Early response to microgravity in the analysis of whole transcriptome and live imaging. Masahiro Chatani¹, Akiko Mantoku¹, Kazuhiro Takeyama¹, Hiroya Morimoto¹, Takehiko Ito¹, Naoki Tanigawa², Koji Kubota², Hiromi Suzuki³, Satoko Uchida³, Fumiaki Tanigaki⁴, Masaki Shirakawa⁴, Yoshio Takano⁵, Akira Kudo¹. ¹Tokyo Institute of Technology, Japan, ²Chiyoda Corporation, Japan, ³Japan Space Forum, Japan, ⁴Japan Aerospace Exploration Agency, Japan, ⁵Tokyo Medical & Dental University, Japan

Introduction: In early on-orbit, it is known that alterations of fluid shift and blood pressure occur rapidly in the astronaut's body. However, other affection including the molecular mechanism of response to microgravity is unclear. We previously reported that mineral density was decreased in the pharyngeal bone region caused by the activation of osteoclasts in medaka fish systematically reared during two months in spaceflight. In this presentation, we examined initial response to microgravity *in vivo*.

Methods: In 2012, medaka fish 6 weeks after hatch were launched to the international space station (ISS) and preserved by RNAlater at early on-orbit; two and half days after launch. Alteration of the gene expression level was examined by the whole transcriptome analysis using HiSeq. In 2014, we performed again the space experiment for real-time tracing of cell signals *in vivo* in ISS. The transgenic medaka larvae after hatch were embedded in a gel and observed by fluorescent microscopy in ISS via remote operation from Tsukuba space center. For this experiment, we established 4 reporter medaka lines; TRAP-GFP/Osterix-DsRed, TRAP-GFP/Osteocalcin-DsRed, Cox2-GFP/TRAP-DsRed, and RANKL-GFP/MMP9-DsRed.

Results and discussion: Whole transcriptome analysis via RNAs extracted from whole-body tissues showed up-regulation of several genes, which are related to stress response, including KLF family. Gene ontology analysis suggested promotion of DNA replication in the flight group. In addition, RNAs extracted from the pharyngeal bone and teeth region showed significant up-regulation of osteoblast- and osteoclast-related genes, indicating that bone cells were preferentially reactive to microgravity. Live imaging of the pharyngeal region in medaka larvae after hatch showed the significant increase of osterix-DsRed and osteocalcin-DsRed signals in the flight medaka group, suggesting that microgravity initially promoted the osteoblast differentiation in early on-orbit.

1,25-Dihydroxyvitamin D Alters Human Skeletal Muscle Mitochondrial Oxygen Consumption through Changes in Mitochondrial Number and Nuclear mRNA Expression. Zachary Ryan¹, Theodore Craig¹, Clifford Folmes², Xuwei Wang³, Ian Lanza⁴, Niccole Schaible⁵, Jeffrey Salisbury⁶, K. Sreekumaran Nair⁴, Andre Terzic², Gary Sieck⁵, Rajiv Kumar¹. ¹Division of Nephrology & Hypertension, Department of Medicine, USA, ²Division of Cardiovascular Diseases, Department of Medicine, USA, ³Division of Biomedical Statistics & Informatics, Department of Health Sciences Research, USA, ⁴Division of Endocrinology, Department of Medicine, USA, ⁵Department of Physiology, Biophysics & Biomedical Engineering, USA, ⁶Department of Biochemistry & Molecular Biology, USA

Vitamin D deficiency is associated with muscle weakness and a myopathy that respond to therapy with vitamin D3. Furthermore, the vitamin D3 analogs, 1,25(OH)2D3 and 1(OH)D3, have been shown to reduce falls in humans. The goal of this study was to assess the mechanisms by which 1,25(OH)2D3 alters skeletal muscle function.

Since skeletal muscle is critically dependent upon oxidative metabolism and ATP synthesis for muscle contraction, we examined whether 1,25(OH)2D3 directly alters mitochondrial function in human skeletal muscle cells. Extracellular flux analysis was utilized to assess the impact of 1,25(OH)2D3 on the rate of skeletal muscle mitochondrial oxygen consumption (OCR). 1,25(OH)2D3 treatment induced a dose-dependent increase in the OCR of human muscle cell primary cultures. Indices of mitochondrial function including basal, ATP-dependent and maximal OCR increased following treatment of cells with 1,25(OH)2D3 without associated changes in glycolytic rates. 1,25(OH)2D3-treatment also increased mitochondrial volume and fragmentation. Vitamin D3 and analogs including 25-hydroxyvitamin D3, 24R,25-dihydroxyvitamin D3 and 1-hydroxyvitamin D3, decreased or did not change mitochondrial OCR. To examine the mechanism by which mitochondrial oxygen consumption is altered by 1,25(OH)2D3, we first confirmed the expression of the vitamin D receptor (VDR) in human skeletal muscle biopsies from normal subjects and in primary cultures of skeletal muscle cells. Knock-down of the VDR in primary cultures of human skeletal muscle cells with a VDR-specific silencing RNA, blocked 1,25(OH)2D3-dependent increases in the OCR. Next generation, whole transcriptome sequencing of mRNAs from 1,25(OH)2D3-treated skeletal muscle cells revealed VDR-dependent changes in the expression of 1947 mRNAs including eighty three nuclear mRNAs encoding mitochondrial proteins. Transcripts that were regulated in skeletal muscle cells by 1,25(OH)2D3 were involved in Janus kinase and signal transducer and activator of transcription, growth factor signaling and cytokine signaling and cell adhesion.

1,25(OH)2D3 alters skeletal muscle mitochondrial activity, volume and the expression of nuclear messenger RNAs encoding mitochondrial and cellular proteins via vitamin D receptor-dependent mechanisms.

Glucocorticoids induce bone and muscle atrophy by distinct mechanisms upstream of atrogenin1 and MuRF1. Amy Y. Sato¹, Ernie Au¹, Danielle Richardson¹, Nicoletta Bivi², Meloney Cregor¹, Kevin McAndrews¹, Hannah M. Davis¹, Teresa Zimmers³, Lilian I. Plotkin¹, Teresita Bellido¹. ¹Indiana University School of Medicine, USA, ²Eli Lil, USA, ³Indiana University Department of Surgery, USA

Excess glucocorticoids (GC), either endogenous as with aging or when used as immunosuppressants, leads to loss of mass in bone and muscle. We investigated herein whether the same or different mechanisms mediate GC-induced osteopenia and sarcopenia. Mice receiving GC for 14 or 28 days (slow release pellets, 2.1 prednisolone mg/kg/day) exhibit 90% reduction in bone formation rate in tibial cancellous, endocortical, and periosteal surfaces; as well as 15% decrease in lean body mass and ~20% decrease in the mass of the tibialis anterior and the gastrocnemius muscles. Expression of the atrophy-associated genes atrogenin1 and MuRF1 was increased in tibia/vertebra and tibialis anterior muscle from GC-treated mice. Moreover, these genes were upregulated by addition of the GC dexamethasone to differentiated primary cultures of calvaria derived osteoblasts, Ob-6 osteoblastic cells, MLO-Y4 osteocytic cells and undifferentiated (myoblasts) and differentiated (myotubes) C2C12 muscle cells. GC also increased the expression of the Notch ligands Dll1 and Jag1, Notch1-4 receptors and Notch target genes Hey1 and Hes1 in tibialis anterior muscles *in vivo*. Moreover, GC decrease C2C12 myotube diameter by ~20%, and the Notch inhibitor GSIXX prevented this effect. In contrast, GC did not increase components of the Notch signaling pathway in bone *in vivo* or in Ob-6 or MLO-Y4 cells *in vitro*. Instead, GC activated the FAK-related kinase Pyk2 in bone cells *in vitro*. Further, whereas WT littermates lost 5% spinal BMD in response to GC, Pyk2 KO mice were resistant to bone loss and gained 5% spinal BMD. In contrast, GC induced similar decreases in lean body mass (8%) and tibialis anterior and gastrocnemius muscle mass (19-25%) in WT and Pyk2 KO mice. Thus, GC activate different signaling pathways (Pyk2 in bone and Notch signaling in muscle), which converge in up-regulation of the same genes atrogenin1 and MuRF1 leading to loss of tissue mass. These findings provide the basis for combination therapy with Pyk2 and Notch inhibitors to treat GC-induced osteopenia and sarcopenia.

Suppressing Sclerostin Activity Alleviates Radiotherapy-Induced Osteoporosis by Accelerating DNA Repair in Osteoblasts and Their Progenitors. Tiao Lin¹, Abhishek Chandra², Xiaoyuan Ma³, Wei-Ju Tseng³, Keith Cengel⁴, Xiaowei Liu³, Ling Qin³. ¹University of Pennsylvania, USA, ²Departments of Orthopaedic Surgery, Perelman School of Medicine, University of Pennsylvania, USA, ³Departments of Orthopaedic Surgery, Perelman School of Medicine, University of Pennsylvania, USA, ⁴Departments of Radiation Oncology, Perelman School of Medicine, University of Pennsylvania, USA

Radiotherapy eliminates tumor cells but has untoward effects on neighboring normal tissues including bone, causing acute and chronic problems such as osteoradionecrosis, osteoporosis, and fractures. We have previously established a clinically relevant focal radiation model in rodent and demonstrated that PTH injections prevented bone loss in irradiated bone by stimulating beta-catenin to promote cell survival after radiation. Since a black box warning of PTH makes it an unlikely option for cancer patients, we explored whether activating Wnt canonical pathway via Sclerostin antibody (Scl-Ab) could be a superior alternative as it has no evidence for cancer concerns. To demonstrate its *in vivo* efficacy, we focally irradiated right distal femoral metaphysis of 2-month-old male C57BL/6 mice at a clinically relevant dosage (8 Gy at day 1 and 3) and treated mice with either vehicle or Scl-Ab (100 mg/kg) weekly. Compared to contralateral femurs, irradiated ones exhibited significant decreases in bone volume fraction (21%) and stiffness (56%) after 4 weeks. Strikingly, Scl-Ab not only blocked such structural deterioration but also improved bone quality in the radiated area to the same levels of non-radiated area. Interestingly, trabecular bone in sclerostin (SOST) KO mice was resistant to radiation, confirming that suppressing SOST activity is effective in reversing radiation-induced bone damage. Histomorphometry analysis revealed that, while radiation greatly reduces osteoblast number and activity and almost eliminates their progenitors, Scl-Ab treatment significantly increases osteoblast number (2.5 fold), mineral surface (4.7 fold), and CFU-F number (1.4 fold). *In vitro*, Wnt3a, a canonical Wnt ligand, almost completely mitigated radiation-induced apoptosis in osteoblasts and their progenitors by activating beta-catenin. We identified Ku70, a critical DNA repair protein, as a critical mediator of Wnt3a/beta-catenin-induced DNA repair after radiation. Lineage tracing using Col2-Cre Rosa-Tomato mice, in which all bone marrow mesenchymal progenitors, adipocytes, osteoblasts, and osteocytes are Td+, demonstrated that Scl-Ab reverted radiation-induced marrow adiposity by switching the fate of progenitors

from adipogenesis to osteogenesis. Taken together, our studies provide proof-of-principle evidence for a novel use of Scl-Ab as a therapeutic treatment for radiation-induced osteoporosis and establish molecular and cellular mechanisms that support such treatment.

Loss of DNMT3b in Chondrocytes Leads to Impaired Angiogenesis and Delayed Fracture Repair. Cuicui Wang*¹, Jie Shen¹, Tzong Jen Sheu², Regis O'Keefe¹. ¹Washington University in St. Louis, USA, ²University of Rochester Medical Center, USA

While cell signaling mediated by local and systemic factors has been extensively investigated, there is less understanding of the role of epigenetic changes in the regulation of bone regeneration. The DNA methyltransferase enzymes (DNMTs) DNMT3a and DNMT3b have tissue specific expression patterns and create unique methylation signatures to regulate gene expression. Using a stabilized murine tibia fracture model we find that *Dnmt3b* is induced early in fracture healing, peaks at 10 days post fracture (dpf), and then declines to nearly undetectable levels by 28 dpf. DNMT3b expression was cell and stage specific. High levels were observed in mesenchymal progenitor cells and in proliferating and prehypertrophic chondrocytes within the fracture callus. To determine a functional role for *Dnmt3b* in fracture healing the gene was conditionally deleted in chondrocytes in fractures of *Agc1Cre^{ERT2};Dnmt3b^{fl/fl} (Dnmt3b^{Agc1ER})* mice by daily administration of tamoxifen (10 mg/kg body weight; dpf 1-7). Fracture callus in mice with gene deletion had delayed chondrogenesis, prolongation of endochondral bone formation with persistence of cartilage matrix, and a delay in the later events of angiogenesis, ossification and bone remodeling. Biomechanical studies demonstrated markedly reduced strength in *Dnmt3b^{Agc1ER}* fractures and confirmed the delay in repair. The angiogenic response was assessed by MicroCT and showed a marked reduction in both vessel number and volume at 10 and 14 dpf in *Dnmt3b^{Agc1ER}* mice. Immunohistochemistry showed decreased PECAM expression, consistent with the reduced angiogenesis. Finally, *in vitro* angiogenesis assays with HUVECs revealed that loss of DNMT3b in chondrocytes significantly reduced capillary tube formation and endothelial migration; however, HUVEC proliferation and apoptosis appeared largely unaffected. To identify specific angiogenic factors involved in the decreased callus vascularization, a protein array was performed using media isolated from cell cultures of control and DNMT3b LOF chondrocytes. Several angiogenic factors, including OPN, PAI1, SDF-1/CXCL12, and TIMP1 are reduced in chondrocytes following loss of DNMT3b. Altogether, our findings establish that epigenetic modulation mediated by DNMT3b is a key event that occurs during the endochondral bone repair process, with gene ablation leading to impaired angiogenesis and delayed fracture repair.

High Bone Mass is associated with bone-forming features of osteoarthritis at non-weight bearing joint sites, independent of Body Mass Index. Aaron Murphy¹, Sarah Hardcastle¹, Martin Williams², George Davey Smith³, Jon H Tobias¹, Celia Gregson^{*4}. ¹Musculoskeletal Research Unit, School of Clinical Sciences, University of Bristol, United Kingdom, ²Department of Radiology, North Bristol NHS Trust, United Kingdom, ³MRC Integrative Epidemiology Unit at the University of Bristol, United Kingdom, ⁴University of Bristol, United Kingdom

Objectives

We have previously reported associations between High Bone Mass (HBM) and (a) radiographic knee osteoarthritis (OA), in part mediated by increased body mass index (BMI) in HBM cases and (b) enthesophytes and osteophytes, suggestive of a bone-forming phenotype in HBM. In this study we aimed to determine (i) whether HBM is also associated with OA at non weight-bearing skeletal sites, (ii) if OA at these sites also displays a bone-forming phenotype and (iii) whether increased BMI contributes to any association found.

Methods

HBM cases (identified by screening 335,115 DXA scans; defined by BMD Z-scores $\geq +3.2$) from the UK-based HBM study were compared with unaffected family controls. A single blinded assessor graded AP dominant hand radiographs from cases and controls for features of OA (osteophytes and joint space narrowing (JSN) (0-3), subchondral sclerosis (0-1)) at the index Distal Interphalangeal Joint (DIPJ) and 1st Carpometacarpal Joint (CMCJ)), using an atlas. Analyses used logistic regression, adjusting *a priori* for age and gender. The role of BMI as a mediating factor was explored by further adjusting for BMI in regression models in Stata v11. A second assessor graded 40 randomly selected radiographs: inter and intra-rater reliability Kappas all ≥ 0.6 .

Results

315 HBM cases (mean age 61.2 years, 75% female) and 184 controls (54.2 years, 84% female) were included. Osteophytes (grade ≥ 1) were more common in HBM (DIPJ: 67% vs. 45%, CMCJ: 70% vs. 50%), with adjusted OR [95% CI] 1.78 [1.11, 2.85], $p=0.017$ and 1.84 [1.19, 2.85], $p=0.006$ respectively; whilst no differences were seen in JSN. Subchondral sclerosis was more common amongst HBM cases than

controls, but was explained by age & gender adjustment. Further adjustment for BMI failed to attenuate the OR for osteophytes in HBM cases vs. controls; DIPJ 1.69 [1.05, 2.74], $p=0.031$ and 1st CMCJ 1.71 [1.09, 2.67], $p=0.019$.

Conclusion

Our findings support a positive association between HBM and OA in non-weight-bearing joints which is independent of BMI. This HBM-associated OA is characterised by osteophytes, consistent with a bone forming phenotype, rather than JSN reflecting cartilage loss. It is possible that the same systemic factors (e.g. genetic architecture) which govern HBM may also increase the risk of bone-forming OA.

Osteoarthritis and chronic back pain as predictors of postmenopausal falls. Nadia Afrin^{*1}, Heli Koivumaa-Honkanen², Toni Rikkonen¹, Heikki Kröger¹, Risto Honkanen¹. ¹University of Eastern Finland, Finland, ²Department of psychiatry, University of Eastern Finland, Finland

Introduction: Musculoskeletal diseases increase falling risk in the elderly. There is less information about this association in postmenopausal women.

Objective: The purpose of this study was to evaluate if and how musculoskeletal diseases predict falls in postmenopausal women.

Methods: Study design was prospective cohort by using Kuopio Osteoporosis Risk Factor and Prevention (OSTPRE) Study cohort. Information about musculoskeletal diseases and use of analgesics as exposure variables were obtained from the year 1999 enquiry and about falls in preceding 12 months as the outcome variable in 2004 enquiry. The study population consisted of 8955 women with complete information about falls and exposure variables. Women were fallers if they reported at least two falls per year (n=2069). Falls were classified into slip (n=727) and nonslip (n=1068) falls. There were 204 women with Rheumatoid arthritis, 1424 with Osteoarthritis, 1073 with Sciatica and 665 women with other back pain. Logistic regression was used as the statistical method.

Results: The women were 57-66 years old in 1999. History of osteoarthritis, sciatica and chronic back pain predicted slip falls as follows: (OR 1.3, 95% CI 1.1-1.5), (OR 1.2, 95% CI 1.0-1.5) and (OR 1.4, 95% CI 1.2-1.8) but rheumatoid arthritis did not do it (OR 0.8, 95% CI 0.5-1.3). The corresponding risks of nonslip falls were: 1.6 (95% CI 1.4-1.8), 1.6 (95% CI 1.4-1.8), 1.5 (95% CI 1.3-1.8) and 1.0 (95% CI 0.7-1.5) respectively. After adjusting for smoking, life satisfaction, self-rated health and number of chronic health disorders did not considerably change the strength of predictions.

Conclusion: Falling tendency is increased by history of main musculoskeletal diseases except rheumatoid arthritis in postmenopausal women.

Subchondral Bone in Human Osteoarthritic Knees Is Characterized By Trabecular Rod Loss and Trabecular Plate Stiffening. Yan Chen^{*1}, Bin Zhou², Ji Wang², Weimei Zhao³, FKL Leung⁴, Xu Cao⁵, William Lu⁶, X Edward Guo². ¹Department of Orthopaedics & Traumatology, Faculty of Medicine, the University of Hong Kong; Bone Bioengineering Laboratory, Department of Biomedical Engineering, Columbia University, USA, ²Bone Bioengineering Laboratory, Department of Biomedical Engineering, Columbia University, USA, ³Department of Orthopaedics & Traumatology, Faculty of Medicine, the University of Hong Kong, Hong Kong, ⁴Department of Orthopaedics & Traumatology, Faculty of Medicine, the University of Hong Kong; Shenzhen Key Laboratory for Innovative Technology in Orthopaedic Trauma, the University of Hong Kong Shenzhen Hospital, Hong Kong, ⁵Department of Orthopaedic Surgery, School of Medicine, Johns Hopkins University, USA, ⁶The University of Hong Kong, Hong Kong

Subchondral bone sclerosis leads to cartilage damage in osteoarthritis (OA). However, treatment with antiresorptive drugs attenuates OA cartilage erosions, suggesting that bone sclerosis may be accompanied by bone loss in OA. Thus, we aimed to evaluate trabecular plate and rod microstructural changes in subchondral bone based on the individual trabecula segmentation (ITS) technique and corresponding mechanical properties in human OA knees. Tibial plateaus were collected from knee OA patients (n=102) undergoing total knee arthroplasty, and from cadaver donors (n=25) without arthritis or bone diseases. The tibial plateaus were scanned using micro computed tomography (μ CT) at 17.3 μ m. Five cubic subchondral bone subregions were extracted from external, central, internal, anterior and posterior areas of both medial and lateral condyles, respectively, and subjected to ITS and μ CT based micro finite element (μ FE) analysis. The specimens were then processed for cartilage evaluation using the OARS system. On medial condyle and in internal and central subregions on lateral condyle where OA was severe, OA group has decreased rod volume fraction and number, while increased rod thickness and length, increased bone volume fraction (BV/TV), plate volume fraction (pBV/TV) and thickness than control group. However, trabecular plate number did not differ.

Moreover, OA group has dramatically increased plate to rod ratios but lower plate-plate, plate-rod and rod-rod junction density. In addition, axial bone volume fraction was drastically higher in OA group, indicating that the orientation of the trabecular bone network was more axially aligned than control group. These striking differences in trabecular bone microstructure resulted in much higher bone stiffness, as assessed by elastic moduli, in OA group. In external, anterior and posterior subregions on lateral condyle where OA was mild, the changes of most ITS parameters were similar to those on medial condyle, while BV/TV, pBV/TV and elastic moduli did not differ, suggesting that trabecular plate and rod changes in subchondral bone may proceed OA changes in cartilage. We found that subchondral bone within human OA knee is characterized by trabecular rod loss and trabecular plate stiffening. These changes lead to uneven distribution of trabecular bone density, and may increase focal shear stresses in cartilage. Trabecular rod loss probably precedes plate stiffening, and thus may play an important role in OA progression.

A novel method for the assessment of joint space width and subchondral bone texture. Richard Ljuhar^{*1}, Astrid Fahrleitner-Pammer², Helena Canhao³, Hans Peter Dimai². ¹Braincon Technologies, Vienna, Austria; ²University of Technology, Vienna, Austria, At, ³Medical University Graz, Division of Endocrinology & Metabolism, Austria, ³Faculdade Medicina Universidade Lisboa, Portugal

OBJECTIVE: Assessment of osteoarthritis (OA) of the knee usually involves AP and lateral radiographs to evaluate medial and lateral joint spaces, but perspective errors and low reproducibility are limiting factors. In addition to joint space width, subchondral bone area may provide important information on the status of OA. However, no adequate standard has been developed so far to quantify subchondral changes. The method described here combines assessment of joint space width (JSW) and fractal analyses of the adjacent subchondral bone area to discriminate between patients with and without OA.

METHODS: The study included 274 standardized knee radiographs from 110 patients with OA, and 164 controls. Knee joint space analysis was performed at the medial and lateral compartment, applying a gradient based algorithm for automated detection of critical landmarks and joint space contour. Furthermore, subchondral bone texture was assessed by using fractal analysis at predefined regions of the proximal tibia. A matrix of 3x8 ROIs was used to gain sufficient textural information (FIG.). Self-similarity of the texture, reflecting 2D projection of the 3D trabecular structure, has been used to calculate the Bone Structure Value (BSV) which provides indirect information on bone quality.

RESULTS: Comparing mean BSVs of the control group and the OA group, a deviation of 7.04% in mean values was determined. The odds ratio showed that the control group had a 6.5 times higher probability to be measured with a BSV above 0.33 than the OA group. A combination of both, JSW & BSV showed a further increase in discriminative power between the control group and OA patients. The most powerful combination of JSW and BSV enabled a discrimination between control/OA in 97.83% of cases. Differences in BSV were found between left/right knee and male/female. Furthermore, a rising BMI was identified to be linked to lower BSV values.

CONCLUSIONS: The novel method described here is sufficient to discriminate between subjects with and without OA. Furthermore, fractal analysis alone may provide information on bone quality aspects. Future work should therefore also focus on the potential role of fractal analysis (in a possible combination with JSW assessments) to serve as a fracture risk assessment tool.

Effects of a Multi-modal Exercise Program on BMD, Muscle Function, Knee Cartilage Structure, Defects and Bone Marrow Lesions in Older Adults: An 18 month RCT. Robin Daly^{*1}, Jenny Gianoudis¹, Yuanyuan Wang², Christine Bailey³, Peter Ebeling⁴, Carvl Nowson¹, Kerrie Sanders⁵, Flavia Cicuttini², Keith Hill⁶. ¹Centre for Physical Activity & Nutrition Research, Deakin University, Australia, ²Department of Epidemiology & Preventive Medicine, Monash University Medical School, Alfred Hospital, Australia, ³NorthWest Academic Centre, The University of Melbourne, Western Health, Australia, ⁴School of Clinical Sciences, Monash University, Australia, ⁵Institute for Health & Ageing, Australian Catholic University, Australia, ⁶School of Physiotherapy & Exercise Science, Curtin University, Australia

Osteoporosis and osteoarthritis (OA) often coexist in older adults. While progressive resistance training (PRT) and weight-bearing impact exercise (Ex) are recommended to improve bone and muscle health and function, few studies have simultaneously examined the effects of such programs on knee and cartilage health in older adults. The aim of this study was to examine the effects of a multi-modal Ex program on bone, muscle and cartilage health in community-dwelling older adults at risk for falls and fracture. This was an 18-month RCT consisting of a 12-month structured and supervised intervention followed by a 6-month translational phase. 162 adults aged 60+ years were randomised to Ex (n=81) or a usual-care control group (n=81). Ex consisted of high velocity PRT, weight-bearing activities (60-180 impacts/session) and balance training 3 days per week for 18 months. Outcome variables included: DXA hip and spine BMD and total body lean mass (LM), and muscle strength, power and function (leg press, stair climb, 4-square test, TUG, sit-to-stand). MRI of the left knee was used to assess tibial cartilage volume, cartilage defects (CD) [tibiofemoral (TF) and patella] and TF bone marrow lesions (BMLs) in a subset of 120 participants. We assessed changes in CD and BMLs as both have been linked to increased cartilage loss and may be indicative of incipient OA. A total of 150 participants (93%) completed the study (97/120 had repeat MRI scans). Ex attendance averaged 55% (range 0-98%). After 18 months there were significant Ex-induced improvements in FN BMD (1.9%, P<0.001), muscle strength, power and function (net benefits 6-15%, P<0.05-<0.001) relative to Con, but no Ex effect on LM. The rate of loss in tibial cartilage volume was similar in both groups (Ex vs Con: medial, -2.5% vs -1.5%, P=0.27; lateral, -3.2% vs -2.5%, P=0.33), and an equal proportion of participants in the Ex and Con group demonstrated progression of CD (Ex vs Con; TF medial, 14% vs 15%; lateral 26% vs 28%; patella 12% vs 19%) and BMLs (Ex vs Con, TF medial 14% vs 17%; lateral 7% vs 5%). Furthermore, tibial cartilage loss was no different between the groups when stratified by the presence of CD or BMLs at baseline. In conclusion, this study indicates that a multi-modal, targeted bone loading exercise program is safe and effective for improving bone health and muscle function in older adults at increased risk of falls and fracture, with no adverse effects on knee cartilage structure.

Activin Receptor Type IIA (ACVR2A) Functions Directly in Osteoblasts as a Negative Regulator of Bone Mass. Brian Goh^{*}, Vandana Singhal, Angelica Herrera, Thomas Clemens, Se-Jin Lee, Douglas DiGirolamo. Johns Hopkins University School of Medicine, USA

Bone and skeletal muscle mass are highly correlated in mammals, suggesting the existence of common anabolic signaling networks that serve to coordinate the development of these anatomically adjacent tissues. The activin signaling pathway is an attractive candidate to fulfill such a role. Our group and others have previously reported that mice treated with soluble activin receptors demonstrate both increased skeletal muscle mass and bone mass. In the present study, we have generated mice with conditional deletion of ACVR2A, ACVR2B, or both, specifically in osteoblasts, in order to determine the contribution of activin signaling in osteoblasts in regulating bone mass. Immunohistochemistry localized ACVR2A and ACVR2B to osteoblasts and osteocytes in trabecular and cortical bone. Primary mouse osteoblasts expressed major activin receptor signaling components, including ACVR2A, ACVR2B, and ACVR1B (ALK4), and demonstrated increased levels of phosphorylated Smad2/3 upon exposure to activin ligands. In vitro, osteoblasts lacking ACVR2B did not show significant changes in differentiation, however, osteoblasts deficient in ACVR2A exhibited enhanced differentiation by measures of alkaline phosphatase activity, mineral deposition, and increased transcriptional expression of *Osterix*, *Osteocalcin*, and *Dmp1*. To test the importance of activin receptor signaling in osteoblasts in vivo, we analyzed the skeletal phenotypes of mice selectively lacking these receptors in osteoblasts and osteocytes (Osteocalcin-Cre). Similar to the lack of effect noted in vitro, ACVR2B deficient mice demonstrated no significant change in any bone parameter. By contrast, both male and female mice lacking ACVR2A had significantly increased femoral trabecular bone volumes at six weeks of age. Further, compound mutant mice lacking both ACVR2A and ACVR2B demonstrated sustained increases in trabecular bone volume, similar to ACVR2A single mutants, in both male and female mice at six and twelve weeks of age. Taken together, these data indicate that activin signaling, predominantly through ACVR2A, functions directly in osteoblasts as a negative regulator of bone mass.

Six-month of Spaceflight and 1 Year Follow-Up Revealed Differential Responses of Cortical and Trabecular Bone Dependent on Bone Localization and Starting Bone Status. Laurence Vico^{1*}, Myriam Normand², Bert Van Rietbergen³, Nicolas Vilayphiou⁴, Hervé Locrelle², Mohamed Zouch⁵, Maude Gerbaix², Galina Vassilieva⁶, Ivan Morukov⁶, Thierry Thomas².
¹University of St-Etienne, France, ²INSERM-U1059, Biologie du Tissu Osseux, University of Lyon, France, ³Eindhoven University of Technology, Netherlands, ⁴SCANCO Medical AG, Switzerland, ⁵Laboratory of Cardio-Circulatory, Respiratory, Metabolic, & Hormonal Adaptations to the Muscular Exercise, Faculty of Medicine Ibn-El-Jazzar, University of Sousse, Tunisia, ⁶INSTITUTE OF BIO-MEDICAL PROBLEMS, Russia

Introduction

Using pQCT, we previously found that the weight-bearing tibial site displayed trabecular and cortical bone losses after 6-month space exposure while the radius, being a non-weight bearing bone, did not exhibit any bone loss. During a 6-month follow-up survey after landing tibial bone loss persisted, suggesting that the time needed to recover is longer than the mission duration (Vico et al., Lancet 2000). In a new series of crewmembers, we aimed to better assess structural and mechanical changes and beyond 6-months after space sojourns up to one year to appreciate if and when bone is regained.

Methods

We measured bone density, microarchitecture and micro-finite element-derived bone strength at the distal radius and tibia using HR-pQCT in 13 spacemen [mean age 43.6 (35-54 years old)] who sojourned in the International Space Station (ISS) during 6 months. Measurements were done before flight, immediately after landing, and after 3, 6, and 12 months follow-up.

Results

Despite inter-individual variability among crewmembers, statistical analysis revealed the following alterations.

Radius: as found in previous missions, no significant bone loss was seen immediately after the flight. However, from 3 to 12 month post-flight Ct.Th and ultimate load, and at 12 month for trabecular BV/TV or density, declines were evidenced.

Tibia: we confirmed in these crewmembers a loss of bone during flight at both cortical and trabecular levels. One year after reentry, the recovery was effective for cortical thickness but not for trabecular BV/TV or density, and ultimate load.

In tibia, a negative correlation was found between Ct.Th preflight and the change in Ct.Th during flight ($R^2 = 0.41$, $p < 0.05$) showing that the thinner the initial cortex is the higher the inflight loss is.

Conclusion

Overall these results highlight the importance of analyzing different skeletal sites and compartments on long-term time journeys. A striking discovery of this study is the fact that the radius shows a progressive increase in fragility after reentry, suggesting that the return to ground following long-term space travel might be fraught with unsuspected skeletal recovery uncertainties.

Osteolineage Notch ligand Jagged1 is critical for maintaining homeostatic trabecular bone mass. Rialnat Lawal^{1*}, Benjamin Frisch², Matthew Hilton³, Laura Calvi². ¹University of Rochester Medical Center, USA, ²University of Rochester, USA, ³Duke University School of Medicine, USA

Notch signaling regulates the progenitor subset of osteolineage cells and osteoblastic differentiation. While Notch receptors have been evaluated extensively, the specific contribution of individual Notch ligands is unknown. Parathyroid Hormone (PTH) regulates the expression of the Notch ligand Jagged1 in osteoblastic cells. Therefore, in the current study we examined if loss of osteolineage Jagged1 in vivo affects bone homeostasis. Selective deletion in osteolineage cells was achieved through excision of floxed Jagged1 alleles in the presence of Prx1 promoter-driven Cre recombinase expression, targeting mesenchymal stem cells (MSCs) and their progeny (P Jag1 mice). P Jag1 mice were viable and fertile and did not exhibit any skeletal abnormalities at 2 weeks or 1 month of age. At 2 months of age however, P Jag1 mice had increased trabecular bone mass without changes in cortical bone compared to wild-type (WT) littermates. Dynamic histomorphometric analysis revealed that osteoblastic activity was increased as demonstrated by significantly increased mineral apposition rate. Immunohistochemical analysis showed increased numbers of osteocalcin positive mature osteoblasts in P Jag1 mice. Also increased phenotypically defined Lin-/CD45-/CD31-/Sca1-/CD51+ osteoblastic cells were measured by flow cytometric analysis. Surprisingly, phenotypically defined Lin-/CD45-/CD31-/Sca1+/CD51+ MSCs were unchanged in P Jag1 mice as measured by flow cytometric analysis, while functional osteoprogenitor (OP) cell frequency, measured by Von Kossa+ colony formation, was decreased. Together these data suggest that osteolineage Jagged1 is critical for maintenance of the OP pool. Coupled with the increase in mature osteoblast numbers and activity, P Jag1 mice had increased osteoclastic activity, suggesting that trabecular increases are not due to osteoclastic defects. Since PTH increases osteoblastic Jagged1, we sought to understand if a role for osteolineage Jagged1 exists in PTH-mediated bone anabolism. PTH-dependent bone anabolism resulted in a significantly greater increase in BV/TV in P Jag1 hind limbs compared to WT. These findings demonstrate a critical role of osteolineage Jagged1 in bone homeostasis, where Jagged1 restricts the transition of OP to maturing osteoblasts. This novel role of Jagged1 not only identifies a regulatory loop maintaining appropriate populations of osteolineage cells, but also provides a novel approach to increase trabecular bone mass, particularly in combination with PTH, by specific modulation of Jagged1.

MMP14 Is a Novel Target of PTH Required for Osteocytic PTH Receptor-Driven Bone Remodeling and Mineral Apposition. Jesus Delgado-Calle^{*}, Gretel G. Pellegrini, Monica Feustel, Kevin McAndrews, Teresita Bellido. Indiana University School of Medicine, USA

PTH has profound effects on the skeleton by acting on osteocytes through mechanisms still unraveling. We report that matrix metalloproteinase (MMP) 14 expression is increased in bones from transgenic mice with constitutive activation of the PTH receptor in osteocytes (caPTHRIOT). Daily injections of PTH (100ng/g) for 1 month also increased MMP14 expression in WT mice, but not in mice with conditional deletion of the PTHR1 in osteocytes. These results demonstrate that MMP14 is a target gene of the osteocytic PTH receptor. MMP14 has been shown to be required for bone formation and maintenance of osteocytic processes during skeletal development; however, its potential role in PTH regulation of bone remodeling is unknown. To address this question we blocked MMP14 activity by injecting the neutralizing MMP14 antibody KD014 (30 mg/kg, sc 2x/wk) to 1 month old caPTHRIOT mice or WT littermate controls. After 2 months, caPTHRIOT mice injected with KD014 exhibited ~10% lower total, spinal and femoral BMD, lower BV/TV in the distal femur (-15%), trabecular thickness (-50%), cortical bone area (BA/TA) (-25%), and cortical thickness (-50%), compared to saline injected caPTHRIOT mice. These effects were preceded by reduction in serum bone formation markers Alp and P1NP and the bone resorption marker CTX after 1 month of treatment in caPTHRIOT mice. Furthermore, the high periosteal and endocortical mineral apposition rate (1.7 and 2.3-fold) and bone formation rate (2.8 and 2.4-fold) exhibited by the caPTHRIOT mice were reversed to WT levels by KD014 treatment. In contrast, WT mice were not affected by KD014. Unexpectedly, the effect of KD014 on bone mass and bone formation occurred even when Sost remained low and Wnt target genes (Axin2, Bmp1 and Smad6) and osteoblast markers (Runx2, col1A, and Osx) remained high in caPTHRIOT mice treated with KD014. In contrast, the elevated expression of Alp, Enpp1, Enpp3 and Ank, key genes involved in extracellular phosphate metabolism and hydroxyapatite deposition, was reversed to WT levels in KD014-treated caPTHRIOT mice. Moreover, KD014 decreased the hydroxyapatite content of caPTHRIOT bones in both trabecular and cortical compartments, as quantified by micro-CT. These results demonstrate that MMP14 is a novel target of PTH required for bone remodeling and mineral apposition driven by PTH receptor signaling in osteocytes, and suggest that regulation of extracellular phosphate metabolism is crucial for full bone anabolism by PTH.

Mineral remodeling characterized by carbonate ion substitution is associated with MMP-13 in both HYP and wild-type mice during pregnancy and lactation. Courtney McEachon¹, Carolyn Macica², Steven Tommasini^{1*}. ¹Yale University, USA, ²Frank H. Netter, M.D., School of Medicine at Quinnipiac University, USA

The skeleton plays a major role in the homeostasis of calcium and phosphate and acts as a reservoir for these essential minerals. We previously used HYP mice, a murine model of X-linked hypophosphatemia (XLH), to study how impaired mineral metabolism affects skeletal adaptations to the increased mineral demands of pregnancy and lactation. The data revealed that both HYP and wild-type mice undergo a form “mineral remodeling” in which phosphate in the mineral matrix is replaced with carbonate. This unique form of remodeling provides phosphate for the developing fetus in the latter phases of development and for lactation without significant net maternal bone loss. However, the mechanism is unknown. We hypothesized that mineral mobilization was facilitated by osteocyte expression of matrix metalloproteinase-13 (MMP-13), which degrades the collagen matrix, freeing up mineral ions for phosphate homeostasis. Here, we analyzed the spatial distribution of the matrix composition of bone in wild-type and HYP mice. Regions of cortical bone were isolated around pores in synchrotron radiation-based FTIR maps and images of MMP-13 immunostaining. Using a custom Matlab algorithm, we measured carbonate ion substitution, collagen cross-linking, and MMP-13 as a function of distance relative to a pore's edge. Our results show the spatial co-localization of MMP-13 expression, carbonate substitution, and collagen cross-linking around intracortical porosities consisting of unmineralized osteoid and osteocyte lacunae (Fig. 1). The highest levels of MMP-13 and carbonate substitution corresponded to alterations in collagen cross-linking and occurred within 5 to 10µm of a pore. Quantitatively, carbonate substitution decayed exponentially as a function of distance, as did the ratio of reducible to non-reducible cross-links. Alterations in matrix composition occurred in both wild-type and HYP, but HYP had a 50% higher baseline of carbonate substitution throughout the skeleton in both the pregnant and lactating states. Together with the elevated expression of MMP-13 in HYP, the data point to a higher osteocyte-mediated contribution to mineral homeostasis due to lack of trabecular bone available for osteoclastic resorption. Also consistent with our hypothesis, these data suggest this mechanism of “mineral remodeling” protects the skeleton from excessive bone loss during periods of high mineral demand and may be essential to the rapid recovery of bone following cessation of lactation.

Inducible WNT16 Inactivation Demonstrates that WNT16 is a Major Regulator of Cortical Bone Thickness in Adult Mice. Sofia Moverare Skrtic^{*1}, Petra Henning¹, Jianyao Wu¹, Karin Gustafsson¹, Klara Sjögren¹, Marie Lagerquist¹, Fu-Ping Zhang², Matti Poutanen², Ulf Lerner¹, Claes Ohlsson¹. ¹Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden, ²Department of Physiology, Institute of Biomedicine & Turku Center for Disease Modeling, University of Turku, Finland

Although substantial progress has been made in the therapeutic reduction of vertebral fracture risk in individuals with osteoporosis, non-vertebral fracture risk has been improved only marginally by currently available treatments, defining an unmet medical need. Our previous unbiased human genome-wide association studies revealed that the WNT16 locus is a major determinant of cortical bone thickness and nonvertebral fracture risk and our subsequent mechanistic studies using global and cell-specific deletion of *Wnt16* in mice demonstrated that osteoblast-derived WNT16 is a key regulator of cortical bone thickness and fracture susceptibility (1-3). However, these mechanistic studies were based on mouse models with lifelong global or tissue-specific inactivation of *Wnt16*, not being able to separate between developmental effects and effects on adult bone metabolism.

To investigate the role of WNT16 specifically for adult cortical bone homeostasis, *Wnt16* was conditionally ablated in adult male mice through tamoxifen-inducible Cre-mediated recombination using *CAG-CreER;Wnt16^{lox/lox}* mice. At 10 weeks of age, tamoxifen was administered i.p. for 4 consecutive days using two different doses, 0.25 and 1 mg/mouse/day, respectively. *CAG-CreER* mice did not have a cortical bone phenotype and, therefore, tamoxifen-treated *CAG-CreER;Wnt16^{lox/lox}* mice were compared with tamoxifen-treated *Wnt16^{lox/lox}* mice at 14 weeks of age.

Tamoxifen dose-dependently substantially decreased the *Wnt16* mRNA levels in the cortical bone of *CAG-CreER;Wnt16^{lox/lox}* mice compared to tamoxifen-treated *Wnt16^{lox/lox}* mice (0.25 mg/mouse/day, $-80.9 \pm 7.0\%$; 1 mg/mouse/day, $-96.3 \pm 1.1\%$, $p < 0.01$). In addition, tamoxifen dose-dependently decreased femur cortical bone thickness in the adult *CAG-CreER;Wnt16^{lox/lox}* mice (0.25 mg/mouse/day $-10.9 \pm 1.3\%$; 1 mg/mouse/day, $-14.1 \pm 2.7\%$, $p < 0.05$). Notably, when evaluated in all mice, cortical bone thickness was directly associated with *Wnt16* mRNA levels in cortical bone ($r = 0.52$, $p = 0.006$), supporting a crucial role of WNT16 in the regulation of cortical bone thickness.

These findings demonstrate that WNT16 regulates cortical bone thickness in adult mice. We propose that new treatment strategies targeting the adult regulation of WNT16 might be useful to reduce fracture risk at cortical bone sites.

Osteoclast-Specific Deletion of Mef2C Causes High Bone Mass Independent of Sost. Nicole M. Collette¹, Deepa K. Murugesu¹, Crista S. Yee², Nicholas R. Hum¹, David Gravano², Jennifer O. Manilav², Alex G. Robling³, Gabriela G. Loots¹. ¹Lawrence Livermore National Laboratory, USA, ²University of California, Merced, USA, ³Indiana University, USA

Mef2C is a transcription factor that binds to *ECR5*, a *Sost* transcriptional regulatory region, and is required for *Sost* expression in osteocytes. *Mef2C* conditional deletion in osteoblasts and osteocytes causes high bone mass (HBM). We have shown that ablation of *Mef2C* in *Mef2C^{CKO}* mice using an osteoblast-specific (*Coll-Cre*) results in *Sost*-dependent HBM; conditional deletion of *Mef2C* with an osteocyte-specific (*Dmp1-Cre*) *Cre* deleter also resulted in HBM. The HBM phenotype in *Mef2C^{CKO}; Coll-Cre* mice was driven by increased bone formation, whereas the HBM phenotype in *Mef2C^{CKO}; Dmp1-Cre* mice was driven by both increased bone formation and decreased bone resorption. To determine whether the HBM phenotype observed in *Mef2C^{CKO}; Dmp1-Cre* mice was attributed solely to *Sost* down-regulation, we characterized bone parameters of *Sost^{KO}; Mef2C^{CKO}; Dmp1-Cre* mice. We found *Sost^{KO}; Mef2C^{CKO}; Dmp1-Cre* mice to have a bone volume: total volume (BV/TV) ratio of over 83% by mCT, or ~700% more bone than control mice, and 2X more bone than *Sost^{KO}* alone, suggesting that *Mef2C* has a significant *Sost*-independent effect on bone mass. Subsequently, we found robust *Mef2C* expression, but no *Sost* expression, in osteoclasts. We also found that *Rosa26-LacZ* reporter mice crossed with the *Dmp1-Cre* allele, but not the *Col1-Cre* allele, expressed in osteoclasts. We hypothesized that *Mef2C* plays a dual role in bone metabolism, as an anti-anabolic and pro-catabolic transcriptional mediator, such that conditional loss of *Mef2C* in osteoclasts impairs osteoclast function and reduces resorption, independent of *Sost*. To determine whether *Mef2C* has a role in osteoclasts, we examined the bone parameters of *Mef2C^{CKO}; Ctsk-Cre*. Immunofluorescent staining confirmed the expected loss of *Mef2C* in *Mef2C^{CKO}; Ctsk-Cre* osteoclasts, while osteoblast/osteocyte expression of both *Mef2C* and *Sost* were unaffected. We found *Mef2C^{CKO}; Ctsk-Cre* femurs to have HBM, approximately 25% BV/TV, compared to 9.4% for *Mef2C^{CKO}* controls. In addition, *Sost^{KO}; Mef2C^{CKO}; Ctsk-Cre* compound mice had 2X more bone mass than *Sost^{KO}*, supporting a new role for *Mef2C* in osteoclasts. To determine whether *Mef2C* is involved in osteoclast differentiation, we quantified osteoclast

precursor populations and found early osteoclast precursors to be 50% reduced in *Mef2C^{KO}*; *Ctsk-Cre* bone marrow compared to wildtype or *Sost^{KO}* controls, suggesting that *Mef2C* significantly influences osteoclast differentiation.

Sclerostin Antibody (Scl-Ab) Increased Bone Mass and Strength in a Mouse Model of Osteogenesis Imperfecta Caused by Wnt1 Mutation. Kyu Sang Joeng¹, Ming-Ming Jiang¹, Terry Bertin¹, Hao Ding², Yuqing Chen¹, Xiaohong Bi², Catherine Ambrose², Brendan Lee¹, Yi-Chien Lee^{*1}. ¹Baylor College of Medicine, USA, ²University of Texas Health Science Center at Houston, USA

Background: Osteogenesis Imperfecta (OI) is a brittle bone disease characterized by low bone mass and multiple bone fractures. Recently, our laboratory and others have identified *WNT1* mutations in patients with OI. We have also established and described a mouse model of OI caused by *WNT1* mutations (*swaying* mouse model). Current treatment options for OI mostly focus on bisphosphonate therapy; however, because of its questionable efficacy in some OI patients and concerns about long-term administration, it is necessary to explore new treatment strategy. Sclerostin is a potent inhibitor of WNT signaling, and several studies have shown that the inhibition of sclerostin greatly enhances bone formation. Therefore, we hypothesized that Scl-Ab treatment could be beneficial for treating *WNT1* related OI and tested this hypothesis using our *swaying* mouse model.

Methods: In this study, we followed two treatment regimens: from week 3 to week 8 (the early treatment group) and from week 9 to week 14 (the late treatment group). *swaying* mice and wild-type littermates were subcutaneously administered vehicle or 25 mg/kg Scl-Ab twice a week for 6 weeks (n=4-10 per group). Bone mass was assessed by microCT, bone strength by three-point bending, and matrix composition by Raman spectroscopy.

Results: First, the Scl-Ab treated *swaying* mice in the early treatment group exhibited reduced fracture rate from 90% (vehicle treated *swaying* mice) to 12.5% fracture rate (Scl-Ab treated *swaying* mice). microCT analysis showed that Scl-Ab treated *swaying* mice exhibited significantly increased bone volume per tissue volume in both the femur and lumbar spine (p-value < 0.01) in both early and late treatment groups. Three point bending analysis at the femur confirmed that the Scl-Ab treated *swaying* mice show increased bone strength parameters including maximum load, stiffness, and post-yield energy. Finally, Raman analysis demonstrated that the Scl-Ab treated *swaying* mice have increased bone collagen content in bone matrix.

Conclusions: These results suggest that Scl-Ab treatment significantly rescued the low bone mass phenotype and increased bone strength in *swaying* mice. These results support future investigations of a potential clinical benefit of Scl-Ab in the management of OI patients with *WNT1* mutations.

Romosozumab (Sclerostin Antibody) Improves Bone Mass and Bone Strength in Ovariectomized Cynomolgus Monkeys After 12 Months of Treatment. Michael S Ominsky^{*1}, Aurore Varela², Susan Y Smith², Jacquelin Jollette², Elisabeth Lesage², Sabina Buntich¹, Rogely W Boyce¹. ¹Amgen Inc., USA, ²Charles River Laboratories Preclinical Services, Canada

Romosozumab, a sclerostin antibody, is a bone-forming agent under clinical investigation for the treatment of osteoporosis. To examine its effects on bone quality over the duration of proposed clinical treatment in a remodeling species, bone mass and strength were assessed in ovariectomized (OVX) cynomolgus monkeys treated for 12 mos.

Cynomolgus monkeys (≥9 yrs) were OVX and 4 mos later were treated with weekly sc injections of either vehicle (Veh) or 3 or 30 mg/kg romosozumab for 12 mos, or 30 mg/kg romosozumab for 6 mos followed by Veh for 6 mos (n=6-16/group). Doses provided a 1x and 20x multiple of clinical exposure.

Bone mass increased dose dependently throughout the skeleton, with 12-mo DXA BMD increases from predose of 14-19% (3 mg/kg) and 24-26% (30 mg/kg) at the lumbar spine and proximal femur. By pQCT, cortical thickness (Ct.Th) increased by 23% from predose at the tibial diaphysis due to geometric changes on both periosteal and endocortical surfaces with 30 mg/kg; increased Ct.Th was also observed *ex vivo* at the femoral neck, femoral diaphysis, and L3 vertebra relative to OVX-Veh. Trabecular bone mass and thickness also increased robustly with both doses of romosozumab. Despite a transient 2% reduction in cortical vBMD at the radius at mo 6, 1 yr of romosozumab at either dose did not affect cortical porosity in the rib, tibia, or humerus, and ash-based tissue mineralization in the humerus or vertebra.

Significant improvements in bone strength were observed, with peak load significantly increased with 30 mg/kg at the femoral diaphysis (21%) and femoral neck (53%), and with 3 and 30 mg/kg in lumbar vertebral bodies (62-131%) and cancellous cores (91-156%), relative to OVX-Veh. Bone mass remained positively correlated with strength at these sites, with no changes in material properties calculated from bending tests at the femoral diaphysis and humeral cortical beams. These bone quality measures were also maintained in the group that transitioned to Veh at mo 6, despite a gradual loss of bone mass.

Romosozumab treatment of OVX cynomolgus monkeys for 12 mos resulted in marked improvements in bone mass, cortical geometry, and bone strength. Romosozumab maintained bone quality as reflected in mass-strength regressions, calculated material properties, and ash analysis. These results support the bone efficacy and safety profile of romosozumab and suggest that treatment-related BMD improvements should yield improved bone strength in osteoporosis patients.

Neutralizing Antibody and Orally Active Small Molecule Inhibitors of the Secreted WNT Inactivating Lipase NOTUM Stimulate Cortical Bone Formation in Ovariectomized Rodents. Robert Brommage^{*}, Andrea Thompson, Melanie Shadoan, Jeff Liu, Sabrina Jeter-Jones, Jie Cui, David Potter, Dawn Bright, Faika Mseeh, Jennifer Bardenhagen, Gwenn Hansen, Peter Vogel, James Tarver, David Powell, Qingyun Liu, Brian Zambrowicz. Lexicon Pharmaceuticals, USA

WNT signaling, involving WNTs, FZDs, LRP6, Sclerostin, DKK1 and SFRP4, plays a key role in bone formation and identification of additional genes in this pathway can provide novel therapeutic approaches to treat osteoporosis. NOTUM is a secreted enzyme that inactivates WNTs by removing a palmitoleic acid group essential for activity. Male and female Notum KO mice have normal soft tissue histology, bone length and trabecular bone parameters, but elevated cortical bone thickness (9 cohorts, total KO N=165) with increased strength. Enzymatic and cell-based assays of NOTUM activity were employed to screen both a chemical library and antibodies generated against mouse NOTUM. Neutralizing antibody 2.78.33 had IC50 potencies of 37 and 4 nM in enzymatic and cell-based assays, respectively. Small molecule (SM) LP-935001 had IC50 potencies of 0.4 and 12 nM in enzymatic and cell-based assays, respectively. Exposure of differentiating MC3Tc-E1 osteoblasts to NOTUM conditioned medium prevented mineralization, which was reversed by cotreatment with SM inhibitors. Eight weeks following surgery, sham-surgery and OVX mice were treated with Ab 2.78.33 (10 mg/kg weekly) for 4 weeks starting at 24 weeks of age. Treatment increased cortical thickness (P < 0.01) similarly in sham and OVX mice in midshaft femur (12%), vertebral body (9%) and femoral neck (6%). Triple fluorochrome labeling on days 7 (calcein), 14 (alzarin) and 21 (demeclocycline) showed 3-fold elevations in midshaft femur endocortical MS at 7 and 14 days but minimal activity at 21 days. BFR was elevated 4-fold between 7 and 14 days. Sixty-three weeks following surgery, OVX rats were treated with LP-935001 (daily oral gavage at 1 and 5 mg/kg) for 12 weeks starting at 80 weeks of age. High dose treatment increased (P < 0.02) cortical bone thickness in midshaft femur (6%), distal tibia (9%), pelvis (12%), vertebral body (7%) and femoral neck (6%). Bone strength was elevated (P < 0.01) in midshaft femur (13%), midshaft tibia (7%) and femoral neck (15%). Two courses of double fluorochrome labeling showed 3.6- and 3.2-fold elevations in distal tibia endocortical BFR during 1 to 3 weeks (alzarin) and 9 to 11 weeks (calcein) of treatment, respectively. These findings demonstrate NOTUM is a WNT inhibitory factor reducing bone formation. As a secreted enzyme inhibitable by neutralizing antibodies and orally active SMs, NOTUM is a potential drug target for stimulating endocortical bone formation and treating osteoporosis.

Parathyroid hormone administration regulates osteoprogenitor numbers and decreases their differentiation into the adipocytic lineage *in vivo*. Henry M. Kronenberg¹, Noriaki Ono², Deepak H. Balani^{*1}. ¹Massachusetts General Hospital & Harvard Medical School, USA, ²University of Michigan, School of Dentistry, USA

The contribution of mature osteoblasts to the bone anabolic response induced by parathyroid hormone (PTH) has been studied extensively. However, the role of osteoprogenitors in fuelling that anabolic response is poorly understood. Recently our group identified osteoprogenitors in young postnatal mice. Using a lineage-tracing strategy, we showed that Sox9 promoter/enhancer labels progenitors with multilineage potential and self-renewing capabilities *in vivo*. In this study we show that Sox9 promoter/enhancer actively labels the multi-potential skeletal progenitors in older mice. Further, we hypothesized that PTH may regulate the numbers of Sox9⁺ progenitors *in vivo* and preferentially direct them towards the osteoblastic lineage, thereby contributing to its anabolic action. To understand if PTH affects proliferation and/or differentiation of progenitors, we utilized a creER-mediated lineage-tracing strategy using 6-8 week old Sox9creER²;Rosa26-tdTomato. Osteocalcin (Ocn)-GFP triple transgenic mice. Mice received 2 mg tamoxifen first and 24h later were started on daily subcutaneous injections of PTH or vehicle for 3, 7 and 21 days. No Tomato⁺ signal was seen in the absence of tamoxifen confirming the non-leakiness of the cre recombinase. Both flow cytometry and histology showed that Tomato⁺ cells were significantly increased in mice that received PTH in a dose and time-dependent manner. PTH increased the proliferation of these cells as corroborated by an *in vivo* EdU assay. The increase in the numbers of Tomato⁺ cells was seen as soon as 3 days after PTH administration in the primary spongiosa, periosteal and the endocortical surfaces. On Day 3 Tomato⁺ cells were not yet Ocn-GFP⁺. On Day 7 and Day 21 we

observed several Tomato⁺ cells that also expressed Ocn-GFP present on bone surfaces and buried as osteocytes. Strikingly, following 21 days of daily PTH injections, mice that were subjected to PTH withdrawal for 4 weeks showed a significant increase in bone marrow adiposity. A fraction of adipocytes was Tomato⁺, which was not observed in corresponding controls. We present novel observations wherein we successfully label adult multi-potential skeletal progenitors and witness increase in proliferation and their differentiation into osteoblastic lineage subsequent to PTH administration. We also show that on PTH withdrawal there is a reduction in the number of Tomato⁺ osteoblasts and concomitant replacement of bone marrow by Tomato⁺ adipocytes.

Peripheral Nerves Provide Essential Cellular Components for Heterotopic Ossification. Elizabeth Salisbury*, Za Waunya Lazard, Eric Beal, Corinne Sonnet, Eleanor Davis, Elizabeth Olmsted-Davis, Alan Davis. Baylor College of Medicine, USA

We have previously developed an animal model of heterotopic ossification (HO), in which we deliver cells producing bone morphogenetic protein 2 (BMP2) to the skeletal muscle of mice. This leads to the recruitment of key cellular players, including transient brown adipocytes (tBAT), chondrocytes, and osteoblasts, that ultimately contribute to bone formation within the muscle. Using this model, we have shown the tBAT formed during HO derives from a cell within the perineurium (nerve sheath) of peripheral sensory nerves. In the studies presented here, we determined that the osteoblasts also have a neural origin and have further characterized the progenitor populations within the nerve. Within the first day following BMP2 induction, we observed a population of cells in the endoneurium (inner nerve layer) expressing the osteoblast markers *osterix* and *dlx5*. However, two days after delivery of BMP2, these cells disappear from the endoneurium and FACS analysis showed these cells to now be found within the blood. In order for these osteoprogenitor cells to exit the nerve and enter the general circulation, they must cross the blood-nerve-barrier (BNB), which protects the microenvironment of the nerve, into the endoneurial vessels. At this time, these osteoprogenitors began to express the tight junction molecule *claudin5*, which may assist these cells in traversing the BNB. In later days, these *osterix*/*claudin5*⁺ cells exit the bloodstream by extravasation to the area of bone formation. To further characterize both the endoneurial and perineurial progenitors within the nerve, we utilized lineage tracing mice. *Wnt1* is a marker of neural crest stem cells. Using an inducible-*Wnt1* Cre fluorescent reporter mouse, we observed what appear to be fluorescent osteoblasts within the site of bone formation, suggesting a unique neural pool of osteoprogenitors. In addition, we found the tBAT perineurial progenitors co-express the glutamate aspartate transporter (GLAST). Interestingly, GLAST expression has been reported within chondrocytes, as well as astrocytic neuroglia. We employed an inducible-GLAST reporter mouse to track this perineurial population, by correlating expression of tBAT (UCP1, ADRB3), chondrocytes (*sox9*), and astrocytes (GFAP). Collectively, these data suggest the peripheral nerves give rise to multiple, key cell types that not only coordinate the formation of, but are also progenitors for, cartilage and bone during HO.

α SMA⁺ macrophages skewed from hematopoietic stem cells by vitamin D3 initiate myelofibrosis and subsequent osteosclerosis. Kanako Wakahashi*¹, Kentaro Minagawa¹, Noboru Asada¹, Yuko Kawano¹, Mari Sato¹, Hiroki Kawano¹, Akiko Sada¹, Shigeaki Kato², Kotaro Shide³, Kazuya Shimoda³, Toshimitsu Matsui¹, Yoshio Katayama¹. ¹Hematology, Kobe University Graduate School of Medicine, Japan, ²Soma Central Hospital, Japan, ³Gastroenterology & Hematology, Miyazaki University, Japan

Myelofibrosis is frequently complicated with osteosclerosis (MF/OS). The pathogenesis is largely unknown and bone marrow (BM) transplantation is the only curable therapy in clinic. Here, we established a novel MF/OS model. We transplanted wild-type (WT) BM cells into lethally irradiated vitamin D receptor (VDR) ^{-/-} mice and found that hematopoietic stem cells (HSCs) selectively disappeared at 3 weeks after transplantation followed by the death of vast majority of mice due to BM failure in 3 months. Since VDR ^{-/-} mice show normal hematopoiesis, we transplanted VDR ^{-/-} BM into lethally irradiated VDR ^{-/-} recipients, which resulted in survival with no BM failure. These data suggested that the loss of VDR ^{+/+} HSCs was due to the exposure to high vitamin D3 (vitD) in VDR ^{-/-} microenvironment. BM cavity at 1-2 months after transplantation of WT BM into VDR ^{-/-} recipients was occupied by spindle shaped cells and silver fibers with prominently increased trabecular bones mainly in metaphysis. This was initiated by the hematopoietic cells since CD45+lineage-c-kit+ cells isolated from WT CAG-EGFP transgenic mice as donor source induced MF/OS in VDR ^{-/-} recipients. Monotonous fibroblastic cells in metaphysical BM were composed of two distinct populations with mutual distribution, 1) GFP+F4/80+ donor-derived macrophages and 2) GFP-*osterix*⁺ host-derived preosteoblasts. Both populations were positive for α SMA. Importantly, VDR mRNA level in HSCs was 30 times higher than lineage⁺ mature hematopoietic cells, and low vitD diet prevented our model from the development of MF/OS. Furthermore, macrophage depletion by clodronate liposome also inhibited the MF/OS. Thus, the true pathogenesis is likely

that α SMA⁺ macrophages as MF-initiating cells are perhaps directly differentiated from HSCs by the strong vitD signal in BM microenvironment, and drive the activity of preosteoblasts as a major producer of collagen fibers which is the origin of OS. In human MF patients, JAK2 V617F is a major disease-initiating mutation. And JAK2 V617F transgenic (JAK2 Tg) mice display MF/OS. We confirmed that marrow fibroblastic cells of JAK2 Tg mice were composed of α SMA+CD169+ macrophages and α SMA+*osterix*⁺ osteoblastic cells. A preliminary data showed that VDR ^{-/-} JAK2 Tg BM induced less severe fibrosis compared to VDR ^{+/+} JAK2 Tg BM when transplanted into WT recipients. We propose that the inhibition of vitD signaling or macrophage-targeted strategies could be novel therapeutic choices for this disease.

Bone lining cells are a major source of osteoblasts during bone remodeling. Brya Matthews*¹, Igor Matic¹, Xi Wang¹, Danka Grecevic², Ivo Kalajzic¹. ¹University of Connecticut Health Center, USA, ²University of Zagreb, Croatia

Mesenchymal stem cells are thought to provide a continuous supply of mature osteoblasts during bone remodeling. However, under certain conditions, bone-lining cells (BLCs) can activate into matrix producing osteoblasts. The ability to identify BLCs and understand their role in bone physiology has been very limited. We propose a novel mechanism of bone remodeling that introduces BLCs as a major source of osteoblasts and preosteoblasts in adult bone. To selectively identify BLCs we labeled osteoblasts and a subset of osteocytes using 10kb-Dmp1CreER12/Ai9 (iDMP-Ai9) mice following tamoxifen treatment (Cre directed Tomato expression). Labeled cortical surface decreased from >90% one day after labeling to 40% by 21 days and then remained stable up to 180 days later. Matrix producing osteoblasts remained labeled long after they would be expected to undergo apoptosis or maturation to osteocytes, suggesting continuous activation of BLCs. To distinguish the fate of BLCs from osteoblasts we crossed the Col2.3 Δ TK suicide gene into iDMP-Ai9 mice. Following ganciclovir treatment, cuboidal osteoblasts were absent, while flat BLCs were labeled. After 21 days of recovery, new osteoblasts form, and new areas of active bone surface are covered by iDMP-Ai9 expressing osteoblasts indicating activation of BLCs. EdU staining demonstrated DNA synthesis and cell division of labeled cells. Similar studies using α SMACreER12, a marker of mesenchymal progenitors, showed contribution to marrow fibrosis, but minimal contribution of α SMA-labeled bone marrow cells to bone formation during recovery. A large proportion of BLCs express mesenchymal stem cell markers while osteoblasts do not (*Sca-1* – 41% vs <1% in Col2.3GFP+ cells, CD51 – 60-80% vs 10-20%, *LepR* – 22% vs 3%), and BLCs have the ability to form colonies and mineralized nodules in vitro, but not adipocytes. Transplanted BLCs can participate in healing of a calvarial defect and differentiate into osteoblasts and osteocytes. In contrast, endogenous BLCs did not make a major contribution to fracture callus formation, or healing of a tibial hole defect. Furthermore we evaluated whether glucocorticoid treatment affects activation of BLCs. Prednisolone treatment in mice following osteoblast ablation showed reduced activation of lining cells after 7 days and delayed the recovery of bone parameters. Our results define the bone lining cell as a major source of proliferating and mature osteoblasts during bone remodeling.

