes in our microarrays, results in decreased proliferation and cyclin A promoter activity as well as accelerated differentiation of ATDC5 cells. These data support a role of ATF-3 in cartilage hypertrophy. Similarly, overexpression of various RGS (regulator of G-protein signalling) proteins also accelerates chondrocyte hypertrophy.

The amalgamation of bioinformatics and functional studies will lead to a comprehensive view of important genetic regulatory mechanisms and signalling cascades that mediate skeletal development. Ultimately, this work will contribute to a better understanding of the pathophysiology of chondrodysplasias and other degenerative bone diseases.

Reduced Bone Mineral Density in Adult Heterozygous *Sox4*$^{+/-}$ Mice. L. S. H. Nissen-Meyer*[1], V. T. Gautvik*[1], S. Reppe*[1], F. P. Reinholt[2], K. M. Gautvik[3], R. Jemtland*[4]. [1]Dept. of Biochemistry, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway, [2]Institute of Pathology, Rikshospitalet University Hospital, Oslo, Norway, [3]Dept. of Biochemistry, Institute of Basic Medical Sciences, University of Oslo, Ullevål University Hospital and Lovisenberg Hospital, Oslo, Norway, [4]Endocrine Section, Dept. of Medicine, Rikshospitalet University Hospital, Oslo, Norway.

The aim of the study was to examine how deletion of a single allele of the PTH-regulated transcription factor *Sox4* gene affected bone mineral density (BMD) and gene expression in mice. Sox4 is vital for normal fetal development, as knock-out mice (*Sox4*$^{-/-}$) die *in utero* from circulatory failure. We have previously shown that PTH regulates Sox4 in osteoblastic and osteosarcoma cells. *Sox4* is also expressed in hypertrophic chondrocytes in mouse embryos. A potential role for Sox4 in osteoblast differentiation has recently been suggested (Billiard et al 2003, J Cell Biochem 89, 389-400). Heterozygous mice appear phenotypically normal. We have determined peak bone mass in the *Sox4*$^{+/-}$ animals compared to wildtypes (wt), and characterised age-related changes in BMD, biochemical and morphological parameters. Gene expression was studied in limbs of *Sox4*$^{-/-}$ embryos compared to wildtypes.

BMD was measured in *Sox4*$^{+/-}$ and wt mice by DEXA (Dual energy X-ray absorptiometry) at regular time intervals. Regions of interest (ROI) include total body, 3 lumbar vertebrae, right femoral neck, femoral shaft and proximal tibia. Blood samples were collected for serum analysis of biochemical bone turnover parameters. *Sox4*$^{+/-}$ and wt mice (180 days) tibiae were fixed immediately after dissection, and embedded in an epoxy resin for subsequent morphologic analysis using light and electron microscopy. Hindlimbs from *Sox4*$^{-/-}$ and wt embryos (embryonic day 14) were subjected to gene expression analysis using the MOE430A array (Affymetrics).

Time curves show a maximal BMD for all groups around 180 days, the *Sox4*$^{+/-}$ males exhibiting significantly lower total body BMD (minus 5.1 %; SE=1.7 %) than wt males ($p<0.05$). In the femoral neck the difference is 15.9 % (SE=3.3 %, $p<0.001$), and similar changes are found in other ROIs. At 180 days, female *Sox4*$^{+/-}$ have slightly lower total BMD than wt females, and significant differences are seen in femoral and lumbar ROIs. Gene expression analysis in embryonic hindlimbs demonstrated changed expression of several genes related to skeletal development.

Our results show that mice with only one functional *Sox4* allele have impaired ability to reach peak BMD and maintain normal bone mass, suggesting a role for Sox4 in normal bone turnover.