Osteocyte-specific Deletion of Cathepsin K Prevents Increased Bone Turnover, Bone Loss and Bone Fragility during Lactation in Mice. Sutada Lotinun*¹, Riku Kiviranta², Vincent Carpentier³, Lynn Neff³, Daniel Brooks⁴, Mary Boussein⁴, Roland Baron⁵. ¹Department of Oral Medicine, Infection & Immunity, Harvard School of Dental Medicine, USA & Department of Physiology & STAR on Craniofacial & Skeletal Disorders, Faculty of Dentistry, Chulalongkorn University, Thailand, ²Department of Medical Biochemistry & Genetics & Department of Medicine, University of Turku, Finland, ³Department of Oral Medicine, Infection & Immunity, Harvard School of Dental Medicine, USA, ⁴Center for Advanced Orthopedic Studies, Beth Israel Deaconess Medical Center, & Harvard Medical School, USA, ⁵Department of Oral Medicine, Infection & Immunity, Harvard School of Dental Medicine & Harvard Medical School, Endocrine Unit, Massachusetts General Hospital, USA

Lactation induces a substantial loss of bone mass in order to provide adequate amounts of calcium to pups through milk production, a process that involves not only osteoclasts and bone resorption but also osteocytes and perilacunar osteolysis (Qing H. et al, J Bone Miner Res, 27:1018-1029 2012). Interestingly, lactation results in enlarged osteocytic lacunae, presumably through perilacunar osteolysis, and induces the expression of cathepsin K (Ctsk) and TRAP in osteocytes. To determine whether the induction of Ctsk in osteocytes contributes to the increased resorption and perilacunar osteolysis induced by lactation, we crossed 10kb DMPI-Cre with Ctsk^{fl/fl} mice to specifically delete Ctsk in late osteoblasts and osteocytes. This resulted in a significant deletion of Ctsk in osteocytes. At steady state, targeted deletion of Ctsk in osteocytes had no effect on bone remodeling and homeostasis in female mice. As

expected, lactating control mice showed increased bone resorption (N.Oc/B.Pm, 1.13^{0.23} vs 1.89^{0.20} mm⁻¹) and decreased bone formation rate per tissue volume (88.32^{9.19} vs 66.04^{5.34} %/year), leading to decreased cancellous bone volume (5.97^{0.54} vs 4.02^{0.23} %) and significantly altered mechanical properties, decreasing max bending moment, failure moment, bending stiffness and estimated strength. Strikingly, this lactation-induced increased remodeling and bone loss was prevented in the absence of Ctsk in osteocytes (N.Oc/B.Pm, 1.89^{0.20} vs 0.48^{0.08} mm⁻¹; BFR/TV, 66.04^{5.34} vs 101.47^{5.51} %/year; BV/TV, 4.02^{0.23} vs 5.52^{0.40} %). Lactation also increased osteocyte lacunar area (23.28^{1.32} vs 31.23^{1.31} μm^2) and osteocyte density (4.99^{0.38} vs 6.54^{0.31} $\times 10^{-4}/\text{cm}^3$) in cortical bone and deletion of Ctsk in osteocytes prevented these changes. Furthermore, deletion of Ctsk in osteocytes also prevented the negative effects of lactation on the mechanical properties of bone. In summary, deleting Ctsk in osteocytes prevented the alterations in bone formation, bone resorption, perilacunar osteolysis, bone volume and biomechanical properties induced by lactation. Our data therefore demonstrate that Ctsk expression in osteocytes contributes to the increased remodeling, bone loss and deterioration of mechanical properties observed during lactation, providing genetic evidence that Ctsk contributes to the regulation of bone remodeling and homeostasis exerted by osteocytes.

Rho-Pkn3 Pathway Regulates the Bone-resorbing Activity of Osteoclasts under Wnt5a-Ror2 Signaling. Shunsuke Uehara^{*1}, Hideyuki Mukai², Teruhito Yamashita³, Takashi Nakamura⁴, Shigeaki Kato⁵, Akira Kikuchi⁶, Michiru Nishita⁷, Yasuhiro Minami⁷, Nobuyuki Udagawa⁸, Naoyuki Takahashi³, Yasuhiro Kobayashi³. ¹Matsumoto Dental University, Jp, ²Biological Research Center, Kobe University, Japan, ³Institute for Oral Science, Matsumoto Dental University, Japan, ⁴Department of Biochemistry & Integrative Medical Biology, School of Medicine, Keio University, Japan, ⁵Soma Central Hospital, Japan, ⁶Department of Molecular Biology & Biochemistry, Graduate School of Medicine, Osaka University, Japan, ⁷Department of Physiology & Cell Biology, Graduate School of Medicine, Kobe University, Japan, ⁸Department of Biochemistry, Matsumoto Dental University, Japan

We previously reported that Wnt5a induces the RANK expression in osteoclast precursors through Ror2-JNK signaling, which in turn, facilitates osteoclast differentiation. Although Ror2 is highly expressed in osteoclasts, it is still unclear whether Wnt5a-Ror2 signaling is involved in the bone-resorbing activity of osteoclasts. Osteoclast-specific Ror2 conditional knock-out mice (*Ror2* cKO) were generated by crossing *Ror2^{fl/fl}* mice with cathepsin K-Cre (*Ctsk^{Cre/+}*) mice. MicroCT analysis of femurs revealed that bone volume in *Ror2* cKO was higher than that in control (*Ror2^{+/+}*; *Ctsk^{Cre/+}*) mice. In addition, serum CTX, a bone resorption marker, was lower in *Ror2* cKO. Osteoclast number in femurs and serum ALPase activity, a bone formation marker, remained the same in *Ror2* cKO. These results suggest that increased bone mass in *Ror2* cKO is due to the impaired bone-resorbing activity of osteoclasts. Osteoclasts formed from bone marrow cells of *Ror2* cKO showed the low bone-resorbing activity on dentine slices due to a defect in actin ring formation. Wnt5a activated both Rho and Rac in control osteoclasts, but not in *Ror2* cKO osteoclasts. Overexpression of constitutively active (CA)-RhoA, but not CA-Rac1, rescued the bone-resorbing activity of *Ror2* cKO osteoclasts. To clarify the mechanisms by which Rho regulates the bone-resorbing activity of osteoclasts, we examined the expression of Rho effectors using real-time RT-PCR. Among 13 Rho effectors, the expression of *Pkn3* (encoding protein kinase N3; Pkn3) was significantly increased during osteoclast differentiation. Phosphorylation levels of Pkns were lower in osteoclasts from *Ror2* cKO than those from control mice. This result suggests that Wnt5a-Ror2 signaling regulates the kinase activity of Pkns including Pkn3. MicroCT analysis showed that the bone volume of femurs from *Pkn3^{-/-}* mice was higher than that from wild-type mice (WT). Serum CTX was lower in *Pkn3^{-/-}* mice. Osteoclast number in femurs from *Pkn3^{-/-}* mice was comparable to that from WT. These results suggest that the bone-resorbing activity of osteoclasts in *Pkn3^{-/-}* mice is impaired. Osteoclasts from *Pkn3^{-/-}* mice showed the suppressed bone-resorbing activity *in vitro*. The enforced expression of full-length Pkn3 rescued the bone-resorbing activity of *Pkn3^{-/-}* osteoclasts, but that of Pkn3 lacking proline rich region did not. Taken together, Wnt5a-Ror2 signaling regulates the bone-resorbing activity of osteoclasts through Rho-Pkn3 pathway.

Maternal Obesity Programs Senescence Signaling and Glucose Metabolism in Fetal Osteoblastic Cells. Jin-Ran Chen^{*1}, Oxana P. Lazarenko², Michael L. Blackburn², Thomas M. Badger², Kartik Shankar². ¹University of Arkansas for Medical Science, Arkansas Children's Nutrition Center, USA, ²University of Arkansas for Medical Sciences & Arkansas Children's Nutrition Center, USA

Nutritional status during intrauterine and early postnatal life impacts the risk of chronic diseases, presumably via epigenetic mechanisms. However, evidence on the impact of gestational events on regulation of bone development is sparse. Here, we designed studies both in rodents and humans to investigate the effects of maternal obesity on bone development. First, female Sprague-Dawley rats were fed either a low-fat AIN-93G control diet or a high fat diet (HFD) (45% fat calories) for 10 wks starting at 6 wks of age. After 10 wks of these diets, lean (from control diet) and obese (from HFD) female rats were time-impregnated (n=6 per group) by control diet male rats. At gestational day 18.5 (E18.5), all fetuses were taken and embryonic osteogenic calvarial cells (EOCCs) were isolated. We found epigenetic regulation of polycomb-regulated genes in embryonic rat from HFD obese dams. Increased enrichment of repressive histone mark H3K27me3 on the gene bodies of IGF1 and TCFAP2 in synergy with decreased H3K27me3 at the promoter of BMP4 was associated with increased cell senescence signaling in EOCCs. BMP4 and EGR1 dependent p53/p21-mediated increase of cell senescence signaling and decreased aerobic glycolysis were imprinted in HFD-EOCCs resulting in decreased osteoblast differentiation potential. Second, twenty four pregnant women [12 obese (pre-pregnancy BMI ≥ 30 Kg/m²) and 12 lean (pre-pregnancy BMI 19 - 25 Kg/m²)] were recruited during last three years. Upon delivery, placentas and umbilical cords (UCs) were collected and cells from the UC matrix were isolated as UC human mesenchymal stem cells (UC MSCs). The UC MSCs were counted and plated in growth media in a single well of a six-well plate. Cells were expanded until the third passage after which they were fluorescently labeled with antibodies against CD13, CD29, CD44, CD90, CD105, CD31, CD34, and CD45 and analyzed via FACS. The UC MSCs of obese mothers displayed less potential toward osteoblastogenesis and more toward adipogenesis. These human MSCs and placentas from obese mothers not only exhibited increased cell senescence signaling and decreased glucose metabolism but also insulin resistance. These findings indicate fetal pre-osteoblastic cell senescence signaling and glucose metabolism programming by maternal obesity in both rodents and humans. *Supported in part by ARS CRIS #6251-51000-005-03S (JRC).*

Roles of Mineralization Heterogeneity and Porosity in the Fracture Resistance of Human Cortical Bone. Mathilde Granke^{*1}, Alexander J Makowski², Sasidhar Uppuganti¹, Jeffrey S Nyman². ¹Vanderbilt University Medical Center, USA, ²Vanderbilt University Medical Center, VA Tennessee Valley Healthcare System, USA

The association between rare atypical femoral fractures and long-term use of bisphosphonates has drawn attention to the loss of heterogeneity in tissue mineralization as a possible mechanism contributing to skeletal fragility. However, there are conflicting reports on whether increased or reduced heterogeneity exists between osteoporotic fracture and control cases, and there is little experimental evidence that heterogeneity is even a determinant of fracture resistance. Based on computational models suggesting that tissue heterogeneity at the microstructural level promotes fracture resistance, we hypothesized that the age-related decrease in fracture toughness in human cortical bone is partly explained by a decrease in heterogeneity of tissue mineralization.

A cortical bone sample was obtained from the lateral mid-diaphysis of 39 human femurs (19 male, 20 female, age = 65 \pm 20 yrs [24-101]) and machined into a single-edge notched beam specimen. Fracture toughness testing of the beam (crack propagating normal to osteon direction) provided the resistance to crack initiation (K_{init}) and overall crack toughness (J). Then, a cross-section adjacent to the fracture path (~2.5 mm x 4.5 mm) was imaged by backscattered SEM (1 μm pixel size). Images were segmented to obtain the distribution of porosity and calibrated using standard materials to convert grey levels into tissue mineralization (wt % Ca) (Fig. 1).

An age-related decrease in K_{init} was significantly associated with micro-structural differences, namely greater intracortical porosity characterized by the presence of larger pores but lower lacunar porosity (Table 1). Resistance to fracture was also negatively correlated with the degree of mineralization ($C_{a,mean}$, $C_{a,peak}$). Mineral heterogeneity ($C_{a,width}$) did not correlate with fracture resistance properties (Table 2). However, an inverse relationship existed between K_{init} and the occurrence of hypomineralization ($C_{a,low}$) in bones from females (r=-0.50, p=0.027). Including gender as a covariate, non-lacunar porosity and hypomineralization explained 46% of the variance in resistance to crack initiation.

These results suggest that the heterogeneity of mineralization existing across numerous osteons and interstitial sites within the cortex is not a major determinant of fracture resistance of human femur cortical bone. However, it does not preclude other types of heterogeneity (e.g. at the osteonal/interstitial interface) from affecting bone fragility.

Cartilage β -Catenin Signaling Plays a Key Role in the Development of Ankylosing Spondylitis. Tianqian Hui*, Wanqing Xie, Shan Li, Chundo Oh, Hee-Jeong Im, Di Chen. Rush University Medical Center, USA

Ankylosing spondylitis (AS) is an autoimmune disease of spine and joint and cartilage is the major tissue affected by this disease. Up-regulation of Wnt/ β -catenin signaling has been reported in patients with AS. In this study, we determined if activation of β -catenin signaling in chondrocytes is the key event leading to destructions of the spine and disc tissues during the development of AS. We have generated chondrocyte-specific β -catenin conditional activation mice (β -cat(ex3)Col2ER), by breeding β -cat(ex3)lox/lox mice with Col2-CreERT2 transgenic mice. 1) We found that severe destruction of disc tissues in 3- and 6-month-old β -cat(ex3)Col2ER mice, including severe loss of cartilage tissues in endplate, disorganized annular fibrosus (AF) and nucleus pulposus (NP) tissues and large amounts of osteophyte formation in the entire spine. 2) We have recently generated immortalized rat AF and NP cell lines (immortalized AF and NP cells have been passed over 50 generations and they maintain proliferation and differentiation properties). We found that treatment with BIO, a GSK-3 β inhibitor (mimic β -catenin activation), stimulated Top-flash reporter activity (6-15 folds) in both AF and NP cells after 24 h treatment. BIO induced Mmp13 (8 and 11 folds) and Ccl2 (6 and 11 folds) expression in AF and NP cells. 3) To determine if Mmp13 is a key downstream target of β -catenin signaling, we generated (β -cat(ex3)/Mmp13)Col2ER double mutant mice and found that deletion of Mmp13 significantly reversed defects observed in disc tissue of β -cat(ex3)Col2ER mice. 4) In addition to the disc tissues, we also observed severe damage and loss of proteoglycan and defects in cartilage structure in the facet joint in 4- and 9-month-old β -cat(ex3)Col2ER mice, demonstrated by Alcian blue and Safranin O staining. 5) CCL2 has been demonstrated as a key mediator in osteoarthritis pain. In the present studies we found that Ccl2 was significantly up-regulated by the activation of β -catenin signaling in both AF and NP cells. We then determined changes in pain-related behavior in 4-9 month old β -cat(ex3)Col2ER mice. The β -cat(ex3)Col2ER mice had significantly increased pain sensitivity as evidenced by lower von Frey thresholds ($P < 0.001$), and this pain behavior sustained throughout the entire experimental period (9 months). Also rearing counts were reduced in 4-9 month old β -cat(ex3)Col2ER mice compared to Cre-negative controls ($P = 0.007$) so does ambulation counts ($P = 0.013$). Taking consideration of our previous observations from β -cat(ex3)Col2ER mice with osteoarthritis phenotype in knee joint and temporomandibular joint, the findings observed in disc and facet joint tissues of β -cat(ex3)Col2ER mice largely resemble key features found in patients with AS. Our findings suggest that activation of β -catenin signaling in cartilage tissue may be the key event leading to spine and joint destruction in patients with AS.

Reduced osteoclast TGF β signaling in the aged skeleton impairs the coupling of bone resorption to bone formation through reduced osteoclast Wnt1 expression. Megan Weivoda*¹, Ming Ruan¹, Christine Hachfeld¹, Larry Pederson¹, Rachel Davey², Jeffrey Zajac², Jennifer Westendorf¹, Sundeep Khosla¹, Merry Jo Oursler¹. ¹Mayo Clinic, USA, ²University of Melbourne, Australia

Osteoclasts secrete factors that couple bone resorption and formation. These processes are uncoupled with age through unclear mechanisms, resulting in age-related bone loss. TGF β is abundant in the bone and is released and activated by osteoclasts. We have shown that conditioned media from TGF β -treated osteoclasts stimulates pre-osteoblast migration and differentiation. Because the concentration of TGF β in bone matrix decreases with age, we hypothesized that reduced osteoclast TGF β signaling contributes to age-related uncoupling of bone resorption and formation. Dominant negative TGF β receptor (Tgfr-2) was expressed in osteoclasts using Ctsk promoter Cre mice (Tgfr2^{Cre/KO}). MicroCT analysis of 5 month-old animals revealed osteopenia in Tgfr2^{Cre/KO} mice with significant reductions in femur and vertebral BV/TV. Histomorphometry of the femurs showed no change in osteoclast numbers; however, osteoblast numbers and bone formation rates were reduced 60% in Tgfr2^{Cre/KO} mice. Mineral apposition rates were unchanged, indicating that the reduced bone formation rate was not a result of impaired osteoblast function. Microarray was utilized to identify genes induced in TGF β -treated osteoclasts and data was validated by qPCR. Of interest, 2ng/mL TGF β induced Wnt1 expression >1000-fold. Wild type osteoclasts cultured on bone, a source of matrix-TGF β , also exhibited Wnt1 induction; this induction was impaired in Tgfr2^{Cre/KO} osteoclasts. IHC of Tgfr2^{Cre/KO} femurs revealed a 53% reduction in osteoclast Wnt1 in vivo. To determine whether osteoclast TGF β signaling was disrupted with aging, we performed IHC on young and old (4 and 26 month) femurs. Consistent with the age-related decrease in matrix TGF β , phospho-SMAD2/3, a marker of Tgfr signaling, was significantly reduced in old bone osteoclasts in vivo. Osteoclasts derived from young and old bone marrow showed similar inductions of Wnt1 expression by exogenous and young bone matrix-TGF β . However, culture of osteoclasts derived from young bone marrow on old bone matrix resulted in a 72% reduction in matrix-induced Wnt1, and IHC revealed that osteoclast Wnt1 expression was reduced 64% in old mice in vivo. These data demonstrate that impaired Tgfr signaling in osteoclasts causes osteopenia by reducing osteoblast numbers and establish a novel paradigm by which TGF β stimulated osteoclasts are a key source of factors such as Wnt1 that promote osteoblastic bone formation at sites of bone resorption.

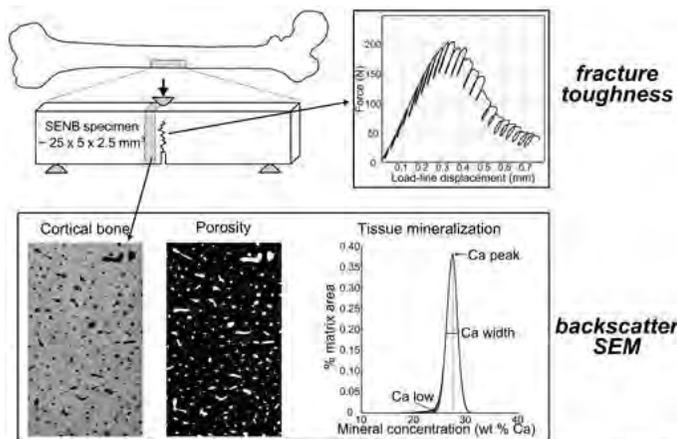

Figure 1: Schematic of the study design. Following fracture toughness testing, a polished cross-section adjacent to the crack propagation site was imaged with quantitative backscattered scanning electron microscopy. SEM images were segmented to separate the mineralized matrix from the pores which encompass the intracortical porosity (pore larger than 100 μ m² that include Haversian canals, Volkmann's canals, resorption cavities) and the lacunar porosity (occupied by osteocytes). The distribution of the calcium concentration within the matrix was characterized by the following parameters: Ca mean (average Ca concentration), Ca peak (most frequent Ca concentration), Ca width (full width half maximum of Ca concentration), and Ca low and Ca high (spread of the distribution on the low and high concentration sides, respectively, defined as the deviation of the mineral distribution from a Gaussian curve).

Table 1: Spearman rank correlation between fracture toughness properties and porosity (r (pval))

Discovery of PCO371, an orally active small-molecule PTH1R agonist for the treatment of hypoparathyroidism. Hiroshi Noda*, Eri Joyashiki, Maiko Hoshino, Tomoyuki Watanabe, Yoshikazu Nishimura, Tohru Esaki, Kotaro Ogawa, Masaru Shimizu, Hidetomo Kitamura, Tatsuya Tamura, Haruhiko Sato, Yoshiki Kawabe. Research Division, Chugai Pharmaceutical Co., Ltd., Japan

Parathyroid hormone (PTH) plays a primary role in maintaining serum calcium (Ca). Hypoparathyroidism (hypoPT) is a rare disease characterized by hypocalcemia and lack of PTH. Conventional therapy of hypoPT, high doses of oral Ca and active vitamin D analogs, can increase the risk of hypercalciuria. Human PTH(1-84) has recently been approved as a treatment option for hypoPT. It would maintain serum Ca while reducing Ca and requirements of vitamin D analogs by replacing the missing hormone. However, due to its short half-life, multiple injections are necessary to maintain serum Ca at a steady level. Since hypoPT is a chronic disorder, there exists an unmet need for orally bioavailable small-molecule which can mimic PTH.

The pharmacological actions of PTH are mediated via the PTH1R, a class B GPCR. No orally active small molecule agonists of the PTH1R have yet been reported. To identify such small molecule agonist, we used a cell-based high throughput screening with LLC-PK1 cells transfected with the human PTH1R (hPTH1R) by using urokinase plasminogen activator activity as a readout. Hit-compounds found from our compound library were optimized to identify a chemical candidate, PCO371, 1-({3,5-dimethyl-4-[2-({4-oxo-2-[4-(trifluoromethoxy)phenyl]-1,3,8-triazaspiro[4.5]dec-1-en-8-yl]sulfonyl)ethyl]phenyl}-5,5-dimethylimidazolidine-2,4-dione). In COS-7 cells transfected with the hPTH1R, the compound stimulated cAMP production and PLC activation in a dose-dependent manner, but not in cells transfected with vector alone. PCO371 displaced ¹²⁵I-labeled hPTH(1-15) that was bound to the membranes in those cells. PCO371 also stimulated Ca release in fetal rat long bone cultures as well as hPTH(1-34) did. These results suggest that PCO371 acts as a full agonist on the PTH1R. Single oral administration of PCO371 showed calcemic and hypophosphatemic actions in thyroparathyroidectomized (TPTX) rats; the effects were more potent and long-lasting than those of hPTH(1-34). In 4-week repeated dosing studies in TPTX rats, once-daily oral PCO371 increased serum Ca to the normal range. Co-treatment with once-daily oral PCO371 and alfacalcidol normalized serum Ca, and also reduced urinary Ca excretion and the requirements of alfacalcidol. These results indicate that PCO371 is the first example of an orally active small-molecule PTH1R agonist that can mimic the biological functions of PTH. It would provide a new option for the treatment of patients with hypoPT.

A Hajdu Cheney Mutant Mouse Exhibits Profound Osteopenia. Ernesto Canalis*, Lauren Schilling, Kyeong Lee, Stefano Zanotti. UConn Health, USA

Notch receptors play a critical role in skeletal development and bone homeostasis. Hajdu Cheney Syndrome (HCS) is a devastating disease characterized by acro-osteolysis, severe osteoporosis with fractures and sudden death. HCS is associated with a gain-of-function of NOTCH2, where point mutations in exon 34 lead to a truncated and stable protein product lacking sequences necessary for its degradation. Despite the skeletal manifestations reported in HCS, mechanisms underlying the bone loss are not known. To understand the disease process, we created a mouse model harboring a Notch2 mutant allele reproducing the mutation found in subjects with HCS manifesting pronounced osteoporosis with fractures. The mutation, 6946C>T in humans and 6955C>T in mice, creates a STOP codon at glutamic acid 2319 in mice, upstream the PEST domain required for Notch degradation. Sequences necessary for Notch2 transcriptional activity are preserved. The 6955C>T mutation was introduced into the Notch2 locus by homologous recombination, verified by DNA sequencing, and mice characterized following removal of the selection cassette. Notch target genes were increased in bone and osteoblast cultures from Notch2Q2319X mice, demonstrating Notch signal activation in the skeleton. Homozygous Notch2Q2319X mutants exhibited newborn lethality, whereas heterozygous mice had pronounced cancellous and cortical bone osteopenia. Compared to littermate controls, microcomputed tomography of Notch2Q2319X mutants revealed a 50-55% decrease in cancellous bone volume and markedly decreased connectivity. Cortical thickness, total and cortical cross-sectional areas were decreased by 20-40%. Histomorphometry revealed a ~30% increase in osteoclast number and eroded surface, and a modest decrease in bone formation. Flow cytometry of bone marrow cells revealed a 20-25% increase in osteoclast precursors in Notch2Q2319X mice, and bone marrow mononuclear cells had an increased capacity to form multinucleated osteoclasts in response to M-CSF and RANK-L, explaining the enhanced bone resorption. Osteoblast cultures exhibited decreased alkaline phosphatase and osteocalcin expression and increased RANK-L mRNA. In conclusion, a genetically engineered HCS mutant mouse recreates the human disease and exhibits pronounced osteopenia due to an increase in the osteoclast precursor cell pool and osteoclastogenesis leading to increased bone resorption. For the first time, the skeletal pathogenesis of HCS is explained.

Decreased cancellous bone mass in a murine model of type 1 diabetes is caused by cell autonomous effects of FoxOs in committed osteoblast precursors and their descendants. Srividhya Iyer*¹, Li Han², Serra Semahat Ucer², Ha-Neui Kim², Aaron Warren², Julie Crawford², John Fowlkes³, Stavros Manolagas², Maria Almeida². ¹Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA, ²Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA, USA, ³Barnstable Brown Diabetes & Obesity Center, University of Kentucky College of Medicine, UK Healthcare, USA

Type1 diabetes (T1D) is associated with osteopenia and increased risk of fragility fracture, as well as poor fracture healing. These skeletal abnormalities are often associated with reduced serum markers of bone formation. As in humans, murine models of T1D generated via genetic or pharmacologic means exhibit decreased bone formation and low bone mass. However, the molecular mechanisms responsible for these effects remain unknown. Nonetheless, insulin increases the proliferation and differentiation of osteoblastic cells in vitro and mice lacking the insulin receptor in osteoblasts have reduced osteoblast numbers and decreased trabecular bone mass. Insulin signaling suppresses the activity of the FoxO transcription factors; and FoxOs inhibit osteoprogenitor proliferation and bone formation by sequestering β -catenin away from TCF-mediated transcription. Prompted by this evidence we investigated here whether FoxOs are responsible for the low bone mass in T1D. To do this, we used mice lacking FoxO1,3,4 in Osx1-Cre expressing cells (FoxO1,3,4^{Osx1-Cre}) and their control littermates (FoxO1,3,4^{fl/fl}). At 4 weeks of age males of both genotypes (n=10-14 per group) were injected with vehicle or 40 μ g/g body weight of streptozotocin (STZ) for five days to induce T1D. Ninety percent of the STZ-injected mice had elevated blood glucose levels (>250 mg/dl) and were considered diabetic. Forty days later mice were sacrificed and micro-CT analysis revealed that the diabetic FoxO1,3,4^{fl/fl} mice had reduced spinal cancellous bone volume, as compared to their non-diabetic controls. These changes were associated with lower trabecular thickness, but unchanged trabecular number. In contrast, cancellous bone volume or trabecular thickness was unaffected in diabetic FoxO1,3,4^{Osx1-Cre} mice. Similar results were obtained in the cancellous bone of the femur. In line with its effect on bone mass, diabetes caused a reduction in vertebral strength in FoxO1,3,4^{fl/fl} mice but not in FoxO1,3,4^{Osx1-Cre} mice. Nonetheless, in difference to cancellous bone, diabetes reduced femoral cortical thickness in both FoxO1,3,4^{fl/fl} and FoxO1,3,4^{Osx1-Cre} mice. Ongoing histologic analysis should elucidate the cellular mechanisms responsible for the differential effects of diabetes in cortical versus cancellous bone. Taken together, our results strongly suggest that FoxOs mediate the deleterious effects of T1D on cancellous bone.

Protein Phosphatase 5 (PP5) conveys negative effect of rosiglitazone on bone by inversely regulating PPAR γ and Runx2 activities. Lance A. Stechshulte*¹, Piotr J. Czernik², Edwin R. Sanchez³, Beata Lecka-Czernik¹. ¹Department Orthopaedic Surgery, Center for Diabetes & Endocrine Research, University of Toledo, College of Medicine & Life Sciences, USA, ²Micro Tomografix Ltd., USA, ³Department of Physiology & Pharmacology, Center for Diabetes & Endocrine Research, University of Toledo, College of Medicine & Life Sciences, USA

Energy metabolism and bone mass are interconnected. Conditions with compromised energy balance, such as diabetes, obesity, and aging, are associated with increased risk of fractures due to decreased bone mass and/or bone quality. This implicates an existence of a common mechanism regulating energy and bone metabolism. Two transcription factors, PPAR γ and Runx2, are key regulators of mesenchymal stem cells (MSCs) differentiation toward adipocytes (AD) or osteoblasts (OB), respectively. PPAR γ and Runx2 are subjected to posttranslational modifications, which determine their activities. Dephosphorylation of PPAR γ at S112 and S273 is required for activation of pro-AD and insulin sensitizing activities, whereas phosphorylation of Runx2 at S319 is required for pro-OB activity. Upon rosiglitazone (Rosi) treatment, which promotes MSCs commitment toward AD and away from the OB lineage, both PPAR γ and Runx2 undergo dephosphorylation which increases PPAR γ and suppresses Runx2 activity. We have recently identified the Protein Phosphatase 5 (PP5) as a specific enzyme inversely regulating PPAR γ and Runx2 activities associated with phosphorylation. In the presence of Rosi, PP5 binds to PPAR γ and Runx2 in the cell nuclei and dephosphorylates both. Knockdown of PP5 in marrow MSCs decreased PPAR γ and increased Runx2 activity and correlated with increased phosphorylation of both factors. Most importantly, PP5 deficiency rendered marrow MSCs unresponsive to pro-AD and anti-OB effects of Rosi suggesting that *in vivo* PP5 may convey negative effects of Rosi on bone. To test this hypothesis, WT and mice deficient in PP5 (PP5-KO) were treated with Rosi for 8 wks at the dose of 20 mg/kg/d. In response to this treatment, WT animals gained 80% of body weight and doubled fat content, whereas PP5-KO mice were resistant to these effects. Most importantly, while Rosi administration resulted in 50% decrease in bone mass of WT, there was only 13% decrease in bone mass of PP5-KO animals. An analysis of gene expression in the OBs freshly isolated from femora endosteal surface indicated that in WT Rosi decreased the expression of OB-specific transcription factors, Osterix and Dlx5, whereas it did not affect the expression of these factors in OBs isolated from PP5-KO mice. In conclusion, PP5 mediates negative effect of Rosi by upregulating PPAR γ and suppressing Runx2 activity. These results also suggest that PP5 is the immediate target for Rosi. This possibility is currently being tested.

Hydrogen Sulfide Is a Novel Regulator Of Bone Formation Implicated In The Bone Loss Induced by Estrogen Deficiency. Francesco Grassi*¹, Abdul Malik Tyagi², Jonathan Adams², Lindsey D. Walker², Jau-Yi Li², John W Calvert³, Laura Gambari⁴, Gina Lisenoli⁴, Jerid Robinson², Roberto Pacifici⁵. ¹Laboratorio RAMSES, Istituto Ortopedico Rizzoli, Italy, ²Division of Endocrinology, Metabolism, & Lipids, Emory University, USA, ³Cardiothoracic Research Laboratory, Department of Surgery, Emory University, USA, ⁴Lab di Immunoreumatologia e Rigenerazione Tissutale, Istituto Ortopedico Rizzoli, Italy, ⁵Division of Endocrinology, Metabolism, & Lipids, Immunology & Molecular Pathogenesis Program, Emory University, USA

Critical for the bone wasting effect of estrogen deficiency is a potent stimulation of bone resorption that is only partially mitigated by an increase in bone formation. The mechanism that prevents bone formation from increasing as much as bone resorption in estrogen deficient humans and animals is unknown. Hydrogen sulfide (H₂S) is a gasotransmitter produced by mammalian tissues known to regulate stromal cell (SC) function and bone formation. To investigate whether H₂S plays a role in ovariectomy (ovx) induced bone loss, serum H₂S levels were measured in 14 week old WT mice, 4 weeks after ovx or sham operation. Serum H₂S was reduced by 55% in ovx mice compared to sham controls. The whole bone marrow (BM) and BM SC mRNA levels of the two key H₂S-generating enzymes, cystathionine β -synthase (CBS) and cystathionine γ -lyase (CSE), were 70-90 % lower in samples from ovx than sham operated mice, demonstrating that estrogen deficiency impairs the SC production of H₂S. To attest to relevance, sham and ovx mice were treated in vivo with the H₂S-donor, GYY4137 (50mg/kg/day IP) or vehicle for 4 weeks starting at surgery or 4 weeks after surgery. GYY4137 normalized the serum levels of H₂S in ovx mice, increased histomorphometric and biochemical indices of bone formation, and completely prevented or reversed the loss of trabecular bone induced by ovx. GYY4137 also blocked or reversed by ~80% the loss of cortical bone. In ovx mice GYY4137 increased CFU-ALP formation, an index of SC commitment to the osteoblastic lineage, and SC differentiation into osteoblasts, as determined by measurements of ALP, RUNX2, Collagen 1, BSP, Osterix mRNA levels. GYY4137 also decreased SC apoptosis. Moreover, H₂S increased the BM mRNA levels of WNT16, WNT2b and WNT6, resulting in Wnt activation in SCs. Studies in human cells showed that β -estradiol induces the expression of CBS and CSE in human BM SCs (hSCs) and confirmed that

H₂S-releasing drugs induce osteogenic differentiation of hSCs. Finally, silencing of CBS and CSE by siRNA abrogated hSCs ability to form mineralized nodules *in vitro*. In summary, our findings show that regulation of H₂S levels is a novel mechanism by which estrogen stimulates osteoblastogenesis and bone formation in mice and humans. Blunted production of H₂S contributes to ovx induced bone loss by limiting the compensatory increase in bone formation elicited by ovx. Restoration of H₂S levels is a potential novel therapeutic approach for postmenopausal osteoporosis.

FGFR3 Modulates Fracture Repair by Controlling the Balance of Intramembranous and Endochondral Bone Formation. Simon Kelley^{*1}, Chunying Yu², Heather Whetstone², Benjamin Alman³. ¹The Hospital for Sick Children, Toronto, Ontario, Canada, Canada, ²The Hospital for Sick Children, Canada, ³Duke University, USA

Fibroblast growth factor receptor 3 (*fgfr3*) mutations cause skeletal dysplasias with disparate phenotypes. Gain-of-function mutations are characterized by disproportionate short stature, whereas loss-of-function mutations are characterized by tall stature. *Fgfr3* is known to be a negative regulator of chondrocyte proliferation affecting long bone growth through endochondral ossification. However we observed that individuals with achondroplasia showed enhanced bone regeneration during distraction osteogenesis (intramembranous ossification) for surgical limb lengthening, thus we hypothesized that *fgfr3* affects mesenchymal proliferation and osteoblast differentiation, which act in concert with its known effects on chondrocyte function to manifest in the abnormal healing of bone fractures. To investigate the role of *fgfr3* in fracture healing we used an established murine semi-stabilized tibia fracture model in genetically modified *fgfr3* knockout mice and their wild type (WT) controls. Fractures were harvested and analyzed at critical time points (Post Fracture Day 3, 7, 14 and 21) using histomorphometry, micro-CT and gene expression analysis (qPCR) to assess fracture callus structure and composition. We showed that *fgfr3* modulates the size and structure of healing fracture callus with the *fgfr3* mutant calli showing peak callus size earlier than their WT controls (PFD7), yet showing reduced callus size at the later time points (PFD14, PFD21) suggesting an acceleration of fracture repair. Despite the overall rapidity of healing, the structural integrity of the healed mutant fractures was diminished. Enhanced endochondral bone formation in *fgfr3*^{+/-} mice accounted for the rapidity of bone healing however early peripheral subperiosteal bone formation from the intramembranous pathway was diminished in *fgfr3*^{+/-} mice suggesting that *fgfr3* has a role in switching between the two major systems of bone formation. Using bone marrow MSCs (BM-MSCs) from *fgfr3*^{+/-} and WT mice an in-vitro colony forming unit-fibroblast (CFU-F) assay, BrdU assay, limiting dilution and qPCR were performed demonstrating that *fgfr3* regulates the number, and proliferative ability of osteochondral progenitors. BM-MSC Colony forming unit-osteoblast (CFU-O), colony forming unit-chondrocyte (CFU-C) assays and qPCR revealed that under-expression of *fgfr3* decreases osteogenic differentiation but increases chondrogenic differentiation recapitulating those findings identified in the fracture model in-vivo. Thus we showed that *fgfr3* affects fracture healing by acting as a switch between intramembranous and endochondral ossification. Modulation of *fgfr3* signaling may offer the ability to direct progenitor cells towards specific bone regenerative pathways, which has enormous appeal for the enhancement of skeletal regeneration and repair.

Intermittent PTH Alleviates Abnormalities of Bone Tissue Heterogeneity Associated with Prolonged Bisphosphonate Treatment by Inducing Substantial New Bone Formation. Allison Altman^{*1}, Yong-Hoon Jeong², Wei-Ju Tseng¹, Chantal de Bakker¹, Ling Qin¹, Lin Han³, Do-Gyoon Kim², X. Sherry Liu¹. ¹University of Pennsylvania, USA, ²Ohio State University, USA, ³Drexel University, USA

Postmenopausal osteoporosis is often treated with bisphosphonates (BP, eg, alendronate, ALN), but over-suppression of bone turnover by long-term BP may reduce bone mineral heterogeneity, increasing the risk of atypical fractures. Our recent study demonstrated that intermittent PTH following long-term ALN in ovariectomized (OVX) rats efficiently improved bone mass and microarchitecture (FigA). The objective of this study was to test whether switching from ALN to PTH would alleviate abnormalities of tissue heterogeneity induced by ALN.

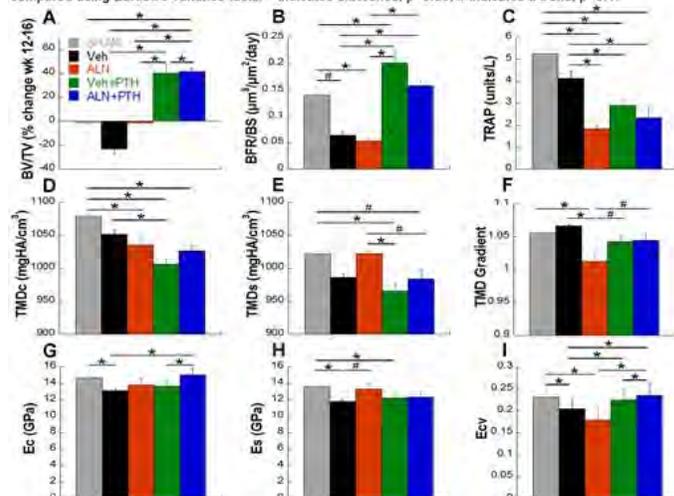

30 4-mo-old rats underwent OVX (n=24; 6x4 groups) or Sham (n=6) surgery. Treatment began at 6-mo-old (wk 0) for OVX rats: Veh (saline wk 0-16); ALN (28µg/kg 2x/wk wk 0-16); Veh+PTH (saline wk 0-12 & PTH 40µg/kg 5x/wk wk 12-16); ALN+PTH (ALN wk 0-12 & PTH wk 12-16). Bone formation (BFR/BS) was assessed by *in vivo* µCT-based dynamic analysis (wk 15&16 scanned@10.5µm) and resorption assessed by serum TRAP. The L2 vertebra were subjected to µCT (3.5µm) and nanoindentation to assess tissue mineral density (TMD) and modulus (E) at both the inner trabecular region (TMDc and Ec) and the edges (TMDs and Es).

In vivo dynamic analysis indicated a 16% lower BFR/BS in ALN vs. Veh, and a 212% and 147% higher BFR/BS in PTH and ALN+PTH vs. Veh, respectively (FigB). Serum TRAP in treatment groups were 42-55% lower than Veh (FigC). TMDs and Es tended to increase in ALN vs. Veh (4% p>0.1 & 13% p<0.1, respectively) with no difference in TMDc or Ec (FigDEGH). However, TMD gradient (TMDc/TMDs) and

the coefficient of variation of E (Ecv) were 5% and 13% lower in ALN vs. Veh, respectively (FigFI), indicating reduced heterogeneity in both tissue mineralization and material mechanical properties. PTH following ALN resulted in a trend of 4% lower TMDs than ALN alone. Moreover, bone tissue heterogeneity was restored as shown by a 3% higher mineralization gradient and 31% greater Ecv in ALN+PTH vs. ALN alone. Interestingly, TMDs was significantly correlated with Es (r=0.58, p<0.01) but TMDc and Ec was not correlated, suggesting that during the mineralization process (bone surface), TMD is a primary determinant of material properties, but once complete (bone center) TMD plays a lesser role.

In summary, prior treatment with ALN does not diminish the potential for PTH to increase new bone formation. By altering the tissue mineralization, PTH acts to alleviate abnormalities in heterogeneity of tissue mechanical properties induced by prolonged ALN treatment.

Figure. (A) Bone volume fraction (BV/TV) percent change during wks 12-16 at the tibia compared using repeated measures ANCOVA covaried by wk 12 BV/TV. (B) µCT-based bone formation rate (BFR/BS) from wk 15-16. (C) Serum TRAP analysis. At L2: (D) central TMD (TMDc), (E) surface TMD (TMDs), (F) surface-central TMD gradient. (G) central modulus (Ec), surface modulus (Es), and modulus coefficient of variation (Ecv) compared using Bartlett's variance tests. * indicates difference, p<0.05; # indicates a trend, p<0.1.

Genome-wide analysis of DNA methylation identifies a novel locus associated with bone mineral density. John Morris^{*1}, Pei-Chien Tsai², Fei Gao³, Vincenzo Forgetta⁴, Yudong Xia³, Celia Greenwood⁵, Elin Grundberg², Tim Spector², Jun Wang³, Jordana Bell², Brent Richards⁵. ¹McGill University, Ca, ²King's College London, United Kingdom, ³BGI-Shenzhen, China, ⁴Lady Davis Institute for Medical Research, Canada, ⁵McGill University, Canada

Osteoporosis is a common, complex disease characterized by increased bone fragility, often resulting in fracture. Bone mineral density (BMD) is measured to diagnose osteoporosis and estimate fracture risk. Studying the genetic determinants of BMD has led to novel disease pathophysiology insights. We sought to study epigenetic associations with BMD, as DNA methylation levels are known to influence or be secondary to disease phenotypes. To assess epigenetic associations with BMD, we undertook a genome-wide association study of DNA methylation levels. Methylation levels were estimated using methylated DNA immunoprecipitation sequencing (MeDIP-seq) to identify differentially methylated regions (DMRs) associated with BMD measured at the forearm, femoral neck, and lumbar spine in the TwinsUK cohort, in 890, 1,518, and 1,397 twins, respectively. An intergenic DMR on chromosome 6q21 was found to be significantly associated with forearm BMD ($P = 5.3 \times 10^{-9}$). Through the usage of publicly available functional genomics data, we have linked the DMR to an enhancer putatively interacting with PRDM1, a gene regulating osteoclastogenesis. Using multiple public data repositories for 3D nuclear conformations (Rao *et al.* 2014, *Cell* 159: 1665), enhancer RNAs (FANTOM5), DNaseI hypersensitivity sites (ENCODE), and epigenetic marks (Epigenome Roadmap), we find evidence that the region encompassing the DMR likely contains a regulatory element of PRDM1, in that it is in close 3D proximity to the PRDM1 promoter and the DNA at these two regions is coincidentally open in relevant cell types such as monocytes, an osteoclast precursor cell. Moreover, recent work suggests rare genetic variants are nominally associated with forearm BMD at this locus. Further work is underway to validate these and any other genetic associations with BMD at this locus. This study represents the most comprehensive genome-wide analysis to date of the role of methylation in BMD. This work forms a basis for future studies that will refine the definitive role of epigenetic mediated effects at this osteoclast locus.

Def6 restrains osteoclastogenesis and inflammatory bone resorption. Nikolaus Binder¹, F. Patrick Ross¹, Christine Miller¹, Lionel B. Ivashkiv¹, Georg Schett², Alessandra Pernis¹, Steven R. Goldring¹, Baohong Zhao^{*1}. ¹Hospital for Special Surgery, USA, ²University of Erlangen-Nuremberg, Germany

Abnormal generation and/or function of osteoclasts lead to pathological bone resorption in inflammatory disorders such as rheumatoid arthritis (RA). Def6, a novel type of guanine nucleotide exchange factor (GEF), plays an important role in the activation of lymphocytes by regulating IRF4 activity and/or exerting its function in conjunction with Swap70, the only other molecule with high homology to Def6. Recent studies show that IRF4 and Swap70 negatively regulate physiological osteoclast differentiation and function, respectively. In addition, Def6 deficiency leads to the development of RA like joint disease with bone erosion in a mouse model. These findings stimulated us to explore the role of Def6 in osteoclastogenesis and inflammatory osteolysis, as well as to investigate its underlying mechanisms of action. In this study, we found that osteoclast precursors from Def6 deficient mice (*Def6*^{-/-}) demonstrated enhanced sensitivity to RANKL in the early differentiation phase. Def6, unlike Swap70, did not affect actin ring formation or the function of osteoclasts. As TNF-alpha is a key pathogenic factor driving inflammatory bone resorption in RA, we next investigated the role of Def6 in TNF-mediated osteoclastogenesis. We found that lack of Def6 markedly enhanced TNF-alpha-induced osteoclastogenesis both *in vitro* and *in vivo* and resulted in increased bone resorption in a TNF-alpha-induced inflammatory osteolysis mouse model. In human system, Def6 levels were decreased in osteoclast precursors obtained from RA patients and were elevated after TNF blockade therapy. Furthermore, the osteoclastogenic capacity of the RA cells was significantly inversely correlated with Def6 expression levels, indicating that Def6 functions as an inhibitory factor in limiting enhanced osteoclast formation and bone destruction in RA. Mechanistically, we found that Def6 suppressed osteoclastogenesis and the expression of key osteoclastogenic factors NFATc1 and c-Fos by regulating an endogenous IFN-beta mediated autocrine feedback loop. Our data identify Def6 as a novel negative regulator of osteoclastogenesis in both physiological and inflammatory conditions and provide a novel mechanism for regulation of osteoclastogenesis driven by the Def6-IFN-beta axis. These results identify Def6 as an attractive therapeutic target to prevent bone destruction in inflammatory arthritis.

Gna13 gain-of-function to protect mice from inflammatory bone loss in rheumatoid arthritis through inhibiting AKT activity in osteoclasts. Mengrui Wu^{*1}, Wei Chen², Yun Lu², Guochun Zhu², Liang Hao², Yi-Ping Li². ¹The University of Alabama at Birmingham, USA, ²UAB, USA

Current resorption inhibitors are effective but far from ideal due to negative side effects (e.g., jaw osteonecrosis and increased bone fragility). Thus, a need for better therapeutic agents is compelling, and endogenous inhibitors may serve as powerful new therapeutic targets in osteoclast-related bone diseases. We found that knockdown of Gna13 *in vitro* and osteoclast-specific conditional knockout (CKO) of Gna13 *in vivo* promoted osteoclast differentiation and function via PI3K/Akt signaling. The average nuclei number of osteoclasts and average size of actin rings were increased in the absence of Gna13 (by 200% and 300%, respectively), which can be reversed by PI3K inhibitor LY294002 and AKT inhibitor MK2206HCl at a dose-dependent manner. On the other hand, over-expression of the constitutively active form of Gna13 (Gna13CA) in monocytes/macrophages and RAW264.7 cells inhibits osteoclast formation by 85%, which can be partly rescued by overexpression of the constitutively active form of AKT (AKTCA). Furthermore, we tested whether an AAV (adeno-associated virus) overexpressing Gna13CA *in vivo* would protect mice from inflammatory bone destruction induced by lipopolysaccharide (LPS) or in the Rheumatoid arthritis mice model induced by TNF α . In the LPS-injection model, both WT and Gna13 CKO mice were subjected to subcutaneous injection over calvaria with LPS or PBS. LPS induced mice showed a 2-fold increase in the number of osteoclasts and 3-fold more bone resorption. While the absence of Gna13 further promotes osteoclastogenesis and bone loss, local administration of AAV-G13CA over calvaria had a marked inhibitory effect on excessive osteoclast formation and bone destruction by LPS, by 60% and 50% respectively. TNF α transgenic mice automatically developed arthritis rheumatology accompanying excessive osteoclast formation and bone destruction. Local administration of AAV-G13CA over metacarpal bones largely reduced the number of osteoclasts and bone loss in the TNF α transgenic mice, by 90% and 72% respectively. Interestingly, cartilage destruction was also inhibited by 75% and swelling was also relieved after AAV-G13CA treatment. In summary, we demonstrated that Gna13 negatively regulates osteoclast fusion and function by inhibiting PI3K/AKT signaling, and Gna13-gain-of-function could serve as a potential and powerful therapeutic treatment to inflammatory bone loss.

The translational repressor Musashi-2 promotes osteoclastogenesis by regulating Numb/Notch signaling. Toshifumi Fujiwara^{*1}, Shiqiao Ye¹, Haibo Zhao². ¹Center for Osteoporosis & Metabolic Bone Diseases, Division of Endocrinology & Metabolism, Department of Internal Medicine, University of Arkansas for Medical Sciences & the Central Arkansas Veterans Healthcare System, USA, ²Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA

Notch receptors are transmembrane proteins that play an essential role in cell fate decisions and the regulation of proliferation and differentiation during development and adult life in mammals. Upon ligand binding, Notch receptors are cleaved by a γ -secretase complex. As a result, the Notch intracellular domain (NICD) is released from the plasma membrane and translocates to the nucleus, where it induces the expression of Notch target genes, including *Hes1*. Mounting evidence indicates that Notch signaling modulates RANKL-induced osteoclast (OC) differentiation *in vitro* and *in vivo*. Numb, an endogenous repressor of intracellular Notch signaling, inhibits osteoclastogenesis through degradation of NICD. Musashi (Msi) 1 and 2 are members of a family of RNA-binding proteins that activate Notch signaling through the translational repression of Numb. Msi1 also modulates tumor cell cycle progression and proliferation by inhibiting the translation of the cyclin-dependent kinase inhibitor p21WAF-1. Aberrant activation of Msi2 promotes acute myeloid leukemia in humans. Here, we report that Msi2, but not Msi1, is predominantly expressed in bone marrow macrophages (BMMs). Both mRNA and protein expression of Msi2 were dramatically increased during OC differentiation. Knocking-down Msi2 expression in BMMs by lentivirus-mediated shRNAs markedly decreased the formation of TRAP+ multinucleated OCs, as evidenced by diminished mRNA and protein expression of OC marker genes, such as TRAP, Cathepsin K, and NFATc1. In addition, loss of Msi2 in BMMs, pre-OCs or mature OCs led to an increase in Numb levels and a significant decrease in both NICD2 and *Hes1*. On the other hand, depletion of Notch2 or *Hes1* expression by shRNAs attenuated OC formation without changing Msi2 expression, suggesting that Msi2 regulates Notch activation in OC lineage cells through Numb. Msi2 deficiency had no effects on BMM proliferation, cell cycle progression, as well as the levels of p21WAF-1, cyclin D1 and D2. Moreover, deletion of Msi2 in OC precursors attenuated RANKL-induced NF κ B activation and promoted OC apoptosis, as demonstrated by increased DNA fragmentation and increased levels of cleaved caspase 3 and poly (ADP-ribose) polymerase. These results indicate that RANKL induces Msi2, which in turn activates Notch signaling during OC differentiation. Hence, Msi2 is critical for RANKL-induced osteoclastogenesis, at least in part, by regulating Numb/Notch/ NF κ B signaling.

Osteoclast-derived exosomal miR-214 inhibits osteoblastic bone formation. Defang Li^{*}, Jin Liu, Baosheng Guo, Chao Liang, Lei Dang, Aiping Lu, Ge Zhang. Institute for Advancing Translational Medicine in Bone & Joint Diseases, School of Chinese Medicine, Hong Kong Baptist University, Hong Kong SAR, China

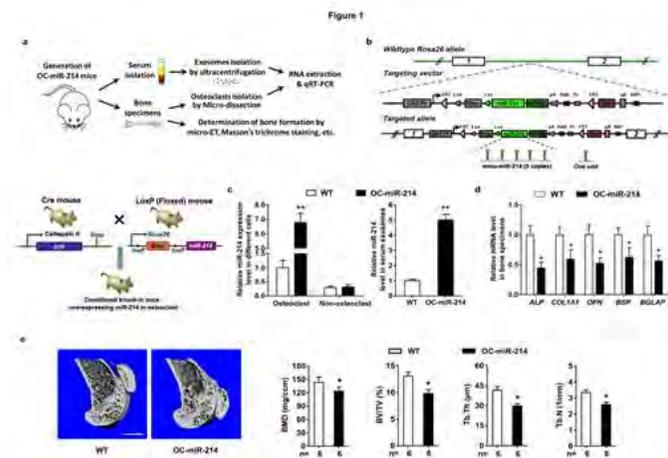

Introduction: Emerging evidences indicate that osteoclasts may direct osteoblasts to regulate bone formation, and that the dysregulation of microRNAs (miRNAs) plays a crucial pathophysiological role on skeletal disorders with a reduction in bone formation. Our previous work demonstrated that exosomal miR-214 transferred from osteoclast could inhibit osteoblast activity *in vitro*. Here we further showed that osteoclast-derived exosomal miR-214 could inhibit osteoblastic bone formation *in vivo*.

Experimental Design: (1) Study 1: To investigate whether osteoclastic miR-214 could inhibit bone formation in the conditional knock-in mice overexpressing miR-214 in osteoclast (OC-miR-214 mice). (2) Study 2: To examine whether exosomal miR-214 secreted from miR-214-overexpressed osteoclast (derived from OC-miR-214 mice) could inhibit bone formation *in vivo*.

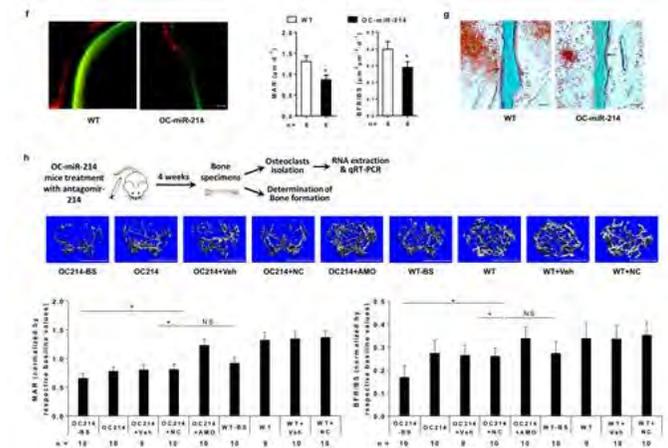

Results: In study 1, we successfully generated OC-miR-214 mice. The osteoclastic and serum exosomal miR-214 level was significantly higher in OC-miR-214 mice than those in WT mice (Fig 1a-c). In contrast, the intra-osseous mRNA levels of the bone formation marker genes *ALP*, *COL1A1*, *OPN*, *BSP* and *BGLAP* were all remarkably reduced in OC-miR-214 mice (Fig 1d). The micro-CT and bone histomorphometric analysis for the distal femora showed that poorly organized trabecular architecture, lower bone mass and lower bone formation in OC-miR-214 mice when compared to those in WT mice (Fig 1e-g). After treatment with antagomir-214, the above parameters were reversed and ameliorated at the distal femur in OC-miR-214+AMO mice (Fig 1h).

In study 2, the intra-osseous fluorescence signal was detected in mice administrated with PKH67-labelled exosomes derived from OC-miR-214 osteoclasts (Fig. 2a-b). Then, we isolated osteoblasts (*Alp*-positive cells) from bone marrow cells by fluorescence activated cell sorting. As expected, the intra-osteoblasts miR-214 level was elevated in mice administrated with PKH67-exosomes (Fig. 2c). Furthermore, the intra-osseous mRNA levels of *ALP*, *COL1A1*, *OPN*, *BSP* and *BGLAP* were remarkably decreased in mice treated with the exosomes (Fig 2d). Furthermore, the micro-CT and bone histomorphometric analysis for the distal femora showed that poorly organized trabecular architecture, lower bone mass and lower bone formation in mice after treatment with the exosomes when compared with the control group (Fig

2e-g).Conclusions: Osteoclast-derived exosomal miR-214 could inhibit osteoblastic bone formation.

Osteoclast lineage cells are a crucial source of Wnt proteins in load-induced bone modeling. Megan Weivoda^{*1}, Ming Ruan¹, Christine Hachfeld¹, Larry Pederson¹, Jean Vacher², Richard Lang³, Bart Williams⁴, Jennifer Westendorf¹, Sundeep Khosla¹, Merry Jo Oursler¹. ¹Mayo Clinic, USA, ²IRCM, Canada, ³Cincinnati Childrens, USA, ⁴Van Andel Institute, USA

Wnt signaling is essential for normal skeletal development. However, the source of skeletal Wnt proteins remains unclear. We previously demonstrated that mature osteoclasts secrete Wnt proteins. Therefore, we hypothesized that osteoclasts are a source of Wnt proteins in the developing skeleton. Real time PCR was utilized to measure Wnt expression during osteoclast differentiation and a genetic mouse model was employed to test the effect of impaired-osteoclast lineage Wnt secretion on skeletal development. Bone marrow macrophages expressed Wnts 2a, 2b, 3a, 4, 5a, 5b, 6, 7a, 7b, 9b, 10a, 10b, and 16. Wnts 1, 5b, 9a, and 11 transcripts increased with osteoclast differentiation whereas Wnts 2a, 2b, 3a, 4, 5a, 6, 7a, 7b, 9b, 10a, 10b, and 16 decreased. Mature osteoclasts expressed Wnt1, 2b, 3a, 4, 5a, 5b, 6, 7b, 9a, 10b, and 11. The membrane-associated chaperone, Wntless (Wls), is required for Wnt secretion. Transgenic CD11b-Cre mice were crossed with Wls flox mice to obtain animals with Wls selectively deleted in the osteoclast lineage. Homozygous deletion of Wls in the CD11b lineage was embryonic lethal; therefore, CD11b positive Wls F/+ mice (CD11b/Wls^{Het}) were assessed at 8 weeks of age. Analysis of bone marrow derived osteoclast conditioned-media confirmed that CD11b/Wls^{Het} osteoclasts secreted less Wnt protein. Ex vivo μ CT of CD11b/Wls^{Het} femurs showed significantly reduced bone volume, trabecular number, and trabecular thickness, with increased trabecular spacing and plate-like structure in cancellous bone. CD11b/Wls^{Het} femurs had reduced cortical thickness at the metaphysis and diaphysis with decreased periosteal perimeter. In contrast, μ CT analysis of CD11b/Wls^{Het} vertebrae showed no significant change in trabecular or cortical parameters, suggesting that osteoclast derived Wnt proteins play a role in mechanical load-induced long bone modeling. Histomorphometry of the CD11b/Wls^{Het} femurs showed significant increases in osteoclast number and modestly reduced osteoblast numbers on the periosteal and trabecular surfaces. Interestingly, CD11b/Wls^{Het} femurs showed a 70% reduction in bone formation rate on the periosteal surface. These data support that the osteoclast lineage is an important source of Wnt proteins in skeletal development, and may be involved in mechanical-load induced bone modeling.

RANKL/OPG double deficient medaka unveils the decision system for the bone resorption site in a whole-body. Masahiro Chatani^{*1}, Yoshiro Takano², Takeshi Todo³, Akira Kudo¹. ¹Tokyo Institute of Technology, Japan, ²Tokyo Medical & Dental University, Japan, ³Osaka University, Japan

Introduction: Bone shape is determined with bone resorption of osteoclasts. Osteoclast differentiation is enhanced by RANKL or inhibited by OPG. However, it is unclear how RANKL and OPG co-operatively regulate bone resorption in a whole body. We previously established the live imaging system using medaka fish, which allowed observation of an osteoclast behavior in a whole-body (Chatani et al., 2011). To clarify the mechanism of how RANKL and OPG control the site of bone resorption in a whole-body, we examined bone modeling during medaka development.

Methods: RANKL-deficient and OPG-deficient medaka were established by using Tilling (Targeting induced local lesions in genomes) and TALEN (Transcription activator-like effector nucleases) methods, respectively. Osteoclasts were live-imaged by using the TRAP promoter-GFP or DsRed transgenic line. To examine the function of OPG and RANKL, we performed cross-breeding of OPG^{-/-} medaka and RANKL^{-/-} medaka.

Results and discussion: We found three significant phenotypes of bone resorption. Firstly, OPG^{-/-}:RANKL^{+/+} medaka induced numerous osteoclasts that absorbed bones of the vertebral body and fin ray, whereas no osteoclasts existed on the vertebral body and fin ray in WT, suggesting that OPG inhibited osteoclast differentiation on the bone surface in WT. Secondly, to examine the role of RANKL in homozygous mutation of the OPG gene, we examined OPG^{-/-}:RANKL^{+/+} medaka. Contrary to expectation, osteoclasts were specifically localized at neural and hemal arches, suggesting the threshold for RANKL-dependent osteoclastogenesis limit on the vertebral body in this mutant. In addition, osteoclasts gathered at only edges of fin rays to degrade bone tissues, indicating the existence of a site where osteoclasts preferentially differentiate with a help of RANKL. Lastly, OPG^{-/-}:RANKL^{-/-} medaka indicated that osteoclasts, which were differentiated in the RANKL-independent pathway, were localized at neural and hemal arches with a defect of bone modeling, and no osteoclasts were observed at the edge of fin ray, indicating the existence of a RANKL/OPG-independent manner that determines osteoclast location on the bone surface. Taken together, our results suggested that the promotion of pre-osteoclast differentiation is regulated by both of RANKL and OPG, and the location of pre-osteoclasts is determined in the RANKL/OPG-independent manner.