Transgenic Mice Constitutively Expressing Histone H4 Gene Display Increased Trabecular Bone Mass Mediated By Histone H4 Alternative Translation. T. Noh*[1], E. Smith*[1], T. E. Myerrose*[1], T. Kohler*[2], M. Namdar-Attar*[3], N. Bab*[3], O. Lahat*[3], J. A. Nolta*[1], R. Müller*[2], I. Bab[3], B. Frenkel[1]. [1]University of Southern California, Los Angeles, CA, USA, [2]Swiss Federal Institute of Technology and University of Zurich, Zurich, Switzerland, [3]The Hebrew University of Jerusalem, Jerusalem, Israel.

The evolutionary conserved *histone H4* genes encode at least two peptides: the 103 amino acid H4 protein and a 14 amino acid circulating mitogen Osteogenic Growth Peptide (OGP). OGP is synthesized *de novo* from H4 mRNA by leaky ribosomal scanning through the imperfect H4 AUG initiator and alternative translation starting at codon 85, a perfect AUG initiator. To test the functionality of *H4* alternative translation *in vivo*, we engineered transgenic mice that ubiquitously and constitutively express a mutant H4 mRNA, *H4tTG1*, which exclusively encodes OGP. Quantitative micro-computed tomographic analysis of femora from 8, 17 and 34 week-old mice revealed marked increases in trabecular bone volume density at all ages. Cortical bone density did not exhibit a significant change. The observed effect on trabecular bone was particularly strong in females, which exhibited a significant 2-fold increase in trabecular bone density compared to wild-type controls. The enhancement of trabecular bone density was accompanied by increased trabecular number and connectivity, parameters that contribute to bone strength. Dynamic histomorphometric analysis demonstrated a significant 35% increase in the percentage of trabecular surface engaged in bone formation and a significant 23% increase in the mineral appositional rate in females. Osteoclast number was not significantly altered. No adverse effects of OGP over-expression were noticeable in transgenic mice up to 18 months of age. Thus, continuous OGP over-expression throughout life results in a specific augmentation of trabecular bone without noticeable effects on cortical bone or extra-skeletal tissues. In summary, transgenic expression of H4 mRNA lacking the upstream initiation codon in post-mitotic cells results in increased trabecular bone accrual.

Identification of Adiponectin Receptor-1, 2 in Osteoblast-like Cell Lines, MG-63 Cells. W. Lee[1], E. Rhee*[1], S. Kim*[1], S. Kim*[1], K. Oh[2], K. Baek[3], M. Kang[3]. [1]Department of Internal Medicine, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Department of Internal Medicine, Hallym University, College of Medicine, Chunchon, Republic of Korea, [3]Department of Internal Medicine, The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea.

Recent clinical study by Lenchik L *et al.* suggested that adiponectin is a novel determinant of bone mineral density and visceral fat in adults. If adiponectin could influence bone metabolism, it could be mediated by adiponectin receptor. Recent reports displayed that adiponectin receptors are found in liver, muscle, pancreas cells, etc. Although the expression of adiponectin was reported in human bone marrow, the expression of adiponectin receptor in osteoblasts has not been reported. Here, we found the expression of adiponectin receptor in MG-63 cells, thus report it. A human osteoblast-like cell line (derived from a human osteosarcoma), MG-63, was purchased from Korean cell line bank. Cells were maintained in Eagle's minimal essential medium, supplemented with 10% fetal calf serum. Total cellular RNA was prepared using the Trizol reagent kit. After quantification by spectrophotometry, it was reverse transcribed and cDNAs were made. PCR was done in a Perkin-Elmer 9600 thermocycler in a 50 ul reaction volume containing cDNA, dNTPs, $MgCl_2$, appropriate oligonucleotide primers of each gene, and AmpliTaq Gold DNA polymerase. The following primers were used: human adiponectin receptor-1, sense 5′-TTC TTC CTC ATG GCT GTG ATG T-3′, anti-sense 5′-AAG AAG CGC TCA GGA ATT CG-3′; human adiponectin receptor-2, sense 5′-ATA GGG CAG ATA GGC TGG TTG A-3′, anti-sense 5′-GGA TCC GGG CAG CAT ACA-3′.