The MicroRNA miR-23a Cluster Regulates the Differentiation of Osteoblasts into Osteocytes. Huan-Chang Zeng^{*}, Yangjin Bae, Yuqing Chen, Terry Bertin, Brian Dawson, Elda Munivez, Jianning Tao, Brendan Lee. Baylor College of medicine, USA

Recent studies have shown that microRNAs play important regulatory roles in skeletal development. However, how microRNAs can control osteocyte differentiation is unknown. The miR-23a cluster is one of the most enriched group of microRNAs in bone and has been reported to be involved in osteogenesis *in vitro*. We generated transgenic mice overexpressing this cluster with the collagen type I (Col1a1-2.3kb) promoter and found significantly increased density of osteocytes. In addition, the transgenic mice exhibited low bone mass phenotype by micro-computed tomography (μ CT) along with decreased numbers of osteoblasts, decreased mineral apposition rate but no significant change of the numbers of osteoclasts by histomorphometric analysis. Real-time PCR analysis of calvarial RNAs revealed increased expression of osteocytic markers including *Dmp1* and *Fgf23* and decreased expression of the mature osteoblast marker *Ocn*. To study the loss of function of this microRNAs cluster, we generated transgenic mice expressing microRNA decoys with the same Col1a1-2.3kb promoter. Although these mice also exhibited low bone mass, histomorphometry showed significantly decreased osteocyte density, opposite that of the gain of function. RNA-Seq and Ingenuity Pathway Analysis of bones from transgenic mice suggested that TGF- β as the potential signaling pathway contributing to osteocytic phenotype. Moreover, *Prdm16*, a negative regulator of TGF- β pathway, was the candidate target of the miR-23a cluster. Consistent with this, we observed transgenic TGF- β reporter activity was increased in the bones of the miR-23a cluster gain of function mice and decreased in the transgenic decoy loss of function mice. When we treated the miR-23a cluster transgenic mice with the TGF- β neutralizing antibody, ID11, at 6 weeks of age for 6 weeks, the low bone mass and osteocyte phenotype was rescued. Finally, *in vitro* osteogenic differentiation of the bone marrow stroma cells from the miR-23a cluster transgenic mice showed increased *Sost* expression as expected, and this increased expression could be suppressed by overexpression of *Prdm16*. Taken together, we identified that the miR-23a cluster could regulate osteocyte differentiation by TGF- β signaling pathway through its target *Prdm16*.

Class IIa HDACs are required for PTH-mediated suppression of SOST in osteocytes. Marc Wein^{*1}, Elizabeth Williams², Nicolas Govea², Shigeki Nishimori², Kenichi Nagano³, Daniel Brooks², Roland Baron³, Mary Bouxsein², Paola Divieti-Pajevic², Henry Kronenberg². ¹Massachusetts General Hospital, USA, ²MGH Endocrine Unit, USA, ³Harvard School of Dental Medicine, USA

Purpose: Intermittent PTH stimulates new bone formation by osteoblasts, in part by suppressing expression of the Wnt pathway inhibitor sclerostin (encoded by the gene SOST) in osteocytes. The signaling pathway between PTH receptor signaling and SOST suppression involves inhibition of MEF2 action, but otherwise is unknown. In chondrocytes, PTHrP blocks MEF2 through actions on class IIa HDACs. Therefore, we hypothesized that class IIa HDACs might similarly block MEF2 activity on the SOST gene in osteocytes. The purpose of this study is to determine the role of class IIa HDACs in PTH-mediated suppression of SOST in osteocytes. **Methods:** The skeletal phenotype of 8 week old global HDAC5^{-/-}, HDAC4^{fl/fl};DMP1-Cre, and double HDAC4/5 knockout (HDAC4^{fl/fl};HDAC5^{-/-};DMP1-Cre, "DKO") mice was determined by histology, micro-CT, and histomorphometry. Bone RNA was collected 90 minutes after a single pharmacologic dose of PTH (300 μ g/kg), and levels of SOST and RANKL were determined by RT-qPCR and semi-quantitative immunohistochemistry. The murine osteocytic cell line Ocy454 was used to study mechanisms of PTH-mediated SOST suppression *in vitro*. HDAC4 and HDAC5 were depleted from Ocy454 cells by CRISPR/Cas9-mediated genome editing and shRNA, respectively. **Results:** DKO mice show cortical osteopenia, woven bone, and increased osteocyte density. None of these phenotypes are present in either class IIa HDAC single knockout strain. DKO mice show 2.5-fold elevated SOST levels at baseline in bone RNA, and fail to suppress SOST mRNA and sclerostin protein in response to acute PTH administration *in vivo*. Each single HDAC null strain shows normal PTH-mediated SOST suppression. PTH-stimulated RANKL upregulation is intact in DKO mice. In Ocy454 cells, PTH stimulates the dephosphorylation of HDAC4 at S246 and HDAC5 at S259/279, and promotes the nuclear translocation of these two proteins. Ocy454 cells lacking both HDAC4 and HDAC5 also fail to down-regulate SOST in response to PTH, while RANKL upregulation occurs normally. **Conclusions:** PTH stimulates the nuclear translocation of HDAC4 and HDAC5 in osteocytes. Both HDAC4 and HDAC5 are required for PTH-stimulated SOST suppression *in vivo* and *in vitro*. The dramatic cortical bone phenotypes present in HDAC4/5 DKO mice are unlikely to be due solely to increased SOST levels, indicating that other functionally important targets for these proteins must exist.

SOST Downregulates Notch Signaling and Reverses the Effects of Notch in Osteocytes. Stefano Zanotti*, Lauren Schilling, Ernesto Canalis. UConn Health, USA

Notch receptors play a critical role in cell fate decisions. Activation of Notch1 in undifferentiated and mature osteoblasts impairs osteoblast differentiation/function, whereas Notch activation in osteocytes causes a distinct phenotype characterized by a pronounced increase in bone mass due to a suppression of cancellous bone resorption and enhanced cortical bone formation. The osteocyte-specific phenotype of the Notch1 activation is attributed to a downregulation of *Sost* and upregulation of *Tnfrsf11b* expression in the bone microenvironment. To explore the contributions of the *Sost* downregulation to the effects of Notch in osteocytes, Notch1 signaling was activated in the context, or not, of *SOST* overexpression. Notch1 activation in osteocytes was achieved by crossing dentin matrix protein (*Dmp1*)-Cre transgenics with *RosaNotch* mice to delete an intervening loxP flanked STOP cassette and allow expression of the Notch intracellular domain under the control of the *Rosa26* promoter. To determine whether the suppression of *Sost* expression by Notch1 contributed to the high bone mass phenotype of the osteocyte-specific Notch activation, *Dmp1-Cre⁺/+;RosaNotch* mice were crossed with hemizygous *Dmp1-SOST* transgenics. The pronounced increase in cancellous bone observed in femurs from *Dmp1-Cre⁺/+;RosaNotch* mice was no longer observed in the context of *SOST* overexpression, and *Dmp1-Cre⁺/+;RosaNotch;Dmp1-SOST* mice were not substantially different from wild type mice. The mechanisms responsible for the reversal of the phenotype by *SOST* involved the downregulation of Notch signaling since *Dmp1-Cre;RosaNotch;Dmp1-SOST* mice had 60 to 80% inhibition of Notch target gene (*Hey1*, *Hey2* and *HeyL*) expression when compared to *Dmp1-Cre;RosaNotch* mice, suggesting that sclerostin reverses the effects of Notch1 in osteocytes by downregulating Notch signaling. The effects of Notch1 in osteocytes were secondary to activation of the canonical pathway, which requires interactions with *Rbpj²*, and they were fully reversed in the context of *Rbpjk* inactivation. In conclusion, by downregulating Notch signaling sclerostin reverses the high bone mass osteocyte-specific Notch1 phenotype indicating that intact Wnt signaling is required for Notch activity in these cells.

Targeted Disruption of BMP Signaling Through Type IA Receptor (BMPRIA) in Osteocyte Suppresses SOST and RANKL, Leading to a Dramatic Increase in Bone Density and Mechanical Strength. Nobuhiro Kamiya*¹, Harry Kim². ¹Tenri University, Japan, ²Texas Scottish Rite Hospital for Children, USA

BMPs are known as ectopic bone inducers. The FDA approved BMP2 and BMP7 for clinical use. However, our recent studies demonstrated challenging evidence that BMP signaling in osteoblasts can negatively regulate endogenous bone mass because loss of BMP receptor IA (BMPRIA) in osteoblasts dramatically increased bone mass in mice. Although more than 90% of bone cells are osteocytes, roles of BMP signaling in osteocytes are largely unknown. The purpose of this study was to investigate BMP function in osteocytes and prove our concept. We generated conditional knockout mice (cKO) with osteocyte-specific deletion of BMPRIA under DMP1 promoter (*Dmp1Cre⁺;Bmpr1a^{flx/flx}*) and compared them with controls (*Dmp1Cre⁺;Bmpr1a^{flx/flx}*). The resulting cKO bones were dramatically sclerotic as assessed by X-ray. Micro CT revealed significantly increased bone parameters in cKO femur and spine (i.e. more than 100% increase in trabecular bone volume, thickness, number, and mineral density). H&E staining demonstrated increased trabecular bone and thickened cortical bone in cKO femur. Osteoclast number assessed by TRAP staining was reduced in cKO bones. These findings were consistent with results from bone histomorphometry (i.e. significantly increased bone volume and reduced osteoclast number in cKO bones). In addition, osteoid volume was increased and bone formation rate was reduced in cKO bones. Interestingly, serum protein levels of SOST and RANKL, as well as gene expression levels of *Sost* and *Rankl* in bones, were significantly reduced in cKO mice. Beta-catenin staining levels as well as Wnt target genes (*Tcf1*, *Tcf3*) were increased in cKO bones. Mechanical strength was better in cKO mice (i.e. max force, displacement, and work failure were increased in cKO femurs). For osteocyte-morphometry, lacuna numbers were significantly increased in cKO bones. Osteocyte shape was disorganized and osteocyte dendrite network was immature assessed by SEM. These results suggest that loss of BMP signaling specifically in osteocytes dramatically increases bone mass presumably through simultaneous inhibition of RANKL and SOST (i.e. osteoclast inhibition and Wnt activation together). It is reported that RANKL and SOST are more expressed by osteocytes than osteoblasts. Thus, BMP signaling through BMPRIA can play more important roles in osteocytes than osteoblasts by controlling RANKL and SOST. This study proves the concept that BMP signaling can negatively regulate endogenous bone mass *in vivo*.

CYR61 Regulates Bone Turnover Through Inhibiting Sclerostin Expression and Angiogenesis in Osteocytes. Gexin Zhao*¹, Chinmay Bhoot², Karen Lyons². ¹UCLA Department of Orthopaedic Surgery, USA, ²University of California, Los Angeles, USA

Cysteine-rich protein 61 (CYR61/CCN1), is found in mineralized tissues and plays an integral role in the differentiation of the osteogenic cells. CYR61 expressed in osteoblast(OBs) and osteocytes(OCy) in bone; however, the role of CYR61 in bone remains unclear. To address this, we generated 3 strains of mice with a conditional deletion of CYR61 in OBs using *OSXcre(pre-OB)*, *COL1cre(OB)* and *OCNcre(mature OB)*. By μ -CT analysis, 3month old male mice exhibited lower BMD and BV/TV within the trabecular bone of femurs, and a decrease in thickness of the cortical bone[Fig1]. This demonstrated that CYR61 is an important protein in OBs and OCy for acquisition of bone mass. Analysis of CYR61 localization demonstrated that mature OBs and OCy are the major source of expression. In accordance, there is no

significant difference in the phenotypes of mice lacking CYR61 in osteoprogenitors vs. mature OBs.

WNT signaling has been shown to be critical in OB differentiation and function [Ref1], and McClung et al. reported neutralization of a bone-specific WNT inhibitor, sclerostin(SOST), can protect patients from osteoporosis[Ref2]. We demonstrated that, at the in vivo level, the mRNA of SOST is increased in *CYR61^{flx/flx}/OCNcre* cortical bone. This increase was also confirmed through immunostain[Fig2]. Moreover, during the osteogenic induction of MSCs, isolated from *CYR61^{flx/flx}* mice and infected by Adenovirus-Cre, SOST mRNA levels were also significantly up regulated in mutants[Fig2]. This increase in SOST in bones lacking CYR61 may contribute to the lower bone mass in these mutants.

CYR61 has been shown previously to exhibit pro-angiogenic activity. To test whether CYR61 impacts vascularization in bone, we found that a lack of CYR61 leads to a decrease in vascular endothelial growth factor (VEGF) expression in the cortical bone of *CYR61^{flx/flx}/OCNcre* mice[Fig3]. This is also confirmed through angiogenesis assays on mouse metacarpals cultured ex vivo, which showed a significant decrease in vascularization. These findings also hold in vivo as the mutant mice show less vascularization by immunostain[Fig3]. Since the VEGF promoter is known to have binding sites for β -catenin/TCF[Ref3], the decreased VEGF may be due to SOST inhibiting WNT signalling and therefore inhibiting VEGF expression. These observations suggest that CYR61 is an important regulator of SOST and VEGF levels to mediate bone dynamics, and CYR61 may be a potential target for treatment for osteoporosis.

Osteocyte-specific HIF-1 α Signaling Regulates Bone Mass and Protects Mice From Osteoporotic Bone Loss. Steve Stegen^{*1}, Ingrid Stockmans¹, Karen Moermans¹, Peter Carmeliet², Geert Carmeliet¹. ¹Laboratory of Clinical & Experimental Endocrinology, KU Leuven, Belgium, ²Angiogenesis & Neurovascular Link, Vesalius Research Center, VIB, & Angiogenesis & Neurovascular Link, Vesalius Research Center, KU Leuven, Belgium

Deeply embedded within the bone matrix, osteocytes depend on adequate oxygen and nutrient delivery to maintain the functioning of the osteocyte network. Cells respond to decreases in oxygen tension, by activating hypoxia-inducible factor (HIF), which is regulated by the prolyl hydroxylase (PHD) oxygen sensors. The role of PHDs in osteocytes remains however unknown.

We therefore generated mice lacking *Phd2* specifically in osteocytes (*PHD2^{ost}*) by crossing *Phd2^{lox/lox}* mice with mice expressing the Cre recombinase under the control of the DMP1 promoter, resulting in osteocytic HIF-1 α , but not HIF-2 α , stabilization. Trabecular and cortical bone mass was increased in 10-week old *PHD2^{ost}* mice compared to wild-type (WT) mice, evidenced by micro-CT analysis. This phenotype resulted from enhanced bone formation together with decreased resorption. Osteoblast number and activity was increased in mutant mice, evidenced by serum osteocalcin levels and static and dynamic histological analysis. Moreover, *PHD2^{ost}* mice displayed an increase in the number of viable osteocytes in cortical bone, which were however more randomly organized. Bone resorption in *PHD2^{ost}* mice was reduced as shown by a decrease in serum CTx levels and number of osteoclasts, quantified on TRAP-stained histological sections. Intriguingly, we found a decrease in bone *Sost* expression, but not *Dmp1* or *Phex*, which could in part explain the changes in bone mass accrual. Activation of the HIF pathway generally leads to enhanced angiogenesis, an effect linked with increased bone formation. The number and size of blood vessels was increased in the bones of *PHD2^{ost}* mice, likely resulting from the elevated bone *Vegf* transcript levels.

As osteocytes also control bone mass during pathology, we subjected *PHD2^{ost}* to unloading and ovariectomy, two models of osteoporosis. Both hindlimb suspension

and ovariectomy resulted in a decrease in trabecular and cortical bone mass in WT mice, while PHD2^{0/-} mice were protected from bone loss.

Together, the high bone mass in PHD2^{0/-} mice is caused by enhanced bone formation and reduced resorption, and was associated with an increase in the number of blood vessels. Furthermore, we show that activation of the HIF pathway in osteocytes protects mice during hindlimb unloading and ovariectomy.

Vitamin K2 treatment prevents postmenopausal bone loss and microarchitectural deterioration of trabecular bone. Sofie Hertz Roenn*, Torben Harsloef, Steen Boenloekke Pedersen, Bente Langdahl. Department of Endocrinology & Internal Medicine, Aarhus University Hospital, THG, Denmark

Background: Clinical studies suggest, that vitamin K2 prevents bone loss and protect against fractures. Vitamin K2 is suggested to affect bone through the bone matrix protein osteocalcin (OC). OC is produced by the osteoblast in an undercarboxylated form (ucOC) that is carboxylated with vitamin K2 as a cofactor. Carboxylated OC promotes mineralization of bone. The aim of the study was to investigate the effect of vitamin K2 on bone mass and quality. **Methods:** In this randomized placebo-controlled double blinded clinical trial, 142 postmenopausal women (60-80 years old) with osteopenia were treated with vitamin K2 (375 µg MK-7) or placebo. Both groups also received vitamin D3 (38 µg/day) and calcium (800 mg/day). Bone mineral density and -quality were assessed by DXA and HRpQCT at baseline and after 1 year. **Results:** BMD of the lumbar spine was unchanged within groups without difference between groups. Total hip BMD decreased significantly in the placebo-group (-0.64±0.44 %, p<0.01), whereas no change was seen in the K2-group. There was no significant difference between groups. HRpQCT of the tibia showed a reduction in trabecular number within the placebo-group (-3.5±2.2 %, p<0.01) but no change in trabecular number within the K2-group (-0.1±1.9 %, p=0.87). The difference between groups was significant (-3.4±2.9 %, p=0.02). Trabecular thickness increased within the placebo-group (+4.0±2.2 %, p<0.01), whereas no change occurred within the K2-group (+0.2±1.7 %, p=0.9). The difference between groups was significant (+3.8±2.8 %, p<0.01). There was no change in BMD. HRpQCT of the radius showed a decrease in total BMD within the placebo-group (-1.7±1.5 %, p=0.03) and within the K2-group (-1.2±0.9 %, p=0.01), without differences between the groups. In both tibia and radius, cortical area and thickness were reduced and trabecular area were increased in both groups (p<0.05 for all) without differences between groups. **Conclusion:** The results suggest that vitamin K2 may prevent the age-related decline in bone mineral density at the hip, however, there was no significant difference between the two groups. The HRpQCT results suggest that vitamin K2 may prevent microarchitectural deterioration by preventing the age-related loss of trabeculae. The concomitant increase in trabecular thickness can be explained by loss of the thinnest trabeculae and trabecularization of the endocortical bone. There is need for long-term investigations of the effect of vitamin K2 on bone.

Bone's Material Composition and Microstructure are Compromised in Women Sustaining Atypical Femoral Fractures During Antiresorptive Therapy. Cherie Chiang*¹, Ego Seeman², Ali Ghasem Zadeh², Sandra Iuliano², Peter Ebeling³, Hanh Nguyen³, Roger Zebaze². ¹Austin Health, Australia, ²Austin Health, University of Melbourne, Australia, ³Monash Medical Centre, Monash University, Australia

Purpose: Anti-resorptive agents like the bisphosphonates reduce the rate of remodelling and fracture risk. However, they may also compromise bone's material strength by reducing the removal of microdamage, by facilitating secondary mineralization of unremodelled matrix and by allowing accumulation of pentosidine crosslinks. Atypical femoral fractures (AFF) are associated with bisphosphonate exposure, but the micro-architecture and bone material composition in affected patients are not well described. The aims of this study were to determine whether women with AFFs have high matrix mineral density and high cortical porosity, relative to age-matched women who sustained typical femoral fragility fractures while receiving anti-resorptive treatment.

Methods: We performed a prospective study comparing patients on anti-resorptive agents who sustained AFFs and controls sustaining low trauma 'typical' fractures while receiving anti-resorptive agents. Patients with AFFs were identified according to the ASBMR taskforce revised definition. Controls with typical fractures were identified from the Austin Health Fracture Capture database and matched by age, gender and duration of anti-resorptive therapy. Bone micro-architecture of the distal tibia and radius were quantified at baseline using high resolution peripheral micro-computed tomography (HRpQCT). The bone matrix mineralisation density and its distribution were quantified using StrAx1.0 (StraxCorp, Melbourne, Australia), an image processing software which use an algorithm to separate bone from background and then separate bone into its cortical, transitional zone and trabecular compartments without thresholding.

Results: Cases with AFF, 19 females with AFF (age: 73.9 ± 7.6 yrs, anti-resorptive treatment: 6.5 ± 2.8 yrs) compared with 23 referent 'controls' - women with typical fractures (age 72.5 ± 9.3 yrs, anti-resorptive treatment: 5.0 ± 3.2 yrs), had higher femoral neck T score (-1.7 vs -2.3, p = 0.018), higher radius cortical volumetric BMD (864.3 vs 808.8, p = 0.01), and lower cortical porosity (44.6 vs 49.2%, p = 0.01). The higher proportion of more fully mineralised bone matrix did not achieve significance (0.23 vs 0.09%, p = 0.06).

Conclusions: Women with AFF have reduced porosity and reduced mineralisation heterogeneity with elevated matrix mineral density relative to women receiving bisphosphonates following typical fragility fractures. These characteristics may assist in managing patients on long term bisphosphonates.

Effects of Abaloparatide on Major Osteoporotic Fracture Incidence in Postmenopausal Women with Osteoporosis - Results of the Phase 3 ACTIVE Trial. Lorraine Fitzpatrick*¹, Greg Williams¹, Willard Dere², Alan Harris¹, Ming-Yi (Tristan) Hu¹, Kate Banks¹, Gary Hattersley¹. ¹Radius Health, USA, ²U of Utah Medical Center, USA

Abaloparatide (ABL) is an osteoanabolic analog of PTHrP being developed for the treatment of postmenopausal osteoporosis (PMO). Of particular concern in these women are major osteoporotic fractures, because these are associated with a higher level of morbidity or increased mortality risk. As has been previously reported from the ACTIVE Phase 3 trial, treatment with ABL significantly reduced the incidence of new vertebral, non-vertebral and clinical fractures while significantly increasing bone mineral density (BMD) in the lumbar spine, total hip and femoral neck. In the ACTIVE double-blind, placebo-controlled Phase 3 fracture prevention trial, postmenopausal osteoporotic women were randomized to receive 18-months of either daily ABL 80-mcg SC, matching placebo (PBO) SC, or open label teriparatide (TPTD) 20-mcg SC. Patients also received calcium and vitamin D supplements. Of the 2,463 patients who were randomized (ITT population), 1,901 (77.9%) completed the study. There were no apparent differences between the groups in baseline demographics or characteristics. 44.5% of patients had a prevalent vertebral fracture, 46.8% had a recent history of least 1 non-vertebral fracture. As part of the ACTIVE study the incidence of major osteoporotic fractures, defined as clinical fractures of the upper arm, the forearm (including wrist), the hip, the shoulder and/or the vertebral spine (spine and/or tailbone) was analyzed. ABL significantly reduced major osteoporotic fracture (n=824, fracture rate (FR) 1.2%) by 67% (HR 0.33, 95% CI 0.16, 0.68) compared to placebo-treated subjects (n=821, FR 3.8%) (p=0.0014) whereas TPTD (n=818, FR 2.7%) was not significantly different from PBO (HR 0.70, 95% CI 0.41, 1.21, p=0.2028). The difference between ABL and TPTD was significantly different (p=0.0437). In conclusion, 18-months of ABL significantly decreased the incidence major osteoporotic fractures in postmenopausal women with osteoporosis when compared to PBO and TPTD. The overall safety and efficacy results suggest that ABL may provide an effective treatment option in the management of PMO.

Effects of Denosumab on Bone Matrix Mineralization: Results From the Phase 3 FREEDOM Trial. David W Dempster*¹, Jacques P Brown², Susan Yue³, Delphine Farlay⁴, Sebastien Rizzo⁴, Jenny Song³, Andrea Wang³, Rachel B Wagman³, Georges Boivin⁴. ¹Columbia University & Helen Hayes Hospital, USA, ²Laval University & CHU de Quebec-(CHUL) Research Centre, Canada, ³Amgen Inc., USA, ⁴INSERM UMR 1033, Université de Lyon, France

Purpose: Low fracture incidence has been demonstrated in women with postmenopausal osteoporosis treated with denosumab (DMAB) for up to 9 years in the FREEDOM Extension (Papapoulos *WCO-IOF-ESCEO* 2015). Several assessments have evaluated effects of DMAB treatment at the tissue level (Reid *JBMR* 2010; Brown *JBMR* 2014) and showed low remodeling consistent with mechanism of action. While reduced bone matrix heterogeneity has been observed in huRANKL mice treated with DMAB for 6 months (Misof *ASBMR* 2011), assessment in clinical biopsies has not been performed. Here, we report the effects of DMAB on bone matrix mineralization in women who underwent transiliac crest bone biopsy in FREEDOM.

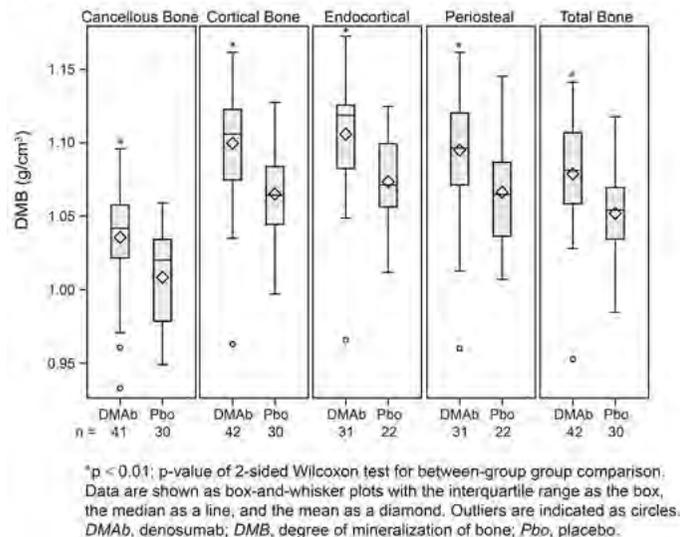

Methods: FREEDOM was a 3-year randomized, double-blind, placebo (Pbo)-controlled study in postmenopausal women who received Pbo or 60 mg DMAB subcutaneously every 6 months (Cummings *NEJM* 2009). A subset of women underwent transiliac crest bone biopsies at year 2 and/or 3 (Reid *JBMR* 2010). In the current study, bone matrix mineralization was assessed in a blinded fashion by digitized quantitative microradiography and analyzed using a Matlab program (Montagner *J X-Ray Sci Technol* 2015). The mean degree of mineralization of bone (DMB) and the heterogeneity index (HI) of the distribution of DMB were calculated for cancellous and cortical bone, endocortical and periosteal sub-compartments of cortical bone, and total bone (cancellous and cortical combined).

Results: In this analysis, 72 bone biopsy samples (42 DMAB, 30 Pbo) from a subset of the FREEDOM bone biopsy assessment (N = 115) were evaluated and analyzed.

Demographics for subjects in this matrix mineralization substudy were comparable to the FREEDOM study. Treatment with DMAB resulted in a significant increase in mean DMB compared with Pbo-treated subjects (Figure) and these findings were consistent across cancellous and cortical compartments ($p < 0.01$). A significantly lower HI was observed in total bone and in all compartments assessed in the DMAB-treated group ($p < 0.05$), consistent with reduced bone turnover in response to DMAB therapy.

Conclusions: Treatment of women with postmenopausal osteoporosis with DMAB resulted in increased bone matrix mineralization and a lower HI compared with Pbo. These data are consistent with expected results based on observations with other antiresorptives (Bala *Eur J Endocrinol* 2011) and with mechanism of action.

Effect of Denosumab (DMAB) and Teriparatide (TPTD) Transitions on Peripheral Bone Mineral Density (BMD) and Microarchitecture: The DATA-Switch HR-pQCT Study. Joy Tsai^{1*}, Alexander Uihlein², Sherri-Ann Burnett-Bowie¹, Robert Neer¹, Padrig Tuck¹, Paul Wallace¹, Mary Bouxsein³, Benjamin Leder¹. ¹Massachusetts General Hospital, USA, ²Northwestern University, USA, ³Beth Israel Deaconess Medical Center, USA

Background: In postmenopausal women, switching from TPTD to DMAB is associated with progressive BMD gains whereas the opposite transition results in progressive decreases in radial BMD and transient decreases at the hip and spine. The effects of these drug transitions on peripheral volumetric and compartmental BMD and microarchitecture are unknown.

Methods: Postmenopausal osteoporotic women completing the DATA study were eligible to enroll in DATA-Switch. Women who received DMAB 60mg every 6 months for 2-years were switched to TPTD (n=27) for years 3-4 and women who received either TPTD 20 µg daily (n=27) or TPTD+DMAB (n=23) switched to DMAB alone. Total, trabecular and cortical density (Tot.vBMD, Tb.vBMD, Ct.vBMD), cortical thickness (Ct.Th) and trabecular microarchitecture of the radius and tibia were measured by high-resolution pQCT.

Results: After a total of 4-years of therapy, the increase in volumetric cortical density at the radius and tibia was greatest in women who received combination therapy followed by DMAB ($P < 0.005$ for all comparisons) (Fig). Specifically, in women switched from TPTD to DMAB, 24-months of DMAB increased or maintained Tot.vBMD, Tb.vBMD, Ct.vBMD, and Ct.Th at both sites, resulting in net 4-year tibia changes of 3.3%, 3.0%, -0.6%, and 8.1%, respectively and net 4-year radius changes of 0.4%, 1.8%, -0.9%, and 2.0%, respectively (Table). In women switching from both drugs to DMAB alone, 24-months of DMAB maintained Tot.vBMD, Tb.vBMD, Ct.vBMD, and Ct.Th, resulting in net 4-year tibia increases of 5.4%, 2.8%, 1.9%, and 8.5%, respectively, and 4-year radius increases of 2.9%, 1.0%, 1.4%, and 5.3%. Conversely, women switching from DMAB to TPTD experienced decreases in Tot.vBMD, Ct.vBMD, and Ct.Th and no change in Tb.vBMD resulting in net 4-year tibia changes of -1.1%, -3.7%, -1.9%, and 1.6%, respectively, and 4-year radius changes of -3.7%, -3.7%, -5.4%, and -1.2%. Trabecular microarchitectural changes were small and did not differ between groups.

Conclusions: DMAB increases Ct.vBMD and Ct.Th in women treated with TPTD whereas the use of TPTD after DMAB results in decreases in these parameters. Whether TPTD-induced Ct.vBMD decreases represent as yet under-mineralized new bone is unclear. Combination therapy followed by DMAB results in the greatest cumulative improvements in peripheral cortical microarchitecture and further supports the therapeutic potential of combined DMAB/TPTD in patients with severe osteoporosis.

Effect of Odanacatib on Bone Density and Estimated Bone Strength in Postmenopausal Women: a CT-Based Sub-study of the Phase 3 Long-Term Odanacatib Fracture Trial (LOFT). Bente Langdahl^{1*}, Tobias DeVilliers², Tony M. Keaveny³, Klaus Engelke⁴, Harry Genant⁵, Shabana Ather⁶, Hilde Giezek⁶, Antonio Lombardi⁶, Albert Leung⁷, Anne de Papp⁶. ¹Aarhus University Hospital, Denmark, ²Mediclinic Panorama & Department of Obstetrics & Gynaecology, University of Stellenbosch, South Africa, ³University of California & O.N. Diagnostics, USA, ⁴Bioclinica-Synarc Germany, Germany, ⁵University of California, USA, ⁶Merck & Co., Inc., USA, ⁷Formerly Merck & Co., Inc., USA

Purpose: Odanacatib (ODN), a selective oral inhibitor of cathepsin K, is in development for the treatment of osteoporosis. In the Phase 3, Long-Term ODN Fracture Trial (LOFT; NCT00529373) of postmenopausal women with osteoporosis, ODN significantly reduced fracture risk and led to progressive increases in BMD at the lumbar spine and total hip (TH) compared with placebo (PBO). The incidence of adverse events (AEs) and serious AEs has been previously presented. Major cardiovascular events overall were generally balanced; however, there were numerically more adjudicated strokes with ODN than with PBO. Final blinded adjudication of major cardiovascular events is ongoing. In a substudy of LOFT, we evaluated the effect of ODN on volumetric BMD (vBMD) of trabecular and cortical bone by quantitative computerized tomography (QCT) and estimated whole-bone strength using finite element analysis (FEA).

Methods: Women ≥ 65 years without a baseline radiographic vertebral fracture (Vfx) and a TH or femoral neck (FN) BMD T-score between -2.5 and -4.0, or with a prior Vfx and a TH or FN T-score between -1.5 and -4.0, were randomized (1:1) to ODN 50 mg/week or PBO. All patients received vitamin D3 (5600 IU/week) and calcium as required to achieve ~ 1200 mg/day. In this sub-study, 164 women (78 ODN, 86 PBO) were enrolled at 10 centers in Denmark and South Africa. The key endpoints included % change from baseline in trabecular vBMD at the spine (primary) and cortical vBMD at the TH (secondary) at 24 months. Additional QCT endpoints included other trabecular, cortical and integral parameters at the spine and hip and estimated whole-bone strength using FEA. Analysis of spine and hip QCT scans was performed using Medical Image Analysis Framework. All endpoints were analysed by a Longitudinal Data Analysis model.

Results: Baseline characteristics in the sub-study population were similar to those in the overall LOFT population. Treatment with ODN significantly increased trabecular, cortical and integral vBMD, at the spine (L1) and TH compared with baseline and PBO (Table 1). ODN increased whole-bone estimated strength at the L1 vertebra and proximal femur, as assessed by FEA, while this remained stable or decreased in the PBO group (Table 2).

Conclusions: In postmenopausal women with osteoporosis, ODN compared with PBO increased trabecular, cortical and integral vBMD in the spine and TH and increased the estimate of whole-bone strength at the spine and hip as assessed by FEA.

Table 1. Differences between ODN 50 mg once weekly and placebo in QCT measurements of vBMD at the spine (total vertebral body) and total hip after 24 months of treatment (FAS population)^a

| Treatment | N | % change from baseline | | P value |
|-----------------------------------|----|-------------------------------|---------------------|---------|
| | | LS mean (95% CI) ^b | Difference (95% CI) | |
| Spine (L1) trabecular vBMD | | | | |
| ODN 50 mg weekly | 46 | 8.05 (4.48, 11.62) | 8.92 (3.90, 13.93) | <0.001 |
| Placebo | 48 | -0.87 (-4.37, 2.64) | | |
| Spine (L1) cortical vBMD | | | | |
| ODN 50 mg weekly | 46 | 8.28 (6.66, 9.89) | 6.89 (4.62, 9.16) | <0.001 |

Analysis of Signaling Downstream of PTHrP in Chondrocytes through Genetic Manipulation. Shigeki Nishimori*, Marc N. Wein, Henry M. Kronenberg, Massachusetts General Hospital, USA

Purpose: Parathyroid hormone-related protein (PTHrP) suppresses chondrocyte hypertrophy. Using mouse genetics, Eric Olson's group showed that Histone Deacetylase (HDAC) 4 suppresses chondrocyte hypertrophy (Vega, Cell 2004) by blocking the action of Myocyte Enhancer Factor (Mef) 2, which drives chondrocyte hypertrophy (Arnold, Dev Cell 2007). By *in vitro* experiments, Andrew Lassar's group showed that PTHrP works upstream of this pathway (Kozhemyakina, MCB 2009). The purpose of this study is systematic genetic analyses of the PTHrP/HDAC4/Mef2 axis.

Methods: We studied mediators downstream of PTHrP in a model of PTHrP overexpression driven by the Collagen 2 promoter (Weir, PNAS 1996). This transgenic mouse has only round proliferating chondrocytes in long bones until one week after birth. PTHrP *in situ* hybridization confirmed that the deletions detailed below did not affect PTHrP overexpression.

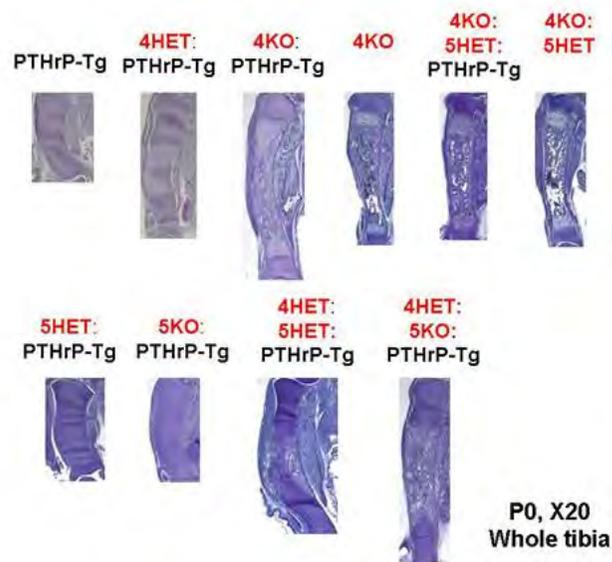

Results: In contrast to the PTHrP-Tg mouse, the HDAC4-HET: PTHrP-Tg mouse has small areas of flat and hypertrophic chondrocytes as well as 50% longer tibia at birth. Surprisingly, the PTHrP-Tg phenotype is almost reversed in the HDAC4-KO: PTHrP-Tg mouse, which has an entire growth plate, bone, and bone marrow at birth. However, several differences between HDAC4-KO: PTHrP-Tg and HDAC4-KO suggest that PTHrP action is mediated by additional mediators, presumably other Class II HDAC proteins (HDAC5, 7, 9).

The phenotype of the HDAC4-KO: HDAC5-HET: PTHrP-Tg mouse is exactly the same as that of the HDAC4-KO: HDAC5-HET mouse, indicating that HDAC5 is an additional mediator of PTHrP signaling. The phenotype of this mouse further suggests that HDAC7 and 9 may not serve as mediators of PTHrP action.

HDAC5-KO or HET have no effect on the PTHrP-Tg phenotype, indicating that HDAC4 alone is sufficient to mediate transgenic PTHrP signaling. However, HDAC5 has a clear role brought out in the context of HDAC4 heterozygosity: in that setting, removal of one or both alleles of HDAC5 blocks PTHrP action.

To investigate a downstream mediator of Mef2 action, we analyzed the HDAC4-HET: Runx2-HET: PTHrP-Tg mouse. This mouse has only round and flat chondrocytes at birth and not the hypertrophs seen in the HDAC4-HET: PTHrP-Tg mouse; this demonstrates the role of Runx2 in driving hypertrophy.

Conclusions: HDAC4 and HDAC5 are the essential downstream mediators of PTHrP signaling. Runx2 works downstream of Mef2 to induce chondrocyte hypertrophy.

Systematic deletions of HDAC4 and 5 in the PTHrP-Tg mouse

Distinct modes of Sox9 action in transcriptional regulation of the developing mammalian chondrocyte. Shinsuke Ohba*¹, Xinjun He², Hironori Hojo², Andrew P. McMahon². ¹The University of Tokyo, Japan, ²W.M. Keck School of Medicine of the University of Southern California, USA

Sox9, an HMG-box-containing transcription factor, is required for chondrocyte specification and differentiation. To understand the modes of Sox9 action in transcriptional programs regulating these processes, we here compared Sox9 association at chondrocyte targets to a broad catalogue of regulatory indicators of chromatin organization and transcriptional activity in rib chondrocytes isolated from

Table 1

Table 2. QCT measurements of estimated strength by FEA of the vertebral body and total hip after 24 months of treatment with ODN 50 mg once weekly or placebo (FAS population)

| | N | Mean % change from baseline (95% CI) ^a |
|--|----|---|
| Compressive strength of vertebral body (L1) | | |
| ODN 50 mg weekly | 46 | 8.98 (5.99, 11.98) |
| Placebo | 47 | -0.77 (-4.16, 2.61) |
| Strength under fall loading conditions at total hip | | |
| ODN 50 mg weekly | 55 | 3.80 (2.29, 5.31) |
| Placebo | 56 | -3.10 (-4.43, -1.77) |

As there were no pre-specified hypotheses for FEA endpoints, analysis was restricted to descriptive statistics.

 This study was sponsored by Merck & Co. Inc., Kenilworth, NJ, USA.

mouse neonates. Chromatin immunoprecipitation sequencing (ChIP-seq) for Sox9 identified 27,656 Sox9-associated regions on the chondrocyte genome. These regions resolved into two distinct classes: Class I regions closely associating with transcriptional start sites (TSSs) and Class II regions outside of the local TSS domains. Class I regions were not enriched with Sox motifs, but co-bound by p300 and RNA pol II. Class I ChIP-seq signal intensities were highly correlated with the expression level of the associated genes that were enriched with general regulators of basal cell activities. In contrast, Class II regions were associated with chondrocyte genes and showed active and tissue-specific enhancer signatures including H3K4me2, H3K27ac, RNA pol II, and p300. The level of expression of the associated genes correlated with the number of enhancer modules grouping into super-enhancer clusters (Cell 153:307, 2013). *De novo* motif analyses identified Sox dimer motifs as the over-represented motifs in Class II regions. Cartilage-specific enhancer activities of Class II regions were verified by *in vivo* reporter assays. The enhancer activities were increased when an individual element was multimerized or endogenous Sox dimer motifs were substituted with the optimum consensus motif predicted from the whole Class II data set; mutations into the endogenous motif cancelled the activities. In addition, electrophoresis mobility shift assay revealed that the Sox9-binding affinities of the endogenous motifs were lower than those of the optimum motif. These data suggest that multiple cooperative Sox9-bound distal enhancers each with a sub-optimal Sox9-binding affinity ensure appropriate expression of chondrocyte genes, whereas Sox9 also engages indirectly through a likely association with the basal transcriptional complex to regulate basal cell activities. Thus, this study reveals Sox9 regulatory landscape in relation to chromatin organization on the genome of the *in vivo* chondrocytes, and will contribute to the identification of gene regulatory networks in skeletal development.

Epidermal Growth Factor Receptor (EGFR) Signaling Is Critical for Maintaining Articular Cartilage and Preventing Osteoarthritis Progression. Haoruo Jia^{*1}, Basak Doyran², Wei Tong¹, Xianrong Zhang³, Motomi Enomoto-Iwamoto⁴, Lin Han², Ling Qin¹. ¹Department of Orthopaedic Surgery, School of Medicine, University of Pennsylvania, USA, ²School of Biomedical Engineering, Science & Health Systems, Drexel University, USA, ³Department of Physiology, School of Basic Medical Sciences, Wuhan University, China, ⁴Department of Surgery, The Children's Hospital of Philadelphia, USA

Osteoarthritis (OA) is a degenerative joint disease characterized by destruction of articular cartilage and aberrant subchondral bone remodeling. We previously identified EGFR as an important signaling pathway for cartilage matrix degradation during endochondral ossification. To delineate its role in articular cartilage maintenance and OA progression, we generated cartilage-specific EGFR knockout mice (Col2-Cre *Egfr^{fllox/Wa5}*, CKO) and their WT (*Egfr^{fllox/+}*) and *Wa5* (*Egfr^{Wa5/+}*, an EGFR dominant negative allele) siblings. At the adult stage, CKO mice had a significantly thinner articular cartilage layer (60% of WT) with less chondrocyte number (41% of WT) and a higher percentage of hypertrophic chondrocytes (CKO 73% vs WT 47%), while *Wa5* cartilage had similar alterations but to a much lesser extent. Osteophytes in knee joints were observed in some CKO mice but never in WT or *Wa5*. Histological analyses revealed that chondrocytes in CKO had much lower EGFR signaling, less proliferation and more apoptosis, compared to those in controls. Primary chondrocyte culture confirmed that activating EGFR stimulates cell proliferation and survival and inhibits their terminal differentiation. Interestingly, atomic force microscopy-based nanoindentation on the medial condyle cartilage of CKO mice detected a significant decrease (78%) in effective indentation modulus (Eind), suggesting that EGFR is indispensable for maintaining the biomechanical function of cartilage. Male mice at 3 months of age underwent surgical destabilization of medial meniscus in the right knees to induce OA. Three months later, WT developed mild-to-moderate OA (Makin score: 6.0 ± 0.5), *Wa5* exhibited advanced OA (11.5 ± 0.5), and CKO had the most severe OA (14.0 ± 0.0) with a complete loss of entire cartilage layer restricted at the medial side. Moreover, we observed a local and drastic subchondral bone plate (SBP) thickening (4.5-fold) only under the cartilage damage area. This was correlated with locally reduced sclerostin amount by osteocytes within SBP and increased number of osteoblasts lining SBP surface. Since subchondral trabecular bone was not altered, we reason that SBP sclerosis is caused by increased mechanical loading after cartilage depletion. Hence, we provide the first direct evidence that chondrogenic EGFR signaling is critical for articular cartilage homeostasis and OA development and that local crosstalk between cartilage and SBP plays an important role in accelerating OA progression.

Phlpp1 Deletion Increases Fgf18 Expression and Protects Against Post-Traumatic Osteoarthritis. Elizabeth Bradley^{*1}, Lomeli Carpio¹, Derek Amanatullah¹, Sanjeev Kakar¹, Lauren Ta¹, Alexandra Newton², Jennifer Westendorf¹. ¹Mayo Clinic, USA, ²University of California, USA

Osteoarthritis (OA) is a degenerative joint disease and leading cause of disability. Although Fgf18 is an emerging candidate, there are no FDA-approved disease

modifying OA drugs (DMOADs). We recently identified the protein phosphatase Phlpp1 as an effector of chondrocyte differentiation *in vitro*. Phlpp1 dephosphorylates and inactivates Akt2 other substrates to arrest matrix production and induce apoptosis. The purpose of this study was to determine if Phlpp1 contributes to OA disease progression and inhibits proper endochondral bone formation in humans and mice. PHLPP1 was highly expressed in human articular cartilage from OA patients, but was undetectable by IHC in articular cartilage samples from FNFx specimens (Fig 1A). To determine if Phlpp1 contributes to OA progression, we evaluated the effects of Phlpp1 deficiency on OA progression in mice using the DMM model. Phlpp1^{-/-} mice showed significant reductions in OARSI scores and subchondral bone thickening (Fig 1B), suggesting that loss of Phlpp1 is protective against OA progression. To elucidate the mechanism of this protective effect, we examined the effects of Phlpp1 deficiency during endochondral bone formation. Phlpp1 null mice exhibit reduced bone density likely due to increased osteoclast formation and growth plate abnormalities, including increased chondrocyte proliferation and matrix production. Furthermore, Phlpp1 deficiency promoted expression of Fgf18 (Fig 1C), a growth factor that facilitates chondrogenesis, chondrocyte proliferation and cartilage regeneration in surgically-induced models of osteoarthritis. Erk1/2 activity and chondrocyte proliferation were also elevated. Chemical inhibition of the Fgf18 receptor, FgfR3, abrogated the increased Erk1/2 phosphorylation observed in Phlpp1 null chondrocytes. Furthermore, blocking FgfR or MEK1/2 signaling suppressed proliferation induced by Phlpp1 deficiency. Phlpp inhibitors also augmented Erk1/2 phosphorylation, matrix content and Fgf18 production (Fig 1D&E). These results demonstrate that suppression of Phlpp1 expression and/or activity is protective against cartilage degeneration. Phlpp1 therefore contributes to cartilage development and OA progression and may be a therapeutic target for OA treatment.

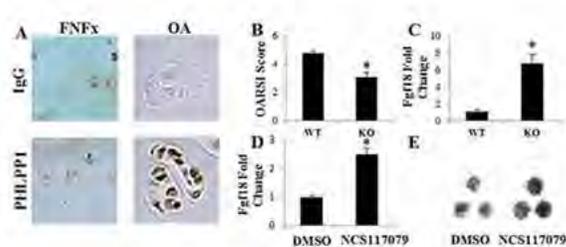

Figure 1. (A) PHLPP1 IHC in human articular cartilage from patients undergoing total joint arthroplasty for OA or FNFx. (B) OARSI scores from DMM surgeries performed on WT or Phlpp1^{-/-} mice. (C) Fgf18 expression was determined in Phlpp1^{-/-} cells by qPCR. (D-E) Fgf18 expression and Alcian blue staining of WT micromasses treated with the Phlpp1 inhibitor NCS117079. *p<0.05.

The Role of Fibroblast Growth Factor 2 Isoforms in Osteoarthritis. Patience Meo Burt^{*1}, Marja Hurley², Thomas Doetschman³. ¹University of Connecticut Health Center, USA, ²UCONN Health, USA, ³University of Arizona, USA

Osteoarthritis (OA) is the leading cause of chronic disability in the U.S., characterized by the loss of articular cartilage and changes in underlying bone. There is no effective therapy for OA. Mice deficient in fibroblast growth factor 2 (FGF2) develop accelerated and more severe spontaneous OA. Thus, FGF2 plays a role in cartilage maintenance, but a comprehensive analysis is indicated since the *Fgf2* gene encodes multiple protein isoforms including high molecular weight isoforms (HMW) with nuclear localization sequences and low molecular weight isoform (LMW) that is exported from cells. We utilized mice in which all FGF2 isoforms are knocked-out (*Fgf2^{ALLKO}*), mice in which only the FGF2HMW isoforms are knocked-out (*Fgf2^{HMWKO}*) that have increased bone mineral density (BMD) compared to wild-type (WT) littermates, and mice in which the FGF2LMW isoform is knocked-out (*Fgf2^{LMWKO}*) that have decreased BMD compared to WT littermates. We hypothesized that *Fgf2^{LMWKO}* mice will develop OA whereas *Fgf2^{HMWKO}* mice will not develop OA compared with WT littermates. To assess for signs of OA, knee joints from 2, 6 and 9 month old *Fgf2^{ALLKO}*, *Fgf2^{HMWKO}* and *Fgf2^{LMWKO}*, and their WT littermate mice underwent digital x-ray imaging and microCT analysis. To determine articular cartilage integrity, Safranin-O staining was performed. Immunohistochemistry was used to examine expression of cartilage degrading metalloproteinases MMP-13 and ADAMTS-5. X-rays revealed no evidence of OA in 2 month-old mice of all genotypes. As shown in Figure 1, x-rays of 6 month-old mice confirmed OA in knees of *Fgf2^{ALLKO}*. Interestingly osteophyte formation, thinning of the subchondral bone at 6 months, and thickening of the bone was observed at 9 months in *Fgf2^{LMWKO}* knees, which was not present in *Fgf2^{HMWKO}* or WT mice. MicroCT analysis of *Fgf2^{LMWKO}* knees revealed changes in trabecular architecture indicative of OA compared to WT, while changes observed in *Fgf2^{HMWKO}* mice were minor compared to their WT controls (this was also observed at 2 years of age). Safranin-O staining (Figure 2) was decreased

and metalloproteinase labeling was increased in articular cartilage and synovium of *Fgf2^{LMWKO}* mice only. Overall, these results suggest that lack of the LMW isoform of FGF2 contributes to the progression of OA, and they offer insight into a factor that causes the disease, while being a potential therapeutic target for OA.

Sost Protects Mouse Joints from Post Traumatic Mediated Cartilage Degradation by Inhibiting MMP-Activity. Jiun Chiun Chang^{*1}, Blaine A. Christiansen², Nicole M. Collette³, Aimy Sebastian⁴, Deepa K. Muruges³, Sarah Hatsell⁵, Aris N. Economides⁵, Craig D. Blanchette³, Gabriela G. Loots⁵. ¹University of California, Merced, USA, ²UC Davis Medical Center, USA, ³Lawrence Livermore National Laboratories, USA, ⁴University of California Merced, USA, ⁵Regeneron Pharmaceuticals, USA

Sclerostin (*Sost*), a Wnt antagonist and a potent negative regulator of bone formation has recently been implicated in regulating chondrocyte function in osteoarthritis (OA). *Sost* levels were found to be elevated in regions of damaged cartilage in a sheep surgical model of OA raising the possibility that *Sost* may have a protective role in post-traumatic osteoarthritis (PTOA); however the mechanism is not yet known. To determine how *Sost* up-regulation may protect the joint from cartilage degradation, we examined the progression of OA using a noninvasive tibial compression model of PTOA in transgenic mice (*TG*) overexpressing *SOST* from a human bacterial artificial chromosome or lacking *Sost* (*KO*). OA development was examined histologically and by micro-computed tomography (μ CT) at 1 day, 6-, 12-, and 16- weeks post injury (PI). Histologically, *TG* injured joints displayed a less severe OA phenotype than injured *WT* or *KO* joints, while *KO* injured joints exhibited accelerated cartilage loss. Quantification of osteophyte formation by μ CT at 16 weeks PI found *TGs* to contain ~49% less and *KOs* ~28% more osteophyte volume than *WT* injured joints. To determine whether *Sost* interferes with the initial catabolic response in cartilage, we quantified the activity of matrix metalloproteinases (MMP) shortly after the injury. Fluorescent MMPsense substrate was administered intravenously PI and MMP activity was quantified 3 days PI. *TG* injured joints displayed ~2-fold less MMP activity than *WT* or *KO* injured joints; MMP activation was similar in *WT* and *KO* injured joints. Intra-articular administration of recombinant *Sost* PI also significantly reduced the activity of MMPs relative to PBS injected controls. Next, we quantified gene expression using RNA sequencing (RNASeq) at 1 day post injury and compared injured and uninjured *WT* and *KO* joints. In this analysis, 84 and 78 transcripts were found to be up-regulated >2-fold in *WT* and *KO* injured joints, respectively. In particular, we found MMPs 2/3/9/13 transcripts to be significantly up-regulated in both *KO* and *WT* injured joints, and the level of up-regulation was significantly higher in *KO* than in *WT* injured joints. Preliminary data suggest that MMP14, an enzyme involved in MMP activation is up-regulated in injured *WT* and *KO* joints, but reduced in *TG* injured joints, suggesting that *SOST* overexpression protects the injured joint from subsequent cartilage degradation by inhibiting the transcription of MMPs and MMP activating enzymes.

Increasing Pediatric Wrist Fracture Rates May Have Major Implications for Future Adult Fracture Burden. Daniel Jerrhag¹, Martin Englund², Ingmar Petersson³, Lennart Landin¹, Magnus Karlsson¹, Bjorn Rosengren^{*1}. ¹Skåne University Hospital Malmö, Lund University, Sweden, ²Clinical Epidemiology Unit, Orthopaedics, Clinical Sciences Lund, Lund University; Epidemiology & Register Centre South, Skåne University Hospital Lund, Sweden, Sweden, ³Orthopaedics, Clinical Sciences Lund, Lund University; Epidemiology & Register Centre South, Skåne University Hospital Lund, Sweden, Sweden

Background

Much effort has been put into monitoring fracture risk in the senior population in order to predict fracture burden in the future. As children with fracture have lower peak bone mass (a determinant of osteoporosis in old age) and higher adult fracture risk it may be possible already today to partly discern the vector of fragility fracture risk in the far future. This would be especially important as estimations have suggested that 50% of the children of today will live 100 years or more.

We set out to examine the current epidemiology of wrist fractures in children, the most common pediatric fracture, and relate results to older pediatric fracture data (from 1950s and onwards) for those at risk of fragility fractures today (current age up to 80 years).

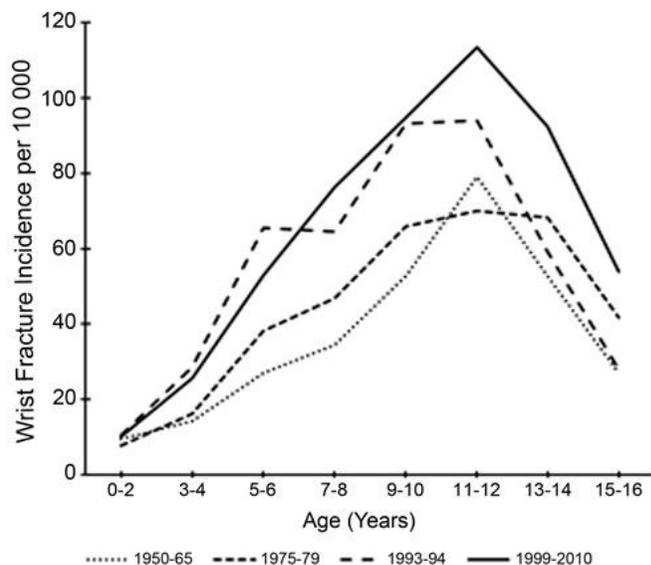

Methods

By use of official in- and out-patient register data in the Skåne region in Sweden we ascertained distal forearm fractures in children aged <17 years during the years 1999-2010 (2.8 million patient years) and estimated overall and age- and sex- specific rates and time trends and compared the results to earlier estimations in the same region from 1950 and onwards.

Results

During the examination period (1999-2010) the overall wrist fracture rate was 63 per 10 000 patient years (75 in boys and 51 in girls). This was an increase compared to earlier (+50% compared to 1950s) with the age specific difference most evident during puberty (Figure) and with a statistically significant different age-rate distribution (Poisson interaction between curves $p < 0.001$). It should be noted that there also within the period of examination (1999-2010) was a statistically significant increase in annual age-adjusted rates for both boys (+1.5 per 10 000 and annum (95%CI 0.7, 2.3)) and girls (+1.2 (0.8, 1.7)) which may further enhance risk increments.

Conclusion: These data suggest that the number of fragility fractures in the future may increase not only on the basis of the projected life-span increase but also due to an increased fracture risk. The origin of the 50% increase in pediatric wrist fracture rate between current children and those aged up to 80 years today (children in the 1950s) remains to be revealed but may be associated to a more sedentary lifestyle with digital amusements and lower physical activity but could also be related to changes in risk behavior

Pediatric wrist fracture rate per age-group and period

Increased Physical Activity in Childhood Reduces Fracture Risk - an 8-Year Intervention Study in 3 534 Children. Marcus Coster*, Jesper Fritz, Jan-Ake Nilsson, Magnus Dencker, Bjorn Rosengren, Magnus Karlsson. Lunds Universitet, Sweden

Purpose: Physical activity (PA) in childhood is associated with high bone mass and superior neuromuscular function, but the long-term musculoskeletal and fracture risk effects are unclear. Method: We conducted a population based clustered randomized controlled PA intervention trial (RCT) in one school where the intervention included 40 minutes of moderate PA per school day for 8 years in 1 339 children (aged six to eight years at study start). 2 195 children in three other schools who continued with the national standard of 60 minutes of PA per week served as controls. We then registered incident fractures during the study period through our regional radiographic archive and estimated annual fracture incidences and risk ratios (RR). We also correlated year of intervention with RR to sustain fracture that year by Spearman's correlation coefficient. In a sub-cohort of 234 children we also measured spine bone mineral content (BMC) and bone mineral density (BMD) with DXA and muscle strength as peak torque (PT) in knee extension (ext) and flexion (flex) by a computerized dynamometer (BiodexÜ). We present data as means with 95% CI. Results: The RR of fracture in intervention children (compared to controls) decreased with each year of extra PA (r=-0.86, p=0.007) so that the RR in the intervention group after eight years was 0.48 (95% CI 0.25, 0.91). The gain in bone mass was greater in the intervention children (compared to the controls), with a mean difference in spine BMD gain of 0.03 g/cm² (95% CI 0.00, 0.06), in PText of 6.5 Nm (95% CI 0.4, 12.6), and in PTflex of 7.7 Nm (95% CI 3.5, 11.9). Conclusion: A population-based pediatric PA intervention program that begins before puberty and continues for eight years induces a highly clinically and statistically significant fracture risk reduction, probably due to PA-induced benefits in BMD and muscle function. We can explain 74% of the variance in the diminished fracture risk during the study period by the intervention.

Are Psychiatric Illnesses and the Medications Used to Treat Them FRAX-Independent Risk Factors? The Manitoba BMD Cohort. William Leslie*¹, James Bolton¹, Suzanne Morin², Sumit Majumdar³, Lisa M. Lix¹, Helena Johansson⁴, Anders Oden⁴, Eugene MClouskey⁴, John Kanis⁴, Jitender Sareen¹. ¹University of Manitoba, Canada, ²McGill University, Canada, ³University of Alberta, Canada, ⁴University of Sheffield Medical School, United Kingdom

Background: FRAX is used for fracture risk assessment in the general population, but its applicability to specific patient subgroups remains incompletely investigated. Psychiatric illnesses and medications used to treat them may adversely impact bone metabolism and increase fracture risk, but have not been systematically studied in relation to FRAX. Methods: From a clinical DXA registry for Manitoba, Canada, we identified women and men age =40 y with baseline DXA in 1996-2011. Population-based data were used to identify FRAX covariates (with alcohol / substance abuse as a proxy for high alcohol intake), mutually exclusive psychiatric diagnoses (most responsible over 3 y prior to DXA), mutually exclusive categories of psychiatric medications (exposure defined by medication possession ratios over 1 y prior to DXA as low if <0.5 and high if >0.5), incident non-trauma major osteoporotic fractures (MOF) and hip fractures (HF). Results: We studied 71,271 women and men (age 64 y [SD 11], 90% female). During 485,322 y (median 7 y), 5750 (8.1%) patients sustained an incident MOF, 1579 (2.2%) an incident HF and 8998 (12.6%) died. Psychiatric diagnoses were depression in 6824 (9.6%), anxiety 6425 (9.0%) and schizophrenia 203 (0.3%); psychiatric medications were used by 21,915 (30.7%) of which 12,263 (17.2%) had high exposure. High exposure to selective serotonin reuptake inhibitors (SSRI), antipsychotics and benzodiazepines were each associated with increased risk for both MOF and HF (adjusted for FRAX with BMD and osteoporosis treatment). Psychiatric diagnoses were not independently associated with fractures when adjusted for psychiatric medications. FRAX with BMD provided significant fracture discrimination in subgroups defined by psychiatric diagnoses or psychiatric medication use (c-statistic MOF 0.66 to 0.73, HF 0.72 to 0.84), similar to the general population (MOF 0.69, HF 0.82). However, FRAX underestimated 10-y fracture risk for subgroups with depression (observed vs. expected ratios MOF 1.29, HF 1.51), or high exposure to SSRI (ratios MOF 1.36, HF 1.57), non-lithium mood stabilizers (ratios MOF 1.63, HF 1.98), antipsychotics (ratios MOF 1.60, HF 2.71) or benzodiazepines (ratios MOF 1.13, HF 1.31). Conclusions: Psychiatric illnesses and medications used to treat them were associated with increased risk for fracture. FRAX underestimated fracture risk in those with depression and high exposure to SSRI, mood stabilizers, antipsychotics and benzodiazepines.

Fracture risk, stratification and calibration (10-y observed/expected) with psychiatric diagnoses and medications.

Predicting Imminent Risk for Fracture in Patients With Osteoporosis Using Commercially Insured Claims Data. M Bonafede¹, N Shi¹, R Barron², X Li², DB Crittenden², D Chandler². ¹Truven Health Analytics, USA, ²Amgen Inc., USA

Purpose

Several risk factors contribute to long-term fracture risk. However, few studies have identified individuals at imminent risk for fracture, defined as risk within the next 12 or 24 months. We aimed to identify risk factors associated with imminent first and subsequent fracture.

Methods

This was a retrospective cohort study using commercially-insured and Medicare supplemental data for patients aged ≥50 years with osteoporosis, a new fragility fracture claim (index date; fracture cohort) or no fracture claim (control cohort) from January 1, 2006 to September 30, 2012, and continuously enrolled ≥24 months prior to index date. Patients with a fracture in the 24-month pre-index period were excluded. Risk factors for imminent first fracture were identified by logistic regression models that included >60 potential risk factors assessed in the 12 or 24 months prior to index date; controls were randomly assigned an index date within the study period. Cox proportional hazards regression models were used to identify risk factors for subsequent fracture for up to 12 months following the index fracture.

Results

Of the 1,324,571 patients with an osteoporosis diagnosis, 163,186 patients met all inclusion criteria, and 19.7% of these had a fracture. Using data from 12 months prior to fracture, predictors more strongly associated with imminent first fracture were mainly fall-related risk factors, including previous falls, wheelchair use, psychoactive medication use (narcotics, SSRIs, and muscle relaxants), every additional decade after age 50, and mobility impairment (Table). In patients with a first fracture, risk factors for subsequent fracture included prior vertebral fracture (HR [95%CI] 1.62 [1.46-1.80], driven by risk of subsequent vertebral fracture), poor health reflected by a higher Charlson comorbidity index (4+, HR [95%CI] 1.26 [1.02-1.56] or 3, HR [95%CI] 1.22 [1.02-1.48]), antidepressant use (HR [95%CI] 1.21 [1.07-1.37]), and every additional decade after age 50 (HR [95%CI] 1.17 [1.12-1.22]). Similar findings were observed with data from 24-months pre-index. Conclusions

Recent falls, psychoactive medications, mobility impairment, older age, and impaired health status predict imminent risk for fracture within 12 or 24 months. Most of these factors also indicate risk of subsequent fracture. Patients with these characteristics warrant prompt intervention for fracture prevention, including potential lifestyle modifications and osteoporosis therapy.