The reaction products were then separated on a 2% agarose gel in Tris borate EDTA buffer. Sequencing of PCR product revealed that it was compatible to human adiponectin-R1 and R2, respectively (using NCBI nucleotide-nucleotide BLAST). We found that human adiponectin-R1 and R2 were expressed in MG-63 cells. It suggests that adiponectin could affect bone metabolism via adiponectin receptors in human.

Hypoxia Stimulates Chondrogenesis by Human Fibroblasts Chondro-induced in vitro by Demineralized Bone. S. Mizuno[1], C. Wykoff*[2], J. Glowacki[1]. [1]Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA, [2]Harvard Medical School, Boston, MA, USA.

In vivo, endochondral osteogenesis induced by demineralized bone powder (DBP) initiates the formation of cartilage and its replacement by bone. *In vitro*, chondroinduction can be modeled by exposing human dermal fibroblasts (hDFs) to DBP contained within a porous collagen sponge [1]. Given that cartilage is a relatively hypoxic tissue, we tested the hypothesis that low pO2 promotes chondroinduction in this system. In this study, we compared chondrogenesis by hDFs in DBP/collagen sponges ± medium perfusion at 5% (hypoxia, Hypo) or 19% O2 (normoxia, Norm).

1 million human dermal fibroblasts (hDFs) was seeded onto porous collagen sponges ± DBP [2] and precultured at Norm for 3 days in DMEM with 10% FBS. The sponges were divided to four culture conditions: Hypo or Norm without/with perfusion of medium (0.33 ml/min). Hypo and Norm were achieved by auto-regulating nitrogen and carbon dioxide inflow in an incubator. At intervals, sponges were harvested for histological and for biochemical evaluation. Sponges were fixed and stained with toluidine blue-O or immunohistologically with prolifering cell nuclear antigen, PCNA. Other sponges were extracted in 4 M guanidine-hydrochloride and ethanol precipitates were used for measurement of chondroitin 4-sulfate (Ch4-S) proteoglycan by ELISA. Other sponges were extracted in urea for Western immunoblot using an antibody for hypoxia inducible factor-1α (HIF) in order to validate hypoxic condition.

Either with/without perfusion, hDFs around and on DBPs were surrounded by fibrous and granular metachromatic matrix. In Hypo, densest fibrous metachromatic matrix was frequently seen near the DBPs. In the DBP/sponges, Hypo significantly enhanced Ch4-S accumulation both without (165%, $p < 0.05$) and with perfusion (160%, $p < 0.05$) compared to Norm. Analysis of PCNA+ cells showed that Hypo did not inhibit proliferation. HIF was not expressed in Norm with perfusion, but was expressed at a low level in Norm without perfusion; this suggests that some cells within the sponge were in fact exposed to low oxygen. HIF was dramatically upregulated by Hypo with/without perfusion, as expected.

In sum, DBP induced chondrogenesis in hDFs; this was significantly increased by Hypo. Thus, exposure to DBP renders hDFs sensitive to hypoxia.

$1,25(OH)_2D_3$ Differentially Regulates Osteoblast Expression of Integrin Beta-1 and Its Partners Alpha-2 and Alpha-5 in a Substrate Dependent Manner. L. Wang[1], P. Raz*[2], D. M. Ranly*[1], C. H. Lohmann*[3], J. Turner*[1], B. D. Boyan[1], Z. Schwartz[1]. [1]Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, USA, [2]Periodontics, Hebrew University Hadassah, Jerusalem, Israel, [3]Orthopaedics, University of Hamburg-Eppendorf, Hamburg, Germany.

$1,25(OH)_2D_3$ decreases osteoblast proliferation and increases osteoblast differentiation. This transition is accompanied by a shape change in vivo and in vitro, suggesting that changes in integrin expression may occur as well. Microrough substrates also induce osteoblast differentiation, and this effect is synergistic with $1,25(OH)_2D_3$. Here we tested the hypothesis that changes in integrin expression over time in culture and regulation of integrin expression by $1,25(OH)_2D_3$ are substrate dependent. Human MG63 osteoblast-like cells were grown for 4, 6, and 8 days on tissue culture plastic and on Ti disks with smooth and rough microtopographies. Cells were treated with $1,25(OH)_2D_3$ [10^{-8}-10^{-9}M] and the expression of beta-1, alpha-2, alpha-5, beta-3, and alpha-v integrins, as well as of the differentiation marker osteocalcin, was determined by real time PCR. Messenger RNAs for osteocalcin, beta-1, and alpha-2 were increased on Ti compared to plastic. $1,25(OH)_2D_3$ increased osteocalcin expression on all surfaces at 4 and 6 days but levels were reduced at day 8. $1,25(OH)_2D_3$ increased alpha-2 and beta-1 expression on plastic and further increased the expression on Ti surfaces compared to plastic. This effect was pronounced at day 8. Levels of alpha-5 mRNA were significantly decreased on Ti surfaces and upon addition of $1,25(OH)_2D_3$ at all time points. Levels of alpha-v mRNA were reduced in response

to $1,25(OH)_2D_3$ on Ti surfaces and on plastic at 6 and 8 days whereas beta-3 expression was not sensitive to time of culture, surface chemistry or topography, or $1,25(OH)_2D_3$ treatment. These results confirm prior studies showing that integrin expression is substrate dependent and show for the first time that they are differentially regulated by $1,25(OH)_2D_3$ and that the effect of $1,25(OH)_2D_3$ is sensitive to physicochemical characteristics of the surface. Digit Tip Regeneration and Global Gene Expression Profiling in the MRL Super-Healer Mouse. R. B. Chadwick*, L. M. Bu*, H. Yu*, Y. Hu*, R. Sachdev*, Q. W. Tan*, J. E. Wergedal, S. Mohan, D. J. Baylink. Molecular Genetics, Musculoskeletal Disease Center, Loma Linda, CA, USA.

The MRL mouse is the only known strain of mouse that shows complete healing of an ear punch without scarring. Additionally, the MRL mouse can regenerate cardiac lesions. The present study sought to test the hypothesis that the MRL mouse also shows superior regeneration properties in the digit tip amputation model. The control mouse was the DBA mouse that exhibited only moderate healing in ear-punch experiments.

Immediately after birth, right paw digit tips of neonatal mice were dissected, with the left front paws as uncut controls. The amount of tissue amputated was measured and consecutive x-ray images were captured of the left and right paws at 7, 14, 21 and 28 days post amputation. Additionally, at four days post dissection, total RNA from the MRL and DBA regenerating digit tips was isolated. Microarray expression profiling was undertaken of this RNA in comparison to RNA from control tissue collected at the time of surgery.

At 14 days post amputation both mouse strains were found to regenerate, however the regeneration rate of the MRL digit tips was greater in comparison to the DBA strain ($p=0.016$). Over 500 genes out of 15,000 on the microarray were significantly differentially expressed ($p < 0.05$) in MRL and DBA mice at day four in comparison to control tissue at day zero. Of these, 170 genes were upregulated and 280 were downregulated in both mouse strains. About 50% of these genes represent ESTs and unknown genes. Pathway analysis reveals that genes in the BMP/TGF pathway are differentially expressed in both mouse strains (BMP-1, Actr2, Smad 4, TGFb1i4, Fstl3, Twsg1, TSC22), thus implicating the BMP/TGF signaling pathway in regulation of digit tip regeneration ($p < 0.05$). Multiple differences between MRL and DBA strains were found in transcription factors that are implicated in embryogenesis, including Mesp2 (involved in Notch signaling and somitogenesis, upregulated 2.8 fold), Net1 (highly expressed in neurons and involved in gastrulation, upregulated 1.7 fold), Bola-like transcription factor (upregulated 4.1 fold) and EST Mm. 270291 (DNA binding zinc-finger protein, upregulated 3.0 fold). We conclude that 1) MRL mice show greater regenerative capacity to heal digit tips compared to DBA mice; 2) The BMP/TGF signaling pathway is involved in digit tip regeneration; 3) Increased regenerative capacity of the MRL mouse may be due to strain specific increased expression of transcription factors that function in embryogenesis and development.