Table. Factors Associated With Imminent Risk of First Fracture Within 12 and 24 Months

| Predictor | 12 Months Prefracture Odds Ratio (95%CI) | 24 Months Prefracture Odds Ratio (95%CI) |
|--------------------------------------|--|--|
| Falls | 6.67 (6.03-7.37) | 4.43 (4.09-4.80) |
| Narcotic use | 2.11 (2.05-2.18) | 1.85 (1.79-1.92) |
| Every additional decade after age 50 | 2.00 (1.98-2.03) | 1.97 (1.94-2.00) |
| Wheelchair use | 1.79 (1.61-2.00) | 1.80 (1.64-1.97) |
| SSRI use | 1.47 (1.41-1.52) | 1.41 (1.36-1.46) |
| Charlson comorbidity index score* 4+ | 1.46 (1.35-1.59) | 1.49 (1.38-1.62) |

Vertebral Fracture Risk in Diabetic Elderly Men: The MrOS Study. Nicola Napoli*¹, Ann Schwartz², Anne Schafer², Peggy Cawthon³, Neeta Parimi², Joseph M. Zmuda⁴, Eric S. Orwoll⁵, Andrew R. Hoffman⁶, Elsa S. Strotmeier⁴, Elizabeth Barrett-Connor⁷, Dennis M. Black². ¹University Campus Bio-Medico di Roma, Italy, ²University of California San Francisco, USA, ³California Pacific Medical Center Research Institute, USA, ⁴University of Pittsburg, USA, ⁵Oregon Health & Science University, USA, ⁶Stanford School of Medicine, USA, ⁷University of California San Diego, USA

Type 2 diabetes (T2DM) is associated with a 50-80% increased risk of hip fractures as well as 30-70% increased risk of fracture of the humerus and foot. However, to date, very limited information is available on the vertebral fracture (VFs) risk in diabetic men. Moreover, although BMD is strongly associated with vertebral fractures in the general population, previous results have shown no association between bone mineral density (BMD) and vertebral fractures in T2DM.

The aim of this study was to evaluate whether the prevalence and incidence of VFs in T2DM men is higher than in their non-DM counterparts and to examine whether the association between lumbar spine BMD and VF is similar in T2DM and non-DM men.

We used data from the Osteoporotic Fractures in Men (MrOS) Study that enrolled 5,994 men (≥65 years). Men without fasting glucose (n=306) or baseline spine x-ray (n=34) were excluded. Diabetes (ascertained by self-report, use of diabetes medication or elevated fasting glucose) was reported in 875 men of whom 80 used insulin. Spine BMD was measured with dual x-ray absorptiometry (DXA) and QCT. Morphometric VFs were identified on spine x-rays at baseline and at 2nd visit on average 4.6 years later, using standard methods. Prevalent VF was defined as semi quantitative score (SQ) ≥2; incident VF was defined as an increase of ≥1 SQ from baseline.

We used logistic regression analysis to a) examine the effect of diabetes status on prevalent and incident VFs and b) estimate the effect of BMD obtained by DXA or QCT as a risk factor for prevalent and incident VFs in T2DM and non-DM men. T2DM men had higher spine aBMD (by DXA), integral and trabecular vBMD (by QCT) (p<0.001 for all examined parameters). Prevalence of VF was not higher in T2DM (6.97%) vs. non-DM men (7.67%) in models adjusted for age, clinic site, race or after adjustment for BMI, aBMD or vBMD (Table 1). Similarly, risk of incident VFs was not higher in T2DM vs. Non-DM men in all analyzed models (Table 1). However, power to detect modest associations was limited. Spine aBMD was negatively associated with prevalent VFs in T2DM [OR=0.69 (0.52-0.91)] and non-DM men [OR 0.56 (0.49-0.63)](p for interaction 0.18). Results were similar for vBMD.

In conclusion, T2DM is not associated with increased risk of prevalent or incident VFs in elderly men. Lower BMD is associated with higher risk of prevalent VFs in DM as well as non-DM men.

| Model adjusted for | Prevalent vertebral fractures OR (95%CI) | Incident vertebral fractures OR (95%CI) |
|---------------------------------|--|---|
| Model 1: age, race, clinic site | 0.91 (0.74-1.18) | 1.05 (0.68-1.62) |
| Model 2: Model 1, BMI | 0.93 (0.70-1.25) | 1.10 (0.71-1.71) |
| Model 3: Model 2, spine aBMD | 1.05 (0.78-1.40) | 1.28 (0.81-2.00) |
| Model 4: Model 2, spine vBMD | 1.30 (0.89-1.88) | 1.40 (0.78-2.53) |

Diabetes and risk of morphometric vertebral fracture in older men

The Burden of Osteoporosis Is Set to Increase Worldwide: Secular Trends in High Fracture Probability 2010-2040. Anders Odén¹, Eugene McCloskey¹, John Kanis¹, Nicholas Harvey*², Helena Johansson¹. ¹Centre for Metabolic Diseases, University of Sheffield, United Kingdom, ²MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom

The burden of osteoporosis has been defined in terms of bone mineral density, fracture incidence and quality of life, but no studies have explored the prevalence of high fracture risk globally. The aim of this study was to quantify the number of individuals worldwide aged 50 years or more at high risk of osteoporotic fracture in 2010 and 2040. For both men and women, a threshold of high fracture probability was set at the age-specific ten-year probability of a major fracture (clinical vertebral, forearm, humeral or hip fracture), equivalent to that of a woman with a prior fragility fracture, an average BMI (24kg/m²) but no other clinical risk factors. All available country-specific FRAX models (covering 78% of the world population) were used to calculate the prevalence of high risk worldwide and by continent through application to the population demography for each country. The burden of disease over time was estimated from future population projections up to 2040 in each geographical region using the medium variant of UN projections. Globally, in 2010, 3.1% of men and 18.2% of women aged at least 50 years had a fracture probability above the fracture threshold, comprising 21 million men and 137 million women. The greatest number of

men and women at high risk were from Asia (55%), followed by Europe (17%). Worldwide, the number of high-risk individuals is expected to double over the next 40 years. Increases were noted for all regions but were particularly marked in Africa and Latin America. The most modest rise (by 30%) was seen for Europe. In conclusion, individuals with high probability of osteoporotic fractures comprise a very significant disease burden to society, particularly in Asia, and this burden is set to increase markedly in the future. These analyses identify the population who might be targeted for interventions to prevent future fracture and thus may usefully inform future health policy.

Intensive bisphosphonate therapy aimed at normalising bone turnover in Paget's disease increases the risk of fractures and requirement for orthopaedic procedures: The PRISM-EZ trial. Adrian Tan*¹, Jemma Hudson², William Fraser³, Peter Selby⁴, Graeme MacLennan², Stuart Ralston¹. ¹University of Edinburgh, United Kingdom, ²University of Aberdeen, United Kingdom, ³University of East Anglia, United Kingdom, ⁴University of Manchester, United Kingdom

The optimal management strategy for Paget's disease of bone (PDB) is unclear but it has been suggested that bisphosphonates should be given with the aim of maintaining biochemical markers within the normal range. Here we report upon the long term outcome of treatment in the PRISM-extension with Zoledronic acid study (PRISM-EZ) in which 502 PDB patients who had already participated in the PRISM study (Langston *et al* JBMR 2010) were treated for a further 3 years using the same treatment allocation. Patients in the symptomatic group (n=232) were treated with bisphosphonates only if they had bone pain, whereas those in the intensive group (n=270) were given bisphosphonates even in the absence of symptoms with the aim of maintaining alkaline phosphatase levels (ALP) within the normal range. Zoledronic acid was the treatment of choice in the intensive group. Baseline characteristics of the treatment groups were similar and both groups had already been treated in PRISM for an average of 4.3 years. At baseline mean levels of ALP were significantly lower in the intensive group (p=0.02) and the difference between groups increased as the study progressed. For example, at year 1, the mean ± SD normalized ALP was 0.71 ± 0.30 (intensive) vs. 1.01 ± 0.81 (symptomatic) (p<0.001). The values were similar at years 2 and 3. There was no difference between the groups in pain or quality of life assessed by the SF36 questionnaire and analgesic use was similar. Fractures were more common in the intensive group (26 vs. 13) as were orthopaedic procedures (15 vs. 8). A time to event analysis correcting for baseline characteristics showed that the risk of fractures and requirement for orthopaedic procedures as a combined endpoint was significantly increased in the intensive group (HR = 1.85, 95% CI (1.04-3.27)). About 25% of the fractures and 50% of the orthopaedic events occurred in Pagetic bone with a non-significant trend for more events in the intensive group. There was no significant difference in number or type of adverse events between groups overall, but osteonecrosis of the jaw developed in one patient in the intensive group. We conclude that intensive bisphosphonate therapy confers no clinical benefit in patients with PDB and may be harmful. Treatment should be directed at treating symptoms rather than normalizing ALP values

Extended Conventional Therapy in Adult Patients with X-linked Hypophosphatemia: Effects on Enthesopathy and Dentition. Jessica Connor*¹, Elizabeth Olear¹, Lee Katz¹, Suher Baker², Ragbir Kaur², Christine Simpson¹, John Sterpka¹, Jane Zhang³, Robert Dubrow¹, Karl Insogna¹, Thomas Carpenter⁴. ¹Yale University, USA, ²Yale-New Haven Hospital, USA, ³Veterans Affairs Connecticut Health Care System, USA, ⁴Yale University School of Medicine, USA

In X-linked hypophosphatemia (XLH), renal phosphate loss leads to rickets, osteomalacia and bowed legs. Affected children are treated with phosphate and active vitamin D metabolites, which improve most skeletal outcomes. Dental abscesses occur frequently, and calcification of tendons and ligaments (enthesopathy) occur in adults. It is unclear whether medical treatment has any long-term effects on extent of enthesopathy or dental abscess formation. Our objective was to investigate the relationship of conventional XLH therapy to enthesopathy and dental disease in adult XLH patients.

We performed a cross-sectional study in 52 XLH patients >18 yrs of age. Treatment exposure since diagnosis was recorded in detail. The number of enthesopathy sites were identified by comprehensive radiographic survey, and self-reported abscess histories were recorded. PHEX mutation analysis was performed. Biochemical measures included serum phosphorus and FGF23, as well as diurnal PTH levels, calculated as area under the curve for 26 hrs (PTHauc). Exposure to treatment was modeled as both proportion of life with treatment and proportion of adult life with treatment by dividing total treatment yrs by age and total treatment yrs over age 17 by yrs of life over 17, respectively. Multiple linear regression was used to

explore associations between treatment exposure and extent of enthesopathy with age, sex, mutation severity, and PTHaC as covariates. Multiple logistic regression was used to assess the association between treatment and odds of having severe dental disease (> 5 abscesses) with age, sex, and mutation status as covariates.

Neither proportional treatment exposure during adulthood, nor throughout the total life span were associated with the extent of enthesopathy ($P>0.85$). Age, BMI, and sex were significant predictors of enthesopathy for both proportional models ($P<0.01$). PTHaC was associated with the extent of enthesopathy ($p=0.05$) for the adult treatment exposure model. Proportion of both adult life and of total life with treatment were significantly associated with severity of dental disease ($P<0.008$). Those with no treatment in adulthood were 25.1 times more likely to experience severe dental disease compared to those treated 100% of adulthood. Extending treatment into adulthood appears beneficial for the prevention of dental disease, however does not seem to either promote or prevent enthesopathy.

Asfotase alfa: Sustained Efficacy and Tolerability in Children with Hypophosphatasia Treated for 5 Years. Cheryl Rockman-Greenberg^{*1}, Katherine L Madson², Amy Reeves², Scott Moseley³, Tatjana Odrlić³, Michael P Whyte². ¹University of Manitoba, Canada, ²Shriners Hospital for Children, USA, ³Alexion Pharmaceuticals, USA

Background. Hypophosphatasia (HPP) is the rare inherited metabolic disease caused by loss-of-function mutation(s) within the gene that encodes the tissue-nonspecific isoenzyme of alkaline phosphatase (TNSALP). The resulting TNSALP deficiency can cause a spectrum of complications in children including premature loss of primary teeth, rickets, poor growth, muscle weakness, compromised physical function, and pain. In 2014, we reported that children 5-12 years old with HPP and treated with asfotase alfa, a recombinant bone-targeted human TNSALP, experienced rapid improvement in skeletal mineralization and physical function, sustained through 3 years (1, 2).

Aims/Objectives. Report the 5 year experience using asfotase alfa to treat these children.

Methods. The outcome assessments of this Phase II, open-label, ongoing extension study of asfotase alfa (6 mg/kg/wk; SC) in patients 5-12 years old include change in HPP-related skeletal manifestations assessed by a 7-point Radiographic Global Impression of Change (RGI-C) scale (-3=severe worsening; +3=near-complete/complete healing); functional ability/disability assessed by 6-Minute Walk Test (6MWT), the Bruininks-Oseretsky Test of Motor Proficiency, 2nd Edition (BOT-2) Strength and Agility composite score, and Child Health Assessment Questionnaire (CHAQ) Disability Index; and safety.

Results. 12/13 patients completed the original 6-month study, entered the extension phase, and received ≥ 5 years of treatment. The most common treatment-related adverse events (AEs) were mild-to-moderate injection site reactions in all patients (e.g., erythema, macule, and lipohypertrophy; 1 event of injection site atrophy assessed as severe). There were no deaths or AEs leading to withdrawal. Significant healing of HPP-related skeletal manifestations was sustained at 5 years (median [min, max] RGI-C: +2.2 [+1.7, +2.7]; $p=0.0005$). Normalization of physical function was sustained through 5 years across the 6MWT, BOT-2 Strength and Agility score, and CHAQ Disability Index (Table 1).

Conclusion. Asfotase alfa was tolerated well over 5 years of treatment. Normalization of HPP-related skeletal manifestations and functional ability is sustained through 5 years of asfotase alfa treatment in children with HPP.

Type I Collagen C-Propeptide Cleavage Site Mutations: Bone Fragility with High Bone Mass. Tim Cundy^{*1}, Chumei Li², Shehla Mohammed³, Emma Duncan⁴, Aideen McInerney-Leo⁴, Paul Roschger⁵, Klaus Klaushofer⁵, Peter Byers⁶. ¹Faculty of Medical & Health Sciences University of Auckland, New Zealand, ²McMaster University, Canada, ³Guys Hospital, United Kingdom, ⁴University of Queensland, Australia, ⁵Ludwig Boltzmann-Institut für Osteologie, Austria, ⁶University of Washington, USA

Osteogenesis imperfecta (OI) is characterized by low bone mass and skeletal fragility. Most cases of OI result from mutations in COL1A1 and COL1A2, which encode the pro α 1(I) and pro α 2(I) chains, respectively, of type I procollagen. In addition to the core triple helical domain characterized by the repeating Gly-Xaa-Yaa triple, these chains contain amino (N)-terminal and carboxyl (C)-terminal regions. Directed by sequences in the carboxyl-terminal domain, these chains combine in a 2:1 ratio into a trimeric structure that then propagates the triple helical collagen structure in a C- to N-terminal direction. Following secretion in the pericellular domain the N-terminal and C-terminal propeptides are cleaved by proteases: in the case of the C-propeptide by BMP1, at an Ala-Asp dipeptide in each chain [1218-1219 in pro α 1(I) and 1119-1120 in pro α 2(I)]. Mutations in BMP1 result in a severe form of OI with a relatively high bone mass and Lindahl et al have described two OI patients with heterozygous mutations at the C-propeptide cleavage site with normal or high bone mass.* We describe here the clinical and laboratory findings in a larger group of 18 subjects (age 3-77) with C-propeptide cleavage site mutations in COL1A1 (A1218T in 5 subjects from 2 families; D1219E in 4 subjects, 1 family) or COL1A2 (D1120N in 5 subjects, 1 family; D1120A in 4 subjects, 1 family). The age at first fracture ranged from infancy to age 17; half had fractured a femur by age 25. Stature was normal (mean height, 47th centile). The sclerae were white and dentinogenesis imperfecta absent or mild, but two patients had fibro-osseous dysplasia of the mandible; deafness was a feature in one family. Radiographs were remarkable for thickened cortices and spinal osteosclerosis. Spine bone density (DXA) was significantly elevated: mean z-score +2.2 (SD 2.3) – with a marked sex difference (male +0.9 (1.2); female +3.6 (2.5), $p=0.016$). Heterotopic calcification was a feature in some families, and quantitative backscattered electron imaging of a bone biopsy showed a shift in mineral density distribution towards exceptionally high bone matrix mineralization although, paradoxically, histology showed an excess of unmineralized osteoid. In this still relatively small sample, we confirm that OI patients (particularly females) with C-propeptide cleavage site mutations have increased bone mineral density. The basis for this remains unknown. Retention of propeptide sequences conceivably could result in more space for mineral within and between fibrils. However, in vitro studies showed that the C-terminal propeptides are still removed from type I procollagen by enzymatic cleavage. The absence of abnormal fibrils suggests that there is an alternative cleavage site. The clinical features appear to be similar in those with COL1A1 and COL1A2 mutations.* K Lindahl et al Hum Mutation 2011 32: 598-609

Change in Fracture Risk After Bariatric Surgery from a Pattern Associated with Obesity to a Pattern Typical of Osteoporosis: A Study Using Healthcare Administrative Databases. Catherine Rousseau^{*1}, Sonia Jean², Philippe Gamache³, Stefane Lebel⁴, Fabrice Mac-Way¹, Laëtitia Michou¹, Claudia Gagnon⁵. ¹Endocrinology & Nephrology Unit, CHU de Quebec Research Centre; Department of Medicine, Laval University, Canada, ²Institut national de santé publique du Québec; Department of Medicine, Laval University; University of Sherbrooke, Canada, ³Institut national de santé publique du Québec, Canada, ⁴Quebec Heart & Lung Institute, Canada, ⁵Endocrinology & Nephrology Unit, CHU de Quebec Research Centre; Department of Medicine, Laval University; Institute of Nutrition & Functional Foods, Canada

Purpose: To investigate whether fracture risk by site change after bariatric surgery.

Methods: This retrospective, population-based cohort study used healthcare administrative databases to compare fracture risk by site of patients who had undergone bariatric surgery between 2001 and 2012 in the province of Quebec, Canada, with the one of age- and sex-matched non-bariatric obese and non-obese controls. Fracture risk by site was also compared before vs. after surgery (or index date) for each group. Fractures were identified using a validated algorithm (sensitivity >80% for most fracture sites) and were grouped as: lower extremity (knee, foot, ankle, tibia and fibula), upper extremity (shoulder, humerus, elbow, forearm, wrist), spine and hip/femur/pelvis. Multivariate conditional Poisson regression models were adjusted for past fracture, comorbidities (cardiovascular disease, hypertension, diabetes, renal failure, chronic obstructive pulmonary disease, depression, osteoporosis, hypothyroidism), material and social deprivation and area of residence.

Results: 10 662 individuals who underwent bariatric surgery (72.6% women; mean age (SD), 42 (11) years), 31 986 obese and 31 986 non-obese matched controls were followed for a mean of 4.2 years (min-max: <1-12 years). Before surgery (or index date), the risk of lower extremity fractures was higher while the one of upper extremity fractures was lower in both the bariatric and obese control groups compared with the

non-obese group (Table 1). However, the risk of central fractures (spine, hip, femur, pelvis) was similar between groups. After surgery, the risk of sustaining a lower extremity fracture decreased by 33% in the bariatric group compared with pre-surgery (Table 2), being still higher than the one observed in the non-obese group although not statistically significant (Table 3). There was however a two-fold increase in upper extremity fractures and a three-fold increase in pelvic, hip or femur fractures following surgery (Table 2). There was no change in the risk of spine fractures post surgery (but the *n* was small). Fracture risk in the obese and non-obese control groups remained stable for all sites before and after the index date.

Conclusions: These results suggest that fracture risk change after bariatric surgery from a pattern associated with obesity to a pattern typical of osteoporosis. Fracture risk assessment and management should be part of postoperative clinical care.

Natural History and Prognostic Factors of Fibrous Dysplasia of Bone in a Modern Cohort of 372 Patients The Francedys Study. [Johanna Benhamou¹](#), [Deborah Gensburger²](#), [Claude Maessien³](#), [Roland Chapurlat^{2*}](#). ¹Université de Lyon, France, ²INSERM UMR 1033, France, ³APHP, France

Fibrous dysplasia of bone (FD) is a rare genetic bone disease that can be responsible for fracture, bone pain and deformity. The prognosis may be difficult to establish because of the coexistence of patients with benign forms of the disease and some others who are severely affected. Their distinction has not been well established so far. We have analyzed the data from the French National Reference Center for FD. Patients can obtain a consultation on their own rapidly (< 2 months) or be referred. We have established a database from standardized electronic medical records. We have made descriptive statistics of the various forms of FD and examined the prognostic factors by multivariable logistic regression analysis, with a parsimonious stepwise method. The primary outcome was a clinically relevant composite index combining bone pain (analogic scale = 3/10) and incident fragility fracture. In our modern (recruitment after 1990) cohort of 372 patients, the median age at diagnosis was 23. The revealing symptom (median age = 18) was bone pain in 44% of patients, a fracture in 9% but the diagnosis was fortuitous in 25% of cases. Monostotic forms represented 58% of patients and polyostotic forms 42%. The femur was the most commonly affected bone (44% of patients), followed by the skull (38%). Twelve percent of patients had McCune-Albright syndrome (MAS). With a median duration of follow-up of 7 years among 211 patients, we observed an incidence of fragility fracture of 17% and 51% of patients had no bone pain at the end of follow-up (with or without bisphosphonate therapy). A delay in diagnosis was defined by an interval of more than 6 months between first symptoms and diagnosis, that was observed in 30% of patients. In univariate analysis, younger age at diagnosis, renal phosphate wasting, a polyostotic form and prevalent fracture were predictors of a poorer prognosis, but in the multivariate model, the polyostotic form was the only significant predictor (OR = 2.04 [1.29; 3.27]). The predictors of surgical treatment were a younger age at diagnosis and first symptoms, the polyostotic forms, renal phosphate wasting, MAS and prevalent fracture, but none could emerge significantly in a multivariable analysis. In conclusion, in a national reference center for FD, one patient on follow-up out of six had incident fragility fracture. A polyostotic form was the main risk factor of a poorer outcome.

H₂O₂ generated in the mitochondria of osteoclasts is required for the loss of cortical bone mass caused by estrogen or androgen deficiency, but not aging. Semahat Serra Ucer^{*1}, Srividhya Iyer², Li Han², Shoshana M Bartell³, Aaron D Warren³, Julie A Crawford², Christine Rutlen², Robert L Jilka², Maria Jose Almeida², Stavros C Manolagas². ¹University of Arkansas for Medical Sciences, USA, ²Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA, ³Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA

Loss of bone mass caused by acute sex steroid deficiency or aging in mice is associated with an increase in reactive oxygen species (ROS). Nonetheless, the former is a state of high bone turnover with increased resorption and formation, albeit unbalanced, while the latter is a state of low turnover and decreased formation. Recent genetic evidence has revealed that H₂O₂ accumulation is important for the differentiation of osteoclasts; and that the anti-resorptive effects of sex steroids in the cortical versus the cancellous compartment are mediated by different mechanisms. Here, we examined the contribution of osteoclast H₂O₂ to the loss of bone mass caused by ovariectomy (OVX), orchidectomy (ORX), or old age, using transgenic mice in which the gene for human catalase - a potent H₂O₂ inactivating enzyme - has been targeted to the mitochondria of LysM-Cre expressing cells (MitoCat;LysM-Cre). Six weeks following OVX of 12-week old LysM-Cre littermate control mice, ROS levels in the bone marrow were increased and cancellous and cortical bone mass were decreased, as compared to sham-operated mice. MitoCat;LysM-Cre mice, however, were protected from the OVX-induced increase in ROS and the cortical bone loss, but not the loss of cancellous bone. Similar to the OVXed MitoCat;LysM-Cre mice, MitoCat;LysM-Cre ORXed at 18 weeks of age and analyzed 6 weeks later were protected from the loss of cortical, but not cancellous, bone. MitoCat;LysM-Cre mice were also protected from the ORX-induced increase in osteoclast number at the endocortical, but not cancellous, bone surface. Furthermore, administration of the antioxidant N-acetylcysteine to C57BL/6J mice prevented the loss of cortical, but not cancellous, bone caused by OVX or ORX. Finally, we aged ovary-intact female MitoCat;LysM-Cre mice and littermate controls and examined their skeletal phenotype at 22 months. Both genotypes exhibited the expected age-related decline in cortical and cancellous bone mass. However, in spite of the higher bone mass seen at 6 months in the MitoCat;LysM-Cre mice, at 22 months both cancellous and cortical bone mass were indistinguishable from the controls. These results demonstrate that the pathogenetic mechanisms responsible for the loss of cortical bone in acute sex steroid deficiency are different than those responsible for the loss of cancellous bone, and also different from the mechanisms causing loss of cortical bone with old age.

A Spontaneous Mutation in Dock7 Results in Extreme Age-Related Loss of Trabecular Bone and Sympathetic Nervous System-Related Bone Loss. Phuong T Le^{*1}, Kathleen Bishop¹, Katherine J Motyl¹, Daniel J Brooks², Kenichi Nagano³, Roland Baron⁴, Mary L Bouxsein², Clifford J Rosen¹. ¹Maine Medical Center, USA, ²Beth Israel Deaconess Medical Center, Harvard Medical School, USA, ³Harvard School of Dental Medicine, USA, ⁴Harvard School of Medicine & of Dental Medicine, USA

Misty mice (*m/m*) have a loss of function mutation in Dock7, a guanine nucleotide exchange factor, resulting in low bone mass, uncoupled bone remodeling, reduced bone formation, decreased osteoblast migration and altered Wnt signaling. In addition, *m/m* exhibit a reduction of preformed brown adipose tissue activity leading to compensatory increases in sympathetic nervous system (SNS) activity and browning of peripheral white adipose depots. Propranolol administration only partially rescues the low bone mass phenotype. Importantly, with advanced age, the skeletal phenotype becomes even more pronounced. We hypothesized that synergy between cell autonomous and non-cell autonomous factors exaggerate the process of age-related bone loss. To test this hypothesis, we first analyzed the static and dynamic histomorphometric parameters of *m/m* and their littermate controls (+/+) at 52 weeks of age. In 52 wk old *m/m*, femoral BV/TV (p=0.003) and Tb.N. (p<0.0001) were significantly reduced by μ CT analysis. However, histomorphometry revealed only 4/10 *m/m* and 8/9 +/+ exhibited any trabecular bone in tibia sections (p=0.027 by chi square). In contrast to 16 wk old *m/m*, neither osteoclast numbers nor surface area was changed at 52 wks of age. Osteoblast numbers were undetectable in *m/m* and marrow adipocytes were elevated 3.5 fold over +/+ (p=0.014). Consistent with reduced bone formation, gene expression of *Alp*, *Col-1*, and *Runx-2* was significantly decreased (p=0.001, .0002, and 0.01 respectively) in *m/m* whole bone. In combination with reduced appositional growth observed by μ CT analysis, these data suggest a defect in periosteal expansion and an acceleration of age-related bone loss in the absence of Dock7. Next, to test the importance of the increased SNS activity as the driver of bone loss in *m/m*, we crossed *m/m* with β 2AR^{-/-}. In mice wildtype for the *Misty* mutation, β 2AR^{-/-} alone had 8.8 \pm 0.4% (p=0.01) increase in femoral aBMD over +/+ at 8 wks of age. Interestingly, female β 2AR^{-/-}, *m/m* exhibited a 6.2 \pm 0.2% (p=0.007) increase

in femoral aBMD over β 2AR^{+/-}, *m/m*, but the β 2AR^{-/-}, *m/m* failed to gain BMD compared to β 2AR^{+/-}, *m/m*. Thus, loss of a single allele in the β 2AR resulted in increased aBMD due to modulation of SNS signaling in the *m/m*. In summary, the low bone mass and age-related bone loss observed in *m/m* results from both changes in SNS activity and a cell autonomous role for Dock7 in bone.

Velcade Enhances Fracture Repair in Aged Mice by targeting Mesenchymal Stem Cells. Hengwei Zhang^{*1}, Xing Li², Michael Zuscik², Brendan Boyce², Lianping Xing². ¹University of Rochester, USA, ²University of Rochester, USA

The Ubiquitin Proteasome System(UPS) influences the differentiation of mesenchymal stem cells(MSCs) to osteoblasts(OBs) during skeletal development and remodeling by regulating the stability of the essential osteoblastogenic proteins, Runx2 and JunB. However, the role of the UPS during fracture healing has not been studied well. We hypothesize that UPS activity is elevated in aging, leading to reduced MSC-OB differentiation and delayed fracture repair, which can be reversed by Velcade, a clinically used proteasome inhibitor. To test this, we performed open tibial fractures in 3-month-old(young) and 20-month-old(aged) C57BL6 mice, treated with Velcade(0.6mg/kg/day, ip, x4) or saline(Ctl), and examined callus volume by microCT and did biomechanical testing. Compared to Ctl, Velcade significantly increased callus volume in both young (3.5 \pm 1.1 vs 1.1 \pm 0.4 mm3) and aged (3.2 \pm 0.8 vs 2.1 \pm 0.4 mm3) mice and also increased bone strength (maximum torque: young: 28 \pm 4 vs 21 \pm 3 N.mm & aged: 19 \pm 2.8 vs 13 \pm 1.4 N.mm). To study if Velcade increases MSC frequency as a cellular mechanism, we examined the percentage of CD45-CD105+Sca1+ MSCs in fracture callus by flow cytometry. Aged mice had significantly fewer MSCs than young mice (%CD45-CD105+Sca1+: 1 \pm 0.2% vs. 1.5 \pm 0.3%), and Velcade significantly increased MSC frequency in the aged population (%CD45-CD105+Sca1+: 3.3 \pm 0.6% vs. 1 \pm 0.2% in Ctl). To determine if Velcade affects protein ubiquitination and degradation, we measured ubiquitinated protein levels in the fracture callus. Compared to young mice, aged mice had higher levels of total ubiquitinated proteins. Velcade increased the levels of key stem cell and osteoblast proteins known to be degraded via the UPS, including Runx2, JunB and stem cell factor Sox2. To investigate if Velcade stimulates proliferation of MSCs in fracture callus, we fractured tibiae of Nestin-GFP mice. We observed >10-fold increase in Nestin+ cells in fracture callus 10 days post-fracture, and among these 70% are CD105+Sca1+, 41% are α SMA+, and 60% are LeptinR+, and all are osteocalcin-. Velcade increased the % of Nestin+ and Nestin+ /BrdU+ cells by 4-10- and 2-fold, respectively. Thus, increased activation of the UPS may contribute to impaired fracture healing in aging by promoting the degradation of proteins involved in MSC proliferation and OB differentiation. Inhibition of USP activity with drugs such as Velcade would be a potential new therapeutic approach for patients with impaired fracture healing.

SIRT6 Deficiency Culminates in Low-Turnover Osteopenia. Toshifumi Sugatani^{*1}, Olga Agapova², Hartmut Malluche³, Keith Hruska². ¹Washington University in St. Louis School of Medicine, USA, ²Washington University School of Medicine, USA, ³University of Kentucky, USA

Sirtuin 6 (SIRT6) is a chromatin-related Class III histone deacetylase enzyme. Recently, it has been reported that SIRT6^{-/-} mice reveals severe premature aging phenotypes including osteopenia. Yet, no detailed skeletal investigation was performed in the study and the underlying molecular mechanisms of SIRT6 in bone metabolism are unclear. Hence, we investigated the bone phenotypes of SIRT6^{-/-} mice in detail, and studied the role of SIRT6 in osteoblastogenesis in culture.

Micro-CT and bone histomorphometry revealed that SIRT6^{-/-} mice produces a low-turnover osteopenia caused by impaired bone formation and bone resorption, which is a similar mechanism to age-related bone loss.

Consistent with the in vivo findings, quantitative alizarin red stain assays revealed drastically reduced osteoblastic mineralization in SIRT6^{-/-} osteoblasts. Osteoclast formation assays revealed that the number of TRAP+ cells were remarkably reduced in SIRT6 deficiency. Taken together, these findings indicate that SIRT6 positively regulates osteoblastogenesis and osteoclastogenesis as a decisive intrinsic factor.

Next, we analyzed the expression of Runx2 and Osx during SIRT6^{-/-} osteoblastogenesis. Surprisingly, Runx2 and Osx levels were gradually up-regulated in time-depend fashion in SIRT6^{-/-} osteoblastogenesis. Given that Runx2 and Osx negatively control osteoblastogenesis at a late stage, excessively elevated Runx2 and Osx in SIRT6^{-/-} osteoblasts may lead to impaired osteoblastic development and bone mineralization.

We found that SIRT6 interacts with Runx2 and Osx, and SIRT6 is recruited and deacetylates histone H3 at Lysine 9 (H3K9) at their target gene promoters, such as Runx2, Osx, ALP, osteocalcin, and Dkk1. Therefore, SIRT6^{-/-} osteoblasts produced the excessive expression of Dkk1 caused by the hyperacetylation of H3K9 in the promoter of Dkk1, a potent negative regulator of osteoblastogenesis. Moreover,

osteoprotegerin, an inhibitor of osteoclastogenesis, was excessively expressed in SIRT6^{-/-} osteoblasts, although osteoprotegerin is not target for Runx2 and Osx. In fact, nuclear accumulation of β -catenin was diminished by conditioned media harvested from SIRT6^{-/-} osteoblasts culture media and NFATc1 levels were also attenuated by the conditioned media during osteoclastogenesis. Taken together, the resulting up-regulation of Dkk1 and osteoprotegerin levels may impair bone remodeling, leading to osteopenia with a low bone turnover in SIRT6^{-/-} mice.

This is first demonstration that the structural changes of chromatin by loss of SIRT6 leads to functional changes that are important determinants of gene expression-related with bone remodeling. In addition, since SIRT6^{-/-} mice reveal characteristic features of low-turnover osteopenia in humans, the cellular and molecular mechanisms of SIRT6 in bone turnover could be potential therapeutic targets for age-related bone loss.

Overexpression of Sirt1 in Mesenchymal Stem Cells Stimulates Skeletal Growth and Osteoblastic Bone Formation. Quanquan Yan^{*1}, Qian Zhang¹, Jianliang Jin¹, Dengshun Miao². ¹Nanjing Medical University, China, ²Nanjing Medical University, Peoples republic of china

Previous study has demonstrated that Sirt1 haploinsufficiency resulted in a significant reduction in bone mass characterized by decreased bone formation and increased marrow adipogenesis, however, it is unclear whether overexpression of Sirt1 in bone marrow mesenchymal stem cells (BM-MSCs) plays an anti-osteoporotic role. To investigate this, we generated a transgenic mouse model overexpressing Sirt1 in BM-MSCs (Prx1-Sirt1^{1E}) and analyzed their skeletal phenotype. The expression levels of Sirt1 were significantly higher in skeletal tissue and BM-MSCs of Prx1-Sirt1^{1E} mice than in those of wild-type mice. Compared to wild-type mice, body weight and size, skeletal size, cortical and trabecular bone volume, osteoblast number, ALP- and type I collagen-positive areas, total numbers of CFU-f, mRNA expression levels of Runx2, ALP, type I collagen and osteocalcin were all significantly increased in the Prx1-Sirt1^{1E} mice. Furthermore, ROS levels were reduced significantly, whereas mRNA levels of anti-oxidative enzymes including SOD1 and 2 and glutathione peroxidase 1 (GPX1) were up-regulated in bony tissues of the Prx1-Sirt1^{1E} mice. We previously have demonstrated that Bmi1 deficiency displayed osteoporotic phenotype with a significant down-regulation of Sirt1 protein expression, therefore we crossed Prx1-Sirt1^{1E} mice with Bmi1^{-/-} mice to generate Bmi1^{-/-} mice with Sirt1 overexpression in BM-MSCs for comparison with the Bmi1^{-/-} and wild-type littermates. Overexpression of Sirt1 in Bmi1^{-/-} mouse BM-MSCs resulted in a longer lifespan, significantly increased body weight and improvement in skeletal growth and osteoblastic bone formation in the Bmi1^{-/-} mice, although the defects were not completely rescued. Furthermore, mRNA levels of anti-oxidative enzymes including SOD1 and 2, and glutathione peroxidase 1 and protein levels of SOD2 and FOXO3a were down-regulated in bony tissues of the Bmi1^{-/-} mice, importantly, Sirt1 overexpression in the Bmi1^{-/-} mice rescued this down-regulation. Taken together, these results demonstrated that overexpression of Sirt1 in BM-MSCs enhanced osteoblastic bone formation and partially rescues the defects in skeletal growth and osteogenesis in the Bmi1^{-/-} mice by inhibiting oxidative stress, consequently, support that Sirt1 is a target for promoting bone formation as an anabolic approach for treatment of osteoporosis.

Discovery of MicroRNAs in Synovium in Regulating Inflammation Leading to Bone Erosion in Rheumatoid Arthritis. Yukiko Maeda^{*1}, Nicholas Farina², Melissa Matzelle³, Paul Fanning³, Jane Lian⁴, Ellen Gravalles³. ¹University of Massachusetts Medical School, Us, ²Department of Biochemistry, University of Vermont, USA, ³University of Massachusetts Medical School, USA, ⁴University of Vermont, USA

Articular bone erosion in rheumatoid arthritis (RA) is a consequence of synovial inflammation that results in significant disability. Synovial cells secrete inflammatory cytokines and RANKL promoting osteoclastogenesis and inhibition of osteoblast function. MicroRNAs (miRNAs) are key regulators of skeletal remodeling and are associated with RA pathogenesis. We hypothesized that miRNAs derived from synovial tissues play a regulatory role in erosion in RA through effects on osteoblasts. Using the serum transfer model of RA, we performed expression profiling of qPCR based 756 miRNAs in pooled synovial samples from non-arthritic and arthritic mice and compared this data set to gene expression from array data. We identified 417 up-regulated genes that are predicted targets of 72 down-regulated miRNAs (1.5 fold or >); and, 536 down-regulated genes as predicted targets of 59 up-regulated miRNAs. Gene ontology analysis of the miRNA-targeted genes revealed significant enrichment of skeletal pathways involved in osteoblast function, including Wnt/ β -catenin signaling. Principal component analysis identified 22 miRNAs with the greatest statistical significance ($P < 0.01$) of expression changes between non-arthritic and arthritic mice. Among these, 11 miRNAs were predicted to target numerous Wnt and BMP signaling pathway components. We validated their expression in isolated synovial fibroblasts and in whole synovium by qPCR and showed that 4 miRNAs were down-regulated by TNF. Target genes of these miRNAs, GSK3 β , Sfrp2, Tbl1

and Osx, were up-regulated at the erosion sites in bone. Among these 11 miRNAs, miR-221 was significantly up-regulated during peak inflammation. Since miR-221 is known to be upregulated in RA patients, we examined the role of miR-221 in osteoblasts. Transfection of miR-221 into primary murine calvarial osteoblasts suppressed osteoblast differentiation and mineralization. A predicted target gene of miR-221, DKK2 that is essential for bone mineralization is suppressed by miR-221 at the protein level. Tcf-1, a downstream target of Wnt signaling is also down regulated by miR-221. These results suggest that miR-221, derived from inflamed synovial tissues, regulates skeletal pathways and osteoblast differentiation in RA. Overall, our data support the hypothesis that miRNAs derived from inflamed synovium contribute to bone erosion, not only by increasing osteoclast activity, but also by inhibiting bone formation in RA.

Selective Antagonism of Beta 2 Adrenergic Receptor Enhances Periosteal Anabolic Response to Mechanical Stimulation in Aged Mice. Sundar Srinivasan, DeWayne Threet, Philippe Huber, Brandon Ausk, Leah Worton, Ronald Kwon, Steve Bain, Ted Gross, Edith Gardiner^{*}. University of Washington, USA

Mechanical stimulation of young bone is anabolic but the aged bone response to loading is muted. Autonomic dysregulation is common in the aged. The sympathetic nervous system (SNS) directly suppresses bone formation under physiological load through osteoblastic beta 2 adrenergic receptor (β 2AR). Pharmacological tests of a potential SNS role in the osteoblastic response to mechanical stimulation using the non-selective β AR antagonist propranolol gave equivocal results, perhaps explained by evidence that β 1AR and β 2AR mediate opposing effects on bone mechanical response *in vivo*. We therefore hypothesized that selective antagonism of only β 2AR would enhance bone mechanotransduction in senescent mice. Aged female C57 mice (22 mo) underwent a 3d/wk, 3wk cantilever bending regimen of right tibia (1700 μ e normal strain, 50 cycles/bout). Mice (4-5/group) randomly received injection of saline or the β 2AR-selective antagonist Butaxamine (3 mg/kg) 0.5 h prior to loading. Mice received calcein labels (d10, d19) for dynamic histomorphometry of the periosteal surface of both loaded (right) and contralateral (left) tibia midshafts. Neither loading nor Butax alone altered osteoblast function but there was a vigorous anabolic response to loading in the Butax treated mice, with p.MAR (+154%), p.MS (+56%) and p.BFR (+282%) all elevated in right vs left tibiae of the Butax group. Further, loading plus Butax treatment significantly augmented p.MAR, p.MS and p.BFR compared to loading plus saline injection (+165%, +59% and +223%, respectively). To estimate synergistic benefit, we determined the ratio for combined effect of load plus Butax versus additive effects of these factors. p.MAR and p.BFR were both synergistically increased, as the interaction between loading and Butax treatment was significant ($p \leq 0.05$) with ratios (combined/additive) of 21.8 and 5.0 respectively. Thus although Butax alone is not sufficient to initiate periosteal osteoblast activity in the aged mouse tibia, when Butax treatment was combined with a mildly osteogenic mechanical loading waveform, osteoblast function was elevated to levels 50% greater than previously observed in young adult mice subjected to equivalent loading. These data suggest that modest exercise preceded by Butax treatment may produce a robust anabolic response in the senescent skeleton. This treatment combination thus holds significant promise as a potential clinical intervention in osteoporosis and other low bone mass disorders.

PHOSPHO1, a Novel Skeletal Regulator of Energy Metabolism. Karla Oldknow^{*1}, Nik Morton², Manisha Yadav³, Carmen Huesa⁴, Mathieu Ferron⁵, Gerard Karsenty⁶, Zohreh Khavandgar⁷, Anvona Guntur⁸, Vicky MacRae⁹, Monzur Murshed⁷, Calvin Vary¹⁰, Clifford Rosen¹⁰, José Luis Millán³, Colin Farquharson¹¹. ¹The Roslin Institute, The University of Edinburgh., United Kingdom, ²The University of Edinburgh, United Kingdom, ³Sanford Burnham Medical Research Institute, USA, ⁴University of West Scotland, United Kingdom, ⁵Institut de recherches cliniques de Montréal (IRCM), Canada, ⁶Columbia University Medical Center, USA, ⁷McGill, Canada, ⁸Maine Medical Center Research Institute, USA, ⁹Roslin Institute University of Edinburgh, United Kingdom, ¹⁰Maine Medical Center Research, USA, ¹¹The Roslin Institute, The University of Edinburgh, United Kingdom

Cell-specific gene deletions in mouse and human genetic studies have identified bone as an endocrine organ capable of regulating whole-body glucose metabolism. We now show that the ablation of PHOSPHO1, a bone specific phosphatase, indispensable for bone mineralization, confers a remarkable degree of protection against obesity and diabetes in mice. *Phospho1*^{-/-} mice (35 day-old) have lower blood glucose (mmol glucose/L), (WT, 9.31 \pm 0.31; *Phospho1*^{-/-}, 7.76 \pm 0.39, $p < 0.01$) and improved glucose and insulin tolerance. Food intake (g/gBW/day): WT, 0.126 \pm 0.006; *Phospho1*^{-/-}, 0.117 \pm 0.006, $p = 0.29$) and energy expenditure are comparable between

35 day-old WT and *Phospho1^{-/-}* mice fed a control diet. At this age there is no difference in BW. *Phospho1^{-/-}* mice (120 day-old) resist obesity on a high fat diet (BW: WT, 38.0±1.54 g, *Phospho1^{-/-}*, 32.4±1.26 g, p<0.05; visceral fat weight: WT, 13.2±1.34g; *Phospho1^{-/-}*, 5.56±1.61g; p<0.01). Despite a 20-fold increase in *Esp* expression (negative regulator of osteocalcin (OCN)), in *Phospho1^{-/-}* osteoblasts (osb) the serum levels of undercarboxylated OCN were normal, suggesting an OCN-independent mechanism of PHOSPHO1-regulated energy metabolism. A key marker of insulin sensitivity in bone (AKT phosphorylation) was elevated (p<0.05) in *Phospho1^{-/-}* mice following a sub-maximal *in vivo* administration of insulin (1mU/g), with no changes noted in liver, muscle and fat. *Phospho1^{-/-}* osb showed an enhanced response to mitochondrial stress parameters *in vitro*, suggestive of improved respiration and increased basal mitochondrial activity. The latter was associated with elevated GLUT4 expression. Furthermore, *Phospho1^{-/-}* osb conditioned medium (OCM), but not WT OCM increased basal insulin sensitivity (AKT and GSK phosphorylation) in WT primary osb, decreased insulin-stimulated sensitivity of INS1e cells and increased insulin stimulated sensitivity in 3T3-L1 cells. *Ucp1* expression and acute cold studies suggested a white adipose tissue browning phenotype in *Phospho1^{-/-}* mice. Mass spectrometry analysis identified >100 differentially expressed proteins in *Phospho1^{-/-}* serum associated with the regulation of glycolysis and gluconeogenesis. Furthermore, these candidates displayed enrichment for microRNA Mir34a and the transcription factor hepatocyte nuclear factor 1, both reported to regulate hepatic glucose homeostasis. These data support the notion that further, yet undefined osb derived factors contribute to whole body energy metabolism.

Critical Role of Galanin in the Hypothalamic Neuronal Regulation of Bone Density and Energy Expenditure by AP-1 Antagonists. Anna Idelevich^{*1}, Kazusa Sato², Glenn Rowe³, Francesca Gori⁴, Roland Baron². ¹Harvard University, USA, ²Harvard Medical School, Harvard School of Dental Medicine, USA, ³Beth Israel Deaconess Medical Center, USA, ⁴Harvard Medical School, Harvard School of Dental Medicine, MGH Endocrine Unit, USA

The hypothalamus regulates whole body metabolism and the skeleton. Virus-mediated stereotaxic gene delivery of Δ FosB, a splice isoform of FosB and an antagonist of AP1, in the ventral hypothalamus (VHT) of mice increases both energy expenditure and bone density. Several hypothalamic neurons are involved in the regulation of metabolism, including the arcuate nucleus (ARC) AgRP NPY, POMC, and CART neurons, as well as ventromedial nucleus (VMN) SF1 neurons, but their specificity for energy and/or bone regulation is unknown. The aim of this study was to identify the individual AP1-responsive neuronal circuits in the VHT that mediate the metabolic and/or skeletal effects, and determine the mechanisms by which they exert their actions. For this purpose, we generated Cre-inducible lentiviral vectors expressing AP1 antagonists (Δ FosB, Δ 2 Δ FosB and DNJunD) or the AP-1 agonist FosB. The expression of these factors was restricted to specific neuronal types by stereotaxic delivery into the VHT of mice expressing Cre-recombinase under the control of neuron-specific promoters, including AgRP-Cre, CART-Cre, NPY-Cre, POMC-Cre, and SF1-Cre. Despite the classically divergent functions of CART and AgRP neurons in energy balance, AP-1 inhibition in either neuron type resulted in increased energy expenditure, lower fat mass with smaller adipocytes and higher bone density. In contrast, AP-1 blockade in SF-1 neurons reduced bone density while increasing energy expenditure, demonstrating differential regulation of bone by distinct hypothalamic nuclei. To elucidate the molecular mechanisms underlying the bone and energy effects, we analyzed VHT gene expression and identified galanin as a potential downstream target of Δ FosB. Accordingly, global deletion of galanin, VHT delivery of the galanin receptor antagonist M35 or silencing of galanin by combining Δ FosB overexpression with galanin shRNA in the same Cre-inducible vector demonstrated that VHT neuronal AP1 machinery mediates both its metabolic and bone effects via the upregulation of galanin in AgRP and/or POMC neurons.

In conclusion 1) Selective inhibition of AP-1 in one of the ARC neuronal subtypes is sufficient to stimulate total body metabolism, decrease fat and increase bone density 2) ARC, but not VMN, mediates the AP-1 inhibition-dependent increase in bone mass, and 3) Downstream of AP1 galanin acts as a central factor common to and/or affecting several types of hypothalamic neurons to regulate bone and energy.

Osteocyte-specific ablation of Ppar γ increases bone mass and improves energy metabolism. Nicolas Bonnet^{*1}, Mirko Trajkovski², Beatrice Desvergne³, Serge Ferrari⁴. ¹University Geneva Hospital (HUG), Switzerland, ²Laboratoire des maladies métaboliques, Medical faculty, University of Geneva, Switzerland, ³Center for integrative Genomics, Faculty of Biology & Medicine, University of Lausanne, Switzerland, ⁴Service des Maladies Osseuses, Medical faculty, University of Geneva, Switzerland

Ppar γ is a master transcriptional regulator of energy metabolism, and both Ppar γ haploinsufficient mice and osteoblast-targeted Ppar γ -deficient mice have increased bone mass and osteoblastogenesis. Here we investigated the role of Ppar γ in late osteoblast/osteocytes (ocy) on bone (re)modeling and energy metabolism. For this purpose Ppar γ -loxP were crossed with Dmpl-cre mice to generate Ocy-Ppar γ -/- (KO) and -Ppar γ /+ (WT) male mice. Tissue and cell specificity of Ppar γ deletion were confirmed by western blot and immunostaining. Metabolic rate and tissue temperature were evaluated by labmaster system and infrared camera. At 3 months of age, total body lean and fat mass, handgrip strength as well as glucose tolerances test (GTT) were comparable in KO and WT. However femoral BMD was significantly higher in KO (78.6±1.3 vs 73.4±2.1mg/cm² in WT, p<0.001). Trabecular and cortical microstructure respectively evaluated at the distal and midshaft femur was improved in KO: BV/TV +28.6%, TbTh +12.5%, CtTV +9.8%, CtBV +12.0% and CtTh +4.5% compared to WT (all p<0.05). Periosteal BFR was higher in KO (+66.5% vs Ppar γ /+, p<0.05), whereas no significant differences were observed at endocortical surfaces. In contrast CTx was decreased in KO (8.6±0.6 vs 12.9±0.5ng/ml in WT, p<0.001). From 3 to 9 months of age, BMD did not further increase in KO but remained higher compared to WT (89.9±2.1 vs 80.6±1.7mg/cm², p<0.001). Age-related changes in fat and lean mass were attenuated in KO (total fat +11.1% and lean -1.9% vs +30.8% and -6.1% respectively in WT, p<0.01). At 9 months of age, handgrip strength, VCO₂/VO₂ and heat production were higher in KO (+33.2%, +4.3% and +13.7% vs WT, p<0.001) without significant differences in food intake. Body temperature was also higher, particularly in the BAT-rich neck region, and in the limbs, i.e musculo-skeletal region (respectively +4.3% and +3.8% vs WT, p<0.001). As a result, GTT was improved in the KO mice (AUC-38.4% vs WT, p<0.01). In conclusion, Ocy-specific ablation of Ppar γ increased periosteal bone formation and lowered bone turnover, resulting in high bone mass from a younger age. Moreover, Ppar γ expression in osteocytes regulates respiratory exchange ratio and metabolic rate, causing age-related changes in body composition and glucose homeostasis. These observations suggest a role for Ocy-Ppar γ in diabetes bone disease. What component of osteocyte is responsible for the metabolism energy effect of Ppar γ remains to be determined.

Fibrillin-1 Regulates Skeletal Stem Cells Fate Determination through Modulation of Local TGF β . Silvia Smaldone^{*1}, Francesco Ramirez². ¹Mount Sinai School of Medicine, USA, ²Ichan School of Medicine at Mount Sinai, USA

A full understanding of the microenvironmental factors controlling the activities of skeletal stem cells (a.k.a., mesenchymal stem cells [MSCs]) in the adult bone marrow holds great promise for developing new therapeutic strategies to mitigate age-related diseases of bone and cartilage degeneration. Bone loss is an understudied manifestation of Marfan syndrome (MFS), a multisystem disease associated with mutations in the extracellular matrix protein and TGF β modulator fibrillin-1. Previous characterization of osteopenia in mice with MFS has implied that fibrillin-1 restricts osteoblast maturation and TGF β driven, osteoblast-dependent, osteoclastogenesis. As MFS mice die from ruptured aneurysm at ~3 month of age, osteopenia progression was studied in mice with conditional inactivation of Fbn1 gene in the developing limbs (*Fbn1^{Prx1-/-}* mice). Longitudinal studies showed that progressive bone loss in *Fbn1^{Prx1-/-}* mice is accounted for by decline of bone formation, secondary to premature depletion of MSCs, combined with constitutively enhanced bone resorption. Significant paucity of marrow adipose tissue in the long bones of *Fbn1^{Prx1-/-}* mice, together with reduced adipogenic potential of cultured marrow cells, suggested an additional defect in MSC differentiation. The finding that an *Fbn1*-silenced osteoprogenitor cell line cultured in adipogenic induction media, yielded fewer than normal adipocytes and exhibited relatively lower PPAR γ levels corroborated this postulate. Consonant with fibrillin-1 modulation of TGF β bioavailability, cultures of marrow stromal cells from *Fbn1^{Prx1-/-}* limb bones showed greater activation of normal amounts of latent TGF β . In line with this finding, systemic TGF β neutralization improved bone mass and trabecular microarchitecture along with normalizing the number of MSCs, osteoprogenitor cells and marrow adipocytes. Lastly, reduced frequency of hematopoietic stem cells (HSC) in bone marrow of adult *Fbn1^{Prx1-/-}* mice, which *in vitro* co-culture experiments with WT GFP-CD45+ cells correlated to fibrillin-1 deficient stroma, suggested that fibrillin-1 constitute an essential structural component of the bone marrow niche. Collectively our findings advance the current understanding of MSC biology, which are necessary for improving regenerative therapies to ameliorate the conditions of patients affected by skeletal disorders.

MiR-144 Inhibits Tumor Growth and Metastasis in Osteosarcoma via Targeting ROCK1. Jing Li^{1*}, Xiaoling Zhang², Kerong Dai³, Qian Chen⁴.

¹Department of Orthopaedics, Alpert Medical School/Rhode Island Hospital, Brown University, USA, ²The Key Laboratory of Stem Cell Biology, Institute of Health Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences & Shanghai Jiao Tong University School of Medicine, China, ³Shanghai Key Laboratory of Orthopaedic Implant, Department of Orthopaedic Surgery, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, China, ⁴Brown University School of Medicine, USA

Abstract

Purpose

Osteosarcoma (OS) is the most prevalent bone tumor in children and young adults. Several miRNAs have been found expressed differentially in osteosarcoma, thus their function may be implicated in the onset and progression of osteosarcoma. Previous studies have shown that Rho-associated, coiled-coil containing protein kinase 1 (ROCK1), a pivotal downstream effector of RhoA/ROCK signaling pathway, is strongly upregulated in osteosarcoma clinical specimens and may be a therapeutic target of this disease. We wondered whether the deregulation of ROCK1 was associated with miRNA regulation.

Methods

The expression levels of miR-144 and ROCK1 in osteosarcoma cell lines and clinical samples were quantified by quantitative real-time PCR and Western blotting. The effect of miR-144 on migration and invasion was measured by wound healing assay and transwell migration assay. Cell cycle distribution was analyzed by flow cytometry. Human osteosarcoma cells were injected into the tibia of athymic mice to induce a tumor. One week after injection, mice were treated by way of multi-point intratumoral injection of miR-144 twice a week. Tumor growth was monitored over time using an in vivo imaging system. Tumors and lungs were harvested at sacrifice for real-time PCR and immunohistochemical staining.

Results

In this study, we found that miR-144 was downregulated in both osteosarcoma cell lines and clinical specimens. ROCK1 was identified as a direct target of miR-144. Overexpression of miR-144 decreased the protein levels of ROCK1 and then influenced the signal transduction of RhoA/ROCK signaling pathway. miR-144 suppressed the proliferation of OS cells by mediating the expression of cell-cycle regulatory molecules and by arresting cells in the G0/G1 phase of the cell cycle. Both migration and invasion of OS cells was inhibited by miR-144. Furthermore, miR-144 intratumoral administration in mice reduced the tumor size and pulmonary metastasis, and prolonged the survival time of tumor-bearing mice.

Conclusions

We reveal for the first time that overexpression of miR-144 represses osteosarcoma cell growth and tumorigenesis, and inhibits osteosarcoma cell migration and pulmonary metastasis. These findings suggest that miR-144, which is downregulated in osteosarcoma, may contribute to osteosarcoma pathogenesis by targeted inhibition of ROCK1 both in vitro and in vivo, and could be a new therapeutic approach for the treatment of disease.

Vitamin D Status and Bone Mineralization: A Histomorphometric Analysis.

Neil Binkley^{1*}, Joan Lappe², KM Davies³, Robert Recker². ¹University of Wisconsin, Madison, USA, ²Creighton University Osteoporosis Research Center, USA, ³Creighton University Osteoporosis Research Program, USA

Background: How to define vitamin D insufficiency is controversial. Vitamin D deficiency impairs bone mineralization. As such, it is reasonable that histomorphometric evidence of mineralization impairment could be used to define vitamin D insufficiency. Indeed, a prior report from cadaveric specimens found osteoid minimization when serum 25(OH)D was ≥ 30 ng/mL. However, it is not known if blood 25(OH)D levels obtained at autopsy are directly comparable to ante-mortem values. Additionally, autopsy specimens (given their absence of tetracycline labeling) do not allow assessment of dynamic variables. Here we report the association of serum 25(OH)D with bone histomorphometric data in postmenopausal women early in menopause.

Methods: 50 women participated in a study evaluating the effect of menopause on histomorphometric variables (previously reported) had transiliac bone biopsies performed 12 months after their last menses. Oral tetracycline was administered prior to transiliac biopsy, which was performed and evaluated in standard manner. In addition to static histomorphometry, dynamic parameters were determined including bone formation rate/bone surface (BFR/BS) calculated as mineral apposition rate (MAR) corrected for obliquity times mineralizing surface/bone surface (MS/BS). MS/BS is the mineralizing surface divided by the total trabecular surface. Activation frequency (Ac.f), the annual probability of new remodeling site activation, was calculated as (BFR/BS)/wall thickness where wall thickness is the mean distance between cement lines (corrected for obliquity) and trabecular surface. Serum 25(OH)D was measured by RIA or competitive protein binding assay. Correlations between histomorphometric results and 25(OH)D were performed using Excel.

Results: Static histomorphometric parameters (osteoid thickness, osteoid volume/bone volume and osteoid surface) were unrelated to 25(OH)D (data not shown). In contrast, MS/BS (figure a) and Ac.f (figure b) were positively correlated ($p < 0.05$) with 25(OH)D concentration.

Conclusion: The increase in bone remodeling seen in early postmenopausal women is strongly dependent on serum 25(OH)D. The mechanism(s) underpinning these results, and the optimal value to facilitate bone mineralization, remain to be defined. Further study of the relationship of dynamic bone parameters with circulating vitamin D metabolites is needed.

Vitamin D plays a complex role in calcium homeostasis, PTH regulation, and promotion of overall health. Maintenance of serum 25(OH)D₃ levels may be critical to skeletal health, cardiovascular health as well as lower mortality rate. A wide range of factors influence the intake, production, and metabolism of vitamin D and thereby contribute to serum 25(OH)D₃ levels. High heritability (70%) of 25(OH)D₃ levels suggests that genetic factors also play a role. The serum response to vitamin D intake is quite variable suggesting that both genetics and environment factors may involve an individual's handling of dietary vitamin D. To investigate the interaction between genetic variants and Vitamin D intake on serum 25(OH)D₃ concentration, we performed a genome-wide association (GWAS) meta-analysis in 34,915 Caucasian men and women using data obtained from 16 cohort studies. Single nucleotide variants (SNVs) were genotyped and un-genotyped SNVs were imputed based on HapMap II project with a total of 2.5M SNVs available for analyses. In each study, we performed a multiple linear regression analyses to estimate the genetic effect of each single SNV and their interaction with vitamin D intake on serum 25(OH)D₃ concentration. Covariates included age, sex, BMI, season of vitamin D measurement and ancestral genetic background. We considered two statistical tests for interactions, (1) a 1 degree of freedom test of the interaction term only (SNVs-Vitamin D intake); and (2) a 2 degrees of freedom joint test of SNVs main effect and the interaction term. An inverse-variance fixed effect meta-analysis was used to combine results from 16 studies. Several genome-wide significant associations ($p < 5 \times 10^{-8}$) with serum 25(OH)D₃ concentration were found for SNVs located in or near *AMDHD1*, *CYP24A1*, *DHCR7*, *GC* and *NADSYN1* genes. We identified several genome-wide significantly associated SNVs ($p < 5 \times 10^{-8}$) potentially interacting with vitamin D intake. These SNVs are located in or near *AMDHD1*, Chr9 *LOC101929563*, *CHD11AP2A2*, *CYP2R1*, *FAR2*, *KLF7*, *LPIN1* and *SEM6A* genes. In summary, our analysis identified potential SNVs-vitamin D intake interactions, suggesting the relationships between vitamin D intake and serum

25(OH)D₃ concentration may be mediated by genetic variation. To validate these findings, a replication study in independent samples is underway.

Effects of High Dose Vitamin D Supplementation on Bone metabolism in Pregnant Women with Hypovitaminosis D – a Randomized Controlled Trial. Gitte Bloch Rasmussen^{*1}, Leif Mosekilde², Tanja Sikjaer³, Peter Vestergaard⁴, Lene Heickendorff⁵, Niels Ulbjerg⁶, Bente Langdahl², Lars Rejnmark³. ¹Aarhus Universitetshospital, Denmark, ²Department of Endocrinology & Internal Medicine, Aarhus University Hospital., Denmark, ³Department of Endocrinology & Internal Medicine, Aarhus University Hospital, Denmark, ⁴Department of Endocrinology, Aalborg University Hospital, Denmark, ⁵Department of Clinical Biochemistry, Aarhus University Hospital, Denmark, ⁶Department of Obstetrics & Gynecology, Aarhus University Hospital., Denmark

Purpose: To study the effects of supplementation with high doses of vitamin D during pregnancy on maternal bone metabolism.

Methods: The study was designed as an investigator-initiated double-blind, randomized, placebo-controlled, parallel-group trial. Women, aged 20-40 years, with P-25OHD < 50 nmol/L all planning pregnancy (N=193), were randomized to a daily supplementation with 70 µg (2800 IU), 35 µg (1400 IU) vitamin D₃ (VitD₃), or placebo. Supplementation was initiated before conception and continued until 16 weeks post partum (PP). Main outcome measures were bone mineral density (BMD) and trabecular bone score (TBS) as assessed by DXA scans at time of inclusion and four months PP. Biochemical markers of bone turnover were measured every three months throughout the study.

Results: A total of 90 women gave birth. Vitamin D supplementation did not affect birth weight. In response to supplementation, P-25OHD levels increased dose-dependently reaching a peak level at the time of giving birth of 118 ± 29 in the 70 µg/day group, 98 ± 32 in the 35 µg/day group, and 60 ± 23 in the placebo group. Four months PP, most women 86% were breast feeding their infants with no differences between groups. Biochemical measurements and paired BMD were available from respectively 84 and 68 women who completed the trial. Within each of the three supplemented groups, BMD at most sites and TBS were significantly decreased 16 weeks after giving birth compared with the pre-pregnancy measurement ($p < 0.001$). Changes in BMD from pre-pregnancy to 16 weeks PP did not differ between groups at the lumbar spine ($p=0.51$), total hip ($p=0.35$), whole body ($p=0.31$), or for TBS ($p=0.52$). At the femoral neck BMD decreased 4.8% in the women treated with 70 µg VitD₃ daily compared to placebo ($p=0.03$). In contrast, the mid distal forearm BMD increased significantly 0.6% in the group treated with 70 µg VitD₃ group compared with the placebo group ($p=0.03$). Changes in plasma levels of bone turnover markers during pregnancy and breast feeding did not differ significantly between groups.