Regulation of Gene Expression in *ank/ank* Mouse Tooth Root Cells by Phosphate and Pyrophosphate. B. L. Foster*[1], E. C. Swanson*[1], F. H. Nociti, Jr.*[1], J. E. Berry*[2], F. Boabaid*[1], M. J. Somerman[1]. [1]School of Dentistry, University of Washington, Seattle, WA, USA, [2]School of Dentistry, University of Michigan, Ann Arbor, MI, USA.

A cementum phenotype has been described for animals with mutations in genes/proteins that regulate the level of extracellular pyrophosphate, *e.g. ank* transmembrane PP_i transporter, plasma cell membrane glycoprotein-1 (PC-1), and tissue nonspecific alkaline phosphatase (TNAP). Here, we isolated cell populations from the tooth root region of *ank/ank* mutant and wild-type (WT) mice, and compared *in vitro* gene expression with phosphate or pyrophosphate treatment.

Cells were harvested from *ank/ank* and WT mice, and cementoblast/PDL cell populations were immortalized using WT SV40 large TAg to create *ank/ank* mutant (SVAT) and WT (SVWT) cells. Cells were treated with inorganic phosphate (P_i) (1, 5, 10mM) or pyrophosphate (PP_i) (0.01, 0.1, 1mM) for 24 hours, and total RNA was isolated. Gene expression was analyzed by real time RT-PCR for bone sialoprotein (BSP), osteocalcin (OCN), osteopontin (OPN), dentin matrix protein-1 (DMP1), matrix Gla protein (MGP), PC-1, and TNAP.

SVAT and SVWT cells contrasted in the basal expression of several genes, including regulators of mineralization (BSP, OCN, OPN, DMP1, MGP) and regulators of P_i/PP_i metabolism (PC-1, TNAP). While SIBLING (Small integrin-binding ligand N-linked glycoprotein) family member BSP was expressed more highly in SVAT mutant cells, two other SIBLING transcripts, OPN and DMP1, were at much lower levels in SVAT cells compared to SVWT cells. SVWT and SVAT also diverged in their response to P_i and PP_i treatments, *in vitro*. SVAT cells were more sensitive than SVWT to up-regulation of OPN by both P_i (20,000% vs. 300% increase) and PP_i (300% vs. 100% increase). DMP1 transcripts in SVAT cells were increased by P_i and PP_i from undetectable levels to higher expression than equivalently treated SVWT cells. Mineralization regulator MGP was up-regulated 150% in SVAT cells by both P_i and PP_i, but was not regulated in SVWT cells. Inversely, TNAP was down-regulated in SVWT cells by P_i (down 65%) and PP_i (down 50%), but was not regulated in SVAT cells.

The cells from *ank/ank* mutant mice have an impaired ability to export PP_i from the intracellular space, resulting in low extracellular PP_i and inflated intracellular PP_i. These studies show that in addition to differences in basal levels of several genes, these cells react differently to P_i and PP_i exposure. Genes involved in regulation of mineralization and P_i/PP_i handling were regulated differently in SVWT and SVAT cells, indicating that altered gene expression may contribute to the hypermineralizing cementum phenotype of *ank/ank* mice, in addition to decreased extracellular PP_i.

Repair of Large Bone Defects in Sheep with Allografts Augmented with Loading of Bone Marrow Stromal Cells. M. B. C. Fernandes*[1], J. S. N. Reis*[1], H. S. H. Martins*[1], P. C. M. Lopez*[1], A. Balduíno*[1], M. L. Aceto*[2], C. E. Ambrósio*[2], A. C. F. Pinto*[2], F. N. Rodrigues*[2], M. A. Miglino*[2], R. Borojevic*[1], M. E. L. Duarte[1]. [1]Histology and Embriology, UFRJ, Rio de Janeiro, Brazil, [2]College of Veterinary Medicine, USP, São Paulo, Brazil.