Conclusion: Pregnant women with vitamin D insufficiency experienced no major beneficial effects of high dose vitamin D supplementation. The pregnancy associated decrease in BMD was not prevented by vitamin D supplementation. Our finding of an aggravated BMD loss at the femoral neck in response to a daily supplement of 70 µg VitD₃ calls for caution on use of high dose vitamin D supplementation during pregnancy.

A randomized, double-blind, placebo-controlled clinical trial on the treatment of vitamin D insufficiency in postmenopausal women. Karen Hansen^{*1}, R. Erin Johnson², Kaitlin Chambers³, Michael G. Johnson³, Christina C. Lemon³, Tien Nguyen Thuy Vo³, Sheeva Marvdashti³. ¹University of Wisconsin, Us, ²St. Lukes Hospital, USA, ³University of Wisconsin, USA

Experts debate optimal 25(OH)D levels for musculoskeletal health. We designed a clinical trial to directly address this controversy. We performed a randomized, double-blind, placebo-controlled clinical trial in postmenopausal women with 25(OH)D levels 14-27 ng/mL by HPLC. We excluded women >75 years old, with hypercalcemia, nephrolithiasis, cancer within five years (excluding skin cancer), malabsorption, glomerular filtration rate <45 mL/minute, adult fragility fracture of the hip, spine or wrist, spine or hip T-score <-2.49, use of bone-active medications within the past 6 months including bisphosphonates, estrogens, calcitonin, teriparatide, oral corticosteroids, anticonvulsants, or vitamin D intake >400 IU/day. The high-dose vitamin D arm received a loading dose (50,000 IU daily x 15 days) to quickly raise 25(OH)D >30 ng/mL, with sham loading of yellow placebo capsules in other arms to maintain blinding. After loading, subjects in the high-dose arm took vitamin D 50,000 IU every 15th day for one year, the low-dose arm took vitamin D 800 IU daily and yellow placebo capsules every 15th day, and the placebo arm ingested daily white placebo and every 15th day yellow placebo capsules. Outcomes were the between-arm one-year changes in total fractional calcium absorption, spine, hip and total body bone mineral density and trabecular bone score. We also measured Timed-Up-and-Go and 5-Sit-to-Stand tests and pain (visual analog scale) at 0, 30, 60, 120, 240 and 365 days. We performed Bonferonni correction of p-values for multiple statistical comparisons. After controlling for baseline absorption, total fractional calcium

absorption increased 1% (10 mg/day) in the high-dose arm, but decreased 2% in low-dose (p=0.005 vs. high-dose) and decreased 1.3% placebo (p=0.03 vs. high-dose) arms. We found no between-arm changes in spine, total hip, mean femoral neck or total body bone mineral density, trabecular bone score or Timed-Up-and-Go score. When controlling for pain, the high-dose arm had the greatest improvement in the 5-sit-to-stand test score vs placebo (p=0.02), but the absolute change (0.4 seconds) was not clinically significant. Hypercalciuria occurred 7 (4 subjects), 1 and 1 times in the high-dose, low-dose and placebo arms (p=0.19). High-dose vitamin D therapy increased calcium absorption but the effect was small and did not translate into changes in bone mineral density. Study results do not support recommendations to maintain serum 25(OH)D levels at or above 30 ng/mL. Instead, our study results support the Institute of Medicine's conclusion that vitamin D repletion is a serum 25(OH)D level of =20 ng/mL.

A Randomized Trial Investigating Impact of Vitamin D Replacement on Indices of Insulin Resistance in Elderly Overweight Subjects. Ghada El-Hajj Fuleihan*¹, Rafic Baddoura², Georges Halabi², Asma Arabi³, Robert Habib³, Maya Rahme³, Singh Ravinder⁴, Moustapha Kassem⁵, Ziyad Mahfoud³, Rose Daher³, Mohamad Kassir³. ¹American University of Beirut-Medical Center, Lebanon, ²Hotel Dieu de France, Lebanon, ³American University of Beirut, Lebanon, ⁴Mayo Clinic, USA, ⁵Odense University Hospital, Denmark

Introduction: Hypovitaminosis D, obesity and diabetes are prevalent in the Middle East, but the impact of vitamin D replacement on indices of insulin resistance, in subjects from this region is unclear.

Objective:

To investigate in a randomized clinical trial (RCT) the impact of high dose vitamin D compared to the Institute of Medicine (IOM) recommended daily allowance (RDA) on indices of insulin resistance in overweight elderly ambulatory individuals.

Methods:

This is a one year, double blind, multicenter RCT of 257 subjects, randomized by center and gender, to calcium citrate 1000 mg and the equivalent of 600IU or 3500 IU of vitamin D3 daily. Exclusion criteria were the presence of diabetes, defined by a fasting blood sugar exceeding 126 mg/dl, or a hemoglobin A1C exceeding 6.4%, the intake of oral hypoglycemic agents, of GFR<30 ml/min, or the presence of severe chronic illnesses. Routine biochemistries, hormonal levels, serum hydroxyvitamin D (25OHD, by LCMS) were measured at entry, 3, 6 and 12 months. The primary outcomes were indices of insulin resistance: McCauley, HOMA and QUICKI. The study had a power of 80%, to pick up a delta in HOMA between the 2 groups of 0.9 (SD 2.1), p=0.05. Numbers represent mean (SD).

Results:

222 subjects completed the study, age 71(4) years, BMI 30 (4) kg/m², 31% were normal, and 69% had impaired fasting glucose or abnormal HgA1C, 55% were female subjects, 45% were on anti-hypertensive, and 30% on lipid lowering drugs. Baseline clinical and biochemical characteristics were comparable between the two groups. 25OHD rose from 20(7) to 26 (6.9) ng/ml in the low-dose, and from 20.9(8.2) to 35.9 (9.8) ng/ml in the high-dose arm, p<0.0001 within and between arms at 1 year. There was a significant rise in FBS within each group, a rise that was not explained by any drift in laboratory performance over the study period, nor by the intake of statins. There were no detectable differences in FBS, nor in any of the indices of insulin resistance, between the two groups at one year (Table). In the multivariate analyses, BMI, but not vitamin D treatment or age, predicted insulin sensitivity indices at one year.

Conclusion:

High dose vitamin D did not improve insulin resistance in elderly overweight individuals. Regardless of the vitamin D dose, an unexpected rise in fasting glucose, that correlated with the rise in 25OHD, and exceeded the anticipated rise in FBS in an aging overweight population, was observed.

Table: Indices of glycemia and insulin resistance in high dose and low dose arms at entry and 1 year.

The Effects of a Longer-Term, Low-Protein Diet on Calcium Absorption and Kinetic Measures of Bone Turnover in Young Women. Jessica Bihuniak*¹, Rebecca Sullivan², Tania Huedo-Medina¹, Irina Rosewater³, Donna Caseria⁴, Kimberly O'Brien⁵, Jane Kerstetter¹, Karl Insogna². ¹Allied Health Sciences, University of Connecticut, USA, ²Internal Medicine Endocrinology, Yale University, USA, ³Internal Medicine Endocrinology, Yale University, USA, ⁴Yale New Haven Hospital, USA, ⁵Cornell University, USA

Increasing dietary protein causes a rise in urine Ca (UCa) while with restricted protein intakes less Ca appears in the urine. Balance studies in the 1970's indicated no change in intestinal Ca absorption as dietary protein increased, which led to the conclusion that the increase in UCa was due to loss of skeletal Ca. However, we have found that in the short term, increasing dietary protein from 1.0 to 2.1 g/kg results in an increase in UCa that is not accompanied by increased bone resorption. Instead the increase in UCa can be nearly quantitatively explained by a concomitant increase in intestinal Ca absorption. Moreover, we recently reported that long-term whey protein supplementation in older adults with adequate protein intakes is not detrimental to bone.

Dietary protein studies have largely focused on the impact of increasing dietary protein on Ca economy. The long-term consequences of low protein intakes on Ca metabolism have been less well studied. The purpose of this study was to use stable Ca isotopes to accurately quantify the longer-term consequences of a protein-restricted diet on Ca absorption and bone turnover. We studied 11 premenopausal women consuming a low protein diet (0.7 g/kg) for 6.5-weeks and assessed Ca absorption and kinetics measures of bone turnover at day 5 (acute changes) and week 6 (new steady state). Mixed-effects longitudinal modeling was conducted with time (i.e. visit) as the fixed effects for each of the continuous dependent variables. Data are expressed as β -coefficient (95% CI). Restricting dietary protein for 6.5-weeks resulted in significant declines in intestinal calcium absorption (%) [-0.43 (-0.77,-0.09); P=0.02] as well as the percent of UCa from the diet [-0.13 (-0.22,-0.04); P=0.01]. This was accompanied by an increase in the fraction of UCa originating from bone [0.13 (0.04,0.22); P=0.01] and increases in serum PTH (pmol/L) [0.18 (0.02,0.33); P=0.03]. We also observed a trend towards more negative bone balance (mmol Ca) [-0.15 (-0.33,0.02); P=0.08].

These data indicate that a diet low in protein, defined as an intake level below the current RDA (0.8 g/kg), causes calcium malabsorption, a rise in PTH and a larger contribution of bone to UCa. In the aggregate, these findings are consistent with the conclusion that a protein-restricted diet induces unfavorable changes in Ca economy in young women.

Reference Ranges and Characteristics of Spine Bone Mineral Apparent Density in U.S. Children – Results from the Bone Mineral Density in Childhood Study. Babette Zemel^{1*}, Karen Winer², Andrea Kelly³, Joan Lappe⁴, John Shepherd⁵, Sharon Oberfield⁶, Vicente Gilsanz⁷, Heidi Kalkwarf⁸. ¹Children’s Hospital of Philadelphia, USA, ²NICHHD, USA, ³The Children’s Hospital of Philadelphia, USA, ⁴Creighton University, USA, ⁵University of California San Francisco, USA, ⁶Columbia University, USA, ⁷Children’s Hospital Los Angeles, USA, ⁸Cincinnati Children’s Hospital & Medical Center, USA

The 2014 ISCD Pediatric Positions Statement recommended height Z-score adjusted (HtZ-adj) bone Z-scores or spine bone mineral apparent density (BMAD) for clinical assessment of bone health in children, especially for those with short stature. Low spine BMAD has been associated with increased fracture risk in children with health conditions that threaten bone health, but reference ranges for U.S. children are not available.

The main objective of this study was to develop spine BMAD reference ranges for African American (AfrAm) and Non-African American (non-AfrAm) youth, ages 5 to 20 years. In addition, we aimed to determine (a) whether this measure minimized the distorting effects of short or tall stature on spine bone density; and (b) whether it was a stable measure (tracked well) over time in comparison to the HtZ-Adj spine BMD-Z and unadjusted spine BMD-Z.

We used data from the Bone Mineral Density in Childhood Study, a mixed longitudinal cohort of healthy children, ages 5 to 20 years, from 5 U.S. centers followed over 6 years (~10,000 observations). Spine scans were acquired on Hologic densitometers (QDR4500/Delphi/Discovery models). Height Z-scores (HtZ) were calculated using the CDC2000 growth charts. Tanner stage was assessed by physical exam. LMS Chartmaker was used to create reference ranges separately for AfrAm and non-AfrAm males and females. For each group, Pearson correlations were used to (1) evaluate associations between spine Z-scores and HtZ; and (2) assess the stability of spine Z-scores during growth, by calculating the “tracking correlations” for children in Tanner stages 1 and 2 at baseline with their year 6 values.

Smoothed reference percentile values for BMAD are shown in Table 1. Correlations between HtZ and BMAD Z-scores ranged from 0.00 to 0.13; the range for HtZ-adj BMD-Z was -0.02 to -0.27, and both were lower than for unadjusted spine BMD Z (0.25 to 0.35) across sex and ancestry groups. The range of tracking correlations from baseline to year 6 for puberty stages 1 and 2 was similar for all Z-scores (range BMAD-Z: 0.61 to 0.79; HtZ-adj BMD-Z: 0.73 to 0.81; unadjusted Spine BMD-Z: 0.61 to 0.79). Both BMAD-Z and HtZ-adj BMD-Z correct for effects of short and tall stature on spine BMD Z-scores and track well over time. BMAD is more easily computed than HtZ-adjBMD. These findings support the use of spine BMAD for assessment of bone health in children.

Skeletal Maturation and Genetically Determined Population Ancestry in Non-Obese, Pre-Pubertal Children. Alessandra Chesi^{1*}, Sani M. Roy², Jonathan A. Mitchell³, Heidi J. Kalkwarf⁴, Joan M. Lappe⁵, Vicente Gilsanz⁶, Sharon E. Oberfield⁷, John A. Shepherd⁸, Soroosh Mahboubi², Karen Winer⁹, Andrea Kelly², Struan F.A. Grant¹, Babette S. Zemel¹, Shana McCormack². ¹Children’s Hospital of Philadelphia, USA, ²Children’s Hospital of Philadelphia, USA, ³University of Pennsylvania, USA, ⁴Cincinnati Children’s Hospital Medical Center, USA, ⁵Creighton University School of Medicine, USA, ⁶University of Southern California Los Angeles, USA, ⁷Columbia University Medical Center, USA, ⁸University of California San Francisco, USA, ⁹NIH, USA

Previous studies have suggested that advanced skeletal maturation in African-American children compared to their non-African-American counterparts is largely accounted for by environmental factors, including nutritional status.

We evaluated the effects of population ancestry, as determined by genome-wide genotyping data, on skeletal maturation in a cohort of non-obese, pre-pubertal children.

The Bone Mineral Density in Childhood Study (BMDCS) included serial simultaneous bone age assessments, anthropometrics, Tanner staging, and body composition data by DXA, along with self-reported population ancestry. The first available bone age assessment for each child (as rated by two expert radiologists according to the standards of Greulich and Pyle) was included. Genetic markers were used to estimate degree of African and European admixture. Body mass index (BMI) z-scores were calculated using CDC 2000 standards. Pre-pubertal (Tanner I) children with BMI >3rd and <95th percentile were included.

The sample included 1,000 subjects, mean age 7.5 ± 1.7 years, 48% female, and 17% African-American, mean BMI z-score 0.19 ± 0.76. The difference between bone age and chronological age was higher in self-reported AA vs non-AA girls (by 4.9 months, p=0.00029) and also higher in AA vs non-AA boys (by 5.5 months, p=0.00016). When defined using genetic markers, proportion of African ancestry was positively associated with the difference between bone age and chronologic age (for girls, c=0.19, p=0.00040 and for boys, c=0.14, p=0.0056). In multivariate regression

analyses after accounting for lean mass, fat mass, height, and age, proportion of African admixture was independently associated with more advanced skeletal maturation in both girls ($b=0.35$, $p=0.017$) and boys ($b=0.37$, $p=0.011$). In addition, increased fat mass was independently associated with skeletal maturation after accounting for ancestry and the clinical covariates in both girls ($b=0.06$, $p=0.01$), and boys ($b=0.09$, $p=0.0013$). The effect of lean mass reached statistical significance in boys ($b=0.07$, $p=0.045$ in boys), and near-significance in girls ($b=0.06$, $p=0.06$).

In non-obese, pre-pubertal girls and boys, skeletal maturation is more advanced in proportion to degree of African ancestry, even after accounting for body composition and size. A better appreciation of ancestry-specific differences in skeletal maturation may inform our understanding of corresponding variations in bone and metabolic health.

Are we still accruing bone mineral content during the third decade of life?

Adam Baxter-Jones¹, Stefan Jackowski², Augusta Rosie Hatton³, Saija Kontulainen². ¹University of Saskatchewan, USA, ²University of Saskatchewan, Canada, ³McGill University, Canada

Introduction: The importance of maximizing bone mineral accrual during the initial two decades of life, the growing years, is clearly recognized. In a five year window around peak height velocity (PHV) approximately 40% of total body bone mineral content (TB BMC) is accrued. The timing of the attainment of peak bone mass (PBM) is suggested to occur anywhere between 15 and 30 years of age. This suggests that little is known about the accrual of TB BMC during the third decade of life, when growth has ceased. Using data from the Saskatchewan Pediatric Bone Mineral Accrual Study (PBMAS) we have previously suggested that TB PBM occurs 6 years post PHV; the end of the second decade of life, approximately 18 and 20 years of age for females and males respectively. The primary purpose of this study was to continue to measure bone accrual in this cohort during the third decade of life. The secondary purpose was to identify sex differences. **Methods:** One hundred and fifty four participants (79 males and 75 females) were drawn from the PBMAS (1991-2011). TB BMC was measured by DXA (cv 0.6%) continuously for 20 years after the attainment of PHV; age range 11 to 34 years of age. Median number of visits was 10 (range 1 to 14). Biological age (BA) was calculated in years from PHV (at PHV BA=0). Percentage increases in TB BMC between PHV and the thirteen BA categories from 8 to 20 years were calculated and compared between BA categories, alpha set to 0.05. **Results:** At a BA of 8 years there was an increase of 40.3% (SD 9.2%) in TB BMC from PHV. At 20 years post PHV the average increase from PHV was 39.4% (SD 6.9%). There were no significant differences in percentage increases between the thirteen BA categories from 8 to 20 years of age ($p>0.05$). No sex specific significant differences were found in accruals from PHV in any of the thirteen BA categories ($p>0.05$). **Conclusions:** These results substantiate our previous observations that PBM occurs at 6 years post PHV and that when aligned by biological rather than chronological age percentage accrual with age is the same in females and males. Unlike some previous studies we found no evidence of accrual in the third decade of life. Although TB BMC did fluctuate during the 15 years preceding the attainment of PBM, the changes appear to be within the error of the measurement.

Effects of maternal calcium supplementation on childhood bone growth differs between males and females. Kate Ward¹, Landing Jarjou², Ann Prentice¹.

¹MRC Human Nutrition Research, United Kingdom, ²MRC The Gambia Unit, Gambia

In a population accustomed to low calcium intakes (approximately 300mg/d) we have described sex differences in the longitudinal effects on bone growth and mineralization of calcium supplementation during childhood¹⁻³. In a separate study of maternal calcium supplementation during pregnancy (ISCRTN96502494)⁴ we have measured childhood bone at age 8-12 years. The aim was to investigate whether there were effects of maternal calcium supplementation on childhood height, weight, bone size and mineralisation, measured using DXA and pQCT, and if so, whether they differed by sex.

In rural Gambia (West Africa) 447 children (216 males; 231 female), mean (SD) age 9.3(0.1)y, 9.2(0.1)y, respectively were measured. Their mothers were randomized to receive 1500mg/d calcium carbonate (Ca), or placebo (P), from 20wk gestation to term; children were not supplemented. At birth, no effects of supplement on infant growth were found^{4,5}. At age 8-12 years, DXA (whole body, spine, hip) and pQCT (tibia) scans were performed. Differences in childhood bone outcomes (DXA: bone mineral content (BMC), bone area (BA); pQCT cortical content, bone cross-sectional area (XSA) and cortical area were tested for a supplement effect using linear regression including sex, length at 52 weeks, current age and a sex-supplement interaction as covariates.

Results are summarized in Table 1. Girls whose mothers were in the Ca group were significantly shorter, lighter and had lower BMC and smaller bones (BA, XSA) with less cortical area than those whose mothers were in the P group. In contrast, there was a trend for boys whose mothers were in the Ca group to be taller, heavier, with greater

BA and BMC than boys whose mothers who received P. There were significant sex-supplement interactions for most anthropometric and bone measures.

Maternal calcium supplementation has affected height, skeletal size and mineralisation at 8-12 y and the differences were divergent in boys and girls. These data highlight the importance of not assuming more is necessarily better for bone health in populations accustomed to lower calcium intakes than international recommendations and that the effects differ between males and females.

Pediatric bone density is influenced by physical activity and genetic variation at known bone density loci. Jonathan Mitchell¹, Alessandra Chesi², Okan Elci², McCormack Shana², Sani Roy², Heidi Kalkwar³, Joan Lappe⁴,

Vicente Gilsanz⁵, Sharon Oberfield⁶, John Shepherd⁷, Andrea Kelly², Struan Grant², Babette Zemel². ¹University of Pennsylvania, USA, ²Children's Hospital of Philadelphia (CHOP), USA, ³Cincinnati Children's Hospital Medical Center, USA, ⁴Creighton University, USA, ⁵Children's Hospital Los Angeles, USA, ⁶Columbia University Medical Center, USA, ⁷University of California San Francisco, USA

Physical activity (PA) mechanically loads the skeleton to increase pediatric bone mineral density (BMD). In addition, genome wide association studies (GWAS) have identified 66 loci that influence BMD and some of these loci may impact skeletal mechanosensitivity. We aimed to determine if GWAS-implicated BMD loci influenced associations between PA and bone mineral content (BMC) and BMD in childhood.

We leveraged the six-year prospective longitudinal study design of the 'Bone Mineral and Density in Childhood Study', comprised of European ancestry children (N=689, 52.4% female). Our outcome variables were femoral neck (FN), total hip (TH) and spine areal-BMD (aBMD) Z-scores, and total body less head (TBLH) bone mineral content (BMC) Z-score, estimated by dual energy X-ray absorptiometry. Our primary exposures included self-report PA and single nucleotide polymorphisms (SNPs) at 66 GWAS-implicated BMD loci, plus interaction terms for PA and each SNP. Linear mixed models were used to analyze our data, by sex, adjusted for age, Tanner stage, BMI and dietary calcium. We applied the Benjamini and Hochberg (BH) method to correct for the multiple testing of 66 loci. Our findings are categorized as follows: 1) interaction P-values that survive BH correction and 2) interaction P-values <0.05 and a genotype specific PA association P-value <3.9x10⁻⁴.

In males, statistical interactions involving SNPs at the *WNT5B* (TBLH-BMC) and *CYLD* loci (FN aBMD) survived BH correction. For example, the effect of PA on TBLH-BMC-Z depended on rs4283041 genotype (BMD-lowering 'risk' C allele) at *WNT5B* ($P=1.1x10^{-4}$); each hour per day (h/d) of PA increased TBLH-BMC-Z for CC homozygotes ($\beta=0.04$, $P=3x10^{-2}$), but not for the TT homozygotes ($\beta=-0.03$, $P=0.078$). In females, rs7195617 (risk G allele) at *AXIN1* interacted with PA to influence TH aBMD-Z ($P=3.9x10^{-4}$); each h/d of PA increased TH aBMD-Z for GG homozygotes ($\beta=0.06$, $P=4x10^{-3}$), but not for AA homozygotes ($\beta=-0.01$, $P=0.310$). Secondary statistical interactions were observed for the following loci in males at ≥ 1 skeletal sites: *DNM3*, *MHC*, *SPTBN1*, *WNT5B*, *C16orf38/CLCN7*, *LEKRI*, *RANKL/AKAP11*, *C6orf97* and *HOXC6*. A secondary statistical interaction was observed for the *FUBP3* locus in females for TH aBMD.

PA may be particularly effective for promoting bone accretion in children with certain genetic backgrounds. These gene-PA interactions findings will aid in developing future strategies to promote optimal bone accretion during childhood.

Deficits in Bone Strength in Girls with a Distal Radius Fracture Track 1 Year after Fracture. Mikko Maatta*¹, Heather Macdonald², Douglas Race², Lindsay Nettlefold², Kishore Mulpuri³, Heather McKay². ¹University of British Columbia, Canada, ²Centre for Hip Health & Mobility, Canada, ³British Columbia Children's Hospital, Canada

We recently reported⁽¹⁾ impaired bone strength in girls with low to moderate energy distal radius fractures (Fx) compared with girls with no history of forearm fractures (NF). In this study we aimed to determine whether bone strength deficits were still present in Fx girls after 12-months.

We assessed the non-dominant (NF) and non-fractured (Fx) distal radius (7% site) bone microstructure at baseline and 12 months using high-resolution pQCT (Scanco Medical) in 95 girls (12.1 ± 1.7 y; 41 Fx, 54 NF). Morphological outcomes included total area (Tt.Ar) and bone mineral density (Tt.BMD), trabecular bone volume ratio (BV/TV), trabecular thickness (Tb.Th) and number (Tb.N), cortical area (Ct.Ar), BMD (Ct.BMD), thickness (Ct.Th) and porosity (Ct.Po). We used finite element analysis to estimate bone strength (failure load, FLoad; ultimate stress, UStress⁽²⁾). We calculated load-to-strength ratio as a ratio of the estimated fall load applied to the outstretched arm after a fall from standing height⁽³⁾ and FLoad. We used one-way ANOVA to compare anthropometry (height (cm), weight (kg), forearm length (mm), body fat and lean mass (kg); DXA, Hologic QDR 4500W). We fit multivariable linear regression to compare 12-month change in bone outcomes as well as bone measures at 12-months between groups adjusting for maturity (Tanner stage), height, ethnicity and body fat at baseline.

During the 12-month follow-up Fx girls gained more body fat than NF girls (1.3 vs 0.7 kg, p<0.05). Fx girls had a smaller increase in FLoad (190 vs. 273 N, p=0.02) and Tt.BMD (6.4 vs. 13.7 mg HA/cm³, p=0.03) compared with NF group. At follow-up, Fx girls had lower bone strength (FLoad: -15%, UStress: -24% and load-to-strength ratio: 11%, p≤0.02) compared with NF girls. Fx girls also had lower Tt.BMD, BV/TV, Tb.Th, Ct.Ar and Ct.Th than NF girls (7-11%, p≤0.03).

We did not observe a catch-up period for bone outcomes in girls with a distal radius fracture. This implies that the bone deficits may track across growth and place girls with a low to moderate energy fractures at greater risk for a recurrent fracture. Greater increases in body fat in Fx girls may be an indication of physical inactivity, which might further increase the risk of future fracture.

Leukemia Inhibitory Factor Receptor (LIFR) Signaling Regulates Breast Cancer Cell Dormancy and Bone Colonization. Rachel Johnson*¹, Alyssa Merkel², Julie Sterling², Joshua Johnson³, Joy Wu³, Amato Giaccia⁴. ¹Stanford University, USA, ²Department of Veterans Affairs, Tennessee Valley Healthcare System (VISN 9), Vanderbilt University Medical Center, USA, ³Department of Medicine, Stanford University, USA, ⁴Department of Radiation Oncology, Stanford University, USA

Breast cancer cells frequently metastasize to the bone marrow, where they may enter a dormant state and remain undetected for years. The tumor-bone interactions that enable cells to exit dormancy are not well understood. Recent findings indicate that the leukemia inhibitor factor (LIF) LIF receptor (LIFR), a member of the interleukin-6 family cytokines, suppresses breast cancer metastases to lung, but it is unknown whether LIFR signaling is involved in bone metastasis. Since LIF inhibits *in vitro* growth of MCF7 breast cancer cells, which home to the bone and lay dormant, we proposed that LIF provides a pro-dormancy signal to breast cancer cells in the bone, and that loss of the LIFR would enable these cells to colonize the bone. Characterization of breast cancer cells with low (MCF7, D2.0R, PyMT, SUM159) and high metastatic potential (MDA-MB-231, D2A1, 4T1BM2) revealed that the former rapidly phosphorylate STAT3-Y705 and induce SOCS3 mRNA levels in response to LIF (3-18 fold, p<0.01-p<0.0001), suggesting that LIF may act as a pro-dormancy factor to disseminated breast cancer cells. In contrast, breast cancer cells that readily metastasize to bone lack a functional LIFR and do not induce STAT3/SOCS3 signaling. Genetic knockdown of LIFR in MCF7 cells converts them to an invasive phenotype in 3D cultures and significantly (p<0.05-0.001) reduces genes associated with dormancy (TSP1 39%, TPM1 27%, P4HA1 26%, miR-190 70%, Selenbp1 29% lower) and a cancer stem cell phenotype (Notch1 48%, Casp3/Scal 29%, Tert 21%, Sox2 71% lower), suggesting that loss of LIFR drives cells toward a proliferative, aggressive phenotype. Intracardiac inoculation of MCF7shLIFR cells resulted in significantly enhanced osteolysis (2.7-fold, p<0.01) over controls. To determine whether extreme low-oxygen conditions of the bone marrow may drive

quiescent tumor cells to exit dormancy, MCF7 cells were cultured in anoxic conditions, resulting in dramatic down-regulation of the LIFR (63%, p<0.01) and SOCS3 (46%, p<0.05) mRNA levels. Furthermore, data mining of The Cancer Genome Atlas database revealed that as hypoxia gene activity increases in invasive breast cancer patients, their LIFR mRNA levels decrease (n=1104 patients, p<0.0001), providing a mechanism by which hypoxia may drive tumor recurrence in bone. These data indicate that LIFR signaling in breast cancer cells maintains dormancy and that anoxic conditions may drive the loss of LIFR, allowing tumor cells to colonize the bone marrow.

The Wnt-miR-218-axis promotes breast cancer -induced osteolytic disease. Hanna Taipaleenmaki*¹, Mohammad Q Hassan², Yukiko Maeda³, Andre van Wijnen⁴, Eric Hesse⁵, Janet L Stein⁶, Gary S Stein⁶, Jane B Lian⁶. ¹University Medical Center Hamburg-Eppendorf, Germany, ²Department of Oral & Maxillofacial Surgery, School of Dentistry, University of Alabama at Birmingham, USA, ³Department of Cell Biology, University of Massachusetts Medical School, USA, ⁴Department of Biochemistry & Molecular Biology, Department of Orthopedic Surgery, Mayo Clinic, USA, ⁵Heisenberg-Group for Molecular Skeletal Biology, Department of Trauma, Hand & Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Germany, ⁶Department of Biochemistry & Vermont Cancer Center, University of Vermont College of Medicine, USA

Signaling pathways crucial in bone development, including Wnt and BMP, are also upregulated in breast cancer cells to cause aggressive tumor growth in the skeleton. Homing of breast cancer cells to bone is facilitated by their ability to express many osteoblast-related genes ('osteomimicry'). We thus asked if osteogenic miRNAs are aberrantly expressed in bone metastatic tumor cells to support the osteomimetic properties. miR-218 is highly expressed in osteoblasts and promotes osteogenic differentiation. Interestingly, we found that miR-218 expression is also significantly up-regulated in bone metastatic MDA-MB-231 breast cancer cells and is not detectable in normal MCF-10A mammary epithelial cells, suggesting a positive role of miR-218 in bone metastasis. Indeed, ectopic expression of miR-218 in MDA-MB-231-Luc cells promoted tumor growth in the bone microenvironment *in vivo* whereas inhibition of miR-218 resulted in impaired growth. Aggressive intratibial tumor growth was accompanied by increased osteoclast activity and bone resorption in the presence of miR-218, while antagonizing miR-218 protected from development of osteolytic lesions. Signaling pathway analyses revealed a positive correlation between aberrant miR-218 expression and high activation of endogenous, metastasis promoting Wnt signaling pathway, demonstrated by the Wnt-responsive TopFlash reporter assay and expression of the Wnt transcriptional mediators. Mechanistically, miR-218 directly targets several inhibitors of Wnt and BMP signaling including Sclerostin, DKK2, sFRP-2, and TOB1, which were validated by 3'UTR, western blot and gene expression analyses. Consequently, ectopic expression of miR-218 further increased Wnt activity in MDA-MB-231 cells while inhibition of miR-218 decreased Wnt signaling. Importantly, bone sialoprotein (BSP) and osteopontin (OPN), both reported to be elevated in serum of breast cancer patients, CXCR-4, a chemokine receptor directly linked to bone metastasis and PTHrP, the key cytokine promoting cancer-induced osteolysis were all upregulated in the presence of miR-218. Inhibition of Wnt signaling abolished the miR-218-induced elevation, indicating a Wnt-dependent activation of these metastatic genes. We conclude that miR-218 activates Wnt signaling to enhance metastatic properties of breast cancer cells and the cancer-induced osteolytic disease, and is therefore an attractive novel therapeutic intervention to prevent the disease progression.

Reciprocal Interactions between Sensory Neurons and Tumor Cells Promote Breast Cancer Progression in Bone, Secondary Visceral Metastasis and Bone Pain. Tatsuo Okui*¹, Masahiro Hiasa¹, Yuki Nagata¹, Fletcher White², G David Roodman¹, Toshiyuki Yoneda¹. ¹Department of Medicine, Hematology Oncology, Indiana University School of Medicine, USA, ²Department of Anesthesia, Paul & Carole Stark Neurosciences Research Institute, USA

Breast cancer (BCa) has a strong predilection for spreading to bone, contributing to increased morbidity and mortality. BCa in bone causes intractable bone pain and subsequently disseminates to visceral organs, resulting in secondary metastasis and increased mortality. Thus, inhibition of bone metastasis is an important goal for managing BCa patients. Interactions between BCa cells and the cellular and molecular elements of the bone microenvironment have been shown to be critical to the pathophysiology of bone metastasis. However, the contribution of the sensory neurons (SN) to bone metastasis is totally unknown. Using the 4T1 mouse BCa model, we tested the hypothesis that bone SN contributes to the progression of BCa bone metastasis, development of secondary metastasis and bone pain via reciprocal

interactions with BCa cells. We first examined the effects of SN on 4T1 BCa. F11 SN cell conditioned medium (CM) stimulated cell proliferation and migration and epithelial-mesenchymal transition of 4T1 cells. We detected high levels of hepatocyte growth factor (HGF) in F11 CM, which increased phosphorylation of the HGF receptor, c-Met, in 4T1 cells. All of these effects were blocked by crizotinib, a c-Met tyrosine kinase inhibitor, or c-Met knockdown in 4T1 cells. Importantly, blocking HGF effects by 4T1 c-Met knockdown or crizotinib in mice injected intratibially with 4T1 cells (4T1 mice) markedly reduced osteolytic lesion size and secondary lung metastasis from bone. These results suggest that SN-produced HGF contributes to bone colonization and secondary metastasis of 4T1 BCa. We next examined if 4T1 BCa has reciprocal effects on SN. We found that 4T1 cells produced high mobility group box 1 (HMGB1) and that 4T1 CM increased F11 neurite sprouting that was blocked by a HMGB1 neutralizing antibody. The 4T1 mice had elevated serum levels of HMGB1 and progressive bone pain with increased sprouting of calcitonin gene-related peptide-positive SN in bone. The HMGB1 antibody or FPS-ZM1, an antagonist of the HMGB1 receptor, RAGE, reduced bone pain. These results suggest that HMGB1 produced by 4T1 BCa increases SN sprouting to enhance bone pain. In conclusion we show that reciprocal direct interactions between BCa and bone-innervating SN appear critical to the progression of BCa bone metastasis, secondary visceral metastasis from bone and induction of bone pain. Disruption of these interactions may provide a novel therapeutic approach for treatment of BCa patients.

EpCAM Promotes Bone Metastases of Breast Cancer by Conferring Cancer Stem-like and Epithelial Properties. Toru Hiraga^{*1}, Susumu Ito², Hiroaki Nakamura¹. ¹Matsumoto Dental University, Japan, ²Shinshu University, Japan

Epithelial cell adhesion molecule (EpCAM), also known as CD326 and epithelial-specific antigen (ESA), has been implicated in multiple cellular functions, such as cell signaling, migration, proliferation, and differentiation as well as cell adhesion. Clinical studies showed that EpCAM is highly expressed in various cancers, including breast cancer, and its overexpression is associated with a poor prognosis. EpCAM is also widely recognized as a marker for circulating tumor cells (CTCs) in peripheral blood, disseminated tumor cells (DTCs) in bone marrow, and cancer stem cells (CSCs). Here, we examined the roles of EpCAM in the development of bone metastasis of breast cancer by using well-characterized animal models. EpCAM-negative and -high-expressing (EpCAM^{neg} and EpCAM^{pos}) cells were firstly isolated from mouse breast cancer cell lines by fluorescence-activated cell sorting. Morphological and real-time RT-PCR data showed that EpCAM^{neg} and EpCAM^{pos} cells exhibited mesenchymal and epithelial phenotypes, respectively. Flow cytometric analysis showed that, during serial subcultures of monolayers after cell sorting, the EpCAM^{pos} population gradually decreased while an EpCAM^{neg} population was generated from EpCAM^{pos} cells in a time-dependent manner. In contrast, EpCAM^{neg} cells did not produce an EpCAM^{pos} population, suggesting that EpCAM^{pos}, but not EpCAM^{neg}, cells possess self-renewal and differentiation potentials. Tumor sphere formation in suspension cultures and tumorigenicity in the orthotopic mammary fat pad of mice were significantly greater in EpCAM^{pos} cells than in EpCAM^{neg} cells. The development of bone metastases induced by an intracardiac injection was markedly increased in mice inoculated with EpCAM^{pos} cells. Furthermore, intracardiac inoculations of the unsorted parental cancer cells demonstrated that the EpCAM^{pos} population in cancer cells that colonized in bone was significantly higher than that in the parental cells. These results suggest that the expression of EpCAM in breast cancer cells is associated with CSC-like phenotypes and contributes to the promotion of bone metastases by enhancing tumorigenicity. Our results also support the possibility that the epithelial phenotypes of EpCAM-expressing cells confer advantageous properties for the development of bone metastases, at least after entering the circulation. Thus, EpCAM may be a potential target for therapeutic interventions to treat bone metastases of breast cancer.

Lysyl oxidase endows colon cancer cells with the ability to thrive in the bone marrow and promotes bone metastasis formation. Caroline Reynaud^{*1}, Laura Ferreras², Marie Brevet³, Philippe Clezardin⁴. ¹INSERM Unité 1033UFR de Médecine Lyon-Est (domaine Laënnec), Fr, ²INSERM Unité 1033UFR de Médecine Lyon-Est, France, ³Hospices Civils de Lyon - Accueil, France, ⁴INSERM & University of Lyon, France

Lysyl oxidase (LOX) catalyzes the cross-linking of collagens and elastin in the extracellular matrix, thereby regulating the tensile strength of many tissues, such as in bone. In cancer, LOX plays a critical role in facilitating tumor growth and metastasis formation in soft tissues. Whether tumor-derived LOX also enables bone metastasis is unknown. In this study, we first showed by immunohistochemistry using patients' tumor specimens, that LOX was expressed in the desmoplastic tumor stroma of pairs of colorectal carcinomas and their matching bone metastases. Preclinical experiments showed that LOX overexpression in different colon carcinoma cell lines enhanced the

formation of osteolytic lesions in animals by promoting both skeletal tumor burden and osteoclast-mediated bone resorption. Additionally, LOX treatment of animals enhanced bone metastasis caused by parental colorectal carcinoma cells. Conversely, the pretreatment of animals with the LOX inhibitor β -aminopropionitrile or the silencing of LOX in colorectal carcinoma cells drastically reduced the formation of osteolytic lesions. Furthermore, we demonstrated that LOX was involved in the early migration of tumor cells into the bone marrow.

In vitro, LOX directly enhanced the attachment of colon cancer cells to type-I collagen, but not to fibronectin. Preliminary experiments also indicated that LOX-overexpressing colorectal carcinoma cells were more prone to adhere to components of the osteoblastic niche, such as osteoblasts or mesenchymal stem cells. Thus, LOX may promote engraftment of colon cancer cells in the osteoblastic niche. Tumor-derived LOX could also promote osteoclast differentiation by enhancing the secretion of osteolytic factors from colon cancer cells such as IL-6. Additionally, the activation of an IL-6 autocrine loop led to cancer cell survival.

In conclusion, our findings provide novel evidence that LOX endows colon cancer cells with the ability to thrive in the bone marrow microenvironment and stimulate osteoclast-mediated bone destruction.

Dickkopf-related protein 1 (Dkk1) exerts immune suppressive effects in cancer by regulating expansion and function of myeloid derived suppressor cells. Lucia D'Amico^{*1}, Aude Helene Capietto¹, Ali Zaman¹, David Bumpass², Roberta Faccio³. ¹Washington University School of Medicine, USA, ²Orthopaedic Surgery, Washington University School of Medicine, USA, ³Department of Orthopedics, Washington University School of Medicine, USA

Emerging evidence suggest the importance of tumor-stroma interactions during tumor progression. Changes in the stromal compartment can promote tumor growth by recruiting and activating a heterogeneous population of immature myeloid cells, often referred to as myeloid-derived suppressor cells (MDSC), that can suppress T cell responses and thus facilitate tumor proliferation. These findings raise a critical question: how is MDSC generation and/or activation driven by the stromal compartment at a primary or metastatic site? We recently found that downregulation of β -catenin in MDSC drives MDSC generation and their ability to inhibit T cell responses in mice and cancer patients. Our new data demonstrate that the Wnt/ β -catenin inhibitor Dkk1 suppresses β -catenin in MDSC during tumor progression. Mice bearing subcutaneous (sc) Lewis Lung Carcinomas (LLC) show increased Dkk1 levels in circulation, produced by tumor-associated fibroblasts and by osteoblasts and osteocytes in bone. To investigate whether Dkk1 promotes MDSC expansion during tumor progression, α -Dkk1 or IgG control Abs (20 mg/kg) were administered 3x/week to WT mice sc injected with LLC. Strikingly, we find that tumor growth is significantly decreased and β -catenin expression in MDSC is restored following α -Dkk1Ab treatment ($p=0.019$). Dkk1 neutralization significantly reduces the % of MDSC in bone marrow and at tumor site while T cell recruitment is increased. To directly test the effects of α -Dkk1Ab on MDSC functionality, we examined the immune suppressive effects of MDSC on T-cell proliferation after Dkk1 targeting. We find that MDSC isolated from tumor bearing mice treated with α -Dkk1Ab have reduced ability to suppress T cell proliferation ($p=0.02$). Next, to determine whether MDSC are the main target of Dkk1 pro-tumor effects, we turned to β -catenin^{fl/fl}/LysMCre c.KO mice to delete β -catenin in MDSC. We find that Dkk1 neutralization fails to reduce tumor growth and MDSC expansion in mice lacking β -catenin in MDSC. Similarly to MDSC from tumor-bearing mice, MDSC isolated from human donors incubated with serum from breast cancer patients in the presence of recombinant Dkk1 show reduced expression of β -catenin target genes. These findings demonstrate that Dkk1 directly targets MDSC in mice and humans and drives MDSC expansion and activation. Our work reveals a novel immunomodulatory role for Dkk1 in regulating tumor-induced immune suppression via targeting β -catenin in MDSC.

Deletion of the Transcriptional Coactivators YAP and TAZ in Mesenchymal Progenitors Promotes Osteoblastogenesis and Increases Bone Mass. Jinhu Xiong^{*1}, Marilina Piemontese¹, Yuko Fujiwara¹, Priscilla Baltz¹, Charles O'Brien². ¹University of Arkansas for Medical Sciences & Central Arkansas Veterans Healthcare System, USA, ²Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA

YAP (Yes associated protein) and TAZ (transcriptional co-activator with PDZ-binding motif) are related transcriptional coactivators that control organ size in a redundant manner. In vitro studies have suggested that high matrix stiffness enhances osteoblast differentiation from mesenchymal progenitors by promoting YAP and TAZ nuclear translocation. However, other studies show that YAP and TAZ suppress osteoblast differentiation. Thus, in vitro studies have not provided consistent results regarding the role of YAP and TAZ in osteoblast differentiation. Here, we deleted

genes for YAP and TAZ from mesenchymal progenitors using the Prx1-Cre transgene, which leads to recombination in all mesenchyme-derived cells in the limbs. Complete loss of YAP and TAZ in mesenchymal progenitors caused embryonic lethality. However, mice with haploinsufficiency of YAP and complete lack of TAZ in mesenchymal progenitors, referred to here as Prx1-Cre;YAP^{fl/+};TAZ^{fl/0}, developed normally. We then analyzed the skeletal phenotype of these mice at 5 weeks of age. Deletion of YAP and TAZ was confirmed by low levels of their mRNAs in the tibia. Micro-CT analysis of the femur revealed high cancellous bone volume with increased trabecular number, trabecular thickness, and decreased trabecular separation in Prx1-Cre;YAP^{fl/+};TAZ^{fl/0} mice compared to control littermates. Femoral cortical thickness was also elevated in Prx1-Cre;YAP^{fl/+};TAZ^{fl/0} mice. Ex vivo culture of bone marrow mesenchymal progenitors from Prx1-Cre;YAP^{fl/+};TAZ^{fl/0} mice showed increased osteoblastogenesis with increased expression of osteoblast marker genes such as osterix, osteocalcin, and collagen 1a1. These results demonstrate that loss of YAP and TAZ in Prx1-Cre-expressing cells promotes osteoblastogenesis and increases both cancellous and cortical bone in young mice, suggesting that these transcriptional regulators inhibit osteoblast differentiation.

Assessing the Skeletal Phenotype of Compound Gja1^{+/-} Runx2^{+/-} Mice. Atum Buo*, Joseph Stains. University of Maryland, School of Medicine, USA

The coupling of osteoblasts and osteocytes by connexin43 (Cx43)-comprised gap junctions permits the sharing of second messengers that coordinate bone cell function and bone mass accrual. However, details are lacking as to the molecular events by which Cx43 converts shared second messengers into signals that converge onto essential osteogenic processes. Previously, we have shown that Cx43 expression modulates the transcriptional activity of Runx2 in MC3T3 cells in vitro. Here, we sought out to determine whether Cx43 is able to regulate the activities of Runx2 in vivo. To achieve this, we used a compound heterozygous breeding strategy to generate mice that are doubly heterozygous for the Cx43 gene (Gja1) and the Runx2 gene. We hypothesized that if Cx43 and Runx2 indeed functionally intersect to regulate osteogenesis in vivo, then the dual hemizyosity of both Cx43 and Runx2 should manifest a skeletal phenotype not visible in wild-type or singly hemizygous animals. To assess skeletal phenotype, we performed micro-CT analysis on femur and skull specimens of 8 week-old Gja1^{+/-} Runx2^{+/-} compound mice, as well as wild-type and single Gja1^{+/-} and Runx2^{+/-} mice for controls. Cortical bone analysis reveals that in both male and female mice, compound Gja1^{+/-} Runx2^{+/-} mice have a marked increase in tissue area, endosteal and periosteal bone perimeter, as well as a striking increase in porosity in comparison to all other genotypes. This indicates that compound hemizyosity of Gja1 and Runx2 resembles the endosteal widening phenotype seen in conditional osteoblast-specific Gja1-knockout mouse models. Furthermore, micro-CT analysis of skulls reveals an interparietal bone defect in compound hemizygous mice. Consistent with this finding, whole-body alizarin red and alcian blue staining of 2 day-old Gja1^{+/-} Runx2^{+/-} neonates displays elements of the skull that are even less mineralized than the characteristically hypomineralized skull of Runx2^{+/-} neonates. In summary, these findings provide preliminary evidence that Cx43 and Runx2 functionally intersect in vivo to regulate bone formation and contribute to the skeletal phenotype of Cx43 conditional knockout mice. Ongoing studies will assess the osteogenic potential of cells from these compound animals, expand the characterization of the cranial phenotype and attempt to rescue the osteoblast dysfunction observed in Cx43 deficient cells by overexpressing Runx2.

DOK3 Affects Bone Homeostasis by Regulating Osteoblast and Osteoclast Differentiation and Function. Mary Beth Humphrey*¹, Junjie Xing¹, Courtney Long². ¹University of Oklahoma Health Sciences Center, USA, ²University of Hamberg-Eppendorf, Germany

Bone homeostasis is maintained by the balance of osteoblasts (OB) mediated bone formation and osteoclasts (OC) mediated bone resorption. RANKL promotes OC differentiation but requires costimulation of immunoreceptor tyrosine-based activation motif (ITAM)-adapters such as DAP12. Downstream of tyrosine kinases (DOK) are cytosolic adaptors which assemble multi-molecular signaling complexes that function to limit tyrosine kinase receptor mediated signaling. Recently, we found that DOK3 negatively regulates DAP12 signaling and inflammatory cytokine production in response to toll-like receptor (TLR) stimulation of macrophages. To test the hypothesis that DOK3 negatively regulates DAP12 signaling in osteoclasts, bone micro-architecture, histomorphometry, and histology of sex matched 16 week old wild type (WT) and DOK3-deficient (DOK3 KO) mice were evaluated. In vitro derived OC from DOK3 KO and WT bone marrow were analyzed for morphology and function. The MCSF and RANKL signaling pathways was investigated. OB differentiation was analyzed by alizarin red S staining and expression of OB markers. Our results show that DOK3 KO mice have significantly reduced trabecular bone mass at the tibia and femur whereas cortical bone is unchanged. Histomorphometry revealed significant decreases in OB surface, numbers, and perimeter but normal bone formation and mineral apposition rates. In vivo, OC numbers were similar between WT and DOK3 KO. In vitro derived OB from DOK3 KO mice had reduced calcified nodules and

mineralization compared to WT. Compared to WT OB, expression of alkaline phosphatase and collagen $\alpha 1$ was decreased in DOK3 KO OB. Mechanistically, decreased OB differentiation was related to failure to achieve sustained WNT3a and β -catenin expression. In vitro derived OC assays revealed that DOK3 pre-OC had increased proliferation in response to MCSF and were more sensitive to RANKL with increased OC differentiation and resorptive capacity.

Restoration of DOK3 expression in DOK3 KO pre-OC significantly reduced OC numbers and decreased resorption. Mechanistically, DOK3 regulates osteoclastogenesis by sequestering of Grb2, Sos1, Lab or Cbl and thus inhibiting Syk and Erk activation. Thus, DOK3 modulates bone remodeling by promoting OB differentiation and inhibiting osteoclastogenesis and bone resorption. Our studies have revealed DOK3 as novel mediator of osteoblastogenesis in vitro and in vivo.

Telomerase Expression Marks Transitional Growth-Associated Skeletal Progenitor/Stem Cells. Diana Carlone*, Rebecca Riba-Wolman, Luke Deary, Alessio Tovaglieri, Dana Ambruzs, Manasvi Shah, Benjamin Mead, David Breault. Boston Children's Hospital, USA

Skeletal progenitor/stem cells (SSCs) play a critical role in postnatal bone growth and maintenance. Recently, distinct SSC populations were shown to contribute to bone formation in a temporal-specific manner. Telomerase (Tert) activity prevents cellular senescence and is required for maintenance of stem cells in regenerative tissues. Here we investigate the role of mTert-expressing cells in postnatal bone development. Quantitative RNA analysis of long bones revealed that mTert is expressed predominantly at weaning (3-4 weeks), suggesting these cells are temporally regulated and mark a discrete developmental time point between rapid bone growth and bone maintenance, which we have termed "transitional growth". We next investigated the location of mTert-expressing cells using our mTert-GFP mouse model, which faithfully recapitulates endogenous telomerase activity. mTert-GFP+ cells were detected within the metaphyseal stroma, with ~75% of them residing adjacent to CD31+ vascular cells, consistent with the proposed location for SSCs. In addition, GFP+ cells were detected within the growth plate and articular cartilage as well as in the bone marrow adjacent to trabecular and cortical bone, regions also proposed to house progenitor/stem cells. mTert-expressing cells exhibited a 30-fold enrichment in CFU-F forming capacity, persisted long-term and contributed to multiple mesenchymal lineages. In vivo lineage-tracing studies showed that mTert+ cells contribute to the majority of bone-forming cells during endochondral bone growth with a subset persisting into adulthood. Additional studies revealed that mTert+ cells give rise to Osx+ osteoprogenitor cells, reinforcing the concept that a hierarchy of progenitor/stem cells exists within the bone. Taken together, these data show that mTert expression marks a distinct SSC population during the transition stage between rapid bone growth and bone maintenance. Additional studies are currently underway to identify the molecular mechanisms and signaling pathways responsible for the age-dependent expression of mTert.

DNA Damage Checkpoint Pathway Modulates The Regulation of Skeletal Growth and Osteoblastic Bone Formation by Parathyroid Hormone-Related Peptide. Ying Zhang*¹, Guangpei Chen¹, Zhen Gu¹, Andrew Karaplis², David Goltzman², Dengshun Miao³. ¹Nanjing Medical University, China, ²McGill University, Canada, ³Nanjing Medical University, Peoples republic of china

We previously demonstrated that parathyroid hormone-related peptide (PTHrP) 1-84 knockin (*Pthrp* KI) mice displayed early senescence, skeletal growth retardation and defective osteoblastic bone formation. To determine whether oxidative stress and DNA damage response pathways were involved in the regulation by PTHrP of skeletal growth and development *in vivo*, we examined alterations of oxidative stress and DNA damage response related molecules in *Pthrp* KI skeletal tissue. Our results demonstrated that ROS levels, protein expression levels of the DNA damage marker g-H2AX and the DNA damage response markers p-Chk2 and p53 were up-regulated significantly, whereas mRNA expression levels of anti-oxidative enzymes including SOD1 and 2, catalase, glutathione reductase (GSR) and glutathione peroxidase 4 (GPX4) were down-regulated in *Pthrp* KI skeletal tissues. We therefore further disrupted the DNA damage response pathway by Chk2 deletion in *Pthrp* KI (*Chk2^{-/-}Pthrp* KI) mice, and compared them with *Chk2^{-/-}*, *Pthrp* KI, and WT littermates. Deletion of Chk2 in *Pthrp* KI mice resulted in a longer lifespan, increased body weight and improvement in skeletal growth, although *Pthrp* KI mice were not normalized. At 2 weeks of age, skeletal growth parameters, including length of long bones, size of epiphyses and width of growth plates, BMD, cortical and trabecular bone volume, osteoblast numbers, and ALP and type I collagen positive bone areas, the mRNA expression levels of Runx2, ALP, and osteocalcin, and the numbers of total CFU-F and ALP positive CFU-F were increased in *Chk2* mice, and reduced in both *Pthrp* KI and *Chk2^{-/-}Pthrp* KI mice compared to WT mice; however these parameters were increased in *Chk2^{-/-}Pthrp* KI mice compared to *Pthrp* KI mice.

Furthermore, gene expression levels of SOD1 and 2, catalase, GSR and GPX4 in skeletal tissues were up-regulated significantly, whereas senescence-associated tumor suppressor genes including p16, p19, p53, p21 and p27 were down-regulated in *Chk2*^{-/-} mice compared to wild-type mice and in *Chk2*^{-/-}*Pthrp* KI mice compared to *Pthrp* KI mice. Our results demonstrate that deletion of *Chk2* in *Pthrp* KI mice can partially rescue defects in skeletal growth and osteoblastic bone formation by enhancing endochondral bone formation and osteogenesis. These studies therefore indicate that the DNA damage checkpoint pathway may function downstream in the action of PTHrP to regulate skeletal growth and development.

Transition of Chondrocytes into Osteoblasts in Endochondral Bones Requires Active Canonical Wnt Signaling. Xin Zhou^{*1}, Ailing Huang², Klaus von der Marck³, Benoit de Crombrughe², Venkata Battula², Michael Andreeff².
¹MD Anderson Cancer Center, USA, ²UT MD Anderson Cancer Center, USA, ³University of Erlangen-Nuremberg, Germany

Recent lineage tracing studies demonstrated that mature chondrocytes, both in cartilage primordia and in established growth plates, as well as chondrocytes in bone repair calluses, were a major source of osteoblasts during endochondral ossification.

To test whether chondrocyte-derived cells might be present in the bone marrow, FACS was performed using 3.5-month *Coll10a1-Cre; ROSA26-YFP* mice. We found that about 0.1% of the total nucleated bone marrow cells were YFP⁺. Likewise in *Coll10a1-Cre; Osx^{fllox/+}* mice, in which *EGFP* expression marks *Osx*-expressing cells after Cre-mediated *LoxP* recombination of the *Osx^{fllox}* allele, GFP⁺ cells were present in the bone marrow. Both the YFP⁺ and the GFP⁺ bone marrow cells, isolated either directly from bone marrow or from a bone marrow MSC culture, were positive for mesenchymal progenitor cell (MSC) markers (Sca1, CD140a, CD140b, CD105), negative for the hematopoietic cell marker CD45 and the erythroid cell marker Ter119. Moreover, the cultured YFP⁺ or GFP⁺ bone marrow cells displayed clonogenic, osteogenic, chondrogenic and adipogenic capacities *in vitro*. Interestingly, more than 30% of the cells, in a bone marrow MSC culture of 4-month-old *Coll10a1-Cre; Osx^{fllox/+}* mice, were GFP⁺. These results provide evidence that hypertrophic chondrocyte-derived mesenchymal progenitor cells were indeed present in the bone marrow and that a significant fraction of the total bone marrow mesenchymal progenitor cells were *Osx*-expressing cells derived from mature hypertrophic chondrocytes. This suggests the hypothesis that the hypertrophic chondrocytes to osteoblasts transition might proceed first through a dedifferentiation and then a redifferentiation step.

Inactivation of β -catenin in hypertrophic chondrocytes led to marked decrease in trabecular formation (Golovchenko *et al*, Bone 2013), suggesting that Wnt signaling may play an important role in regulating hypertrophic chondrocytes to osteoblasts transition. In 2-week-old *Coll10a1-Cre; Ctnnb1^{fllox/fllox}; ROSA-tomato* mice, only tomato⁺ bone marrow cells, but no tomato⁺ osteoblasts were observed on trabecular and endosteal surfaces, and no tomato⁺ osteocytes within the cortex, implying that Wnt signaling is needed for chondrocyte-derived progenitors to differentiate into mature osteoblasts.

Sarcopenia and age-related muscle impairment: histology and imaging in a close relationship. Umberto Tarantino^{*1}, Jacopo Baldi¹, Manuel Scimeca², Elena Bonanno², Elena Gasbarra³, Eleonora Piccirilli⁴. ¹University of Rome Tor Vergata, orthopaedics & traumatology, Italy, ²University of Rome Tor Vergata, Anatomic Pathology Department, Italy, ³University of Rome Tor Vergata, orthopaedics & traumatology, Italy, ⁴University of Rome Tor Vergata, Department of orthopaedics & traumatology, Italy

Background: Sarcopenia is a pathological condition of impaired muscle quality that may be predictive of an increased fragility fracture risk in the elderly. In the elderly the muscle patrimony becomes poorer in terms of power, strength and resistance. In this context, our experience aims to describe in a multimodal way macro- and micro-structural changes that muscle tissue undergoes during the physiological aging process using histological analysis and Nuclear Magnetic Resonance imaging. **Methods:** We performed vastus lateralis biopsies in 25 women with osteoporosis (OP group) and in 25 women underwent surgery for hip osteoarthritis (OA group). Patients were clinically characterized performing DeXA, T-score and after radiographic assessment by Kellgren-Lawrence scale. The study was approved by the local Ethical Committee. Immunohistochemistry was performed to evaluate muscle fibers type, fast and slow, satellite cells activity, myostatin and CD44, bone-muscle cross-talk molecules and BMP-2 and BMP-4 and mineralization markers. A Magnetic Resonance Diffusion tensor Imaging protocol was performed; we evaluated the T1, T2, Fractional Anisotropy and the Mean Diffusivity. **Results:** in this study we measured vastus lateralis musculature diffusion properties of OP subjects and compared them with OA patients. Our findings revealed in OP a preferential type II fiber atrophy. The analysis of DTI parameters reveals that the FA was significant lower in OP as compared to OA subjects. The correlation analysis showed a strong significant correlation between DTI parameters and the muscle fat of OP and OA subjects. In particular, a positive correlation was found between FA and fat fraction.

In addition, Our results clearly indicate a similar pattern of BMP-2 and BMP-4 expression in bone and muscle tissues. In particular, we demonstrated that muscle tissues of elderly patients frequently express BMPs close to degenerated areas or adipose tissue. However, the expression of these molecules was significantly higher in osteoarthritis group as compared with osteoporotic patients. **Conclusion:** Our experience demonstrates the usefulness of new diagnostic techniques for understanding pathophysiological mechanisms shared by sarcopenia and osteoporosis. Our DTI analysis showed that the MD and the three eigenvalues were significantly higher in OP as compared to OA subjects. Moreover, an opposite trend was obtained for the FA parameter. The finding that both the activity of satellite muscle stem cells and bone remodeling are related to the same factors, BMP-2 and BMP-4, could shed new light on molecular mechanism of more relevant bone-muscle related diseases of the elderly, such as sarcopenia, osteoarthritis and osteoporosis.

Evaluation of cutpoints for low lean mass and slow gait speed in predicting death in the National Health and Nutrition Examination Survey 1999-2004. Ching-Lung Cheung^{*1}, Karen Lam², Bernard Cheung². ¹The University of Hong Kong, Hong kong, ²University of Hong Kong, Hong kong

Background: Sarcopenia is commonly defined as loss of muscle mass with limited muscle function or strength. Different cutpoints of low lean mass and slow gait speed have been proposed by different professional working groups. We compared the performance of different cutpoints of low lean mass and slow gait speed in predicting death. **Methods:** We analyzed data of participants aged 65 or above from the continuous National Health and Nutrition Examination Survey conducted between 1999 and 2004 (N=2,841), and the subsequent follow-up data on mortality up to December 31, 2006. For low lean mass, cutpoints based on appendicular lean mass (ALM) alone, ALM adjusted for body mass index (ALMBMI) and ALM adjusted for height squared (ALMH2) were evaluated. For slow gait speed, the cutpoints based on 0.7m/s, 0.8m/s, 0.9m/s, and 1.0m/s were evaluated. A Cox-proportional hazard regression model with adjustment for multiple confounding factors was used for the association analyses. **Results:** For low lean mass, the cutpoints based on ALMBMI (<0.512 in women and <0.789 in men) showed the most significant association and highest hazard ratio (HR) with death (HR=1.72; 95% CI: 1.28-2.29; P<0.001). Similar associations were observed in sex-specific analyses. All cutpoints of low lean mass had similar AUC values, except the AUC of low ALMBMI was shown to be significantly higher than that of ALMH2 in men. For slow gait speed, all cutpoints tested showed significant association with death in the full model (P<0.001), while the cutpoint 0.9m/s showed the highest HR (HR=2.39; 95% CI: 1.79-3.20). Similar associations were observed in sex-specific analyses and all cutpoints of low gait speed had similar AUC values. In addition, participants with both low ALMBMI and low gait speed (<0.9m/s) had the highest HR (HR=3.67; 95% CI: 2.42-5.57; P<0.001) when compared to participants with low ALMBMI only, low gait speed only, or without low ALMBMI or low gait speed. **Conclusions:** Low lean mass defined by ALMBMI showed the strongest association with death; while slow gait speed (cutpoints ranging from 0.7m/s to 1.0m/s) showed significant association with death, with the strongest association being observed for the cutpoint of 0.9m/s. Further studies validating the cutpoints are warranted before using them in clinical settings.

Hyperparathyroidism is Associated with Osteosarcopenia in Older Individuals with a History of Falling. Pushpa Suriyaarachchi^{*1}, Fernando Gomez², Carmen L. Curcio², Ruth Huo³, Derek Boersma¹, Oddom Demontiero¹, Piumali Gunawardene⁴, Gustavo Duque⁴. ¹Musculoskeletal Ageing Research Program, Sydney Medical School Nepean, The University of Sydney, Australia, ²Research Group on Geriatrics & Gerontology, Faculty of Health Sciences, International Association of Gerontology & Geriatrics Collaborative Centre, University of Caldas, Colombia, ³Faculty of Medicine, University of New South Wales, Australia, ⁴Musculoskeletal Ageing Research Program, University of Sydney, Australia

BACKGROUND: In older persons, the combination of osteopenia/osteoporosis and sarcopenia (osteosarcopenia) has been proposed as a subset of frail individuals at higher risk of institutionalization, falls and fractures. Therefore, identification of the risk factors for osteosarcopenia is pivotal. Although vitamin D has been associated with a higher risk of osteosarcopenia, the role of parathyroid hormone (PTH) in this syndrome remains unknown. In this study, we evaluated the role of PTH in a population of older individuals with a history of falling.

METHODS: This is a cross sectional study of 760 subjects (mean age=79, 65% women) assessed between 2009-2014 at the Falls and Fracture Clinic, Nepean Hospital (Penrith, Australia). Assessment included medical history, physical examination, bone densitometry and body composition by DXA, posturography, grip strength, gait parameters (GaitRITE), and blood tests for nutrition and secondary causes of sarcopenia and osteoporosis. Patients were divided in 4 groups: 1) Osteopenic (BMD<-1.0 SD in femoral neck); 2) sarcopenic (following the European Consensus criteria); 3) osteosarcopenic and; 4) non-sarcopenic/non-osteopenic. Difference between the groups was assessed using with one-way ANOVA and X² analysis. Multivariable

linear regression evaluated the association between the groups and PTH levels adjusted for age, vitamin D, renal function and albumin.

RESULTS: Our analysis showed that 24% of the subjects had high PTH (>6.8 pmol/L). These subjects were older (81 ± 3, p<0.01), reported a higher number of falls/year (3 ± 1, p<0.01), and showed lower grip strength (18 ± 1Kg, p<0.06), limits of stability (108 ± 6, p<0.008), BMD (-0.7 ± 0.2, p<0.02), and gait velocity (55 ± 6cm/sec, p<0.01). Compared with the other groups, subjects with high PTH showed increased prevalent osteosarcopenia (6.88; CI: 0.9-52).

CONCLUSION: In summary, we have reported an independent association of high PTH levels with osteosarcopenia in a population at high risk of falls and fractures. As a potential mechanism, the chronic elevation of PTH could have a catabolic effect on both muscle and bone, which may be independent of serum levels of vitamin D. In conclusion, our results suggest an important role of PTH in osteosarcopenia that deserves further exploration.

Greater Grip Strength is associated with Larger Cortical Thickness in Men and Larger Bone Size in Women: The Framingham Osteoporosis Study. Robert McLean¹, Xiaochun Zhang², Kerry Broe², Ching-An Meng², Elizabeth Samelson¹, L Adrienne Cupples³, Marian Hannan¹, Mary Bouxsein⁴, Douglas Kiel¹. ¹Hebrew SeniorLife Institute for Aging Research & Harvard Medical School, USA, ²Hebrew SeniorLife Institute for Aging Research, USA, ³Boston University School of Public Health, USA, ⁴Beth Israel Deaconess Medical Center & Harvard Medical School, USA

The sensitivity of bone to mechanical loading might underlie the observation that age-related loss of muscle strength is associated with bone loss. Greater grip strength has consistently been associated with higher areal bone density across several studies of older adults, though fewer have examined bone volumetric density and structure, and results have been mixed. Further, we are aware of only one previous study of grip strength and bone microarchitecture in older men, while none have examined women. Thus, our understanding of the relation between age-related changes in muscle and bone is incomplete. Our objective was to determine the association of grip strength with distal radius bone density, size and microarchitecture among 402 men and 541 women aged ≥50 years in the community-based Framingham Offspring cohort. At the non-dominant arm, grip strength (kg) was measured by hand-held dynamometer (maximum of 3 trials), and bone size, microarchitecture and density of the distal radius were assessed by HR-pQCT (Scanco Medical AG). For men and women separately, analysis of covariance was used to calculate least squares-adjusted mean (SE) bone measures for sex-specific quartiles of grip strength, and test for linear trends, adjusting for age, height and weight. Mean age in the study population was 70 years (range 51-92). Mean grip strength was 37 kg in men and 21 kg in women. From quartile 1 (low) to quartile 4 (high), total cross-sectional area increased in women (P for trend<0.0001), while a similar trend in men had a P for trend=0.06. Cortical thickness increased across quartiles in men (P trend=0.006), but not in women. In both sexes, grip strength was not associated with cortical porosity, trabecular thickness, trabecular number, nor with cortical bone area fraction (cortical area/total area). Density did not increase across grip strength quartiles, though in women there was suggestion of a decrease in total density with increasing grip strength quartile (P trend=0.046). We found that at the non-weight bearing distal radius, greater grip strength was associated with larger bone cross-sectional area, particularly in women, but with larger cortical thickness in men only. Our results suggest that while mechanical loading does not seem to influence bone density at the distal radius, it may contribute to bone size. Findings also indicate that the response of cortical bone to loading may differ between men and women.

Least squares-adjusted* mean (SE) distal radius bone density, size and microarchitecture for quartiles of grip strength among men and women in the Framingham Osteoporosis Study.

Sarcopenia Predicts Fracture Risk in 65-year Old Healthy Community-dwellers. Andrea Trombetti*, Mélyny Hars, Emmanuel Biver, Thierry Chevalley, Serge Ferrari, René Rizzoli. Division of Bone Diseases, Geneva University Hospitals & Faculty of Medicine, Switzerland

Sarcopenia is associated with an increased risk of adverse outcomes, including falls. However, the contribution of low skeletal muscle mass to fracture risk remains unknown. Various thresholds for low lean mass have been proposed for sarcopenia definition, but their ability to predict hard outcomes like incident fractures is not established. In this study, we investigated the prevalence of low lean mass and its association with 3-year fracture incidence in a homogeneous cohort of healthy 65-year old community-dwellers. Nine hundred thirteen subjects (729 women; age 65.0 ± 1.4 years), enrolled in the Geneva Retirees Cohort (GERICO) study, were prospectively followed-up. Total (TLM) and appendicular (ALM) lean masses were assessed using DXA. The various thresholds proposed by Baumgartner et al, the European Working Group on Sarcopenia in Older People (EWGSOP 1 and 2), the International Working Group on Sarcopenia (IWG), or the Foundation for the National Institutes of Health Sarcopenia Project (FNIH) were applied. Low trauma clinical fracture incidence over a 3-year period was recorded. The associations between lean mass and incident low trauma fractures were assessed using univariate and multivariate logistic regression models. During an average follow-up of 3.4 ± 0.9 years, 40 (4.4%) participants sustained at least one incident low trauma fracture. The prevalence of low lean mass was 11.2%, 17.1% and 3.5% according to Baumgartner or EWGSOP 1, EWGSOP 2 or IWG, and FNIH thresholds, respectively. Baseline ALM and TLM were lower in subjects with incident fractures compared to those without fractures (17.2 ± 3.3 vs 18.6 ± 4.3 kg, p<0.02, for ALM; 41.2 ± 7.0 vs 43.7 ± 8.8 kg, p<0.04, for TLM). After adjusting for sex, age, length of follow-up and FRAX probability with BMD, low lean mass was associated with a 2.3 (CI95%: 1.0-5.1; p<0.05) (Baumgartner or EWGSOP 1 threshold) and 1.3 (CI95%: 0.6-2.7; ns) (EWGSOP 2 or IWG threshold)-fold increase in low trauma fracture risk. No patient with FNIH low lean mass criteria experienced any low trauma fracture. Our results show that low appendicular lean mass, as defined with Baumgartner or EWGSOP 1 threshold, is a predictor of incident fractures in a large cohort of healthy 65-year old community-dwellers, independently of FRAX score. The increased risk is clearly related to the threshold for low lean mass selected. Whether assessing in addition muscle function improves low trauma fracture risk prediction remains to be determined.

Poor peripheral nerve function increases the risk of injurious falls: the Health, Aging and Body Composition Study. Elsa S. Strotmeyer*, Mary E. Winger¹, Jane A. Cauley¹, Robert M. Boudreau¹, Teresa M. Waters², Julie M. Donohue¹, Steven M. Albert¹, Ann V. Schwartz³, Suzanne Satterfield², Sasa Zivkovic¹, Aaron I. Vinik⁴, Melissa Garcia⁵, Tamara B. Harris⁵, Anne B. Newman¹. ¹University of Pittsburgh, USA, ²University of Tennessee Health Science Center, USA, ³University of California, San Francisco, USA, ⁴Eastern Virginia Medical School, USA, ⁵National Institute on Aging, USA

Older adults have subclinical sensorimotor nerve declines, though the relationship to injurious falls is unknown. Clinical neuropathy has been associated with fractures; however age-related impairments and non-fracture injuries have not been investigated. Sensorimotor nerve function in the Health, Aging and Body Composition Study (Medicare-eligible at 1997/98 baseline, 52% women, 38% black, 22% diabetes) was related to incident injurious falls from linked Medicare claims. Monofilament detection (10-g/1.4-g), sensory vibration threshold (inability to detect: >131 μ), peroneal motor nerve conduction velocity (NCV, low: <40 m/s) and amplitude (CMAP, low: <1 mV) were assessed at 7/00-6/01 exam (N=2,399). Injurious falls from clinic exam to 12/31/08 were identified from Medicare claims for N=2,375 (99%) as fall code (E880-888) plus non-fracture injury (N=161), and/or fracture code (800-829) with (N=91) or without (N=367) a fall code. Traumatic, intentional or pathologic injuries were excluded (N=38). Censoring performed at initial injurious fall (N=619 in 3.8 ± 2.4 years), or at earliest date of: Medicare fee-for-service end (N=1), last follow-up (N=13), death (N=525), or 12/31/08 claims dataset end (N=1217) in 6.9 ± 2.1 years. Fracture injuries were more likely from inpatient hospital claims compared to non-fracture injuries (28% vs. 3%; p<0.05). Participants with injurious falls were more likely to be white (71% vs. 58%), women (65% vs. 47%), older (age 77 ± 3 vs. 76 ± 3 years), and had lower BMI (26.8 ± 4.9 vs. 27.6 ± 4.8 kg/m²), all p<0.001. Cox regression models for each sensorimotor measure were developed for total fall injuries and stratified by fracture injuries, adjusted for demographic, BMI, lifestyle factors, comorbidity, leg strength and medications (total count and with potential to affect falls). Sensitivity analyses removing injuries possibly unrelated to falls (e.g., vertebral fracture) were consistent. In adjusted models (Table 1), 1.4-g and 10-g insensitivity increased incident injurious fall risk. Vibration threshold and motor CMAP/NCV were not related when including fracture injuries. When fall injuries with or without fractures were stratified, associations were largely consistent though inability to detect vibration was also related to increased risk of non-fracture injuries. Sensory, though not motor, nerve impairment increased injurious fall risk, and simple monofilament tests may be a particularly important predictor in older adults.

Genetic or Pharmacological Ablation of Fgf23 Ameliorates Progression of Chronic Kidney Disease in Mice. OLENA ANDRUKHOVA¹, Svetlana Slavic², Sathish Kumar Murali², Bill Richards³, Reinhold G. Erben². ¹INST. OF PHYSIOLOGY, PATHOPHYSIOLOGY & BIOPHYSICS, Austria, ²Department of Biomedical Sciences, University of Veterinary Medicine, Austria, ³Amgen Inc, USA

Clinical studies have shown that circulating fibroblast growth factor 23 (FGF23) is associated with disease progression, cardiovascular risk, and mortality in patients with chronic kidney disease (CKD). Here, we sought to elucidate further the role of Fgf23 and its co-receptor Klotho in the pathogenesis of CKD in mice by a dual approach, using genetic loss-of-function together with pharmacological inhibition models. CKD was induced by 5/6 nephrectomy in 3-month-old wild-type (WT) mice, vitamin D receptor (VDR) mutant mice, Fgf23-/-VDR?? (Fgf23/VDR), and Klotho-/-VDR?? (Klotho/VDR) compound mutant mice. All mice were kept lifelong on a rescue diet enriched with calcium, phosphorus, and lactose to prevent secondary hyperparathyroidism in VDR mutant mice. Sham-operated (SHAM) mice served as controls. In addition, SHAM and CKD WT, VDR, and Klotho/VDR mice were treated with low dose anti-FGF23 antibody (anti-FGF23Ab, 50 µg per mouse, two times per week) over 8 week post-surgery. This dose of anti-FGF23Ab reduced circulating Fgf23 in CKD mice to Sham control levels. Genetic ablation of Fgf23 in Fgf23/VDR compound mutant or treatment of WT and VDR CKD mice with anti-FGF23Ab partially or completely protected against the CKD-induced weight loss, increase in mortality, reduction in glomerular filtration rate, albuminuria, volume expansion, hypernatremia, hypercalcemia, hyperphosphatemia, hypertension, and left ventricular functional impairment observed in untreated and vehicle-treated WT and VDR mice, 8 weeks post-surgery. Moreover, anti-FGF23Ab treatment of Klotho/VDR CKD mice, which were characterized by the highest circulating Fgf23 concentrations among all CKD groups, reduced the increased mortality and accelerated disease progression observed in these mice to levels found in Fgf23/VDR mutants, demonstrating that Fgf23 also has Klotho independent effects at high circulating levels. Genetic ablation or pharmacological inhibition of Fgf23 prevented hypercalcemia and volume overload in CKD mice by down-regulating renal sodium-transporting molecules, and increasing urinary excretion of sodium and calcium. Collectively, our data suggest that elevated Fgf23 contributes to the pathogenesis of CKD in a vitamin D hormone- and partially Klotho-independent manner. Hence, our study may provide a mechanistic explanation for the association between circulating FGF23 and disease progression in CKD patients.

Inhibition of Fibroblast Growth Factor Receptor Signaling Partially Rescues Hypophosphatemic Rickets in FGF2 High Molecular Weight Isoform Transgenic Mice. Liping Xiao^{*}, Erxia Du, Patience Meo Burt, Marja Marie Hurley. University of Connecticut Health Center, USA

Vitamin D and phosphates improves serum phosphate (Pi) and rickets in some X-linked hypophosphatemic rickets (XLH) patients but increases circulating FGF23, which further complicates therapy. Mice harboring high molecular weight FGF2 isoforms (HMWTg) in osteoblast lineage phenocopy human XLH and Hyp murine model of XLH and HMWFGF2 was upregulated in bones of Hyp mice. Since abnormal FGF receptor signaling is important in XLH, HMWTg mice were used to examine the effect of the FGFR inhibitor NVP-BGJ398 (BGJ398, Novartis) on hypophosphatemic rickets.

Five week old HMWTg or Vector control male mice were orally gavaged with BGJ398 50mg/kg or Vehicle, 3 times/week, for 8 weeks. Body weight, tail length, bone mineral density (BMD) and bone mineral content (BMC) were measured biweekly. At 8 weeks, serum was collected to measure calcium (Ca), Pi, FGF23 and PTH and 24h urine to measure Pi. Mice were labeled with calcein and xylene orange (XO) 7 and 2 days prior to sacrifice. Femur and tibia length was measured and Digital x-rays and micro-CT was performed on excised bones. BGJ398 normalized serum Pi, reduced urine Pi, decreased serum PTH but further increased FGF23 (Table 1).

BGJ398 normalized tail, tibia and femur length but further decreased vertebral BMD and BMC and femur BMD in HMWTg (Table 1). Micro-CT of vertebrae (Table 2) showed further decreased BV/TV, Trab.Number and increased Trab Spacing with BGJ398 treatment. Micro-CT of femurs (Table 3a) showed increased Trabecular Tissue density in BGJ398 treated HMWTg. BGJ398 rescued abnormal architecture (arrow head) and mineral defect in cortical bone (arrow) (Figure 1) and increased cortical thickness, reduced porosity, increased endosteal perimeter and cortical tissue density in HMWTg (Table 3b). Histologic examination of femurs (Figure 2) revealed that BGJ398 improved cancellous bone (black arrow head), cortical bone structure (black arrow), growth plate, and double labeling in cortical bone (white arrows) in HMWTg. BGJ398 increased osteoclast number and surface, double labeled surface, MAR and bone formation rate in femur trabeculae of HMWTg.

We conclude that BGJ398 partially rescued hypophosphatemic rickets and could be considered as a new treatment for XLH. However, BGJ398 treatment increased serum FGF23 that could further exacerbate the mineralization defect. Furthermore HMWFGF2 may have effects on bone matrix mineralization independent of FGFR.

Table 1. Final adjusted Cox regression models for sensorimotor nerve impairment predicting total fall injuries, non-fracture injuries, and fractures.

| | Total fall injuries (N=619/2375) | Non-fracture fall injuries (N=161/2375) | Fracture injuries (N=458/2375) |
|--|----------------------------------|---|--------------------------------|
| Hazard Ratio (95% Confidence Interval) | | | |
| Sensory nerve | | | |
| Monofilament insensitivity, 10-g | 1.5 (1.1, 2.0) [†] | 2.4 (1.5, 3.9) [†] | 1.2 (0.9, 1.8) |
| 1.4-g | 1.3 (1.1, 1.6) [†] | 1.3 (0.9, 1.9) | 1.3 (1.1, 1.6) [†] |
| Inability to detect vibration >131µ | 1.1 (0.8, 1.6) | 2.2 (1.3, 3.8) [†] | 0.9 (0.6, 1.5) |
| Motor nerve | | | |
| NCV <40 m/s | 1.1 (0.9, 1.4) | 1.2 (0.8, 2.0) | 1.1 (0.8, 1.5) |
| CMAP <1 mV | 1.2 (0.9, 1.6) | 1.5 (0.9, 2.5) | 1.1 (0.8, 1.6) |

[†]p-value<0.01. Age, sex, race, site, diabetes (yes/no), BMI and total number of medications were retained in all models, with additional covariates removed at p>0.1. Modified Mini-Mental State score was retained in all models for total fall injuries and non-fracture fall injuries, and Cystatin C>1.0 mg/L in 1.4-g/10-g insensitivity models for total fall injuries and non-fracture fall injuries and in vibration model for total fall injuries.

Erythropoietin and FGF23 cross-talk during iron-deficiency anemia. Erica Clinkenbeard^{*}¹, Keith Stayrook², Hitesh Appaiiah³, Taryn Cass⁴, Emily Farrow⁵, Mircea Ivan⁶, Rebecca Chan⁷, Ernestina Schipani⁸, Thomas Clemens⁹, Kenneth White⁴. ¹Indiana University-Purdue University Indianapolis, USA, ²Department of Pharmacology & Toxicology, Indiana University School of Medicine, USA, ³Department of Medical & Molecular Genetics Indiana University School of Medicine, USA, ⁴Department of Medical & Molecular Genetics, Indiana University School of Medicine, USA, ⁵Department of Pediatrics, University of Missouri-Kansas City School of Medicine, USA, ⁶Department of Medicine/Hematology-Oncology, Indiana University School of Medicine, USA, ⁷Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, USA, ⁸Departments of Orthopaedic Surgery & Medicine/Endocrinology, University of Michigan School of Medicine, USA, ⁹Department of Orthopaedic Surgery, Johns Hopkins School of Medicine, USA

The mechanisms controlling FGF23-mediated phosphate metabolism during normal and disease conditions remain unclear. We previously determined that anemia/hypoxia increased bone FGF23. This finding is important for late onset autosomal dominant hypophosphatemic rickets (ADHR) where FGF23 is elevated during iron deficiency, and in CKD, where conjoint manifestations of anemia/iron deficiency, high serum FGF23, and defects in phosphate metabolism occur. Herein, our goal was to identify the molecular mechanisms controlling FGF23 production during anemia. In this regard, we first tested the role of the transcription factor Hypoxia inducible factor-1 alpha (HIF1α). In vitro studies using iron chelators demonstrated significant HIF-reporter activity (10-fold; p<0.05), and HIF1α knock-down resulted in 95% reduction of FGF23 mRNA (p<0.02) in UMR-106 and U2OS osteoblastic cells. In vivo, mice lacking HIF-1α in osteoblasts [HIF1α^{fl/fl}/OCN-cre] or lacking both HIF-1α and HIF-2α in osteoprogenitors [HIF1/2^{fl/fl}/OSX-cre] were provided iron-restricted diets to induce anemia. In contrast to in vitro studies, upon induction of anemia conditional null mice retained similar abilities as Cre⁺ littermates to increase FGF23 mRNA (>40-fold) and total protein (16-fold). Serum erythropoietin (EPO) dramatically rose in the HIF-null mice (40-60 fold, p<0.01), therefore this hormone was next tested as an independent FGF23 regulator. In concert with positive indicators of EPO delivery, including splenomegaly and elevated bone transferrin receptor (5-fold; p<0.01), EPO injections dose-dependently increased FGF23 mRNA and total protein (>40-fold maximal; p<0.01), as well as doubled intact FGF23 (p=1x10⁻⁶) in WT and HIF1α^{fl/fl}/OCN-cre⁺ mice. Next, the juvenile cystic kidney ('Jck') PKD/CKD mouse model was tested over a 4-20 week time course and found to have iron deficiency and anemia at 12 weeks of age concomitant with elevated EPO and FGF23. EPO administration to 6-week old Jck caused an early rise in intact FGF23 to levels greater than in age-matched WT mice (686.3 vs 407.2 pg/mL; p<0.01). Together, our findings demonstrate that in addition to HIF-dependent pathways, EPO drives FGF23 production, and in conditions of renal insufficiency may increase secretion of active FGF23. Considering the overlapping toxicity of EPO/ESAs and FGF23, our findings have significant implications for optimizing emerging and current interventions for syndromes involving disturbed iron and phosphate metabolism.

During postnatal life, longitudinal bone growth relies upon the ability of its cellular residents to receive and respond to local and systemic stimuli through a complement of transmembrane signalling receptors (cargo). The parathyroid hormone receptor type 1 (PTHr) is a class B GPCR critical for bone growth, remodelling, and mineral ion metabolism. In response to stimulation, PTHr is rapidly

Table3

internalised and recycled from early endosomes to the plasma membrane (PM) via the retromer sorting ensemble. Sorting Nexin 27 (SNX27), a PDZ-domain containing member of the Phox-homology (PX) family of SNXs, is an endosome-associated cargo adaptor that operates in unison with the retromer to ensure the fidelity of cargo selection during activity-dependent endosome-to-PM retrieval. Here we show that SNX27 functions as a crucial regulator of postnatal bone growth by linking PTHR trafficking to the retromer endosome-to-PM recycling pathway. Using micro-computed tomography (microCT) and histomorphometry we demonstrate that mice lacking SNX27 exhibit severe disturbances in postnatal bone growth. Analysis of long bones of 4-week-old SNX27-deficient mice revealed a drastic reduction in bone size and net volume, decreased trabecular number, and a conspicuous growth plate defect. Mechanistically, we demonstrate that these abnormalities are attributable, in part, to cell-autonomous disturbances in the signalling, trafficking and function of the PTHR. By co-immunoprecipitation and isothermal titration calorimetry (ITC) we show that PTHR is a direct SNX27 binding cargo whose affinity is enhanced by an order of magnitude in the presence of the retromer. At the atomic level, we demonstrate that PTHR associates electrostatically with the binding pocket of SNX27-PDZ domain via its canonical C-terminal PDZ-binding motif (PDZbm: E-T-V-M) and identify several upstream amino acids critical to the high affinity SNX27-PDZ: PTHR-PDZbm interaction. In response to agonist stimulation, we demonstrate that PTHR is internalised into early endosomes, an event that coincides with the rapid mobilisation of SNX27 and recruitment of the retromer complex. Finally, we show that depletion of the SNX27-retromer by shRNA knockdown misdirects PTHR trafficking to lysosomes, resulting in a net reduction of PTHR expression at the cell surface. Therefore, SNX27 serves as endosomal cargo adaptor that links PTHR trafficking to the retromer to preserve bone growth and homeostasis throughout postnatal life.

Thyroid Hormone Receptor β (TR β) Signaling is Critically Involved in Regulating Secondary Ossification via Promoting Transcription of the IHH Gene in the Epiphysis. Weirong Xing¹, Patrick Aghajanian², Heather Watt², Catrina Alarcon², Subburaman Mohan². ¹Musculoskeletal Disease Center, Jerry L. Pettis Memorial Veteran's Admin., USA, ²Jerry L. Pettis Memorial VA Medical Center, USA

We recently demonstrated that thyroid hormone (TH) is indispensable for the initiation and progression of the secondary ossification center (SOC) at the epiphysis. TH action is mediated through two nuclear TH receptors, TR α and TR β . The ligand binding TR α is ubiquitously expressed and is the most abundant form of TR expressed in bone. While the role of TR α is well established, less is known about the relevance of TR β -mediated signaling in bone development. A two day treatment of Tshr^{-/-} mice with TH increased the TR β mRNA level at day 7 by 3.4 fold (P<0.001) but had no effect on the TR α mRNA level at the proximal tibial epiphysis. Accordingly, treatment of serum-free cultures of tibia-derived cells from 3-day old mice treated with T3 increased TR β expression by 2.1 and 13-fold, respectively, at 24 and 72 h. To determine the role of TR β signaling, we evaluated the effects of GC1, a TR β -specific agonist, on bone formation in vivo in the epiphysis. TH deficient Tshr^{-/-} mice were treated daily for 10 days (day 5-14) with GC1 (0.2 or 2 μ g/day) or vehicle and the amount of bone formed at the proximal tibial epiphysis was quantitated by micro-CT at postnatal day 21. GC1 treatment at 0.2 or 2.0 μ g increased BV/TV by 225% and 263% of vehicle treatment (P<0.001), respectively. Two day treatment with GC1 (0.2 μ g/day) increased expression levels of IHH by 100-fold, osterix by 15-fold and osteocalcin by 59-fold (all P<0.001) compared to vehicle at day 7 in the proximal tibial epiphysis. While expression of type X collagen was increased by 238-fold (P<0.001), type II collagen expression was reduced by 25% (P<0.05). Since IHH is a key regulator of endochondral ossification and since the distal promoter regions of the IHH genes of different species each contain TH responsive elements (TREs), we next evaluated if TH acts directly on the IHH gene to promote transcription. We inserted a 1 kb portion (-5918 to -4919) of the mouse IHH promoter containing putative TREs in front of the TK minimal promoter of the pTAL-SEAP reporter gene and found that a 1 nM GC1 treatment increased alkaline phosphatase activity by 20-fold (P<0.01) compared to vehicle at 48 h in chondrocytes. In conclusion, our data demonstrate a novel role for TR β in secondary ossification at the epiphysis that involves transcriptional up-regulation of the IHH gene.

Osteocytic JAK/STAT signalling controls corticalization of long bones by estradiol and testosterone-dependent mechanisms. Daechul Cho¹, Narelle McGregor¹, Brett Tonkin², Holly Brennan², Rachelle Johnson², Roger Zebaze³, David Handelsman⁴, T John Martin², Natalie Sims^{*1}. ¹St. Vincent's Institute of Medical Research, Australia, ²St. Vincent's Institute of Medical Research, Australia, ³Austin Health, University of Melbourne, Australia, ⁴ANZAC Research Institute, The University of Sydney, Australia

Cortical morphology at the metaphysis of long bones is a key determinant of bone strength in old age. Cortical bone in this region forms by coalescence of trabeculae arising from the growth plate, but the control of this process is poorly understood.

SOCS3 (Suppressor of Cytokine Signalling 3) is a JAK/STAT inhibitor specific for glycoprotein 130 (gp130), leptin and G-CSF receptors. Male and female mice lacking SOCS3 in osteocytes (DMP1Cre.SOCS3^{fl/fl} (f/f)) had significantly higher trabecular bone volume (BV/TV, by micro CT) at 6 weeks of age (4.5-fold, p<0.01) compared to DMP1Cre.SOCS3^{w/w} controls (w/w). At 12 weeks of age, both male and female f/f mice had greater osteoid surface, volume, osteoblast surface and mineralizing surface (p<0.01), but bone mass phenotypes were sex-divergent: male f/f BV/TV was half of male w/w (p<0.05) while female f/f BV/TV was 7-fold higher (p<0.001) than female w/w. There were no alterations in bone length. The female f/f high bone mass was most dramatic in the metaphysis where trabecular bone was continuous with, and indistinguishable from, highly porous cortical bone, suggesting defective metaphyseal corticalization.

To determine whether estrogen was responsible for this phenotype, male and female f/f and w/w mice were orchietomized (ORX) or ovariectomized (OVX) at 6 weeks of age, and treated until 12 weeks of age with 17- β -estradiol (E₂) or non-aromatizable dihydrotestosterone (DHT) by slow-release silastic implant. In w/w mice these E₂ and DHT doses prevented OVX and ORX-associated bone loss, respectively. In female f/f mice, OVX reduced BV/TV and partially restored cortical integrity; E₂ prevented these changes. DHT normalized the female f/f phenotype such that trabecular and cortical bone were readily distinguished. When male f/f mice were treated with E₂, the phenotype fully recapitulated that of female f/f mice: cortical bone in the metaphysis was highly porous and indistinguishable from abundantly calcin-labelled trabecular bone.

These data suggest that trabecular coalescence, required for compartmentalization of cortical and trabecular bone, is controlled not by longitudinal growth, or the activity of cells at the growth plate, but rather by SOCS3 inhibitory actions in the osteocyte. In this model of high osteoblast activity, testosterone promoted trabecular coalescence while estradiol prevented it, pointing to sex steroid-dependency in the process of trabecular coalescence during formation of strong cortical bone.

Osteoblast-Activated Notch1 signaling in Hematopoietic Cells Induces Acute Myeloid leukemia. Marta Galán-Díez^{*1}, Aruna Kode¹, Sanil J Manavalan¹, Julie Teruva-Feldstein², Govind Bhagat³, Ellin Berman⁴, Stavroula Kousteni³. ¹Columbia University Medical Center, USA, ²Mount Sinai Health System, Icahn School of Medicine at Mount Sinai, USA, ³Columbia University, USA, ⁴MSKCC, USA

An activating mutation of b-catenin in osteoblasts induces acute myeloid leukemia (AML) in mice (*Ctmb1*^{CAosb} mice) through upregulation of *Jagged1* expression in the same cells. As a result, Notch signaling is activated in long term hematopoietic stem cell progenitors (LT-HSC cells). Activated β -catenin/Notch signaling was also identified in a subset of AML patients, indicating the relevance of these observations to human disease. To obtain genetic proof of this mechanism, we inactivated Notch signaling specifically in HSCs of *Ctmb1*^{CAosb} mice by inactivating either the Notch1 or the Notch2 receptor. Bone marrow cells isolated from mice lacking *Notch1* or *Notch2* in HSCs were transplanted into the liver of 2 day-old, lethally-irradiated *Ctmb1*^{CAosb} mice. Overall chimerism, 2 weeks after transplantation, reached 50%-70% in all examined tissues with 67%-80% chimerism within the LT-HSC population, the Leukemia Initiating Population in the *Ctmb1*^{CAosb} mice. Notch signaling was decreased as tested by the expression of Notch transcriptional targets. Recipients of *Notch2*-deficient hematopoietic cells had blasts and dysplastic neutrophils in their peripheral blood, their numbers ranged from 18-75% and 20-70%, respectively, within 20 days following transplantation. Transplanted mice maintained low body weight and died within 5 weeks following transplantation. In contrast, transplantation of *Ctmb1*^{CAosb} neonates with *Notch1*-deficient hematopoietic cells prevented AML development, progressively increased body weight and rescued lethality as transplanted *Ctmb1*^{CAosb} mice survived for the entire observation period of 31 weeks. To examine the leukemogenic potential of *Jagged1*/Notch signaling in human disease we co-cultured CD34+ cells isolated from healthy individuals with U2OS human osteosarcoma cells overexpressing *Jagged1*. Exposure of CD34+ cells to *Jagged1* favored myeloid lineage specification. At the same time, it induced myeloid block, an event indicating an increase in early myeloid progenitors that arrest in an undifferentiated state and usually leads to the development of myeloid blasts. Taken together, these results indicate that activation of Notch signaling in HSCs can mediate the leukemogenic signal of osteoblasts and that this event is facilitated by the Notch1 receptor. Moreover, the results suggest that, similar to mice, activation of *Jagged1*/

Notch signaling from osteoblasts to hematopoietic progenitors can induce myeloid bias and arrest in human cells.

NOTCH Signaling in Skeletal Progenitors is a Critical Determinant in Fracture Repair and Nonunion. Cuicui Wang^{*1}, Jason Inzana², Anthony Miranda³, Zhaoyang Liu², Jie Shen⁴, Regis O'Keefe⁴, Hani Awad², Matthew Hilton³. ¹Washington University in St. Louis, USA, ²University of Rochester, USA, ³Duke University, USA, ⁴Washington University in St. Louis, USA

Fracture nonunions develop in 10-20% of fractures, resulting in prolonged disability. Current data suggests that bone union during fracture repair is achieved via proliferation and differentiation of skeletal progenitors within periosteal tissues surrounding bone, while bone marrow stromal/stem cells (BMSCs) and other skeletal progenitors may also contribute. The NOTCH signaling pathway is a critical maintenance factor for BMSCs during skeletal development, although the precise role for NOTCH and the requisite nature of BMSCs following fracture is unknown. To determine whether NOTCH and/or BMSCs are required for fracture repair, we performed non-stabilized and stabilized fractures on NOTCH mutant mice with targeted gene deletion in different cell lineages, including BMSCs, committed chondrocytes, and committed osteoblasts. We demonstrate that non-stabilized tibia fractures on Prx1Cre;RBPjkf/f mutants displayed characteristics most commonly observed in human hypertrophic nonunions, while Agc1CreERT2;RBPjkf/f and Col1Cre;RBPjkf/f fractures healed normally. Although the Prx1Cre;RBPjkf/f mutants did form a substantial external callus involving periosteal progenitors, they did not develop an appropriate internal callus which ultimately resulted in fracture nonunion. Furthermore, Prx1Cre;RBPjkf/f mutants exhibited a marked reduction in the BMSC pool, indicating that BMSCs are a vital component of fracture repair that likely acts to form the internal callus providing stability to the fracture and promoting healing. Similarly, rigidly fixed femur fractures on Prx1Cre;RBPjkf/f mutants also resulted in fracture nonunion that strongly resembles those seen in atrophic nonunion patients, suggesting that insufficient stabilization is not absolutely required for fracture nonunion in these mutants. Taken together, our findings provide the first genetic evidence whereby NOTCH signaling removal specifically within skeletal progenitors results in BMSC depletion and fracture nonunion, while NOTCH removal in committed chondrocytes and maturing osteoblasts leads to no impairment in fracture healing. Our use of multiple fracture modalities has proven the requisite role for BMSCs and NOTCH signaling within BMSCs during fracture repair, irrespective of fracture stability and vascularization. Finally, this work strongly supports the concept that different skeletal progenitor populations contribute to the fracture repair process in unique ways.

Transplanted Hematopoietic Stem Cells form Functional Osteoblasts that Deposit Collagen and Repair Bone in a Mouse Model of Osteogenesis Imperfecta. Yongren Wu¹, Hai Yao¹, Makio Ogawa¹, Amanda LaRue², Meenal Mehrotra^{*3}. ¹Medical University of South Carolina, USA, ²Medical University of South Carolina, Ralph H Johnson VAMC, USA, ³Medical University of South Carolina & Research Services, Ralph H Johnson VAMC, USA

Osteogenesis imperfecta (OI), an autosomal dominant disorder caused by mutation in one of the two genes that encode type I collagen, is the most common hereditary bone disease. At present there is no cure for OI. One of many strategies that are being tested experimentally involves stem cells. Previously we have shown that transplantation of bone marrow (BM) cells highly enriched for hematopoietic stem cells (HSCs) can ameliorate bone defects seen in OI mice. We have also demonstrated that HSCs give rise to osteoblasts during normal bone turnover as well as non-stabilized fracture repair. Therefore, we hypothesized that HSC transplantation will lead to replacement of affected osteoblasts with normal cells leading to correction of collagen defects and preventing OI pathologies. Thus, transplantation of a clonal population derived from a single EGFP⁺ HSC into irradiated OI mice (*oim*; B6C3F₁ *ala-Coll1a2^{oim}*) was used to test our hypothesis. Dramatic improvements were observed on micro-CT analysis of tibia including increase in bone volume, trabecular number and trabecular thickness with a concomitant decrease in trabecular spacing in clonally engrafted *oim*. Analysis of control *oim* demonstrated continued deterioration in bone parameters. Mechanical testing of humerus exhibited an increase in parameters such as stiffness in clonally engrafted *oim* when compared to control *oim*, similar to that seen in normal mice. Dynamic histomorphometry showed a significant increase in mineral apposition rate in engrafted *oim* as compared to control *oim*. Paraffin sections of decalcified bones showed the presence of numerous GFP⁺ cells within bone which stained positive for osteocalcin, demonstrating that HSCs engraft in bone and differentiate to osteoblasts. Picosirius red staining of sections from clonally engrafted *oim* showed the presence of structurally improved collagen when compared to control *oim*. The collagens extracted from clonally engrafted *oim* contained a mixture of both $\alpha 1$ and $\alpha 2$ chains, similar to those from normal mice,

while those from control *oim* shown presence of only $\alpha 1$ chain. Immunofluorescent staining demonstrated that the GFP⁺ cells in bone (HSC-derived) were the ones which secreted Col1a2. These data indicate that HSC transplantation leads to clinical improvements in *oim* and that HSC-derived osteoblasts are functional. These findings are significant in that they can be applied to long-term studies to enhance and accelerate bone healing in OI.

Identification of a Distinct Progenitor Cell within Long Bones that Gives Rise to Bone Marrow Adipocytes In Vivo. Ryan Berry^{*1}, Tracy Nelson¹, Rose Webb¹, Clifford Rosen², Matthew Rodeheffer¹, Mark Horowitz¹. ¹Yale University, USA, ²Maine Medical Center Research Institute, USA

Marrow adipose tissue (MAT) was identified in the bone marrow (BM) more than a century ago but has recently been associated with age, metabolic disease and low bone volume, highlighting the importance of studying this often neglected adipose tissue depot. However, little is known about the origin, development and function of MAT, as the identity of the BM adipocyte precursor (AP) cell is unknown. We have performed lineage tracing of BM adipocytes following induction of BM adipogenesis with either rosiglitazone-enriched diet or lethal irradiation and BM reconstitution to determine the ontogeny of BM adipocytes and identity of BM AP cells. Irradiation of double fluorescent mT/mG reporter mice (which harbor a constitutively expressed membrane targeted tdTomato cassette (mT) upstream of a Cre-responsive membrane targeted eGFP cassette (mG)) followed by reconstitution with C57BL/6 (B6) BM resulted in the presence of tdTomato traced BM adipocytes, indicating that BM APs do not reside within the transplanted BM but are irradiation-resistant cells within the host bone that likely line the endosteum. Following either irradiation/reconstitution or 8 wks of rosiglitazone diet, all BM adipocytes were eGFP⁺ and therefore traced in Adiponectin-Cre:mT/mG, Prx1-Cre:mT/mG, Twist2-Cre:mT/mG and Osx1-Cre:mT/mG mice. BM adipocytes were uniformly tdTomato⁺ and therefore untraced in Vav1-Cre:mT/mG and Myf5-Cre:mT/mG mice. In contrast, using a lipid-specific dye we are unable to visualize any adipocytes in non-induced BM. Between 50-70% of BM adipocytes were eGFP⁺ in Pdgfra-Cre:mT/mG mice depending on the type of induction. Importantly, only 20-25% of BM adipocytes were eGFP⁺ in OCN-Cre:mT/mG mice regardless of the type of induction. We have shown that all adipocytes in classical WAT depots are traced in Pdgfra-Cre:mT/mG mice. We have recently discovered that white adipocytes are uniformly untraced in Osx1-Cre:mT/mG mice. Therefore the uniform tracing of BM adipocytes by the endosteal cell/osteoblast promoters Osx1, Prx1 and Twist2 coupled with the absent or non-uniform tracing of BM adipocytes by Myf5 and Pdgfra indicate that BM adipocytes compose an adipose tissue depot that is distinct from brown or white adipose tissue. Our work supports the idea of a bi-potent "mesenchymal stem cell" lining the endosteum that generates both osteoblasts and BM adipocytes, but future work will decipher if distinct sub-populations of cells give rise to adipocytes and osteoblasts in vivo.

Deletion of PTH/PTHrP Receptor in Osteoprogenitors Deregulates Local Bone Marrow Vasculature in Mice. Cristina Panaroni^{*}, Joy Wu, Joshua Johnson, Ke Yuan, Vinicio de Jesus Perez. Stanford University School of Medicine, USA

Osteogenesis and angiogenesis in skeletal tissues are coupled via paracrine factors and cell-cell interactions. Osterix-expressing (Osx) cells, here referred as osteoprogenitors, co-invade cartilage with growing vessels during endochondral bone formation. Early in mouse life, Osx cells are detected in bone tissue and bone marrow (BM) stroma adjacent to or in contact with blood vessels. Parathyroid hormone (PTH) acting through the PTH/PTH-related peptide receptor (PPR) promotes bone growth but also alters the bone marrow microenvironment by relocating blood vessels to sites of new bone formation and expanding hematopoietic and mesenchymal stem cells. Disruption of PPR in mature osteoblasts and osteocytes not only reduces trabecular bone formation but also impairs endochondral angiogenesis. We have previously reported that ablation of PPR in osteoprogenitors (Osx-PPRKO mice) results in severe osteopenia. Here we show that deletion of PPR in osteoprogenitors disrupts bone marrow vasculature in proximity to trabecular bone. In vivo fluorescent labeling of the vascular networks in Osx-PPR KO mice revealed a reduction in BM blood vessels, especially along the endosteal bone surface. Immunostaining of frozen bone sections for the endothelial marker CD31 demonstrated a reduction of CD31⁺ endothelial cells specifically along the trabeculae. To examine whether osteoprogenitors directly regulate angiogenesis, we performed an *in vitro* matrigel tube formation assay seeding endothelial cells in the presence or absence of Osx sorted cells. We found that the presence of Osx cells increased by 22% the total tube length, by 27% the total tube number, by 33% the total branching points and by 50% the total loops formed by endothelial cells. However, expression of PPR in Osx cells was not required. We therefore performed PCR array analysis of 84 genes involved in endothelial cell biology in sorted osteoprogenitors from Osx-PPR KO and control mice, and found that genes involved in vasoconstriction, coagulation, chemotactic activity and inflammatory response were significantly upregulated, whereas the expression of VEGF-A gene, the major contributor to vessel sprouting and endothelial cell proliferation, was 50% reduced in Osx-PPR KO cells. In

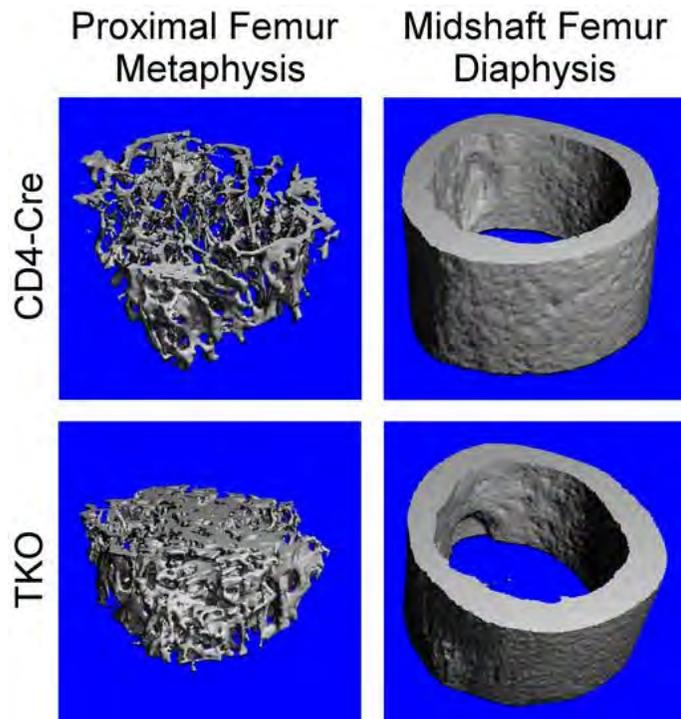

summary, these data indicate that Osterix-expressing cells actively support angiogenesis and PPR signaling in osteoprogenitors locally regulates the BM vasculature.

T-cell specific deletion of TIEG alters chemokine expression profiles and results in increased bone mass in mice. Malayannan Subramaniam^{*1}, AKM Khryul Wara², Fang Fang², Kevin Pitel¹, Mark Feinberg², John R. Hawse¹. ¹Mayo Clinic, USA, ²Harvard Medical School, USA

TGF β Inducible Early Gene-1 (TIEG) is known to play important roles in skeletal development and has been shown to be critical for optimal TGF β , BMP and estrogen signaling in bone. Recently, TIEG has been shown to play a central role in mediating CD4⁺ T-cell effector functions and in the development of T-regulatory cells through its control of TGF- β 1 signaling and FOXP3 expression. Based on these observations, as well as the known roles of the immune system in regulating bone metabolism and skeletal homeostasis, we sought to examine the effects of CD4⁺ T-cell specific deletion of TIEG on the mouse skeleton. Two-month old CD4-Cre control and T-cell specific TIEG knockout (TKO) mice were first analyzed using pQCT of the right tibia. Minimal differences were detected within the tibial metaphysis with the exception of a 10% increase in total density in TKO mice. However, substantial differences in multiple cortical parameters were detected at the tibial diaphysis as significant increases in total content (22%), total density (7%), cortical content (25%), cortical density (5%), cortical area (22%), cortical thickness (14%), periosteal circumference (9%) and endosteal circumference (5%) were observed in TKO mice relative to CD4-Cre controls. Micro-CT analysis of the femoral metaphysis revealed increased bone volume (61%), bone volume/tissue volume (50%), trabecular number (10%) and trabecular thickness (40%) with a concomitant decrease in trabecular spacing (7%) in TKO mice (see Figure). At the femoral diaphysis, increased bone volume (25%) and bone volume/tissue volume (7%) was also observed in TKO mice relative to controls (see Figure). At the cellular level, TKO CD4⁺ T-cells had increased expression of INF γ and decreased expression of RANKL and TRAF6. In response to CD3 activation, TKO CD4⁺ T-cells exhibited higher expression of INF γ , IL-2, IL-4, and IL-17 compared to controls. Since RANKL and TRAF6 are critical for osteoclastogenesis, and since INF γ and IL-4 are known to inhibit osteoclastogenesis, these data suggest that loss of TIEG expression in CD4⁺ T-cells may impair differentiation of osteoclast precursors *in vivo* leading to the observed increases in bone mass of TKO mice. These data for the first time identify TIEG as an important osteoimmunological molecule due to its ability to regulate skeletal homeostasis through the functions of CD4⁺ T-cells and provide a novel model system for further elucidating our understanding of osteoimmunology.

Conditional Disruption of *miR17~92* in Osteoclasts Results in Activation of Functional Activity of Osteoclasts and Substantial Loss of Trabecular Bone in Mice. Kin-Hing William Lau^{*1}, Virginia Stiffel¹, Matilda Sheng². ¹Jerry L. Pettis Memorial VA Medical Center, USA, ²Loma Linda University, USA

This study sought to investigate the potential regulatory role of *miR17~92* in osteoclast resorption by examining the skeletal effects of conditional disruption (cKO) of the *miR17~92* cluster in osteoclasts, which were generated by crossing *miR17~92* LoxP mice with *Ctsk*-Cre mice. The average knockdown of *miR17~92* in osteoclasts of cKO mutants was >70%. The body weight of cKO mutants and wild-type (WT) littermates was not different, but the femur length was reduced by 6%. pQCT analysis of femur reveals that cKO mutants had 28.8% decrease in Tb.BMC, 12.4% decrease in Tb.BMD, along with 6.8% increase in endosteal circumference. The low bone mass phenotype was confirmed by μ -CT analyses, which shows that cKO mutants had significantly ($p < 0.01$ for each) lower Tb.BV (\downarrow 50.2%), Tb.BV/TV (\downarrow 53.5%), Tb.Conn-Dens (\downarrow 41.6%), Tb.N (\downarrow 31.6%), Tb.Th (\downarrow 10%), Ct.BV (\downarrow 8.4%), and Ct.Th (\downarrow 5.3%), along with 37.4% increase in Tb.Sp. *In vitro*, the total number of marrow-derived osteoclasts (generated by treating osteoclast precursors with RANKL/c-MSF for 6 days) formed from cKO precursors was not greater than those derived from same number of WT precursors, while the average number of nuclei in *miR17~92* cKO osteoclasts was almost twice as many as that in WT osteoclasts. The average size of derived osteoclasts of cKO mutants was almost twice ($p < 0.05$) as large as that of WT osteoclasts. The average size of resorption pits created by cKO osteoclasts was also twice as large as those formed by WT osteoclasts ($p < 0.05$). In addition, the expression level of several genes known to be associated with osteoclast activation (*ATP6v0d2*, *Igfb3*, *Mmp9*, *OC-Stamp*, and *Oscar*), but not those genes associated with osteoclastogenesis (*Rank*, *Traf6*, *Acp5*, *Mitf*, and *Nfatc1*), was significantly ($p < 0.05$) increased in cKO osteoclasts, suggesting that disruption of *miR17~92* in osteoclasts enhances osteoclast activity and not osteoclastogenesis. The *Ctsk*-Cre-mediated disruption of *miR17~92* did not have discernible effect on the growth plate. There was also no significant difference in MAR or in BFR/B.Pm between cKO mice and WT littermates. The B.Pm of cKO mice was increased by 48.7%; a finding consistent with an increased bone turnover. There were also no significant differences in cellular ALP activity in osteoblasts or bone nodule forming ability of stromal cells of cKO mutants *in vitro*. In conclusion, *miR17~92* has an important regulatory function in osteoclast activity but not in osteoclastogenesis.

DNA Demethylation Ameliorates Inflammatory Bone Loss in Scurfy Mice by Modulating both Myeloid and Lymphoid lineages. Tim Chen^{*1}, Gaurav Swarnkar¹, Gabriel Mbalaviele², Yousef Abu-Amer³. ¹Department of Orthopaedic Surgery, Washington University School of Medicine, USA, ²Division of Bone & Mineral Diseases, Department of Internal Medicine, Washington University School of Medicine, USA, ³Department of Orthopaedic Surgery & Cell Biology & Physiology, Washington University in St. Louis School of Medicine, USA

Inflammatory responses contribute to the development of copious disorders including cancer and osteolysis. The interplay between inflammation and bone loss is well established. Epigenetic modulation is one of the most promising approaches for cancer therapy. Decitabine, a cancer treatment drug used for hematological malignancies, hypomethylates DNA by inhibiting DNA methyltransferases (DNMTs). Given the growing evidence of epigenetic regulation in inflammatory diseases and scarce information regarding its role in osteolysis, we tested the role of decitabine as a therapeutic agent to treat inflammatory bone diseases. We have recently reported that scurfy (*Sf*) mice, which lack Foxp3⁺ Treg cells exhibit severe osteopenia ensuing from myeloid lineage skewing, vast increase of granulocyte/macrophage progenitors (GMPs) and osteoclast (OC) precursors induced by pathogenic CD4⁺ T cell-mediated hypercytokinemia. Using *Sf* as a therapeutic model for inflammatory bone loss, we injected 16-day-old *Sf* and WT mice with decitabine or PBS. After 2 weeks, inflammatory indices were dramatically reduced in treated mice evident by weight gain, lack of dermatitis and skin ulcers. Mice were then sacrificed for *ex vivo* osteoclastogenesis, μ CT and FACS analysis for hematopoietic progenitors and lineage cells. Interestingly, not only *in vivo* decitabine treatment greatly inhibited the OC potential of unfractionated bone marrow cells, this inhibitory effect appeared to be more profound for *Sf* derived cells. FACS analysis revealed significant reduction of the frequency of GMPs and OC precursors in decitabine-treated *Sf* mice. More intriguingly, the frequencies of both CD4⁺ helper and CD8⁺ cytotoxic T cells were both greatly increased in the bone marrow and spleen of decitabine-treated *Sf*, implying that decitabine not only affected the myeloid but also the lymphoid lineage. Indeed, direct treatment with decitabine inhibited hyper-osteoclastogenesis of *Sf* bone marrow cell culture in a dose dependent manner (0.4-10 nM). Co-culture of CD4⁺T cells and bone marrow macrophages showed CD4⁺T cells derived from decitabine-treated *Sf* lost their osteoclastogenic activity compared to CD4⁺T cells from PBS treated *Sf* mice. μ CT analysis also revealed increased bone mass in decitabine treated *Sf* mice compared to PBS treated *Sf* controls. Taken together, our data unraveled the

potential for targeting epigenetic pathways as ways to treat inflammatory bone loss similar to hematological malignancies.

Osteolytic Macrophages in Inflammatory Bone Resorption of Cherubism Mice Lacking c-Fos. Mizuho Kittaka*, Joshua Prather, Tomoyuki Mukai, Teruhito Yoshitaka, Yasuyoshi Ueki. University of Missouri-Kansas City School of Dentistry, USA

TRAP-positive (+) multinucleated osteoclasts are regarded as the exclusive bone-resorbing cells in pathological inflammatory bone resorption. This consensus is based on observations that bone destruction is absent in osteoclast-free animal models of inflammatory bone disease such as TNF- α transgenic mice deficient in c-Fos. Therefore, we hypothesized that ablation of osteoclasts would rescue the inflammatory bone destruction in *Sh3bp2^{KIKI}* mice, a knock-in (KI) mouse model of cherubism (*Sh3bp2^{KI}*). These mice exhibit TNF- α -dependent macrophage inflammation and increased RANKL-induced osteoclastogenesis resulting in inflammatory bone destruction. To test this hypothesis, we created *Sh3bp2^{KIKI}* mice on a c-Fos-deficient background. Surprisingly, although less severe than on a c-Fos^{+/+} background, the bone erosion was still present in *Sh3bp2^{KIKI}/c-fos^{-/-}* mice by micro-CT analysis. This bone erosion occurred even though no TRAP+ cells were detected in *Sh3bp2^{KIKI}/c-fos^{-/-}* mice. H&E staining showed inflammatory infiltrates surrounding joints and on the surface of long bones in *Sh3bp2^{KIKI}/c-fos^{-/-}* mice, presumably responsible for the bone erosion. Elevation of serum TNF- α levels and inflammatory infiltrates in liver, stomach, and lymph nodes were observed. Gene expression levels of *Mmp-9*, *-12*, and *-14* were increased in inflamed joints of *Sh3bp2^{KIKI}/c-fos^{-/-}* mice compared to *Sh3bp2^{+/+}/c-fos^{-/-}* mice, while *cathepsin K* expression was comparable. Tissue staining with antibodies against CD68 and MMP-9 showed that the cellular infiltrates at the eroded bone surfaces were positive for both. Levels of serum ICTP, a marker for bone resorption by MMPs, were elevated in *Sh3bp2^{KIKI}/c-fos^{-/-}* compared to *Sh3bp2^{+/+}/c-fos^{-/-}* mice, while serum CTX levels, another marker by cathepsin K, were not significantly increased. To test if bone erosion is observed in a different osteoclast-deficient model, *Sh3bp2^{KIKI}* mice on a *Rankl^{-/-}* background were created. The *Sh3bp2^{KIKI}/Rankl^{-/-}* mice showed bone erosion, but which was less severe than *Sh3bp2^{KIKI}/c-fos^{-/-}* mice. These results suggest that macrophages that express MMPs carry out the bone erosion in *Sh3bp2^{KIKI}/c-fos^{-/-}* mice with a mechanism that is independent of TRAP+ osteoclasts. Our data further suggest that gain-of-function of SH3BP2 and loss-of-function of c-Fos are required for the development of osteolytic macrophages that play a critical role in this unique mechanism of inflammatory bone resorption.

A role for V-ATPase V0 domain subunit *el* in bone homeostasis. Tak Cheng*¹, Hua Ying¹, An Qin², Nathan Pavlos¹, Euphemia Landao¹, Qing Jiang³, Kerong Dai², Ming-Hao Zheng¹. ¹Centre for Orthopaedic Research, School of Surgery, The University of Western Australia, Australia, ²Shanghai Key Laboratory of Orthopaedic Implant, Department of Orthopaedics, Shanghai Jiao Tong University School of Medicine, China, ³Australian-China Joint Centre for Bone & Joint Disease, Nanjing University, China

Vacuolar-type H⁺-ATPases (V-ATPases) proton pumps function to acidify a diverse range of intracellular organelles required to sustain cellular homeostasis. In osteoclasts (OCs), V-ATPases are uniquely enriched on the surface of the ruffled border membrane where they serve to acidify the underlying extracellular milieu, a prerequisite for bone resorption. The mammalian V-ATPase complex is composed of at least 14 subunits (organized into two functionally and structurally distinct domains, the cytoplasmic V1 and the membrane-embedded V0), of which the hydrophobic V0 domain *e* subunit(s) (i.e. *el* and *e2* paralogs) remain poorly characterized. Here, using the Cre-LoxP system, we demonstrate that *el* is the major functional isoform expressed in OCs. Whereas mice with conditional knockout (cKO) of the *e2* isoform in either mature OCs (Cathepsin K (CtsK^{Cts}) or OC precursors (RANK^{Cts}) have normal bone mass, conditional deletion of the *el* counterpart results in severe OC-rich osteopetrosis (CtsK^{Cts}-*el* cKO mice; designated *el*^{DOC} herein) and/or embryonic lethality (RANK^{Cts}-*el* cKO), respectively. Histomorphometric assessment revealed that the marrow spaces of femurs from *el*^{DOC} mice were completely occluded by unresorbed bone. Consistently, deletion of *el* significantly impaired the bone resorptive function of OCs derived from *el*^{DOC} spleen cells, but did not alter overall OC differentiation. Mechanistically, this impairment is due to a disruption in extracellular and intracellular acidification as evidenced by live cell confocal microscopy and *in vitro* acidification assays. Interestingly, loss of *el* resulted in destabilization of the V-ATPase complex with reduced expression of V0 $\alpha 3$ subunit and uncoupling of V1 and V0 domain assembly. This disruption was further confirmed by Bioluminescence Resonance Energy Transfer (BRET) proximity assays which found that the integrity of the V0 domain was compromised due to reduced association between critical V0 subunits. Collectively, our data indicate that the V-ATPase V0 domain *el* subunit is an integral component of the OC acidification machinery.

Disclosures: Tak Cheng, None.

Deletion of Plekhm1 in mice increases bone mass by attenuating osteoclast lysosome secretion and bone resorption. Toshifumi Fujiwara*¹, Shiqiao Ye¹, Takashi Nakamura², Stavros C Manolagas¹, Haibo Zhao³. ¹Center for Osteoporosis & Metabolic Bone Diseases, Division of Endocrinology & Metabolism, Department of Internal Medicine, University of Arkansas for Medical Sciences & the Central Arkansas Veterans Healthcare System, USA, ²Department of Biochemistry & Integrative Medical Biology, School of Medicine, Keio University, Japan, ³Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA

Mutations of Plekhm1 (Plk1), a lysosome adaptor protein, cause osteopetrosis in humans and incisor-absent (ia) rats, due to impaired lysosome trafficking and ruffled border (RB) formation in osteoclasts (OCs). To elucidate the mechanism(s) by which Plk1 regulates lysosomal secretion we generated mice with global deletion of Plk1 in C57BL/6J mice, by crossing Plk1-floxed mice with Hypoxanthine guanine phosphoribosyl transferase (HPRT)-Cre (Plk1;HPRT); as well as mice with OC-specific Plk1 deletion using LysM-Cre (Plk1;LysM), or Cathepsin K (CTSK)-Cre (Plk1;CTSK). All three models had normal tooth eruption and bone development as well as normal osteoblast differentiation and bone formation. Plk1;LysM mice displayed a transient and mild increase in trabecular bone mass (BV/TV), but only in females. Both female and male Plk1;CTSK and Plk1;HPRT, on the other hand, had over a 30% increase in BV/TV at 2-month and 5-month of age as compared to their littermate controls, measured by micro-CT and histomorphometry. OC generation from Plk1 null bone marrow macrophages was indistinguishable from controls. Similarly, actin-ring formation and microtubule organization were normal in Plk1 null OCs. However, the resorptive capacity of Plk1 null OCs was markedly reduced. Specifically, a series of morphological, functional, and live cell imaging studies revealed that loss of Plk1 caused an accumulation of enlarged lysosomes around the nuclei and loss of OC RB. Yet, the biogenesis and lytic functions of lysosomes and the formation of autophagosomes in OCs were unaffected. Using immunoprecipitation (IP) and mass spectrometry we identified several novel Plk1 interacting proteins in OCs, including Def8, Fam98a, and Ndel1. These interactions were confirmed by co-IPs in 293T cells. Further, we determined that Def8 bound to the C-terminal part of Plk1 and this promoted Plk1's interaction with Rab7, a lysosome-associated small GTPase. Fam98a and Ndel1, both of which regulate vesicular trafficking on microtubules, interacted with N-terminal of Plk1. More importantly, knocking down the expression of these genes in OCs by shRNAs dramatically inhibited lysosome secretion and bone resorption. These results demonstrate that Plk1 is indispensable for bone homeostasis in mice as is the case in rats and humans. Furthermore, our work has uncovered a molecular apparatus linking lysosomes to microtubules through Plk1-Rab7 for lysosome transportation/secretion and bone resorption in osteoclasts.

Actin cytoskeleton regulators Nck1 and Nck2 are required for supporting osteoblastic migration, bone formation and bone mass under the control of IGF-1 and for suppressing osteoclastic bone loss. Smriti Aryal A.C*¹, Yoichi Ezura¹, Yayoi Izu¹, Masaki Noda¹. Department of molecular pharmacology, Tokyo medical & dental university, Japan

Nck are actin cytoskeleton regulators. Mammals carry 2 Nck genes Nck1 & Nck2 (collectively termed Nck). To elucidate Nck actions in bone cells, mice carrying floxed Nck2 & Nck1-/- were crossed to transgenic mice expressing cre recombinase under the control of 2.3kb type I collagen (osteoblast specific) & Cathepsin K (osteoclast specific) promoters. Our data showed that osteoblast specific Nck-dKO (Ob-Nck-dKO) bone showed significant reduction in trabecular BV/TV & number resulting in osteoporosis. Bone histomorphometry showed significant reduction in mineral apposition rate, bone formation rate, mineralized surface per bone surface, osteoblast number & surface along with alteration in osteoblast shape in Ob-Nck-dKO bone compared to Ct. qRT-PCR showed significant reduction in osteoblast genes in Ob-Nck-dKO bone. *In vitro* migration, mineralized nodule formation & shape of Ob-Nck-dKO primary osteoblast were significantly altered. Furthermore, Nck1 overexpressing osteoblast showed increase in migration & motility. Bodian staining of Ob-Nck-dKO cortical bone showed significant reduction of the osteocyte processes. To examine *in vivo* effects of Nck on bone formation & osteoblast spreading, bone marrow ablation (BMA) & calvaria defect experiments were conducted. 3D μ CT after 1 week of BMA showed significant reduction of BV/TV in Ob-Nck-dKO bone compared to Ct. To examine osteoblast spreading, 2 calvaria defects were made on the parietal bone of wild type mice, defects were then implanted with Dil labelled Ct & Nck.dKO cell pellets, after 1 week BV/TV & spreading of defect with Nck.dKO cells were significantly reduced compared to Ct cells. To know the mechanism for Nck induced osteoblast migration, migration assay using Ct & Nck.dKO cells towards IGF-1 was done, which showed significant suppression of Nck.dKO osteoblast migration towards IGF-1. Co-immunoprecipitation showed binding of Nck to IRS-1 in osteoblast after IGF-1 stimulation, suggesting that IGF-1R couple IRS-1 to Nck and mediates the signaling required for osteoblast migration. Moreover, 3D μ CT of osteoclast specific Nck-dKO (Oc-Nck-dKO) bone showed significant reduction in trabecular BV/TV, number & separation compared to Ct. Oc-Nck-dKO bone showed significant increase in osteoclast genes & reduction in serum & urinary calcium levels

compared to Ct. Taken together, our data shows that Nck are required for supporting osteoblast migration, bone mass under IGF-1 stimulation & for suppressing osteoclast bone loss.