Repair of large bone defects is a major problem in orthopedic surgery since autologous bone grafts are not available in large amounts and harvest is often associated with donor-site morbidity. In contrast, bone allografts are readily available in different shapes and sizes and, tissue-processing and sterilization procedures have virtually eliminated the risk of infectious disease transmission. Bone marrow stromal cells (BMSC) are responsible for the maintenance of bone turnover through life and can be considered as a mesenchymal progenitor. The purpose of the current study was to verify if cultured autologous BMSC loaded onto allografts would elicit a more effective bone repair at the site of a large segmental defect in the sheep tibia. Three weeks before surgery, 20-30mL marrow aspirates were harvested from the iliac crest. Marrow samples were washed twice in DMEM, filtered through a 40µm cell strainer, suspended in DMEM supplemented with 10% FCS and antibiotics and plated at the density of $6x10^7$ in 150 cm² culture flasks. The medium was changed after 24 hours and then twice a week. Cultures reached confluence 21-27 days after the initial plating. Segmental bone defects, 30 mm in length, were created in the left tibial diaphysis of eight mature female sheeps. Four animals were treated with $1,4x10^7$-10^8 *ex-vivo* expanded autologous BMSC loaded onto a cortical allograft previously packed with cancellous chips. Allografts were harvested from two donors of the same breed as the receptor sheep, sterilized by γ-radiations (25 000 gray), kept frozen at -80º C and thawed immediately before use. The healing response was evaluated histologically and by computed tomography at 6, 10, 14 and 18 weeks after surgery and compared with four control animals treated with cell-free allografts. Union was established more rapidly at the interface between the host bone and allografts that had been loaded with BMSC. In cell-loaded allografts a larger osseous callus had developed around the periphery and along the adjacent host bone. In retrievals from animals treated with cell-loaded allografts healing at the cortical-cortical junctions took place by bridging external callus from the host bone and extended on the surface of the allograft. Our results indicated a significant advantage in the healing of the segmental bone defects when BMSC were delivered together with the bone allograft. In all time points, bone integration as well as functional recovery was more conspicuous in allografts loaded with BMSC.

Effect of Dietary Magnesium Reduction to 25% of Nutrient Requirement on Bone and Mineral Metabolism in the Rat. R. K. Rude. Keck School of Medicine, University of Southern California, Los Angeles, CA, USA.

Previous studies have demonstrated that severe Mg deficiency results in osteoporosis in rodent models. We now report the effects of more moderate dietary Mg restriction (25% of nutrient requirement (NR)) on bone and mineral metabolism in the rat. At 2, 4, and 6 months, serum Mg, Ca, PTH, and $1,25(OH)_2D$ were measured in control and Mg deficient animals. Femurs and tibias were collected for mineral content, histomorphometric, and immunocytochemical analyses. As shown below, serum and bone Mg were significantly reduced by 2 months and continued so through 6 months. sCa did not differ between groups. sPTH became lower in Mg depleted animals at 4 and 6 months. Serum 1,25-D was significantly reduced by 4 and 6 months of study. Histomorphometry demonstrated decreased bone volume and trabecular thickness. This was confirmed by micro-CT which also showed that trabecular volume, and number were significantly lowered ($p<.02$; data not shown).

TNFα immunocytochemical localization in osteoclasts was increased 138% of controls at 2 months, 138% at 4 months and 150% at 6 months. Increased TNFα may be due to increased substance P which was increased to 313% of control at 2 months and 179% at 4 months and 432% at 6 months. These data demonstrate that Mg intake of 25% NR in the rat causes bone loss which may be secondary to increased release of substance P and TNFα.

Modulation of Morphological and Mechanical Properties in Distraction Osteogenesis by Minodronic Acid. M. Takahashi*, K. Yukata*, Y. Matsui, S. Takata, A. Abbaspour*, N. Yasui*. Orthopedic, Tokushima University, Tokushima, Japan.