Heritability and Genetic Correlations for Bone Microarchitecture: The Framingham Study Families. David Karasik^{*1}, Yanhua Zhou², Mary L. Bouxsein³, Kerry E. Broe⁴, L. Adrienne Cupples², Serkalem Demissie², Douglas P. Kiel⁵. ¹Hebrew SeniorLife; Bar Ilan University, USA, ²Biostatistics, BU School of Public Health, USA, ³BIDMC, USA, ⁴Institute for Aging Research, HSL, USA, ⁵HSL, USA

Genetic factors contribute to the risk of long bone fractures; however, there is no data on whether the genetic variance captured by volumetric bone mineral density (vBMD) and bone microarchitecture measured with advanced imaging is above and beyond that for conventional areal bone mineral density (aBMD). This study aimed to estimate the heritability (h^2) of bone cortical and trabecular microstructure indices, measured by high-resolution peripheral quantitative computed tomography (HRpQCT) and the extent to which they share genetic regulation with femoral neck aBMD measured by DXA. Bone microarchitecture was measured by HR-pQCT (Scanco Medical, AG) at the distal tibia (n=1,059) and distal radius (n=1,022) in adults of European ancestry from the Offspring Cohort of the Framingham Heart Study. Femoral neck (FN) aBMD was measured by DXA (Lunar DPX-L). Heritability estimates (h^2) were calculated, adjusting for covariates (age, sex, and menopause (in women)) and bivariate genetic correlation analysis was performed, using a variance components model.

Estimates of h^2 adjusted for covariates ranged from 0.533 (cortical porosity) to 1.0 (total cross-sectional area, CSA) in the tibia, and from 0.207 (trabecular number) to 0.926 (cortical porosity) in the radius. Additional adjustment for FN BMD had no major effect on h^2 estimates (Table 1). In bivariate analysis, there was a high genetic correlation between multivariable-adjusted cortical vBMD at the tibia and radius (RhoG=0.960), while correlations between cortical vBMD and FN aBMD were much lower (RhoG=0.389 and 0.352, at the tibia and radius, respectively). Environmental correlations (RhoE) were negligible (Table 2).

Here we report data from extended families from population-based cohort, men and women. Our study suggests that, in adults of European ancestry, bone microarchitecture indices are heritable. Moreover, high RhoG between vBMD of the radius and tibia suggests that there is common genetics that governs vBMD regardless of the specific long bone; lower genetic correlation between cortical vBMD of the radius and tibia and aBMD of the hip might suggest that there are unique factors for peripheral cortical vBMD that are not captured by aBMD. These results point toward importance of further work to identify the specific variants underlying genetic susceptibility to long bones fracture, bone density and structure.

TABLE 1: Heritability of Bone Microarchitecture before and after adjustment for FN BMD

| Trait | Radius | | Tibia | |
|--------------------------------------|-------------|---------------------|-------------|---------------------|

Whole-genome sequencing and deep imputation identifies non-coding variants near *EN1* with large effects on bone mineral density. Vince Forgetta^{*}, Brent Richards. McGill University, Canada

Presented by Vincenzo Forgetta on behalf of the UK10K and GEFOS.seq Consortia.

The extent to which low-frequency (minor allele frequency [MAF] between 1-5%) and rare (MAF $\leq 1\%$) variants contribute to medically relevant complex traits in the general population is largely unknown. Bone mineral density (BMD), a highly heritable trait and a major predictor of osteoporotic fractures. While dozens of common genetic variants have been found to be associated with BMD, only one rare population-specific coding variant has been identified to date. To identify non-common variants in the general population associated with BMD, we performed a large-scale meta-analysis derived from whole-genome sequencing from the UK10K consortium (n=2,882), whole-exome sequencing (n= 3,549), deep imputation of genotyped samples using a combined UK10K/1000Genomes reference panel (n=26,534), and *de-novo* replication genotyping (n= 20,271) in 27 population-based

cohorts of European ancestry (n_{total} = 53,236). We identified a low-frequency novel non-coding variant near *EN1* with an effect size that is 4-fold larger than that of the mean of previously reported common variants for lumbar spine BMD (rs11692564[T], MAF = 1.7%, replication effect size = +0.20 standard deviations [SD], $P_{meta} = 1.7 \times 10^{-14}$). Upon combined discovery and replication meta-analysis, three additional novel non-coding variants encompassing *EN1*, two being of low-frequency, also achieved genome-wide significance ($P < 1.2 \times 10^{-8}$) for lumbar spine or femoral neck BMD. Meta-analysis of 29,103 cases and 311,229 controls found 3 of 4 variants to be strongly associated with decrease risk of fracture, including the lead variant rs11692564[T] (OR = 0.83 [95% CI: 0.76-0.91] $P = 4.7 \times 10^{-5}$). Using an *En1*^{Crefllox} mouse model, we observed that conditional loss of *En1* results in low bone mass, likely as a consequence of high bone turn-over. We also identified a novel low-frequency non-coding variant with an effect on forearm BMD which is 2.2-fold larger than that of any previously reported common variants near *CPED1* and *WNT16* (rs148771817[T], MAF = 1.1%, replication effect size = +0.39 SD, $P_{meta} = 1.1 \times 10^{-11}$). All identified low-frequency variants were not present in the HapMap reference panel, illustrating the utility of using larger whole genome sequencing-based reference panels for deep imputation of rare and low-frequency genetic variants. Lastly, a comprehensive analysis also revealed enrichment in genetic associations with BMD for functional variants, as measured by evolutionary constraint or their deleterious effect on protein coding genes. These findings provide evidence that low-frequency non-coding variants have large effects on BMD in the general population, thereby providing rationale for whole-genome sequencing-based approaches to study the genetic architecture of complex medically-relevant traits in the general population.

Femoral Neck BMD is the Preferred Site in the Assessment of Hip Fracture in Elderly Men. (10 Year Follow Up of MrOs Sweden). Helena Johansson^{*1}, Anders Odén², Magnus Karlsson³, Mattias Lorentzon⁴, Björn Rosengren³, Östen Ljunggren⁵, Claes Ohlsson⁴, Nicholas Harvey⁶, Eugene McCloskey⁷, John Kanis⁷, Dan Mellström⁴. ¹Centre for Metabolic Bone Diseases, University of Sheffield Medical School, Sweden, ²Centre for Bone & Arthritis Research (CBAR), Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, UK; Sweden, ³Clinical & Molecular Osteoporosis Research Unit, Department of Clinical Sciences, Lund University & Department of Orthopedics, Skane University Hospital, Malmö, Sweden, Sweden, ⁴Centre for Bone & Arthritis Research (CBAR), Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, Sweden, ⁵Department of Medical Sciences, University of Uppsala, Uppsala, Sweden, Sweden, ⁶MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, UK; NIHR Southampton Biomedical Research Centre, University of Southampton & University Hospital Southampton NHS Foundation Trust, Tremona Road, Southampton, UK, United Kingdom, ⁷Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, UK, United Kingdom

Low bone mineral density (BMD) is a well-established risk factor for hip fracture. The aim of the present study was to determine the relative performance characteristics of total hip (TH), femoral neck (FN) and trochanteric (Tr) BMD in the prediction of all hip fractures, cervical fractures and peritrochanteric hip fracture.

We studied the relationship between baseline BMD measured by DXA (Lunar Prodigy in two centers and Hologic QDR 4500-A-Delphi in one, instruments cross-calibrated) and incident hip fracture by site among 2984 elderly men drawn from the general population and recruited to the MrOS study in Sweden. Men were followed for up to 12.2 years (average 8.6 years). An extension of Poisson regression was used to investigate the relationship between BMD and the hazard function of fracture expressed as a gradient of risk (GR=HR/SD decrease).

During follow up 198 men sustained one or more hip fractures (6.6%). 109 incident hip fractures were cervical and 85 were peritrochanteric. The performance characteristics are presented in the Table. For all hip fracture outcomes, the highest GR was provided by FN BMD and was significantly better than Tr BMD. For cervical fractures FN BMD outperformed BMD at other sites, statistically significantly so in the case of Tr BMD. For peritrochanteric fracture the GRs were similar at all BMD sites. The associations were similar when adjusted for radiographic vertebral fracture and other fractures at baseline. The GRs were stable with age and time since baseline.

Although measurements of BMD at all regions of the hip predicted incident hip fracture, femoral neck BMD appeared to perform best across all hip fracture types and thus may constitute the preferred site of measurement in elderly men.

1139

Table. GR (95% CI) for hip fracture at different sites of BMD measurement (adjusted for age)

| BMD site | Outcome hip fracture | | |
|--------------|----------------------|-------------------|------------------|
| | All | Cervical | Trochanteric |
| Total hip | 2.40 (2.05-2.80) | 1.87 (1.51-2.31) | 3.06 (2.37-3.94) |
| Femoral neck | 2.68 (2.24-3.22) | 2.28 (1.81-2.88) | 3.06 (2.33-4.01) |
| Trochanter | 2.17 (1.87-2.52)* | 1.61 (1.31-1.98)* | 2.94 (2.28-3.78) |

FRAX underestimates hip fracture risk in older men with CKD. Thomas Nickolas*¹, Stephanie Shiau¹, Kyle Nishiyama¹, Natalia Cortez¹, Elizabeth Shane¹, Maria Rodriguez-Barradas², David Rimland², Cynthia Gibert², Roger Bedimo², Amy Justice³, Julie Womack³, Michael Yin¹. ¹Columbia University, USA, ²Veterans Affairs Medical Center, USA, ³Yale University, USA

Fracture incidence rates are 4- to 14-fold greater in patients with severe chronic kidney disease (CKD, eGFR <30 mL/minute and ESRD) than in the general population. However, fracture risk screening is discouraged in patients with severe CKD despite their predisposition to fractures. This is because measurement of bone mineral density (BMD) by dual energy X-ray absorptiometry is not recommended by the Kidney Disease Improving Global Outcomes guidelines. Thus, validation of methods that predict fracture independent of BMD in patients with severe CKD is needed. The World Health Organization's FRAX[®] tool predicts 10-year risk of major osteoporotic (MOP) and hip fracture without BMD, but no studies have validated its calibration in patients with severe CKD. We hypothesized that FRAX[®] would be well calibrated to predict 10-year risk of MOP and hip fractures in patients with eGFR <30 mL/minute. We used The Veterans Aging Cohort Study Virtual Cohort (VACSVC) to compare the calibration of FRAX[®] without BMD across ranges of kidney function. VACSVC is a prospective study of HIV-infected Veterans matched with uninfected Veterans by age, sex, race/ethnicity, and geographic region. We included 13,668 men age 50-70 years with complete data in 2000 to approximate all but two factors (history of secondary osteoporosis and parental hip fracture) for modified-FRAX calculation without BMD and 10-year observational data for incident fragility fracture. Accuracy of the modified-FRAX calculation was compared by observed/estimated (O/E) ratios of fracture. eGFR was estimated by CKD-EPI formula, CKD stage was defined by National Kidney Foundation criteria, and normal kidney function was ≥60mL/min. None of the patients were on dialysis and 1.1% (N=160), 1.0% (N=142) and 7.5% (N=1031) of patients had CKD stages 5, 4 and 3 respectively (Table). For MOP fractures, calibration of the modified-FRAX was similar across CKD stages. For hip fractures, modified-FRAX underestimated risk by 10-fold for subjects with severe CKD (Stages 4 and 5). When the analysis was restricted to the 9,307 uninfected subjects, modified-FRAX underestimated hip fracture risk by 9- and 15-fold for CKD stages 4 and 5, respectively. These findings question the utility of FRAX for prediction of fragility fracture, especially at the hip in older male CKD patients. These data require validation in other CKD cohorts and support the need for the development of an accurate CKD-specific fracture prediction tool.

| Table 1 | N | Observed | Expected | O/E | 95% CI |
|------------------------------------|-------|----------|----------|-------|-------------|
| Major osteoporotic fracture | | | | | |
| CKD Stage 5 | 160 | 5 | 3.44 | 1.46 | 0.61, 3.50 |
| CKD Stage 4 | 142 | 7 | 3.94 | 1.78 | 0.85, 3.73 |
| CKD Stage 3 | 1031 | 35 | 32.53 | 1.08 | 0.77, 1.50 |
| Normal Kidney Function | 12335 | 516 | 336.66 | 1.53 | 1.41, 1.67 |
| Hip fracture | | | | | |
| CKD Stage 5 | 160 | 4 | 0.39 | 10.23 | 3.84, 27.26 |
| CKD Stage 4 | 142 | 5 | 0.47 | 10.64 | 4.43, 25.56 |
| CKD Stage 3 | 1031 | 6 | 3.70 | 1.62 | 0.73, 3.61 |
| Normal Kidney Function | 12335 | 143 | 30.79 | 4.64 | 3.94, 5.47 |

Altered trabecular microarchitecture in youth with type 1 diabetes mellitus. DEBORAH MITCHELL*, Mary Bouxsein, Madhusmita Misra. MASSACHUSETTS GENERAL HOSPITAL, USA

Type 1 diabetes (T1D) confers a significantly elevated risk of fracture which is only partially explained by low areal bone mineral density (aBMD). As microarchitecture is an important additional determinant of bone strength, the goal of this study was to investigate the degree to which microarchitecture is affected in T1D. Since the onset of T1D is typically in early childhood, we hypothesized that microarchitectural deficits would be apparent in growing children. This was a cross-sectional study of 83 girls ages 10-16 years (16 T1D and 67 controls). Subjects with T1D were at least 1 year post-onset. Microarchitecture of the distal radius (7% site) and tibia (8% site) was assessed by high-resolution peripheral quantitative computed tomography (HR-pQCT), and micro-finite element analysis was used to estimate bone strength. Mean duration of disease in T1D was 4.6 ± 2.8 years, and mean HgbA1c since onset was 8.6 ± 1.2%. The groups were well-matched for age, bone age, race, and height. Weight was higher among T1D subjects, leading to a higher BMI Z-score (0.9 ± 0.6 vs. 0.2 ± 0.9, p<0.001). Groups did not differ for serum calcium, phosphate, 25-hydroxyvitamin D, and parathyroid hormone. Z-scores for aBMD at the spine and subtalar body did not differ between groups, and these comparisons remained non-significant after adjustment for BMI Z-score. As shown in Figure 1, at the radius, T1D had higher total cross-sectional area (p=0.02 after adjustment for bone age and BMI Z-score). This difference was driven by higher trabecular area (adjusted p=0.03) while cortical thickness was non-significantly lower in T1D. As shown in Figure 2, while cortical volumetric BMD (vBMD) did not differ between groups, trabecular vBMD was lower at the tibia in T1D (adjusted p=0.04). There were no differences in trabecular number, but trabecular thickness trended lower in T1D at the tibia (adjusted p=0.07). Between-group differences in trabecular parameters at the radius were similar though not statistically significant. Cortical porosity did not differ between groups. Estimated failure load did not differ at the radius but was lower at the tibia in T1D (adjusted p=0.04). Overall, though aBMD did not differ between groups, we detected unfavorable trabecular vBMD and microarchitecture in T1D, particularly at the distal tibia. These results suggest that impaired trabecular bone contributes to the fracture risk in T1D, and that this insult occurs early in the course of the disease.

Reference Point Microindentation Supplements Existing Clinical Factors for Improved Fracture Risk Assessment at the Femoral Neck. Thomas Jenkins¹, Louise Coutts¹, Stefania D'Angelo², Douglas Dunlop³, Richard Oreffo⁴, Cyrus Cooper², Nicholas Harvey⁵, Philipp Thurner⁶. ¹Bioengineering Science Research Group, Faculty of Engineering & the Environment, University of Southampton, Southampton, UK, United Kingdom, ²MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom, ³University Hospital Southampton NHS Trust, Southampton, United Kingdom, ⁴Centre for Human Development, Stem Cells & Regeneration, Institute for Developmental Sciences, Faculty of Medicine, University of Southampton, Southampton, United Kingdom, ⁵MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, UK, United Kingdom, ⁶Vienna University of Technology, Austria

Current approaches to fracture risk assessment, combining BMD and clinical risk factors, most frequently in FRAX[®], do not incorporate any direct measure of bone biomechanical properties. A new technique, Reference Point micro-indentation (RPI), which permits such a direct assessment of bone quality, appears to discriminate patients with fragility fracture from controls through *in vivo* measurements at the tibia¹, but it is unclear how this relates to testing at the site of most clinically devastating fracture, the femoral neck.

Femoral neck samples were collected at surgery following low trauma hip fracture (n= 46; 17 male, 83 (IQR 77-87) years), and compared with 16 cadaveric femoral neck samples, free from bone disease, obtained from a tissue bank (7 male; 65 (IQR 61-74) years). RPI measures (Biodent HfcTM, ActiveLife Scientific) were compared between fracture patients and controls using Mann-Whitney U-tests, and discriminative ability using ROC analysis. A subset of fracture patients returned for DXA assessment (Hologic Discovery), and BMD values for cadaveric samples were retrieved using a phantom-calibrated micro-computed tomography device (HMX, Nikon) in radiography mode.

The RPI measured Total Indentation Depth (TID) was higher in femoral neck samples from osteoporotic fracture patients (131.3 µm) than that of cadaveric controls (105.9 µm) p < 0.001. This difference persisted with adjustment for age, sex, BMI and height (p < 0.001). TID demonstrated good discrimination between fracture and controls using ROC analysis (AUC = 0.89). RPI appeared to measure a property distinct from existing clinical factors with low correlation between TID and each of FRAX probability (r = 0.31, p = 0.026, n = 53), and BMD (r = -0.32, p = 0.063, n = 35). The clinical thresholds for FRAX and BMD did not identify the majority of individuals in the fracture group (60% to 86%), and yet, in this subset the ROC values are still high for TID (AUC = 0.88 to 0.93) showing potential to supplement current techniques, together having a sensitivity up to 100% (for an 80% specificity). Alternatively, summation of normalised TID to normalised BMD or FRAX probability also resulted in an improved AUC (0.95 To 0.99).

In conclusion, the RPI technique at the femoral neck discriminated fracture cases from controls independent of BMD and traditional risk factors. The approach, in its clinical form, may therefore usefully add to risk assessment, and requires testing in prospective cohorts.

Bisphosphonates reduce fracture risk in postmenopausal women with diabetes: Results from FIT and HORIZON trials. Ann Schwartz^{*1}, Eric Vittinghoff¹, Douglas C. Bauer¹, Steven R. Cummings², Andrew Grey³, Michael R. McClung⁴, Nicola Napoli⁵, Ian R. Reid³, Anne L. Schafer¹, Robert B. Wallace⁶, Dennis M. Black¹. ¹University of California, San Francisco, USA, ²California Pacific Medical Center, USA, ³University of Auckland, New Zealand, ⁴Oregon Osteoporosis Center, USA, ⁵Universita Campus Bio-Medico di Roma, Italy, ⁶University of Iowa, USA

Type 2 diabetes is associated with increased fracture risk but also with higher bone density, reduced bone formation, and higher levels of advanced glycation end-products. There is concern that the anti-fracture efficacy of bisphosphonate therapy may be reduced in diabetic patients. To test this hypothesis, we performed a post hoc subgroup analysis of combined individual-level data from two randomized placebo-controlled trials, the Fracture Intervention Trial (FIT) of alendronate (ALN) and the Health Outcomes and Reduced Incidence with Zoledronic Acid (ZOL) Once Yearly-Pivotal Fracture Trial (HORIZON-PFT). Baseline diabetes (DM) was identified from self-report, DM medication use, or an elevated fasting glucose (≥ 126 mg/dl) or non-fasting glucose (> 200 mg/dl). Incident non-vertebral fractures were centrally adjudicated. Morphometric vertebral fractures were ascertained from spine x-rays at annual visits. For clinical fracture, Cox models were used to estimate treatment efficacy in DM and non-DM women, with stratification of the baseline hazard by trial and diabetes status. For morphometric vertebral fractures, logistic regression was used, with DM status and trial as covariates. In FIT 6,459 postmenopausal women

with femoral neck (FN) T-score ≤ -1.6 received daily ALN (5-10 mg) or placebo (PBO) for up to 4 years. DM status could not be determined for 38 participants who were excluded from these analyses. In HORIZON-PFT 7,736 postmenopausal women with osteoporosis based on FN T-score and/or baseline vertebral fracture received a once-yearly infusion of ZOL (5 mg) or PBO for up to 3 years. At baseline in FIT and HORIZON-PFT, respectively, mean age was 68 and 73 years and mean BMI was 25.1 and 25.3 kg/m². There were 87 of 869 DM and 1,411 of 13,288 non-DM women with ≥ 1 non-vertebral fracture. There were 44 of 769 DM and 786 of 12,312 non-DM women with ≥ 1 morphometric vertebral fracture. Compared with placebo, treatment reduced risk of non-vertebral and morphometric vertebral fractures in DM and non-DM women (figure). In DM, relative risk of non-vertebral fracture was 0.52 (95% CI 0.33-0.80) and of morphometric vertebral fracture was 0.34 (95% CI 0.18-0.67), comparing bisphosphonate treatment with placebo. This post hoc analysis of randomized trial data indicates that, among postmenopausal women with low bone density and/or prevalent vertebral fracture, bisphosphonates reduce fracture incidence in those with diabetes.

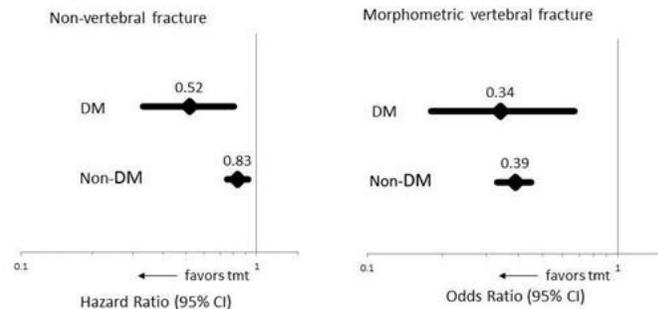

Figure. Relative risk of fracture, comparing bisphosphonates with placebo, in DM and non-DM women

Abaloparatide (ABL) is an osteoanabolic analog of PTHrP being developed for the treatment of postmenopausal osteoporosis (PMO). The ACTIVE trial was a double-blind, placebo-controlled (PBO) Phase 3 fracture prevention trial in which 2463 women with PMO were randomized to receive 18-months of daily subcutaneous administration of ABL 80 µg, PBO, or teriparatide (TPTD) 20 µg. All patients received calcium and vitamin D supplements. As has been previously reported, treatment with ABL significantly reduced the incidence of new vertebral, non-vertebral and clinical fractures while significantly increasing bone mineral density (BMD) in the lumbar spine (LS), total hip (TH) and femoral neck (FN) (Miller, ENDO 2015, Miller, ECTS 2015). In addition, more subjects treated with ABL experienced BMD increases in LS, TH and FN when compared to those treated with PBO or TPTD. In the ACTIVEExtend trial, subjects enrolled in the ACTIVE trial, who completed 18 months of treatment with either ABL or PBO, and who were deemed eligible were offered up to 24 additional months of treatment with alendronate (ALEN) at a dose of 70 mg per week. The objectives of the ACTIVEExtend trial are to assess the vertebral and non-vertebral fracture rate, BMD change, and safety associated with 6 months of treatment with ALEN following 18 months of treatment with ABL. Additional endpoints are to provide information on fracture rate, BMD change and safety after 24 months of ALEN treatment following treatment with ABL. 91% of eligible subjects from the ACTIVE trial (N=1139) were enrolled, and will undergo clinical fracture assessment, BMD, bone marker, and safety evaluations every 6 months for 24 months, as well as vertebral fracture assessments at months

6 and 24. All subjects will have completed their first six months of treatment; and the rates of vertebral and clinical fractures, changes in BMD, and safety results will be presented.

Romozosumab Improves Strength at the Lumbar Spine and Hip in Postmenopausal Women With Low Bone Mass Compared With Teriparatide.

TM Keaveny¹, DB Crittenden², MA Bolognese³, HK Genant⁴, K Engelke⁵, B Oliveri⁶, JP Brown⁷, BL Langdahl⁸, YC Yang², A Grauer², C Libanati⁹. ¹UC Berkeley, Berkeley & O.N. Diagnostics, USA, ²Amgen Inc., USA, ³The Bethesda Health Research Center, USA, ⁴UCSF & Synarc Inc., USA, ⁵Synarc Germany, Germany, ⁶Hospital de Clínicas, INIGEM, Argentina, ⁷Laval University & CHU de Québec (CHUL) Research Centre, Canada, ⁸Aarhus University Hospital, Denmark, ⁹UCB Pharma, Belgium

Purpose

Romozosumab is a bone-forming agent that inhibits sclerostin. In a phase 2 study (NCT00896532), 12 months of romozosumab increased DXA BMD in postmenopausal women with low bone mass (McClung *NEJM* 2014). A subset of these women underwent spine and hip quantitative computed tomography (QCT) imaging, confirming the BMD gains (romozosumab vs teriparatide integral volumetric BMD gains of 17.7% vs 12.9% at the spine and 4.1% vs 1.2% at the hip). To investigate the effects of romozosumab on bone strength, we performed a finite element analysis (FEA) on these QCT scans.

Methods

This international randomized study enrolled postmenopausal women with lumbar spine, total hip, or femoral neck T-scores ≤ -2.0 and ≥ -3.5 . In this analysis, subjects received blinded subcutaneous romozosumab 210 mg monthly, placebo, or open-label teriparatide (20 mcg daily). QCT scans were performed at the L1 & L2 lumbar vertebrae and proximal femur at baseline and month 12. Subject-specific vertebral strength for a simulated compression overload and femoral strength for a simulated sideways fall was estimated blinded-to-treatment using an FDA-approved non-linear 3D FEA (VirtuOst, O.N. Diagnostics). Whole-bone and compartment strength changes were estimated. The “cortical” compartment was defined as all bone within 2 mm and 3 mm of the periosteal surface for the spine and hip, respectively, plus any high-density bone (>1.0 g/cm³ of apparent density); the trabecular compartment was defined as all other bone.

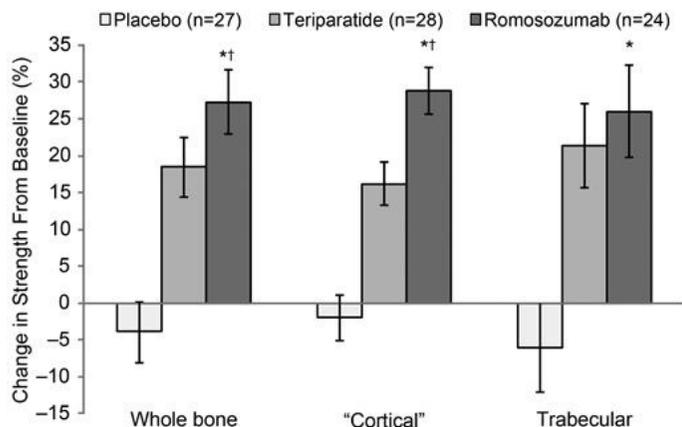

Results

At the spine, romozosumab increased strength from baseline by 27.3% at month 12, which was substantially higher than placebo (-3.9%) and teriparatide (18.5%; Figure A). This strengthening effect was due to contributions from both the “cortical” and trabecular compartments. At the hip, despite a small sample size for the romozosumab group, strength increased compared with baseline for romozosumab (3.6%), but did not change for placebo or teriparatide (Figure B). Again, both “cortical” and trabecular compartment changes contributed to the overall strengthening observed with romozosumab.

Conclusions

Romozosumab increased strength at the spine and hip over 12 months, with strength improving in the “cortical” and trabecular compartments at both sites. These strength improvements, documented using a validated method for assessing fracture risk and monitoring treatment, confirm and extend existing data and support romozosumab evaluation in the ongoing phase 3 clinical program.

Background/Purpose: Odanacatib (ODN), a selective oral inhibitor of cathepsin K, is in development for the treatment of osteoporosis. In the Phase 3, Long-Term Odanacatib Fracture Trial (LOFT; NCT00529373) of postmenopausal women with osteoporosis, ODN significantly reduced fracture risk and led to progressive increases in BMD at the lumbar spine (LS) and total hip (TH) compared to placebo. The incidence of adverse events (AEs) and serious AEs has been previously presented. Major cardiovascular events overall were generally balanced but there were numerically more adjudicated strokes in the ODN group. Final blinded adjudication of all major cardiovascular events is ongoing. Pre-specified subgroup analyses evaluated the efficacy of ODN in different patient subgroups.

Methods: Women aged ≥ 65 years without a baseline radiographic vertebral fracture (VFX) and a TH or femoral neck (FN) BMD T-score between -2.5 and -4.0 or with a prior VFX and a TH or FN T-score between -1.5 and -4.0 were randomized (1:1) to ODN 50 mg/week or placebo. All patients received vitamin D₃ (5600 IU/week) and calcium as required to achieve ~ 1200 mg/day. Treatment effects on the primary endpoints (new and worsening morphometric vertebral, incident hip, and non-VFX) were investigated in subgroups of patients, including baseline age, race, intolerance to bisphosphonates, prior radiographic VFX, and baseline BMD.

Results: 16,713 women were randomized (16,071 included in analyses) at 387 centers in 40 countries. Baseline mean age was 72.8 years, 57% Caucasian, 46.5% with prior VFX. Mean BMD T-scores were: LS -2.7, TH -2.4, and FN -2.7. The risk reduction of ODN vs. placebo for primary fracture endpoints was generally consistent across all subgroups. For morphometric VFX, the relative risk reductions (RRR) for participants with or without a prior VFX were 51% and 60%, respectively; for age groups < 70 and ≥ 70 years, the RRRs were 57% and 53%, respectively (Table). RRR for morphometric VFX based on baseline LS BMD T-score tertiles (≥ -2.22 ; $-3.25 <$ to < -2.22 ; ≤ -3.25) were 54%, 47% and 58%, respectively. In bisphosphonate-intolerant patients, the RRR for morphometric VFX, hip and non-VFX were 52%, 48% and 17% respectively consistent with the overall study population.

Conclusion: In postmenopausal women with osteoporosis, the effect of ODN vs. placebo was generally consistent among various predefined subgroups in reducing the risk of new and worsening morphometric vertebral, hip and non-VFX.

Hip BMD by DXA Can Reliably Estimate Reduction in Hip Risk in Osteoporosis Trials: A Meta-Regression. Dennis M. Black*¹, Eric Vittinghoff¹, Richard Eastell², Mary Bouxsein³, Charles McCulloch¹, Peggy M. Cawthon⁴, Steven R. Cummings⁵, Stephanie L. Harrison⁵, Anne de Papp⁶, Victor Dishy⁷, Andreas Grauer⁸, Ursula Klause⁹, Bruce H. Mitlak¹⁰, Bruce Schneider¹¹, Sanya Fanous-Whitaker¹², Jeff Zachwieja¹³, Chiyuan A. Zhang¹, Douglas C. Bauer¹. ¹University of California, San Francisco, USA, ²University of Sheffield, United Kingdom, ³Harvard University, USA, ⁴San Francisco Coordinating Center; California Pacific Medical Center, USA, ⁵San Francisco Coordinating Center, California Pacific Medical Center, USA, ⁶Merck & Co., Inc., USA, ⁷Daichi Sankyo, Inc., USA, ⁸Amgen Inc., USA, ⁹Roche Diagnostics Corporation, Indianapolis, USA, ¹⁰Eli Lilly & Co., USA, ¹¹Food & Drug Administration, USA, ¹²Foundation for the National Institutes of Health, USA, ¹³Dairy Research Institute, USA

Hip fractures (hip fx) are the most serious consequence of osteoporosis, and it is therefore critically important to develop new agents that can reduce hip fx risk. However, due to the relatively low rate of hip fx, randomized trials have become large and prohibitively expensive. To facilitate future drug development, it would be valuable to have a surrogate measure that could be used to design more efficient RCTs. The potential value of changes in DXA BMD to predict fracture reductions was studied in 2 meta-regressions (2002), one for spine and the other for non-vertebral fractures (NVFx). However, since 2002, new trials with >45,000 additional subjects and adding data for 5 new drugs (Zoledronate, Denosumab, Lasofoxifene, Basedoxifene and Tibolone) have been published. Moreover, no studies have addressed the relationship between BMD changes and hip fx reduction.

We performed a study-level meta-regression to examine the relationship between change in total hip BMD and fracture reductions including aany osteoporosis treatment trials published through March, 2015. We searched the literature for placebo-controlled trials of anti-resorptive or anabolic drugs in which hip fx and NVFx were adjudicated and change in BMD was measured in osteoporotic women. Trials with <5 hip fx were excluded. We modeled the relationship between estimates of the effect of treatment on change in BMD (active-placebo % difference at study end) and log of relative risk of hip fx and NVFx using linear models weighted by study size. We identified 14 trials including about 73,000 women for hip fx, and 30 trials with >75,000 women for NVFx (mean follow-up 3 yrs, range 1-4). For hip fx (figure), the results showed a strong relationship between active-placebo total hip BMD change and reduction in hip fracture risk. For example, for 2 drugs with 2% vs 6% hip BMD effect, the model predicted a 10% vs. 59% reduction for hip fx (r²=0.57, p<.0001). For NVFx, the relationship was weaker: comparable risk reductions were 6% vs 21% (r²=0.14, p=0.004).

We conclude that on a study level, the difference between active vs. placebo change in DXA hip BMD with treatment can strongly predict fracture reductions for that treatment, particularly for hip fx. Further evaluation is warranted to determine the extent to which changes in DXA hip BMD, perhaps augmented with bone turnover and other imaging data, may be useful as a surrogate for hip fx reductions in future trials.

Relationship Between Total Hip BMD T-score and Incidence of Nonvertebral Fracture With up to 8 Years of Denosumab Treatment. S Ferrari*¹, C Libanati², CJF Lin², S Adami³, JP Brown⁴, F Cosman⁵, E Czerwiński⁶, LH de Gregório⁷, J Malouf⁸, J-Y Reginster⁹, NS Daizadeh², A Wang², RB Wagman², EM Lewiecki¹⁰. ¹Geneva University Hospital, Switzerland, ²Amgen Inc., USA, ³University of Verona, Italy, ⁴Laval University & CHU de Québec Research Centre, Canada, ⁵Helen Hayes Hospital, USA, ⁶Krakow Medical Center, Poland, ⁷CCBR, Brazil, ⁸Universitat Autònoma de Barcelona, Spain, ⁹University of Liège, Belgium, ¹⁰New Mexico Clinical Research & Osteoporosis Center, USA

Purpose: The relationship between BMD T-score and fracture risk has not been established in patients on therapy. We previously reported that denosumab (DMAB) treatment over 8 years enables a substantial proportion of women with osteoporosis to achieve non-osteoporotic BMD T-scores (Ferrari, ASBMR 2014). Further improvement in T-score would only be meaningful if it is associated with fracture reductions; thus, we investigated the relationship between total hip BMD T-score and the incidence of nonvertebral fracture through 8 years of DMAB therapy.

Methods: For these analyses, women received DMAB for 3 years during the FREEDOM trial (N=3902). A large subset of these women enrolled in the Extension and received DMAB for up to an additional 5 years, for a total of up to 8 years of continued treatment (N=2343). A repeated-measures model was first used to estimate each subject's BMD T-scores during the entire follow-up, specifically at each unique nonvertebral fracture time among all subjects at risk at the time of each fracture. Cox's proportional-hazards model was then fitted with time to nonvertebral fracture as the response and total hip BMD T-score time course as a time-dependent covariate.

Results: The incidence of nonvertebral fracture was lower with higher total hip BMD T-score throughout a wide and clinically relevant T-score interval (Figure). For example, total hip BMD T-scores of -2.5 and -1.5 were associated with 1-year nonvertebral fracture incidences of about 3.0% and 2.0%, respectively. The relationship flattened at a T-score somewhere between -2.0 and -1.0, similar to what is known to occur in untreated subjects. This inverse relationship between total hip BMD T-score and nonvertebral fracture incidence was maintained regardless of age or prior fracture (data not shown).

Conclusions: Higher total hip BMD T-scores during DMAB treatment were associated with a lower incidence of nonvertebral fractures, which is similar to the relationship previously established in treatment-naïve patients. Improvements of similar magnitude in BMD would result in different reductions in fracture risk depending on the baseline BMD value. Our findings highlight the importance of BMD measurement in patients on osteoporosis treatment as a predictor of fracture risk and support the concept that a specific T-score should be further evaluated as a practical goal for therapy.

Wnt1 Regulates Bone Homeostasis by Regulating the Function of Osteoblasts. Kyu Sang Joeng*, Brendan Lee, Yi-Chien Lee, Ming-Ming Jiang, Terry Bertin, Yuqing Chen, Baylor College of Medicine, USA

Many studies have shown that canonical WNT/ β -catenin signaling regulates bone homeostasis; however, the key WNT ligand involved in this process was largely unknown. Recently, *WNT1* mutations have been reported to cause Osteogenesis Imperfecta (OI) and early-onset osteoporosis. Interestingly, our lineage tracing experiments suggested that *Wnt1* is expressed in a subset of osteocytes. Based on these studies, we hypothesized that *Wnt1* expressed in osteocytes regulates bone homeostasis. To test our hypothesis, we generated an osteocyte-specific *Wnt1* loss-of-function mouse model (*DMP1-Cre; Wnt1^{fl/fl}*). Interestingly, *DMP1-Cre; Wnt1^{fl/fl}* mice exhibit spontaneous tibial fractures (70% fracture rate) and severe low bone mass (4-fold decrease in trabecular BV/TV and 40% reduction in cortical bone diameter). Subsequent histomorphometric analyses showed that the osteopenic phenotype is due to decreased osteoblast activity, but not due to changes in osteoclasts. To confirm WNT1 function in bone, we next generated an osteocyte-specific *Wnt1* gain-of-function mouse model (*DMP1-Cre; Rosa26^{Wnt1/+}*). As expected, the *DMP1-Cre; Rosa26^{Wnt1/+}* mice exhibited a dramatic increase in trabecular bone mass (5-fold increase in BV/TV) and cortical bone diameter (50% increase) resulting solely from increased osteoblast activity. To confirm WNT1 function in osteoblasts, we overexpressed *Wnt1* in mouse stromal cell lines (ST2). The expression of *Wnt1* dramatically enhanced osteoblast differentiation and mineralization *in vitro*. Taken together, our data strongly support that *Wnt1* expressed in osteocytes functions in bone homeostasis by regulating osteoblast activity. To understand the genetic mechanism driving these effects, we generated *DMP1-Cre; Rosa26^{Wnt1/+}; β -catenin^{fl/fl}* mice to assess whether β -catenin mediates WNT1 function in bone formation. We hypothesized that, if WNT1 signaling is mediated by β -catenin, *DMP1-Cre; Rosa26^{Wnt1/+}; β -catenin^{fl/fl}* mice would recapitulate the phenotypes of *DMP1-Cre; β -catenin^{fl/fl}* mice. Interestingly, *DMP1-Cre; Rosa26^{Wnt1/+}; β -catenin^{fl/fl}* mice phenocopied the cancellous bone phenotype of *DMP1-Cre; β -catenin^{fl/fl}* mice, whereas the cortical bone diameter of *DMP1-Cre; Rosa26^{Wnt1/+}; β -catenin^{fl/fl}* mice was significantly increased compared to *DMP1-Cre; β -catenin^{fl/fl}* mice. These results suggest that β -catenin mainly mediates WNT1 function in cancellous bone formation, while both β -catenin dependent and independent mechanisms mediate WNT1 function in cortical bone formation.

Critical and Interrelated role of Parathyroid Klotho and CaSR in Regulating PTH Synthesis and Parathyroid Gland Growth. Yi Fan*¹, Tadatashi Sato¹, Michael Densmore¹, Hannes Olauson², Tobias E. Larsson², Hakan Toka³, Beate Lanske¹. ¹Harvard School of Dental Medicine, USA, ²Karolinska Institute, Sweden, ³Nephrology & Hypertension, Eastern Virginia Medical School, USA

The parathyroid gland (PTG) maintains mineral ion homeostasis by detecting low serum-Ca²⁺ and secreting PTH. The Calcium-Sensing Receptor (CaSR) is a key component in this system. Klotho (KL) is also expressed in the PTG and is a co-factor for Fibroblast Growth Factor-23 (FGF23), which suppresses PTH in a regulatory feedback mechanism. To determine the specific role of KL in the PTGs and to test possible interactions between KL and CaSR in PTH regulation, we generated mice with PTG-specific deletion of KL (PTG-KL-KO), CaSR (PTG-CaSR-KO) and both (PTG-DKO) using Cre-LoxP recombination. We utilized ROSA26^{tdTomato} mice to visualize and collect PTGs. Mutant mice lacking CaSR either alone or in combination with KL were severely growth retarded, and developed osteomalacia and rickets-like abnormalities. In particular, PTG-DKO mice exhibited a significantly lower body weight with a more severe skeletal phenotype and shorter life expectancy than PTG-CaSR-KO mice. To explore a potential interaction between KL and CaSR in PTG-tissues to modulate mineral ion homeostasis, we compared serum biochemistries at P10. Ablation of KL alone in PTG had no effect, whereas both PTG-CaSR-KO and PTG-DKO mice displayed hypercalcemia, hypophosphatemia and significantly elevated PTH, iFGF23 and 1,25(OH)D levels. Most notably, PTG-DKO mice had markedly higher serum PTH, iFGF23 and 1,25(OH)D when compared to PTG-CaSR-KO mice, indicating a suppressive function of KL on the PTG in the absence of CaSR. CaSR ablation also resulted in significantly decreased KL expression on mRNA and protein levels. The moderately to severely elevated serum PTH in PTG-CaSR-KO and PTG-DKO mice might depend on KL gene-dosage effects. Moreover, mice deleted for CaSR displayed PTG hyperplasia. Dual ablation of KL and CaSR resulted in a further enlargement of PTG size with more severe and disrupted morphological structure when compared to CaSR deletion alone. Immunostaining to assess the PTH expression pattern showed that CaSR ablation leads to increased PTH protein expression. Interestingly, in the extremely hyperplastic PTG of PTG-DKO mice, some areas of altered structure failed to express PTH protein due to increased apoptosis. Real-time PCR analyses showed no differences in PTH mRNA expression level, suggesting that parathyroid cell population might be disrupted by KL and CaSR deletion. Our results indicate a critical and interrelated role of KL and CaSR in modulating PTH biosynthesis and PTG structure.

Bmp2 Controls the Runx2/Osx Transition and Regulates Mineral Metabolism in Osteoblasts. Valerie Salazar*¹, Luciane Capelo², Satoshi Ote³, Vicki Rosen³. ¹Harvard School of Dental Medicine, Us, ²Universidade Federal de São Paulo, Brazil, ³Harvard School of Dental Medicine, USA

Bone morphogenetic proteins (BMPs) and canonical Wnts (cWnts) control many aspects of skeletal development, postnatal bone growth, and adult skeletal homeostasis. Current therapies based on BMP or cWnt signaling are developed and approved for use in humans, and yet the underlying mechanisms by which each pathway regulates osteoblast differentiation and function remain poorly understood. Among all BMPs expressed in bone, *Bmp2* is sufficient to induce ectopic bone formation, and is necessary in *Prx1*⁺ cells for bones to grow properly in width and acquire biomechanical stability. We monitored Wnt-induced osteoblast differentiation in a variety of murine osteoprogenitor cell types with reduced or ablated expression of endogenous *Bmp2*. As expected, *wild type* (*WT*) osteoprogenitors underwent differentiation and produced a mineralized matrix when cultured with rWnt3a. However, Wnt3a-induced osteoblast differentiation was not observed in limb bud cells stably expressing *Bmp2* RNAi, nor in primary bone marrow stromal cells where floxed alleles of *Bmp2* had been removed using either Adeno-Cre or endogenously expressed *Prx1-Cre*. Responsiveness to Wnt3a could be fully rescued, and even enhanced, by complementation with recombinant BMP2. To test the significance of these results *in vivo*, we induced cWnt signaling by removing a single copy of *Dkk1* in mice that were otherwise *WT* (*Dkk1^{+/-}*) or lacked *Bmp2* in *Prx1*⁺ cells of the limb (*Dkk1^{+/-}; Bmp2^{Prx1:Ala}*). By 2 weeks of age, *Bmp2^{Prx1:Ala}* mice had developed narrow appendicular bones with a ~75% decrease in moment of inertia, and this cortical phenotype was not improved by compound haploinsufficiency of *Dkk1*. Importantly, *Bmp2^{Prx1:Ala}* cells express essential molecules of cWnt signaling machinery, and are able to upregulate Tcf/Lef-target genes in a manner equivalent to *WT* cells following exposure to Wnt3a. Moreover, *Bmp2^{Prx1:Ala}* cells express a wide variety of other BMP ligands. Despite this, microarray analysis revealed that *Bmp2^{Prx1:Ala}* cells treated with Wnt3a fail to progress through the *Runx2/Osx* checkpoint, and do not upregulate many genes required for mineral metabolism including *Alpl* and *Phospho1*. By stark contrast, *Bmp2^{Osx1:Ala}* cells treated with Wnt3a differentiate and mineralize normally. In summary, these data point to pre-Osx1⁺ progenitors as a primary source and target of *Bmp2*, and uncover a previously unknown role for *Bmp2* in osteoblast mineral metabolism that is not compensated for by other BMPs or canonical Wnts.

Chondrogenesis is an essential physiological phase of endochondrogenesis but not separated from osteogenesis. Yinshi Ren^{*1}, Yan Jing¹, Xin Zhou², Junjun Jing¹, Jingya Wang¹, Jian Feng¹. ¹Baylor College of Dentistry, USA, ²The University of Texas MD Anderson Cancer Center, USA

For decades, it has been widely accepted that hypertrophic chondrocytes undergo apoptosis prior to endochondral bone formation and that chondrogenesis is a separate physiological process from osteogenesis. However, new studies suggest that chondrocytes can directly transform into bone cells using a cell lineage tracing process. In this study, we initially found only modest numbers of apoptotic cells but high levels of anti-apoptotic *Bcl-2* expression in hypertrophic chondrocytes, indicating that most hypertrophic chondrocytes do not undergo apoptosis. Interestingly, we also revealed dividing hypertrophic chondrocytes by BrdU staining, and high alkaline phosphatase activity (early bone marker) (Fig.1). An ex vivo culture of newborn cartilage on a chick chorioallantoic membrane showed that after 5 days, the cells on the periphery of the explants had begun to express *Col1* (bone marker) and produce bone-like matrices (Fig.2). The cartilage-specific cell lineage tracing approach in mice containing Rosa 26tdTomato (tracing marker), 2.3 *Col1*GFP (bone cell marker), and *Aggrecan* CreERT2 (one-time Tamoxifen-induced) or *Col10*-Cre (activated from E14.5 throughout adult stage) proved the direct transformation of chondrocytes into bone and endothelial cells in vivo (Fig.3). Importantly, deletion of *Bmpr1a* in chondrocytes (via crossing *Bmpr1a* flox and *Aggrecan* CreERT2 with one-time the Tamoxifen induction) led to a lack of cartilage and striped subchondral bone, but replaced it by intramembranous bone in the metaphysis (due to a compensated bone formation by the perichondrium), which greatly destroyed the normal shape and structure of long bone and led to a short status (Fig.4). This finding supports the novel concept that the chondrogenesis is an initial phase of endochondrogenesis, in which some of these chondrocytes undergo apoptosis, some divide, some become bone cells, and some give rise to endothelial cells for de novo vessel formation in subchondral bone formation. Taken together, this multi-pronged approach not only demonstrates that a majority of chondrocytes directly transform into bone and blood vessel cells, but also challenge the dogma that chondrogenesis is a separate process from osteogenesis during endochondral bone formation.

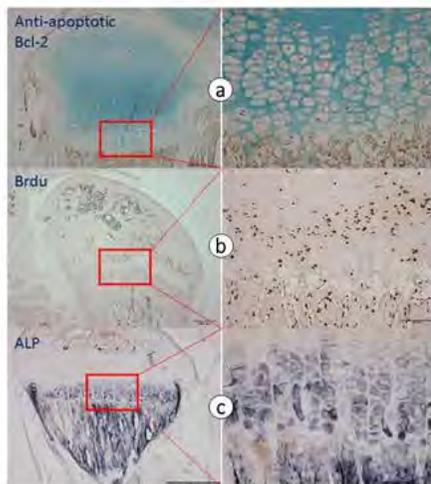

Figure 1. *Bcl-2*, *BrdU* and *ALP* expression in hypertrophic chondrocytes in wild type long bone. a), Anti-apoptotic marker *Bcl-2* is highly expressed in hypertrophic chondrocytes, indicating most of these cells may have another cell fate rather than apoptosis. b), Hypertrophic chondrocytes have the proliferating capability shown by *BrdU* labeling. c), High *ALP* activity in hypertrophic chondrocytes.

Figure 1

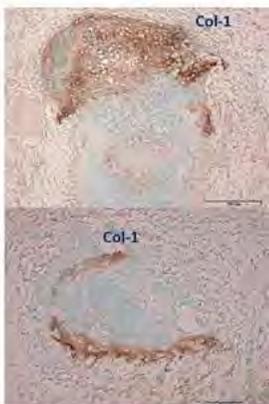

Figure 2. *Col-1* expression of ex-vivo cartilage culture on chick chorioallantoic membrane. Condyle cartilage is carefully dissected out from new born mice embryo and cultured on the chick chorioallantoic membrane. *Col-1* (bone marker) is strongly expressed on the periphery of the explants after 5 days of culture, indicating cartilage cells can directly transform into bone cells and lay down bone matrix ex-vivo.

An Sp7/Dlx transcriptional complex specifies mammalian osteoblasts. Hironori Hojo^{*1}, Shinsuke Ohba¹, Xinjun He¹, Lick Pui Lai¹, Andrew McMahon¹. ¹USC Broad-CIRM Center, USA, ²Dept. of Bioengineering, Univ. of Tokyo, Japan

Sp7/osterix encodes a key transcriptional regulator essential for mammalian osteoblast specification. To identify *Sp7*'s osteoblast regulatory program *in vivo*, we engineered a new mouse allele of *Sp7* by gene targeting. This allele produces a normally functioning fusion protein with a C-terminal addition of a Biotin-3xFLAG cassette to facilitate biochemical characterization of *Sp7* targets. We performed chromatin immunoprecipitation with FLAG antibody and DNA sequencing (ChIP-seq) using isolated neonatal calvarial osteoblasts. In addition, we obtained an osteoblast transcriptional profile by RNA-sequencing of neonatal calvarial osteoblasts. Bioinformatic analysis of these data sets identified *Sp7* engagement at putative regulatory regions for a large number of osteoblast-enriched genes. *In vitro* studies confirmed activities of the several predicted enhancers including those flanking *Coll1a1*, *Runx2* and *Notch2*. Transgenic mouse analysis of the *Notch2* enhancer verified osteoblast specific enhancer activity. Unexpectedly, *de novo* motif analysis on the *Sp7* ChIP-seq data identified an AT-rich sequence (AT-motif) as the primary *Sp7* interaction site; *Sp*-family members are known to bind to a GC-rich consensus motif. Functional analysis demonstrated that this AT-motif was required for *Sp7*-mediated enhancer activation but *Sp7* fails to bind this target sites, raising the possibility that partner proteins mediate *Sp7* with genomic targets. Bioinformatics, biochemical and *in vitro* expression analyses revealed that *Dlx*-family members were highly expressed in osteoblasts, bound to the AT-motif directly, and underwent protein-protein interactions with *Sp7*. Further *Sp7* and *Dlx5* ChIP-seq analysis showed that most of *Sp7* binding regions in genome were shared with *Dlx5*, an identical AT-motif that recovered from *Sp7* ChIP-seq on primary osteoblasts was the most enriched sequence

in the shared regions, and a positive correlation was observed in the strength of engagement exhibited by Sp7 and Dlx5. Gain- and loss-of-function studies showed that the transcriptional complex has synergistic effects on the transactivation of their targets and the Dlx members were required for Sp7 to associate with DNA and induce target gene expressions. Together these data support a novel model of Sp7 action. In this, Sp7 does not directly bind DNA targets. Instead, Dlx-family members bind to an AT-motif within osteoblast enhancers and recruit Sp7 to activate osteoblast-specific gene regulatory programs.

AMPK favors the Smurf1-dependent ubiquitination of Runx2 in vivo. Junko Shimazu*, Jianwen Wei, Gerard Karsenty. College of Physicians & Surgeons, Columbia University, USA

The regulation of osteoblast differentiation by glucose taken up by the mesenchymal progenitor cells relies in large part on the ability of glucose to inhibit the activity of AMPK that would otherwise promote the ubiquitination of Runx2. An involvement of AMPK in protein ubiquitination has never been reported in any cell type before. Therefore it is important to decipher the molecular bases of this novel function of AMPK and to verify them in vivo. To address these questions we tested whether E3 ubiquitin ligases expressed in osteoblasts and known to be involved in Runx2 degradation could be phosphorylated and activated by AMPK. Using a bioinformatics analysis we identified Serine 148 in the E3 ubiquitin ligase Smurf1 that is involved in Runx2 degradation, as a putative AMPK phosphorylation site. Through the use of a specific phosphor-antibody directed against Smurf1 when phosphorylated at Serine 148 we could demonstrate that AMPK phosphorylates Smurf1 at Serine 148 in osteoblasts and that this post-translational modification is necessary for Smurf1 ability to ubiquitinate Runx2. To demonstrate the in vivo relevance of this cascade AMPK-Smurf1-Runx2, we generated mice in which Serine 148 in Smurf1 was mutated to alanine to prevent its phosphorylation. The resulting Smurf1ki/ki mice were born at the expected mendelian ratio. A Western blot analysis showed that Runx2 is markedly more abundant in the bones of Smurf1ki/+ mice and even more in those of Smurf1ki/ki mice thus establishing in vivo the importance of this phosphorylation event for the function of Smurf1. Alcian blue/alizarin red staining of skeletal preparations of showed a premature closure of cranial suture in the skull of Smurf1ki/ki newborn mice as well as significantly longer clavicles. To demonstrate that these phenotypic abnormalities were caused in part by an increase in Runx2 activity we generated and analyzed Smurf1Ki/+; Runx2+/- mice. Alcian blue/alizarin skeletal preparations showed that there was already a significant rescue of the cleidocranial dysplasia phenotype otherwise present in Runx2+/- mice in the Smurf1Ki/+; Runx2+/- mice analyzed. Runx2+/-; Smurf1Ki/ki mice are currently being generated. These results identify for the first time a role for AMPK signaling in the ubiquitination of Runx2 and identify a single Serine residue in the E3 ubiquitin ligase Smurf1 as carrying the brunt of its function.

Increased Micro Crack Density in Patients with Low Turnover Renal Osteodystrophy. Logan Burgess*¹, Constance Wood¹, David Pienkowski¹, Hanna Mawad¹, Hartmut Malluche². ¹University of Kentucky, USA, ²University of Kentucky Medical Center, USA

Renal Osteodystrophy (ROD) is a common abnormality in patients with chronic kidney disease (CKD). Patients with ROD experience bone fractures more than 4 times the normal rate. Previous work in our laboratory showed that patients with ROD and high bone turnover have abnormal bone mineralization; this was not observed in patients with ROD and low bone turnover. Patients with low turnover; however, were reported to have more fractures than patients with high turnover. The present study was conducted to evaluate bone microdamage (an important parameter governing bone quality and load-bearing mechanical competence) in patients with low versus high bone turnover ROD.

Anterior iliac crest double tetracycline-labeled bone biopsies received sequentially in the Bone Diagnostic and Research Laboratory at the University of Kentucky were screened to identify 7 patients with high turnover ROD and 7 patients with low turnover ROD. Inclusion criteria were signed informed consent from female Caucasian patients aged 40-70 years with CKD stage 5D and ROD with low or high bone turnover diagnosed from undecalcified histologic bone sections. Men and patients of non-Caucasian races were excluded to focus on the patient group with the highest fracture risk.

Bone samples were stained with basic fuchsin under vacuum using an established protocol. Bone quality was assessed by measuring microcracks in 100 µm thin undecalcified sections using bone histomorphometry software at 40X magnification. Crack number, crack length, and accompanying area of mineralized bone were measured in a total of 50 optical fields for each sample. Data were analyzed by using analyses of covariance (SAS Institute).

Adjusted for bone area, the mean number of cracks was 2.2X greater in low turnover bone compared to high turnover bone (p=0.016). Mean crack length was not significantly different for high versus low turnover and was not correlated with bone area. This is the first study showing an increased number of microcracks in low turnover bone in patients with ROD adjusted for turnover-related changes in bone area. These findings are consistent with previous studies demonstrating an increase in microcrack number in low turnover canine bone treated with bisphosphonates. These results may offer a contributory mechanism for the increased fracture risk in this population and call for the early diagnosis and management of low bone turnover.

TBK1 Plays A Critical Role In Myeloma-Induced Osteoclast Formation. Quanhong Sun*, Peng Zhang, Juraj Adamik, Deborah Galson. University of Pittsburgh, USA

Increased osteoclast (OCL) formation is the hallmark of multiple myeloma (MM) bone disease, yet the underlying molecular mechanisms are incompletely understood. Our study showed that conditioned media (CM) from cultures of the human MM cell line MM1.S increased OCL formation by both the OCL precursor cell line 4B12 and mouse primary bone marrow monocyte (BMM) cultures when exposed to the MM-CM (1:100) for the M-CSF plus RANKL-driven differentiation stage. The MM-CM exposure increased expression of both IL-6 and RANK mRNA at day 2 (D2) over the RANKL-induced increases in cultures in control media. However, we found that BMM cultures treated with MM-CM only during the M-CSF-driven proliferation stage (D-3 to D0) demonstrated a more dramatic increase of both OCL formation and the nuclei number per OCL than those exposed to the MM-CM only during the differentiation stage (D0 to D3) or during both stages, although all three MM-CM

exposure paradigms were effective at increasing OCL numbers. We have previously reported that TBK1, an IKK family member with roles in innate immunity, is not required for normal OCL formation in vitro, but is required for the measles virus nucleocapsid protein (MVNP) enhancement of OCL formation and IL-6 production resulting in a pagetic OCL phenotype. We hypothesized that perhaps TBK1 plays a similar role in another model of inflammatory OCL formation such as MM-induced OCL formation. Therefore, we examined TBK1 in MM-CM treated BMM proliferation cultures. MM-CM exposure during the BMM proliferation phase resulted in a dose-dependent increase in expression of IL-6, RANK, and TBK1 mRNA at D0 compared to BMM cultures in control media. We reported that an increased ratio of TBK1 to optineurin (OPTN) enhanced OCL formation. Western blot analyses of TBK1 and OPTN revealed that MM-CM added after the proliferation phase, but in the absence of RANKL, increased total TBK1 protein and the TBK1/OPTN ratio within 12 h. Further, MM-CM increased the level of activated TBK1 (phosphoS172-TBK1) within 2 min. Of key interest, knockdown of TBK1 in BMM significantly attenuated the ability of MM-CM to affect OCL differentiation without altering OCL differentiation in control media. These data suggest MM cells require TBK1 to enhance OCL formation and that targeting TBK1 would decrease multiple myeloma bone disease, a major source of the mortality and morbidity in multiple myeloma patients.

Unraveling the Vitamin D Paradox in African Americans. Mageda Mikhail*, John Aloia, Louis Ragolia, Shahidul Islam. Winthrop University Hospital, USA

Context: African Americans have a lower total serum 25-hydroxyvitamin D [25(OH)D] but superior bone health. This has been referred to as a "paradox". A recent publication found that free serum 25(OH)D is the same in black and white women. However, the study was criticized because an indirect method was used to measure free 25(OH)D.

Objective: We hypothesized that although total serum 25(OH)D is lower in African Americans, free serum 25(OH)D measured directly would not differ between races.

Design: White and black healthy postmenopausal women were matched for age and BMI. Serum total 25(OH)D, PTH, 1,25(OH)2D, vitamin D binding protein (VDBP) and bone density were measured. Direct measurement of serum free 25(OH)D was carried out using ELISA.

Setting: Ambulatory research unit in a teaching hospital.

Outcome: Cross-racial comparison of serum free 25(OH)D.

Results: A propensity match resulted in selection of a total of 164 women. Total 25(OH)D was lower in black women (19.5±4.7 vs. 26.9±6.4 ng/ml) but direct measurement of free 25(OH)D revealed almost identical values (5.25±1.2 vs. 5.25±1.3 ng/ml) between races. VDBP was significantly lower in blacks when using a monoclonal based ELISA (151±73 vs. 264.8±95 mcg/ml), but not a polyclonal based ELISA. Serum PTH, 1,25(OH)2D and bone density were higher in African Americans.

Conclusion: VDBP is lower in black women. Free serum 25(OH)D is the same across races despite the lower total serum 25(OH)D in black women.

Bone Remodeling in Patients With Hypoparathyroidism Treated for 3 Years With Recombinant Human Parathyroid Hormone, rhPTH(1-84), in the Open-Label RACE Study. Michael Mannstadt*¹, John P. Bilezikian², Bart L. Clarke³, Tamara J. Vokes⁴, Mark L. Warren⁵, Hjalmar Lagast⁶, Dolores M. Shoback⁷, Michael A. Levine⁸. ¹Massachusetts General Hospital Harvard Medical School, USA, ²College of Physicians & Surgeons, Columbia University, New York, NY, USA, ³Mayo Clinic Division of Endocrinology, Diabetes, Metabolism, & Nutrition, Rochester, MN, USA, ⁴University of Chicago Medicine, Chicago, IL, USA, ⁵Endocrinology & Metabolism, Physicians East, PA, Greenville, NC, USA, ⁶NPS Pharmaceuticals, Inc, Bedminster, NJ, USA, ⁷SF Department of Veterans Affairs Medical Center, University of California, San Francisco, San Francisco, CA, USA, ⁸Children's Hospital of Philadelphia, Philadelphia, PA, USA

Deficient endogenous parathyroid hormone (PTH) in hypoparathyroidism patients is associated with marked abnormalities of bone metabolism, which can lead to aberrations in bone microarchitecture and increased bone mineral density (BMD). In the pivotal phase III placebo-controlled trial and in a phase III, dose-blind, fixed-dose study, rhPTH(1-84) treatment improved mineral homeostasis and bone-remodeling characteristics in patients with hypoparathyroidism. We report on skeletal indices from patients who completed the Month 36 visit in the ongoing, long-term, open-label rhPTH(1-84) study.

Patients with hypoparathyroidism who completed either or both of the phase III studies initiated open-label treatment with subcutaneous rhPTH(1-84) at 25 or 50 µg/

day. Doses could be up-titrated to 50, 75, or 100 µg/day as needed to reduce conventional treatment with oral calcium and active vitamin D and to maintain serum calcium at 8.0–9.0 mg/dL. Because patients had completed the previous phase III studies, baseline was defined as the start of rhPTH(1-84) treatment. Bone turnover was evaluated by serum levels of bone turnover markers (BTMs), and BMD was assessed by dual-energy x-ray absorptiometry. Data are shown as mean ± SD.

This interim analysis included patients who were assessed at the Month 36 study visit as of September 30, 2014. Between baseline and Month 36, optimized albumin-corrected serum calcium levels were maintained (baseline, 8.4±0.7 mg/dL; Month 36, 8.2±0.7 mg/dL) and serum phosphorus decreased (baseline, 4.8±0.6 mg/dL; Month 36, 4.2±0.7 mg/dL). BTMs increased from low-normal levels between baseline and Month 36, indicating increased bone turnover. 3-year values were lower than peak values of BTMs achieved earlier in the time course (Table). There were very small changes in BMD at Month 36, with the lumbar spine trending upward and the other sites trending downward (Table). The most frequently reported adverse events were hypocalcemia (35%), muscle spasm (29%), nausea (27%), and paresthesia (25%). 3-year rhPTH(1-84) treatment in adults with hypoparathyroidism was associated with sustained improvements in mineral and bone homeostasis, as indicated by maintenance of serum calcium, decreases in serum phosphorus, increases in serum BTMs, and reductions in most BMD Z-scores. The results provide further support for the long-term efficacy and safety of rhPTH(1-84) treatment for hypoparathyroidism.

Table. Effects of rhPTH(1-84) on Bone Parameters

| | Baseline | | Maximum Value* | | Month 36 | |

PTH(1-84) Treatment is Safe and Effective in Hypoparathyroidism for Seven Years. Mishaela Rubin*, Natalie Cusano, Wen-Wei Fan, Yasmine Delgado, Farnoosh Mahdavi, Juviza Rodriguez, Aline Costa, Donald McMahon, John Bilezikian. Columbia University, USA

Hypoparathyroidism (HypoPT) is a rare disorder in which PTH is absent from the circulation. The biochemical profile includes hypocalcemia, hyperphosphatemia and hypercalciuria, while the densitometric hallmark is above average bone mineral density (BMD). We previously found that PTH(1-84) treatment for 6 years improves these abnormalities. Yet because HypoPT is a lifelong condition, there is a need to extend these findings. We now report 7-year data on the efficacy and safety of PTH(1-84) treatment in HypoPT.