The limb lengthening procedure using an external fixator is an excellent treatment to rebuild the functional limbs for many troublesome cases. However, it has several problems such as persistent treatment until removal of external fixator, and mechanical fragility of regenerated bone. These problems were related to the high activity of bone resorption in distraction gap. The characteristic zonal structure is detected radiographically in a rabbit model of distraction osteogenesis, where the sclerotic zone has been absorbed from each original cortex. We hypothesized that the regenerated bone was sufficient to sustain the load if it was not remodeled. To prove this we administered potent third-generation bisphosphonate to rabbit undergoing distraction osteogenesis.

A lengthening protocol is composed of a 3-week of distraction at a rate of 0.7 mm/day after one-week waiting period, and a 4-week consolidation period. Fifteen immature rabbits were divided into the following three groups; group 1 was administered only saline as a control, group 2 and group 3 were administered weekly doses of 0.004 mg/kg and 0.4 mg/kg of minodronic acid for 6 weeks from the operation, respectively. Radiological examination was performed with an aluminum wedge that allowed quantifying radiographic bone density of the zonal structure in distraction gap. Although group 1 showed zonal patterns according to respective time points during the consolidation, group 3 showed neither remodeling zone nor tubular structure in distraction gap at any time point. In bone density study, group 2 demonstrated same zonal patterns as group 1, but showed wider sclerotic zones than group 1. In distal remodeling zone, both group 1 and 2 indicated same bone density value (3 mm Al-thickness). In group 3, the whole bone densities in the distraction gap have gained over 5 mm Al-thickness uniformly at last. After extraction, lengthened tibiae were examined the mechanical properties by three-point bending test. Group 3 was significantly stronger in all of mechanical properties than others.

In conclusion, bisphosphonate modulated the remodeling in distraction osteogenesis and strengthened the mechanical property of regenerated bone.

Effects of Calcitonin on Subchondral Trabecular Bone Changes and on Osteoarthritic Cartilage Lesions following Acute Anterior Cruciate Ligament Deficiency. D. H. Manicourt*[1], C. Behets*[2], D. Chappard[3], M. Azria[4], J. P. Devogelaer[1]. [1]Rheumatology Unit, St-Luc University Hospital, Brussels, Belgium, [2]Human Anatomy Research Unit, St-Luc University Hospital, Brussels, Belgium, [3]Lab Histology-Embryology, Faculty Medicine Angers, Angers, France, [4]Research Department, Novartis Pharma Inc, Basel, Switzerland.

As subchondral bone remodeling may contribute to cartilage breakdown in osteoarthritis (OA), we evaluated to what extend calcitonin (CT) might affect cartilage and bone changes in the early stages of canine experimental OA. Twelve dogs underwent transection of the anterior cruciate ligament (ACLT) of the right knee. After ACLT, each animal received a daily nasal spray delivering either 400 units of CT (CT-treated group; n = 6) or a placebo (PL-treated group; n = 6). At day 84 postsurgery, animals were sacrificed, and cartilage changes were graded. Bone mineral density (BMD) and volume fraction (BVF) were assessed by pQCT in different regions of interest (ROIs) of the subchondral cancellous bone of tibial plateaus (TP).Statistics included a 2x2 factorial analysis with CT + or - as one factor and ACLT + or - as the other. Non-operated (N-OP) knees were normal in both groups. In PL-treated group, ACLT knees all exhibited OA changes which predominated in the medial knee compartment. Further, when compared to N-OP knees, the BMD and BVF of ACLT joints were both markedly reduced in medial TP ($p < 0.001$) but not in lateral TP. In contrast, in CT-treated group, cartilage OA lesions of ACLT knees were significantly reduced ($p < 0.001$) and there was no difference in BMD and BFV between N-OP and ACLT knees. These findings suggest that the loss of subchondral trabeculae contributes to cartilage breakdown, possibly by enhancing cartilage deformation upon joint loading. By counteracting bone loss, CT reduced cartilage OA lesions and, thus, might be useful in the treatment of OA in cruciate-deficient dogs.