Twenty one HypoPT subjects (46.5 ± 3 yrs; 17 female; duration HypoPT 19 ± 3 yrs) were studied. Etiologies were postsurgical (n=11), autoimmune (n=9) and DiGeorge (n=1). Baseline medications were calcium 3289 ± 288 mg/d; calcitriol 0.73 ± 0.1 µg/d; vitamin D 6669 ± 5112 IU/d and HCTZ 10.5 ± 4 mg/d. Serum calcium was 8.5 ± 0.2 mg/dL, undetectable PTH levels and serum phosphate of 4.4 ± 0.2 mg/dL; BMD measurements (g/cm²) were lumbar spine (LS) 1.230 ± 0.05; femoral neck (FN) 0.970 ± 0.04, total hip (TH) 1.079 ± 0.04 and distal 1/3 radius (DR) 0.731 ± 0.01.

PTH(1-84) was started at 100 µg every other day and changed after 3 yrs to doses ranging from to 25–100 µg/d. Calcium supplementation fell by 60% to 1307 ± 343 mg/d (p=0.0001) as did calcitriol by 56% to 0.32 ± 0.1 µg/d (p=0.006). Vitamin D intake and HCTZ dose did not change. Serum calcium remained stable (8.5 ± 0.2 to 8.7 ± 0.2 mg/d; p=NS) while 24-hr urinary calcium decreased by 32% from 262 ± 29 to 178 ± 26 mg (p=0.03). There was no change in serum phosphate, Mg or creatinine (0.99 ± 0.04 to

1.07 ± 0.1 mg/dL; p=NS), while total alkaline phosphatase increased (69.1 ± 4 to 79.1 ± 3.2 U/L; p=0.04). BMD increased by 4.6 ± 1.7% at LS (p=0.01), 3.0 ± 1.3% at TH (p=0.02), did not change at FN and fell 3.6 ± 1.4% at DR (p=0.02). One kidney stone and 3 minor fractures occurred. An elevation of serum calcium above the upper limit of normal occurred in only 5% of all measurements.

These data suggest that 7 years of PTH(1-84) treatment in HypoPT maintains normal calcium metabolism. Reductions in calcium and calcitriol requirements and urinary calcium excretion were maintained along with normal serum calcium levels. BMD changes were consistent with site-specific effects of PTH. These data, the longest-term clinical experience with continuous PTH treatment for any condition, suggest that PTH(1-84) is a safe and effective long-term option in HypoPT.

Does Cortical Bone Loss Precede Menopause? Ashild Bjornerem*¹, Ali Ghasem-Zadeh², Roger Zebaze², Xiaofang Wang², Minh Bui³, John L Hopper³, Ego Seeman². ¹UiT The Arctic University of Norway, Norway, ²Endocrine Centre, Austin Health, Australia, ³Centre for Epidemiology & Biostatistics, School of Population & Global Health, University of Melbourne, Australia

Remodelling is slow before menopause and there is little compelling evidence of a negative bone balance at the level of the basic multicellular unit. Bone loss is held to be predominantly trabecular in origin before menopause with appearance of cortical bone loss after menopause. We hypothesized that shortly before menopause cortical bone loss occurs by intracortical and endocortical remodeling, so porosity will increase, as 80% of the skeleton is cortical, most bone loss will be cortical, not trabecular.

Images of the distal tibia were obtained using high-resolution peripheral quantitative computed tomography (HR-pQCT; Scanco Medical) in 249 pre-, 32 peri- and 103 postmenopausal women aged 27–75 years at baseline of a twin study in 2008–2009, Melbourne, Australia. During an average of 3.1 years (SD 0.7) follow-up, 173 women remained pre-, 49 changed from pre- to peri-, and 30 from peri- to postmenopausal. Total, trabecular and cortical volumetric bone mineral density (vBMD), and cortical porosity of the total cortex, compact cortex, outer and inner transitional zones were quantified using the StrAx1.0 software, and annual changes were calculated.

In women who remained premenopausal and were below 40 years of age at baseline, cortical and trabecular vBMD decreased annually by 1.7 and 1.0 mg HA/cm³ respectively, and porosity of each cortical compartment increased by 0.1–0.2% (all p<0.05). In women 40–45 years of age, cortical vBMD decreased by 4.9 mg HA/cm³, and porosity increased by 0.2–0.5% (all p < 0.001). In women > 45 years of age, cortical vBMD decreased by 8.1 mg HA/cm³ and porosity increased by 0.4–0.8% (all p<0.001), no trabecular bone loss was detected in these two groups.

In premenopausal aged 40–54 years becoming perimenopausal, cortical vBMD decreased by 10.6 mg HA/cm³ and porosity increased by 0.4–0.8% (all p<0.001). In perimenopausal women aged 46–55 years becoming postmenopausal, cortical vBMD decreased by 15.9 mg HA/cm³ and porosity increased by 0.5–1.5% (all p<0.001). In both groups, no trabecular bone loss was detected. In postmenopausal women aged 49–75 years, cortical and trabecular vBMD decreased by 9.9 and 0.7 mg HA/cm³ respectively, porosity increased by 0.3–0.9% (all p<0.01).

Of the distal tibia total bone loss of 157 mg HA between 27 and 75 years of age; 4, 11, and 85% occurred before, across and after menopause, respectively, and 72% was cortical and 28% trabecular.

We infer that intracortical and endocortical remodeling produces modest cortical bone loss before menopause, most bone is lost after menopause and cortical exceeds trabecular bone loss.

Effect of Teriparatide Treatment on Vertebral Strength in Postmenopausal Women with Osteoporosis Assessed Using a Patient-Specific Finite Element Model of the Disc-Vertebra-Disc Unit. Chuhee Lee¹, Margaret A Paggioli¹, Eugene V McCloskey¹, Nicola FA Peel², Jennifer S Walsh¹, Richard Eastell¹, Lang Yang*¹. ¹University of Sheffield, United Kingdom, ²Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom

Teriparatide (TPTD, PTH 1-34) treatment increases BMD, but the increase is not sufficient to explain the reduction in fracture risk entirely. The aim of this study was to apply a novel patient-specific finite element (FE) model of the disc-vertebra-disc (DVD) unit to quantify the effect of TPTD treatment on vertebral strength. In an open-label single-centre study, 20 postmenopausal women (age 64.4 ± 15.4 years) with osteoporosis (BMD T score < -2.5 at spine or hip) were treated with TPTD (FORSTEO, 20 micrograms daily) for 104 weeks. QCT scans of the lumbar spine were performed at baseline, 26, 52 and 104 weeks with a resolution of 0.62x0.62x0.62 mm³. The DVD FE models of the L2 vertebrae were generated using brick elements.

Transverse-isotropic, elastic-perfectly plastic material properties were assigned to the vertebra. Linear-elastic properties were used for the nucleus pulposus and annulus ground matrix, whereas 4 fibre layers were embedded in the annulus matrix to simulate collagen fibres. A pure compressive loading condition was simulated. Vertebral strength was defined using a 0.2% offset method in the load-displacement curve. Percentage changes from baseline were calculated at individual level. TPTD treatment increased not only the densitometric variables but also the FE-estimated vertebral strength (Table 1 and Figure 1). The mean (SE) percentage increases at the year-2 visit were 11% (2%) for DXA L1-L4 BMD, 22% (6%) for QCT L1-L3 vBMD and 30% (8%) for the FE estimated strength, respectively. In conclusion, vertebral strength derived from the in vivo DVD FE model shows a larger treatment effect relative to the baseline value than densitometric variables.

Table 1. Mean (SD) of the measurements at each visit

| | Baseline | Week 26 | Week 52 | Week 104 |
|--------------------------------------|-------------|--------------|--------------|--------------|
| DXA L1-L4 BMD (g/cm ²) | 0.73 (0.04) | 0.77 (0.05)* | 0.79 (0.04)* | 0.82 (0.05)* |
| QCT L1-L3 vBMD (mg/cm ³) | 86 (17) | 96 (20) | 104 (20)* | 103 (22)* |
| L2 DVD FE strength (N) | 1318 (251) | 1540 (327)* | 1668 (268)* | 1698 (332)* |

* indicates that the mean is significantly different from the baseline value at P<0.05

Effect of Transforming Growth Factor-Beta Inhibition on the Fracture Resistance of Bone in a Mouse Model of Type 2 Diabetes. Jeffry Nyman¹, Stephen O'Brien², Sasidhar Uppuganti³, Amy Creecy³, Mathilde Granke³, Paul Vozyian³, Kuber Sampath². ¹Vanderbilt University Medical Center, USA, ²Genzyme Research Center, USA, ³Vanderbilt University, USA

Individuals with type 2 diabetes (T2D) are twice as likely to suffer a fracture as non-diabetics of the same age. A lower BMD does not explain this increase in fracture risk, suggesting that diabetes deleteriously affects bone quality. The inhibition of TGF-β with a monoclonal antibody (GC1008 for humans, 1D11 for rodents) is a potential treatment for diabetic nephropathy. Since TGF-β signaling is inversely related to bone quality, we hypothesized that treating diabetic mice with 1D11 increases the fracture resistance of bone. The unknown effect of diabetes on bone material properties for the KK-Ay mouse model of T2D motivated two parallel experiments: i) non-diabetic a/a mice vs. diabetic KK-Ay/a mice and ii) 13C4 (control antibody) vs. 1D11 (anti-TGF-β antibody) in diabetic KK-Ay/a mice. One kidney was removed from all 41 female KK-Ay/a mice at 9 wks of age. They were then fed a high fat diet (24% kcal fat), while 12 age-matched female a/a mice ate a control diet (12% kcal fat). At 12 wks of age, diabetic mice were given 13C4 (n=14) or 1D11 (n=13) at 5 mg/kg (ip 3x/wk) for 12 weeks. After euthanasia, the femoral mid-shaft was imaged by μCT to obtain tissue mineral density (Ct.TMD), structural parameters, and porosity and ii) subjected to 3pt bending to estimate material properties. The femur metaphysis was also analyzed by μCT. All KK-Ay mice weighed more than the non-diabetic mice, and 1D11-treatment did not significantly lower circulating levels of glucose (Fig. 1). Diabetic mice had higher BV/TV and significantly greater Tb.Th than the non-diabetic mice. BV/TV, Tb.Th, and Tb.N were higher for 1D11- than for 13C4-treated diabetic mice. Moreover, 1D11-treatment rescued the diabetes-related decrease in Tb.TMD. Although structurally bigger (higher Imin), the femoral cortex was thinner for the diabetic mice with treatment having no effect. Ct.TMD was also lower for diabetic bone, but 1D11-treatment did not increase Ct.TMD as it did for trabecular bone. Cortical porosity was higher with diabetes, and 1D11-treatment lowered this porosity. There were no significant differences in structural or material strength of bone between the control and T2D mice. Instead, toughness was lower for the diabetic animals. Although 1D11-treatment did not prevent this loss in toughness, it did increase bone strength (Table 1). As in humans, diabetes in KK-Ay mice increases cortical porosity. TGF-β inhibition could ameliorate diabetes-related decrease in material strength.

Lossing Trabecular Plate and Rod Number in Wrist Fractures. Bin Zhou¹, Will Smith², Ji Wang³, Yue Yu³, Kyle Nishiyama⁴, Emily Stein⁴, Elizabeth Shane⁴, X.Edward Guo³. ¹Columbia University, USA, ²Biomedical Engineering, Columbia University, USA, ³Biomedical Engineering Department, Columbia University, USA, ⁴Department of Medicine, Columbia University, USA

Trabecular plates and rods determine biomechanical properties of trabecular bone and individual trabecula segmentation (ITS) based plate-rod parameters have been shown to provide additional power to discriminate groups of patients with fragility fractures and vertebral fractures, independent of areal bone mineral density. We hypothesized that wrist fracture patients (WFX) also have abnormal trabecular plate and rod microstructure and compromised bone strength compared with healthy controls (C). We applied ITS and nonlinear micro finite element (μFE) analyses to high-resolution peripheral quantitative computed tomography (HR-pQCT) scans of

distal radius (DR) and tibia (DT) from wrist fracture patients and their matched controls.

Areal BMD (aBMD) of the spine, hip and forearm by DXA and HR-pQCT scans (*XtremeCT*, *Scanco Medical*) of the DR and DT were performed on postmenopausal women with (69±8 years, n=50) and without (69±6 years, n=50) wrist fracture history. ITS was applied to segment the trabecular bone network into individual trabecular plates and rods to measure plate- and rod-related microstructural parameters. Bone stiffness, yield strength and failed tissue fraction in cortical, trabecular plate and rod were calculated based on μ FE analyses.

Mean DXA T-scores were in the osteopenic range at all sites and were not different between WFX and C. At the DR, plate and rod bone volume fraction (pBV/TV, rBV/TV), plate and rod trabecular number (pTb.N, rTb.N), plate-plate and plate-rod junction density (P-P Junc.D, P-R Junc.D) and axial bone volume fraction (aBV/TV) were 25%, 10%, 8%, 4%, 22%, 19% and 20% lower in WFX than C (Fig, p<0.05). At the DT, pBV/TV, pTb.N, P-P Junc.D, P-R Junc.D and aBV/TV were 17%, 6%, 14%, 10% and 14% lower in WFX (p<0.05). Bone stiffness and yield strength were 13% and 16% lower at the DR, and 11% and 12% lower at the DT in WFX (Table). Trabecular plate compression failed fraction was 26% and 17% lower and rod compression failed fraction was 17% and 12% lower in WFX, at the DR and DT respectively.

In conclusion, despite similar aBMD by DXA, postmenopausal women with prior wrist fracture have lower plate and rod bone volume, fewer trabecular plates and rods, less connectivity between rods and plates at both the DR and DT, and lower bone stiffness and strength. Application of ITS, μ FE and failure analyses to HR-pQCT scans of the DR and DT can discriminate postmenopausal women with and without wrist fractures independent of aBMD.

Nanomechanical Properties of Human Bone with Varying Continuous Bisphosphonate Treatment Durations. David Pienkowski^{1*}, Constance L. Wood², Hartmut H. Malluche³. ¹University of Kentucky, USA, ²Department of Statistics, University of Kentucky, USA, ³Nephrology: Bone & Mineral Metabolism, USA

Oral bisphosphonates (BPs) have well-known short-term benefits on bone mass for patients with osteoporosis, but reports of atypical fractures with longer-term BP use generate concerns for adverse bone quality changes. Deformation resistance is a key aspect of bone quality and is determined by extrinsic structure and intrinsic material properties. The present study sought to quantify changes in the material properties of human bone from patients treated with BPs for varying durations. Iliac crest bone samples (n=82) from Caucasian females aged 40 – 80 years diagnosed with osteoporosis and continuously treated with oral BPs for varying (0.2 – 16 years) durations were studied. Bone samples (n=12) from comparable subjects with osteoporosis never exposed to BPs were also studied. Exclusion criteria were: osteogenesis imperfecta, genetic bone diseases, osteomalacia, hyperparathyroid bone disease, chronic kidney or Paget's disease, endocrine abnormalities, drug/alcohol abuse, and non-oral BP bone metabolism altering drugs. Young's modulus (a metric of intrinsic material deformation resistance) was measured in all samples using an established nanoindentation technique. Modulus was calculated at 30 sites (6 trabeculae X 5 sites/trabeculae (left & right edges (E), left & right middles (M), and center (C)) per sample. Repeated measures polynomial regression was used to model the relationships among patient age, modulus, and BP treatment duration at each of the 3 (E,M,C) trabecular locations. Adjusted for patient age, modulus differed by trabecular location (p<0.0001) and displayed a quadratic relationship (p-values of coefficients for linear and 2nd-order terms were 0.0039 and 0.0233) with BP treatment duration. These relationships showed: 1) increasing modulus with increasing BP treatment duration, 2) modulus peaks of 16.20, 16.80, and 17.30 GPa at E, M, and C at 8.52 years of BP treatment, 3) modulus declines with longer BP treatment duration. The observed peak and subsequent decline in modulus are novel and consistent only with our prior study showing a similar quadratic relationship between bone strength calculated from finite element analyses of trabecular structure and varying BP treatment duration. Unlike short-term modulus increases, modulus declines with longer-term BP treatment duration are unclear. Data from this and our prior study show that BP treatment duration is related to changes in both the extrinsic and intrinsic properties of human bone.

Multiscale characterization of material properties of cortical tissue from patients with atypical femoral fractures. Ashley Lloyd^{1*}, Bernd Gludovatz², Christoph Riedel³, Emma Luengo¹, Joseph Lane⁴, Robert Ritchie⁵, Björn Busse³, Eve Donnelly¹. ¹Cornell University, USA, ²Lawrence Berkeley National Laboratory, USA, ³University Medical Center Hamburg-Eppendorf, Germany, ⁴Hospital for Special Surgery, USA, ⁵University of California, Berkeley, USA

Bisphosphonates (BPs) reduce fracture risk in postmenopausal women by up to 50%. However, prolonged BP treatment has been associated with rare atypical femoral fractures (AFFs) characterized by transverse brittle morphology. Because BPs reduce remodeling, they could alter bone tissue material properties. However, mechanical properties of tissue from patients with AFFs have yet to be studied.

Thus, the objectives of this study were to compare the nanoscale mechanical and compositional properties, and the microscale fracture properties, of bone tissue from patients with AFFs to those of patients with typical fragility fractures and patients without fractures.

Biopsies of proximal femoral cortical bone adjacent to the fracture site were obtained from postmenopausal women during fracture repair surgery (fracture groups), or total hip arthroplasty (non-fracture group). Patients were allocated to four groups: atypical fractures, all with history of BP use (+BP Atypical: n=7, age 73 ± 12y, BP 9.3 ± 4y); typical fragility fractures with and without BP use (+BP Typical: n=6, age 88 ± 6y, BP 9.5 ± 6y; -BP Typical: n=6, age 85 ± 3y); and non-fracture without history of BP use (-BP Non-fx: n=5, age 69 ± 5.5y).

Mineral composition was assessed with quantitative backscattered electron imaging and Raman imaging. Nanomechanical properties were assessed with nanoindentation. Fracture properties were assessed with in-situ fracture toughness testing of cortical beams (~0.5x0.5x5mm). Cortical microstructure and crack paths were assessed with micro-computed tomography.

Raman mineral:matrix ratio was greater in atypical samples compared to controls (+BP Atypical vs. +BP Typical +18%, vs. -BP Non-fx +29%). Distributions of tissue mechanical and compositional properties showed trends toward atypical samples having narrower distributions than controls with significant differences versus non-fracture controls (Raman crystallinity -34% p<0.05, modulus -29% p<0.10, hardness -31% p<0.05) (Fig. 1). Preliminary analysis shows propagation of cracks through cortical bone in relation to osteons in atypical fracture samples and controls (Fig. 2). The elevated tissue mineralization in atypical samples suggests increased tissue age and increased brittleness relative to controls. The decrease in heterogeneity is consistent with a reduction in overall bone toughness due to a loss of intrinsic toughening behavior. Both are consistent with the transverse fracture morphology

observed radiographically.

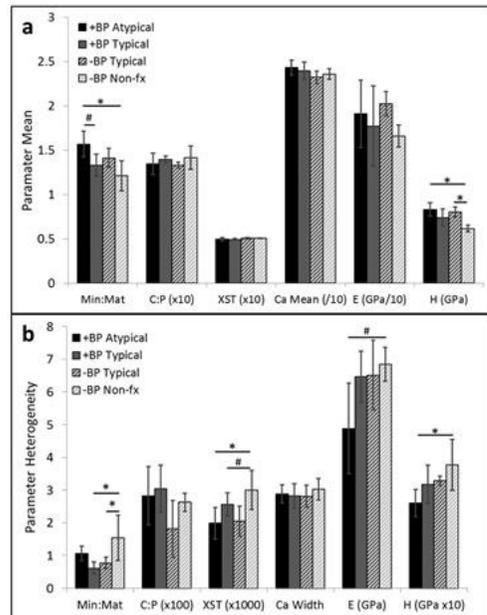

Fig. 1 Comparison of compositional parameters measured by Raman microscopy (Min:Mat: mineral to matrix ratio, C:P: carbonate to phosphate ratio, XST: crystallinity) and qBEI (Ca mean, Ca width), and nanomechanical properties measured by nanoindentation (E: reduced modulus, H: hardness). *p<0.05 #p<0.10 (a) Parameter means (b) Parameter distribution widths

Osteocyte Lacunar Characteristics as a Function of Genotype and Age in Bone Tissue. Valerian Peterson¹, Brad Hugenroth¹, Brett Rosauer¹, Diane Cullen¹, Mohammed Akhter^{*2}. ¹Creighton University, USA, ²Creighton University Osteoporosis Research Center, USA

The purpose of this study is to examine and compare the osteocyte lacunar characteristics in mouse femurs representing different genotype and age. It is hypothesized that osteocyte lacunar properties in bone tissue are a function of genotype and age. To test this hypothesis we used two mouse genotypes (high bone

mass [HBM], and C57BL/6J wild type [WT]) and two age groups (6 and 22 months old). Femurs from HBM (n=12) and WT (n=12) mice representing two age groups (6 and 22 months) were embedded in quick setting plastic (EpoThin Resin) in order to help cut 300 to 400 μm thick sections. Each femoral section's anatomical was identified and scanned using high resolution MicroXCT-200 (Carl Zeiss/Xradia Inc.). All scans were done using 40X objective lens to obtain the best possible resolution of 0.6μm pixel size. Each femur was scanned at the anterior-medial site with a field of view (FOV) of 0.5mm x 0.5mm, and 1000 images/specimen were collected with a scan time of 3 to 4hrs. All images were analyzed using Avizo 8.1software (FEI) to segment the osteocyte lacunar voids in the bone tissue. The lacunar voids with different sizes are shown in cortical bone with part of the mineral removed digitally (Figure -1). The voids range (50 μm³ to 610 μm³) that best represents the osteocyte lacunar were analyzed for their average volume (μm³), surface area (μm²), and density (#/mm³) along with an average distance from adjacent lacunae (μm) and void sphericity. A two way ANOVA was used to determine the genotype- and age- related differences (P<0.05). Osteocyte lacunar properties showed both genotype- and age-related differences in some of the measured properties (Table-1). While lacunar volume showed no difference due to genotype and age, the surface area was greater in HBM at younger age when compared to WT. There is a significant age-related increase in the lacunar density for WT which was also greater than HBM at older age. The near neighbor distances decrease with age in WT and remained lower than HBM at older age. Sphericity, a measure of a lacunar void being a true sphere (Sphericity =1) or ellipsoid (Sphericity < 1), suggest that WT lacunar voids are more spherical than those in HBM in younger age only. We conclude that there is both genotype- and age-related influence on osteocyte lacunar characteristic in some of the measured variables, and that may play a major role in skeletal health and response to exercise (mechanical stimuli).

Unloading conditions negatively affects bone homeostasis via endothelial-osteoblast-osteoclast interactions in vitro and in vivo. Vimal Veeriah*, Mattia Capulli, Angelo Zanniti, Nadia Rucci, Anna Teti, University of L'Aquila, Italy

Skeletal homeostasis is a major target of mechanical unloading. Endothelial cells (ECs) are sensitive to mechanical stimuli and to bone-seeking factors, therefore we hypothesized that ECs are implicated in the regulation of bone metabolism during unloading. ECs were subjected to MicroGravity, then Conditioned Media (MG-EC-CM) were collected and used to treat mouse primary osteoblasts. MG-EC-CM increased osteoblast proliferation (+1.5-fold;p=0.003) and decreased Alkaline Phosphatase (ALP) activity (-53%;p<0.001) and matrix nodule formation (-66%;p=0.010) compared to unit gravity EC-CM. MG-EC-CM increased osteoblast RANKL expression and osteoclastogenesis in osteoblast-bone marrow mononuclear cell co-cultures (+56%;p<0.001). It also induced the expression of the osteoblast differentiating factor, Lipocalin 2 (Lcn2) (+48-fold;p<0.001), whose silencing rescued ALP activity (+52%;p=0.024), decreased RANKL expression and reduced osteoclast formation (-38%;p=0.004), with no effect on osteoblast proliferation. MG-EC-CM enhanced osteoblast NO-Synthase 2 (NOS2) and CycloOxygenase 2 (COX2) expression, while inhibition of NOS2 or NO signaling reduced osteoblast proliferation and rescued ALP activity (+38%;p=0.004). Nuclear translocation of the Lcn2/NOS2 transcription factor, NF-kB, was observed in MG-EC-CM-treated osteoblasts and in MG-ECs, alongside a high expression of the NF-kB activator, IL-1β (+96-fold;p=0.002), with NF-kB inhibition reducing osteoblast proliferation and rescuing ALP. Lcn2 (+22-fold) and NOS2 (+12-fold) were also incremented in ex-vivo calvaria cultured with MG-EC-CM, and in tibias and calvarias (p=0.021) injected in-vivo with MG-EC-CM. Furthermore, the tibias of in-vivo models of mechanical unloading, including tail-suspended mice and mice treated with botulin A toxin to induce transient muscle paralysis, featuring decreased bone mass, showed higher expression of IL-1β (+5.8-fold;p=0.004), Lcn2 (+10-fold;p=0.002) and NOS2 (+23-fold;p=0.001), suggesting their involvement in the in-vivo EC-osteoblast crosstalk. We conclude that, MG-EC-CM induces Lcn2 and NOS2 in osteoblasts through IL-1β. Lcn2 impairs osteoblast differentiation and enhances RANKL expression and osteoclastogenesis, while NOS2 increases osteoblast proliferation. Targeting this EC-osteoblast-osteoclast regulatory loop could help improve the bone phenotype in unloading conditions.

Effects of 1 Month Spaceflight and 8 Days Recovery on Bone Structural and Quality Properties of Mice. Maude Gerbaix*¹, Vasily Gnyubkin¹, Delphine Farlay², Hélène Follet², Patrick Ammann³, Norbert Laroche¹, Boris Shenkman⁴, Guillemette Gauquelin-Koch⁵, Laurence Vico¹. ¹INSERM U1059, Biologie du Tissu Osseux, Université de Lyon, France, ²UMR-U1033-INSERM, Université de Lyon, France, ³Hôpitaux Universitaires de Genève (HUG), Switzerland, ⁴Institute for Biomedical Problems, Russian Academy of Sciences, Russia, ⁵Centre National d'Etudes Spatiales, France

Introduction

Site specific loss of bone mass is commonly observed after spaceflight both in human and rodent. However, bone quality response to flight and earth recovery remains poorly known. This study aims to characterize bone intrinsic properties alterations after spaceflight and to determine the bone events occurring during short term recovery.

Methods

Two groups of five C57/Bl6 male mice exposed to one month of spaceflight on the Russian Bion-M1 satellite were compared (Andreev-Andrievskiy A. et al., PloS One 2014). One group was euthanized 12 hours after landing (Flight), the other 8 days later (Flight+Rec). A ground synchronous control group (Ground Control) was placed in the same housing, climate and food conditions as two others during one month. Bone structure was evaluated by microCT, osteoclast activity by TRAP staining and intrinsic bone qualities by nanoindentation, microradiography and infra-red spectroscopy.

Results

At femur, spaceflight significantly decreased BV/TV, Ct.Th and increased TRAP+ osteoclasts at the periosteal surface. Nano indentation indicated a significant decrease in cortical plastic and elastic properties (modulus, hardness and working energy). One week of recovery tended to rescue these properties mainly at the third trochanter. Nevertheless, Ct.Th remained smaller in the Flight+Rec vs flight groups.

At vertebrae, spaceflight significantly decreased BV/TV which tended to be rescued by recovery. Degree of mineralization and mineral and collagen intrinsic quality (mineralization index, crystallinity, mineral and collagen maturity) remained unchanged.

Conclusions

One month of spaceflight severely altered the bone structure and intrinsic mechanical properties of femur without affecting mineralization and collagen of vertebrae. Interestingly, one week of recovery primarily tended to rescue the bone structure of vertebrae. Femur cortical plastic and elastic properties almost recovered whereas its cortex remained thinner. A better understanding of the adaptation of

trabecular and cortical compartments to microgravity and recovery as well as their intrinsic properties could help anticipate spationauts bone loss.

Greater Bone Accrual Occurs in African American Youth Before and After Puberty Compared to Euro-American Youth. Laura Armas*¹, Patrice Watson¹, Vicente Gilsanz², Thomas Hangartner³, Heidi J. Kalkwarf⁴, Kalkwarf⁴, Sharon Oberfield⁵, John Shepherd⁶, Karen K. Winer⁷, Babette Zemel⁸, Joan M. Lappe¹. ¹Creighton University, USA, ²Children's Hospital Los Angeles, USA, ³Wright State University, USA, ⁴Cincinnati Children's Hospital Medical Center, USA, ⁵Columbia University, USA, ⁶University of California at San Francisco, USA, ⁷Unice Kennedy Shriver National Institute of Child Health & Human Development, USA, ⁸Children's Hospital of Philadelphia, USA

African American (AfrAm) adults have higher bone mass than people of European ancestry (EuAm) of the same sex and age, and this difference is not present at birth. Greater peak bone mass is achieved through higher rates of bone accrual. Our purpose is to investigate when the greatest difference occurs in bone accrual between AfrAm and EuAm children. The BMDCS was a multicenter cohort study with 2014 subjects, ranging in age from 5 to 19 yrs who were evaluated annually for up to 7 visits. Bone mineral content (BMC) and areal bone mineral density (aBMD) of total body, lumbar spine and hip were acquired by DXA and Tanner staging (TS) was assessed by physical exam. Each pair of consecutive DXA's on a given subject was converted into a single observation of velocity: ((BMC at 2nd visit – BMC at 1st visit)/ time between visits (yrs)). Observations were categorized by ancestry group, sex, and TS. (See Table.) TS was further classified as pre-pubertal if TS was 1 at start and end of velocity interval, and as post-pubertal if TS was 5 at the start and end of the interval. In boys and in girls, mixed effects regression was used to investigate the effects of ancestry on BMC and aBMD velocity in pre-pubertal, peri-pubertal and post-pubertal groups, and on BMC/ BMD increase from start to end of peri-puberty, defined as TS 2 at beginning of interval to TS 4 at end of interval. Ancestry group differences during peri-puberty: BMC and BMD velocity were strongly associated with TS, and ancestry by TS interactions were observed. The model was used to compare total BMC/BMD accrual (gm) during peri-puberty, and no significant ancestry group differences were observed in either sex or at any bone site. Ancestry group differences in BMC/BMD velocity: 1) prepuberty, significantly higher accrual velocities in AfrAm. AfrAm boys had higher velocities for TBBMC/BMD, hip BMC/BMD, and spine BMD. AfrAm girls had higher velocities for TBBMC. 2) post-puberty, significantly higher accrual velocities in AfrAms. AfrAm boys had higher velocities for TBBMC/BMD and hip BMC. AfrAm girls had higher velocities for spine BMD. Findings from this large cohort are in agreement with previous findings that AfrAm have higher bone accrual than whites during pre-puberty and not during peri-puberty. In addition, we conclude that AfrAm vs EuAm BMC/BMD differences may be partially accounted for by differences in accrual velocity in post-puberty. 1. Maternal Gestational Vitamin D Supplementation and Offspring Bone Mass: A Multicentre Randomised, Double-Blind, Placebo-Controlled Trial (MAVIDOS). Cyrus Cooper¹, Nicholas C Harvey¹, Nicholas J Bishop², Stephen Kennedy³, Aris T Papageorgiou³, Robert Fraser⁴, Saurabh V Gandhi⁴, Stefania D'Angelo¹, Sarah R Crozier¹, Rebecca J Moon¹, Nigel K Arden⁵, Elaine M Dennison¹, Keith M Godfrey¹, Hazel M Inskip¹, Inez Schoenmakers⁶, Ann Prentice⁶, Zulf Mughal⁷, Richard Eastell⁸, David M Reid⁹, Kassim Javaid⁵, MAVIDOS Study Group¹. ¹MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, ²Academic Unit of Child Health, Sheffield Children's Hospital, University of Sheffield, United Kingdom, ³Nuffield Department of Obstetrics & Gynaecology, John Radcliffe Hospital, University of Oxford, United Kingdom, ⁴Sheffield Hospitals NHS Trust (University of Sheffield), United Kingdom, ⁵Oxford NIHR Musculoskeletal Biomedical Research Unit, Nuffield Department of Orthopaedics, Rheumatology & Musculoskeletal Sciences, The Botnar Research Centre, University of Oxford, United Kingdom, ⁶MRC Human Nutrition Research, Elsie Widdowson Laboratory, United Kingdom, ⁷Central Manchester University Hospitals, United Kingdom, ⁸Academic Unit of Bone Metabolism, University of Sheffield, United Kingdom, ⁹School of Medicine & Dentistry, Medical School, University of Aberdeen, United Kingdom

There is increasing evidence that maternal gestational vitamin D insufficiency might adversely influence offspring bone development. We evaluated the efficacy of 1000IU/day cholecalciferol during pregnancy for optimisation of neonatal bone mass in a UK multicentre randomised double-blind placebo-controlled trial (MAVIDOS, ISRCTN82927713).

Pregnant women with a serum 25-hydroxyvitamin D [25(OH)D] 25-100nmol/l at 12 weeks gestation were randomised to either 1000IU cholecalciferol/day or matched placebo until delivery. Plasma 25(OH)D concentration was measured in a central laboratory at 14 and 34 weeks gestation (Diasorin Liaison). Within two weeks after birth, whole body bone mineral content (BMC) of the offspring was assessed by dual-energy X-ray absorptiometry.

DXA information was available for 665 infants for the intention to treat analysis. Whole body BMC was non-significantly greater in infants born to mothers supplemented with vitamin D (61.6 ± 11.7 g vs 60.5 ± 11.1 g, $p=0.21$). However, in a pre-specified analysis, there was an interaction between treatment allocation and season of birth ($p=0.04$), such that infants born in winter months (December-February) to mothers randomised to cholecalciferol had greater BMC than infants of mothers randomised to placebo (63.0 ± 10.8 g vs 57.5 ± 10.9 g, $p=0.004$), a difference >0.5 SD. Similar patterns were observed for bone area and bone mineral density. At 34 weeks gestation, mean 25(OH)D was greater (68.2 ± 21.9 nmol/l vs 43.4 ± 22.4 nmol/l, $p<0.001$) and the proportion of women with vitamin D insufficiency [25(OH)D <50 nmol/l] reduced (16.6% vs 63.5%, $p<0.001$) in the women who had received the vitamin D supplement compared to placebo. In the placebo group, 25(OH)D declined from 14 to 34 weeks in women who delivered in winter or spring, but increased in those who delivered in summer or autumn (all $p<0.001$). These seasonal differences were entirely removed by vitamin D supplementation, with 25(OH)D rising from 14 to 34 weeks irrespective of season of birth ($p<0.001$). No safety issues were identified.

Maternal supplementation with 1000IU/day cholecalciferol during pregnancy increases bone mass in offspring born during winter months, and prevents the seasonal decline in 25(OH)D in these mothers. These findings have implications for public health policy relating to antenatal vitamin D supplementation. CC and NCH are joint first author.

The Effect of Insulin Resistance on the Cortical Bone-IGF-I Relationship in Children. Joseph Kindler¹, Norman Pollock², Emma Laing¹, Kathleen Hill Gallant³, Stuart Warden⁴, Connie Weaver³, Munro Peacock⁵, Carlos Isaacs², Richard Lewis¹. ¹The University of Georgia, USA, ²Georgia Regents University, USA, ³Purdue University, USA, ⁴Indiana University, USA, ⁵Indiana University School of Medicine, USA

During pubertal maturation, insulin-like growth factor I (IGF-I) plays a key role in bone mass accrual and cortical bone expansion. Although normal maturational growth is accompanied by fluctuations in insulin resistance, excessive insulin resistance during adolescence has been identified as a negative predictor of appendicular cortical bone size and strength. The aim of this study was to determine whether the relationships between IGF-I and cortical bone geometry differ among children with normal and higher insulin resistance. Participants included 61 healthy black and white boys and girls (mean \pm SD age 11.3 ± 1.2 years). Tibia and radius cortical bone and muscle cross-sectional area (MCSA) were assessed via peripheral quantitative computed tomography (Stratec XCT 2000) at the 66% site relative to the

distal growth plate. In sera, IGF-I (ng/ml) was measured by ELISA, insulin (uU/mL) by RIA, and glucose (mmol/L) by the enzymatic Autokit glucose method. The homeostasis model assessment of insulin resistance (HOMA-IR) was calculated ($\text{[insulin} \times \text{glucose]} / 22.5$). Based on the HOMA-IR cutoff of 4.0, normal ($n=30$) and higher ($n=31$) insulin resistance groups were determined. Multiple linear regression analyses were conducted adjusting for race and sex. Subsequent analyses were performed controlling for MCSA. In all children, IGF-I was a positive predictor of tibia cortical bone mineral content (Ct.BMC; $\beta=0.31$, $p<0.01$), area (Ct.Ar; $\beta=0.34$, $p<0.01$), and thickness (Ct.Th; $\beta=0.34$, $p<0.01$), and polar strength strain index (pSSI; $\beta=0.25$, $p<0.05$). The relationship with Ct.Th persisted after leg MCSA adjustment ($\beta=0.24$, $p<0.05$). However, these relationships were modified when children were divided by insulin resistance status. In the normal insulin resistance group: 1) IGF-I positively predicted tibia Ct.BMC ($\beta=0.47$, $p<0.01$; $\beta=0.32$, $p<0.05$), Ct.Ar ($\beta=0.44$, $p=0.01$; $\beta=0.28$, $p<0.05$) and Ct.Th ($\beta=0.61$, $p<0.01$; $\beta=0.59$, $p<0.01$) with and without MCSA-adjustment; 2) IGF-I positively predicted radius Ct.BMC ($\beta=0.53$, $p<0.01$), Ct.Ar ($\beta=0.49$, $p<0.01$), Ct.Th ($\beta=0.43$, $p<0.05$), and pSSI ($\beta=0.45$, $p<0.05$); and 3) after controlling for MCSA, IGF-I positively predicted radius volumetric density ($\beta=0.50$, $p<0.05$) and Ct.BMC ($\beta=0.32$, $p<0.05$). Conversely, IGF-I was not associated with any cortical bone outcomes among children with higher insulin resistance. To our knowledge, this is the first study to identify insulin resistance as an important factor involved in the cortical bone-IGF-I relationship.

Decreased bone mass in perinatally HIV-infected school-aged South African children on antiretrovirals. Stephen Arpadi¹, Stephanie Shiau¹, Renate Strehlau², Francoise Pinillos², Faezah Patel², Louise Kuhn¹, Ashraf Coovadia², Sarah Ramteke¹, Jonathan Kaufman³, Michael Yin¹. ¹Columbia University Medical Center, USA, ²University of the Witwatersrand, South Africa, ³Mount Sinai School of Medicine, USA

Background: Decreased bone mineral content (BMC) and bone mineral density (BMD) by dual-energy X-ray absorptiometry (DXA) have been described in children with HIV-infection. However, no studies have been conducted in resource limited settings, where $>90\%$ of HIV-infected youth now live.

Methods: We present baseline results of the bone sub-study of CHANGES, a prospective, two-year observational cohort study of 220 HIV+ and 180 HIV- prepubertal South African children who initiated ART before age 2. Weight- (WAZ) and height- (HAZ) Z-scores were calculated using WHO standards and CD4 and HIV RNA levels were measured. BMC and BMD of the whole body (WB) and lumbar spine (LS, L1-4) by DXA were assessed using a Hologic Discovery W densitometer (Hologic Inc, Bedford, MA). Reference curves from the BMD in Childhood Study were used to generate Z-scores for WB and LS BMC (Kalkwarf 2007). All measures were compared between HIV+ and HIV- children by t-tests and chi-squared tests.

Results: 220 HIV+ children (49.1% male) and 180 HIV- children (55% male) were included. HIV+ children were younger than controls (mean age 6.4 vs. 7.1 years, $p<0.01$). All HIV+ children were on antiretroviral therapy (ART). Half were on a ritonavir-boosted lopinavir-based and half were on an efavirenz-based regimen, both in combination with two nucleoside reverse transcriptase inhibitors, including lamivudine and abacavir or stavudine, but not tenofovir. Mean duration on ART was 5.6 years. 93.2% had HIV RNA <400 cps/mL at the time of evaluation. Mean CD4% was 37.3. HIV+ children had lower mean WAZ (-0.82 vs -0.56 , $p<0.01$) and HAZ (-1.37 vs -1.16 , $p=0.03$) than HIV-children. WB BMC and BMD were lower in HIV+ compared to HIV- children, and the difference remained significant after adjustment for weight and height ($p<0.01$) (Table 1). Similarly, LS BMC and BMD were lower in HIV+ compared to HIV- children, but not after adjustment for weight and height. Similar patterns were observed with WB and LS BMC Z-score. When analysis was limited to 60 HIV+ and 53 HIV- children with normal growth (WAZ and HAZ between -1 and 1), WB BMC, WB BMD, LS BMC and LS BMD remained lower in the HIV-infected group.

Conclusions: Despite early initiation of ART and excellent virologic control, in this sample of South African school aged children, HIV+ children receiving ART have lower indices of bone quality by DXA compared to HIV- controls. Differences cannot entirely be accounted for by smaller body size alone.

Table 1

| Measurement | HIV+ | HIV- | P-value |
|-----------------------------|-----------------|-----------------|---------|
| WB BMC (g) | 416 \pm 98 | 496 \pm 123 | <0.001 |
| WB BMD (g/cm ²) | 0.51 \pm 0.06 | 0.56 \pm 0.07 | <0.001 |
| LS BMC (g) | 14.5 \pm 3.1 | 16.1 \pm 3.4 | <0.001 |
| LS BMD (g/cm ²) | 0.46 \pm 0.06 | 0.49 \pm 0.07 | <0.001 |
| WB BMC Z-score | -3.32 \pm 1.8 | -2.06 \pm 1.6 | <0.001 |
| LS BMC Z-score | -2.18 \pm 1.6 | -1.59 \pm 1.3 | <0.001 |

Growth, Body Mass Index, Bone Health And Ambulatory Status Of Boys With Duchenne Muscular Dystrophy (DMD) Treated With Daily Versus Intermittent Oral Glucocorticoid Regimen. Nicola Crabtree¹, Raja Padidela², Nicholas Shaw¹, Wolfgang Hogler¹, Helen Roper³, Imelda Hughes², Judith Adams⁴, Anjali Daniel², Zulf Mughal². ¹Birmingham Children's Hospital, United Kingdom, ²Royal Manchester Children's Hospital, United Kingdom, ³Heart of England Hospital, United Kingdom, ⁴Manchester Royal Infirmary, United Kingdom

Oral glucocorticoids (GC; prednisolone dose of 0.75 mg/kg/day), help to preserve muscle strength and prolong independent walking in boys with DMD. This study compared longitudinal growth, body mass index (BMI), bone mineral density (BMD), vertebral fractures (VFs) and ambulatory status in boys with DMD on daily (DAILY) or intermittent (INTER; 10 days on & 10 days off), oral GC regimens.

Fifty DMD boys from two centres were included in the study; 25 boys each were on the DAILY or the INTER regimen. Size adjusted lumbar spine BMD (LS BMAD), total body less head BMD (TBLH), VF assessment and forearm pQCT data were analysed in all boys at three time points; baseline, 1 and 2 years.

At their first (baseline) assessment, there were no significant differences in mean (SD) age (8.3 (2.5) years) or any of the bone parameters, but DAILY boys were already shorter ($p=0.013$) with higher BMI ($p=0.014$). There were no documented VFs; however 1 DAILY and 3 INTER boys had suffered long bone fractures. All DAILY boys were still ambulant whereas 5 INTER boys had already stopped walking. Prior to the 2 year assessment, 6 of the DAILY boys had sustained symptomatic VFs and were subsequently commenced on IV bisphosphonate therapy; these boys were excluded from further follow-up bone parameter comparisons. At 2 years, 6 DAILY boys and 10 INTER boys had lost ambulation and the difference in height between DAILY and INTER boys had increased significantly ($p<0.001$). The DAILY boys also had significantly higher BMI SDS but lower BMAD and TBLH Z-Scores. Most notably, significantly more DAILY boys had VFs compared to INTER boys (13 DAILY versus 4 INTER; $p = 0.015$). Only 2 of the 16 boys with VFs also had low BMAD ($z<-2$); in contrast 14 had low TBLH BMD Z-scores and 11 had low trabecular BMD Z-scores.

Boys on a daily GC regimen appear to remain ambulant longer but at the cost of significantly greater VFs, greater adiposity and markedly diminished growth. In contrast, the boys on the intermittent GC regimen had fewer fractures but lost ambulation earlier. In both groups, LS BMAD was a poor predictor of VFs.

EphB/ephrin-B interactions regulate stromal cell fate determination and bone marrow support. Stan Gronthos¹, Thao Nguyen¹, Louise Purton², Koichi Matsuo³, Agnes Arthur⁴. ¹University of Adelaide, Australia, ²St. Vincent's Institute of Medical Research, Australia, ³School of Medicine Keio University, Japan, ⁴School of Medical Sciences, Australia

Bone marrow mesenchymal stromal/stem cells (BMSC) residing within a perivascular niche, are essential for regulating skeletal tissue homeostasis, including bone formation and repair. However, the molecular signals that maintain multipotential MSC populations within the stem cell niche and the mechanisms that drive their support of hematopoiesis are not well understood. The tyrosine kinase receptor, EphB4, mediates cross-talk between BMSC and hematopoietic populations during bone remodelling, fracture repair and arthritis, through its interactions with the ligand, ephrin-B2. The present study demonstrated that BMSC transgenic EphB4 mice (EphB4 Tg), over-expressing EphB4 under the control of collagen type-1 promoter, exhibited higher frequencies of osteogenic cells and hematopoietic stem/progenitor cells, correlating with a higher frequency of long-term culture-initiating cells (LTC-IC), compared to wildtype mice. EphB4 Tg stromal feeder layers displayed a greater capacity to support LTC-IC in vitro, where blocking EphB4/ephrin-B2 interactions decreased LTC-IC output. Similarly, shRNA mediated EphB4 knock-down in human bone marrow stromal cells reduced their ability to support high ephrin-B2 expressing CD34+ hematopoietic stem/progenitor cells in LTC-IC cultures. Notably, irradiated EphB4 Tg mouse recipients displayed enhanced bone marrow reconstitution capacity and enhanced homing efficiency of transplanted donor hematopoietic stem/progenitor cells relative to wildtype controls. Studies examining the expression of hematopoietic supportive factors produced by stromal cells indicated that CXCL12, Angiopoietin-1, IL-6, FLT-3 ligand and osteopontin expression were more highly expressed in EphB4 Tg stromal cells compared to wildtype controls. These findings indicate that EphB4 facilitates stromal mediated support of hematopoiesis, and constitute a novel component of the HSC niche.

Inhibition of FGF-23 Signaling Ameliorates Anemia in a Mouse Model of Chronic Kidney Disease. Despina Sitara¹, Lindsay Coe^{2*}, Regina Goetz², Moosa Mohammadi², Stefano Rivella³. ¹New York University College of Dentistry, USA, ²New York University, USA, ³Weill Cornell Medical College, USA

We recently reported that Fibroblast Growth Factor-23 (FGF-23), the primary regulator of phosphate homeostasis and vitamin D metabolism, also regulates erythropoiesis. High FGF-23 levels are associated with several diseases including Chronic Kidney Disease (CKD) and correlate with declining renal function and disease progression. Anemia is a common complication in CKD caused by insufficient renal production of erythropoietin (EPO), the hormone responsible for red blood cell production (RBC) in the bone marrow (BM). The primary physiological stimulus of Epo induction is hypoxia through activation of the hypoxia inducible factors (HIFs). We recently reported that administration of FGF-23 in wild-type mice rapidly decreases erythropoiesis and the hematopoietic stem cell (HSC) pool size, whereas genetic inactivation of Fgf-23 results in increased red blood cell (RBC) production and HSC frequency in the circulation and BM of young adult mice and in fetal livers. Moreover, our data show that loss of Fgf-23 is associated with significantly high EPO levels and increased HIF mRNA expression, suggesting a novel role for FGF-23 as a negative regulator of erythropoiesis. Therefore, our hypothesis is that high FGF-23 levels may contribute to the development of anemia in CKD and, if so, blocking FGF-23 signaling may present a viable treatment option for CKD patients. To test this, we used a mouse model of CKD induced by 5/6 nephrectomy (Nx) and injected them with a competitive inhibitor of FGF-23 binding to its receptor. 5/6 Nx mice exhibit significantly lower EPO levels, however, treatment with the FGF-23 inhibitor results in significantly elevated Epo levels compared to vehicle-treated mice. This increase in Epo is due to an induction of HIF mRNA expression. Most importantly, we found that treatment of 5/6 Nx mice with the FGF-23 inhibitor restores erythroid cell production to normal levels. Taken together, our data show that blocking FGF-23 signaling improves erythropoiesis and ameliorates anemia in a mouse model of CKD, suggesting a novel therapeutic strategy for the treatment of anemia associated with CKD and other diseases.

Megakaryocytes: Regulators of Bone Mass and Hematopoiesis. Marta Alvarez^{*}, LinLin Xu, Evan Himes, Brahmananda Chitteti, Ying-Hua Cheng, Andrew Engle, David Olivos, Paul Childress, Edward Srour, Melissa Kacena. Indiana University School of Medicine, USA

Emerging evidence demonstrates that megakaryocytes (MK) play a key role in regulating skeletal homeostasis and hematopoiesis. Recent reports show that MK reside in close proximity to hematopoietic stem cells (HSC). Genetic depletion of MK resulted in mitotic activation of HSC suggesting that MK maintain HSC quiescence. Other studies demonstrated that following irradiation, surviving MK migrate to endosteal surfaces whereby numbers of osteoblast (OB) lineage cells dramatically increase and promote engraftment of transplanted HSC. Our studies have shown that MK markedly increase proliferation of OB lineage cells while simultaneously inhibiting differentiation. We also showed that less mature OB lineage cells are better able to support hematopoiesis.

Here we investigated if MK directly impact hematopoiesis or whether they indirectly support HSC function through their interaction with OB lineage cells. Our data strongly suggest that LSK (Lin-Sca+CD117+, an enriched HSC population) co-cultured with MK and OB generate significantly higher numbers of colony forming cells (a gauge of HSC function) compared to LSK co-cultured with either MK or OB alone. The functionality of this in vitro data was confirmed in vivo with transplantation studies which showed increased engraftment in mice transplanted with LSK cells co-cultured with OB and MK compared to LSK cells co-cultured with OB alone (Figure 1). To test if loss of MK negatively impacts osteoblastogenesis and consequently hematopoiesis through impeding the hematopoiesis enhancing activity of OB, we generated conditional knockout (CKO) mice where cMpl, the receptor for the main MK growth factor, thrombopoietin (TPO), was deleted specifically in MK (cMpl^{fl/fl} x PF4Cre). Unexpectedly, these mice exhibited a 10-fold increase in platelet numbers, megakaryocytosis, a dramatic expansion of phenotypically defined hematopoietic precursors, and a remarkable 20-fold increase in the bone volume fraction (Figure 2).

Collectively, these data indicate that while MK modulate HSC function, this activity is in part mediated through interactions with OB and suggest an intricate and complex role for TPO and MK in HSC regulation. While work is needed to further elucidate mechanisms, understanding the coordinated interaction between MK, OB, HSC, and TPO/cMpl should inform the development of novel treatments to enhance HSC recovery following myelosuppressive injuries, as well as bone loss diseases, such as osteoporosis.

FR0060

Osteoblast Fibronectin Stimulates Myelopoiesis and Affects the Behavior of Myeloid-Derived Cells *In Vivo*. Stephanie Rosnagl^{*1}, Sabrina Kraft¹, Eva Altrock¹, Carla Sens¹, Katrin Rau¹, Verena Klemis¹, Inaam Nakchbandi². ¹University of Heidelberg & Max-Planck Institute of Biochemistry, Germany, ²Max-Planck Institute of Biochemistry & University of Heidelberg, Germany

Osteoblasts affect hematopoietic stem cell differentiation. They also produce fibronectin isoforms that affect their own differentiation (J Bone Miner Res 2010). The aim of this work was therefore to determine whether osteoblast fibronectin affects hematopoiesis.

Conditional deletion of fibronectin in differentiating osteoblasts (cKO) resulted in a 30% decrease in myeloid cells in the bone marrow due to defective differentiation of the progenitors without affecting peripheral blood counts. Osteoblasts produce several fibronectin isoforms. An isoform containing the extra domain A (EDA-FN) enhanced myelopoiesis *in vitro* while other isoforms did not. EDA-FN binds to $\alpha 4\beta 1$, $\alpha 9\beta 1$ and enhances binding to $\alpha 5\beta 1$ integrin. Further studies identified $\alpha 5\beta 1$ integrin as the mediator of CD11b differentiation in response to EDA-FN.

The myeloid cells of the bone marrow can differentiate to myeloid-derived suppressor cells (MDSCs). Fibrosis represents a wound healing process where MDSCs prevent an excessive immune response. Indeed, induction of liver fibrosis in mice resulted in enhanced fibrosis in cKO animals that have less MDSCs. Another function of MDSCs is the detrimental inhibition of the immune response against tumors. A decrease in MDSCs in cKO animals was therefore associated with enhanced defense against cancer and suppressed cancer growth in two different cancer models. Adoptive transfer experiments injecting *in vitro* differentiated CD11b+ cells in mice with cancer cells confirmed the causal relationship between EDA-mediated CD11b differentiation and effects on cancer growth. Thus, the presence of EDA during CD11b+ cell differentiation is responsible for the anti-inflammatory behavior of these cells.

We next wondered whether EDA affects the immune signature of myeloid cells. The mRNA expression of cytokines involved in MDSCs response was evaluated in various types of isolated CD11b+ cells. The pro-inflammatory factors IL-6, iNOS and IFN- γ were higher and the anti-inflammatory Arg-1 was lower in cells from healthy cKO bone marrow, cKO tumors, or *in vitro* differentiated CD11b+ cells not exposed to EDA. Thus, EDA supports the differentiation of CD11b+ cells with anti-inflammatory immune profile.

In summary, EDA-containing fibronectin originating from the osteoblasts acts via $\alpha 5\beta 1$ to enhance the differentiation of anti-inflammatory myeloid cells. While this is beneficial under normal wound healing conditions and fibrosis, it contributes to enhanced cancer growth.

NELL-1 induces Expansion of Sca-1+ Mesenchymal Stem Cell Population for Bone Formation. Aaron James^{*1}, Jia Shen², Greg Asatrian², Swati Shrestha², Ben Wu³, Xinli Zhang², Kang Ting², Chia Soo⁴. ¹University of California, Los Angeles, USA, ²Division of Growth & Development & Section of Orthodontics, School of Dentistry, USA, ³Department of Bioengineering, School of Engineering, USA, ⁴UCLA Division of Plastic Surgery & Department of Orthopaedic Surgery & the Orthopaedic Hospital Research Center, University of California, Los Angeles, USA

Introduction: Recombinant (r)NELL-1 has been studied as an alternative osteoinductive factor to BMP2 (Bone Morphogenetic Protein2) in pre-clinical orthopaedic models. Moreover, rNELL-1 has been recently described as a novel systemic agent that reverses osteoporotic bone loss. This study aims to identify a mechanism of action that unifies both the local and systemic bone-forming effects of rNELL-1. **Methods:** The local and systemic effects of rNELL-1 were examined across animal models, including (1) NELL-1 deficient mice, (2) intramedullary rNELL-1 injection in the rat, (3) systemic rNELL-1 injection in the mouse, and (4) non-human primate spinal fusion. Intramedullary rNELL-1 injection was performed utilizing a TCP carrier, while systemic injection was via repeated rNELL-1 intravenous injection. Interlumbar spinal fusion in primates was performed using a scaffold composed of demineralized bone matrix and rNELL-1 (up to 1.7mg/ml). In each model, stem cell populations were analyzed using a combination of FACS for stem cell markers (including Sca-1 and Stro-1), CFU assays, and immunostaining for Sca-1+ MSC. Bone formation was confirmed by a combination of radiologic (micro computed tomography), histologic, static and dynamic histomorphometric, and immunohistochemical analyses. **Results:** NELL-1 deficient mice demonstrated marked reductions in the numbers of Sca-1+CD45- bone marrow MSC (Fig. 1A), reduction in stem cell content, and a significant osteoporotic phenotype (Fig. 1B). rNELL-1 treatment had converse effects on stem cell content and bone formation. Either local intramedullary or systemic rNELL-1 injection showed increased numbers of Sca-1+CD45- bone marrow MSC (~75% increase in cell number, Fig. 1C), increased MSC content (CFU-F assays), accompanied by an increase in bone anabolic markers, and microCT based bone measurements (Fig. 1D). Finally, rNELL-1 implantation in a non-human primate spinal fusion model led to 100% fusion rates (Fig. 1E), significantly increased BV/TV and BMD, and histological evidence of bony bridging. Significantly, more Sca-1+ MSC were identified within the marrow cavity of newly formed trabecular

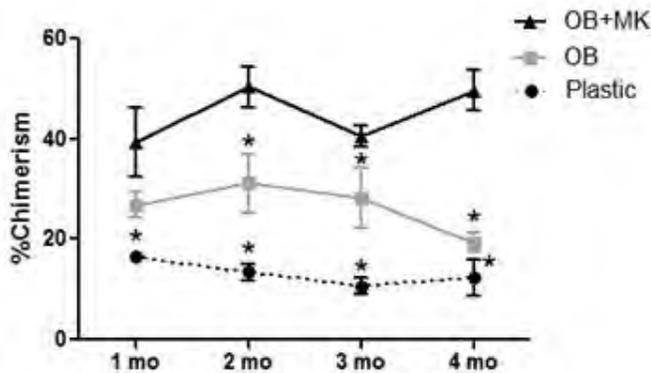

Figure 1 % engraftment from LSKs co-cultured with OB+MK, OB, or LSK alone.

Disclosures: Marta Alvarez, None.

bone with rNELL-1 treatment (Fig. 1F). Discussion: In summary, rNELL-1 induces bone formation across small and large animal models either via local implantation or intravenous delivery. NELL-1 induces an expansion of Sca-1+ cells and MSC content in bone marrow milieu, resulting in clinically significant bone anabolism and repair.

N-cadherin in Osteolineage Cells Modulates the Tumor Environment. Francesca Fontana¹, Jacqueline Kading², Jingyu Xiang³, Marcus Watkins⁴, Katherine Weilbaecher³, Roberto Civitelli⁴. ¹Bone & Mineral Diseases, USA, ²Division of Bone & Mineral Diseases, Washington University School of Medicine in St Louis, USA, ³Division of Molecular Oncology, Washington University School of Medicine, USA, ⁴Division of Bone & Mineral Diseases, Washington University School of Medicine, USA

Tumor establishment and growth entail interactions with the environment through cell-cell contact and secretory factors. N-cadherin (Ncad) in tumor cells has been shown to promote migration and metastases in animals; it was also proposed to facilitate engraftment and growth of disseminated tumor cells (DTC) in bone via adhesion to osteogenic cells. We and others have shown that Ncad is expressed in bone cells, and genetic ablation of the Ncad gene (*Cdh2*) in osteolineage cells leads to low bone mass and reduced osteoprogenitor number, while it accelerates osteogenic differentiation via increased Wnt and PTH signaling. To determine the role of Ncad in interactions between bone and tumor cells, we conditionally deleted *Cdh2* using a Cre recombinase driven by a doxycycline-repressible *Sp7* promoter *Cdh2^{fl/fl};Sp7-Cre* (cKO), and inoculated cKO and wild type mice with breast cancer cell (BCC) lines derived from a MMTV-PYMT tumor in a Black6 background. Moderately stunted growth was observed among cKO mice (20% lower body weight at 3 months vs. wild type, $p=0.004$), and this was prevented by perinatal doxycycline treatment – which suppresses *Sp7-Cre* expression – without effects on tumor growth. Crossing of *Sp7-Cre* mice with the *Ai9* reporter mice revealed effective targeting of 7.6% (range 5-9%) of total bone marrow cells (by FACS). Surprisingly, 2% (range 0.7-3%) of tumor-associated stromal cells were also targeted by *SP7-Cre*, implying a biologic effect of the tumor on the host microenvironment. Injection of a murine breast cancer cell line (MMTV) and a bone-metastatic derivative line (BO1) in the mammary fat pad and tibia of cKO resulted in similar tumor growth relative to control mice at both sites. However, subcutaneous inoculation of the BO1 line resulted in larger tumors in cKO than in wild type mice by caliper measurement (20% by day 10 and 30% by day 12; two-way ANOVA for genotype vs. time <0.001). Bone marrow DTC, detected through GFP expression (10^1 - 10^3 per million bone marrow cells), were observed in the presence of subcutaneous primary tumors as well as months after tumor resection, without significant differences between cKO and wild type mice. Our results suggest that Ncad is dispensable for the engraftment and growth of BCC to the bone; however, we find that Ncad plays an unexpected role as a negative regulator of stromal support of tumor growth via paracrine or endocrine mechanisms.

Pivotal role of TAK-1 in tumor growth and bone destruction in myeloma: therapeutic impact of TAK-1 inhibition. Jumpei Teramachi^{1*}, Masahiro Hiasa¹, Asuka Oda¹, Hirofumi Tenshin¹, Ryota Amachi¹, Takeshi Harada¹, Shingen Nakamura¹, Hirokazu Miki², Isturo Endo¹, Tatsuji Haneji¹, Toshio Matsumoto¹, Masahiro Abe¹. ¹Tokushima University, Japan, ²Tokushima University Hospital, Japan

Multiple myeloma (MM) has a unique propensity to develop and expand almost exclusively in the bone marrow and generates destructive bone disease. We have reported that Pim-2 is overexpressed in MM cells and their surrounding cells, namely bone marrow stromal cells (BMSCs) and osteoclasts, in bone lesions, and that treatment with Pim inhibitors markedly suppressed MM tumor growth while preventing bone destruction in MM-bearing animal models, indicating Pim-2 as an important therapeutic target in MM. We recently found TGF- β -activated kinase-1 (TAK-1) as an upstream mediator responsible for Pim-2 up-regulation. In the present study, we therefore aimed to clarify the role of TAK-1 in tumor growth and bone destruction in MM. TAK-1 was constitutively over-expressed in MM cells while only marginally in normal peripheral blood mononuclear cells. The TAK-1 inhibitor LLZ1640-2 dose-dependently suppressed cell growth, and induced caspase-dependent apoptosis in MM cells. LLZ1640-2 almost completely abolished TNF- α -induced NF- κ B, p38MAPK and ERK activation and IL-6-induced STAT3 activation in MM cells. LLZ1640-2 as well as TAK-1 knock-down decreased VCAM-1 expression and IL-6 production in BMSCs, and MM cell adhesion to BMSCs to impair BMSC support of MM cell growth. Interestingly, phosphorylation of TAK-1 was induced in BMSCs and MC3T3-E1 preosteoblastic cells by addition of cytokines known as inhibitors of osteoblastogenesis in MM, including IL-3, IL-7, TNF- α , TGF- β and activinA, as well as MM cell conditioned media (MMCM), suggesting TAK-1 as a common mediator to suppress osteoblastogenesis in MM. Furthermore, LLZ1640-2 abolished up-regulation of Pim-2, an inhibitory mediator of osteoblastogenesis, in BMSCs and MC3T3-E1 cells by MMCM to restore mineralized nodule formation. Moreover, the TAK-1 inhibition up-regulated in MC3T3-E1 cells phosphorylation of Smad1/5 and p38MAPK by BMP-2 while suppressing Smad2/3 phosphorylation by TGF- β , suggesting potentiation of BMP-2-mediated anabolic signaling. TAK-1 was also up-regulated along with osteoclastogenesis. TAK-1 inhibition by LLZ1640-2 suppressed the induction of c-fos and NFATc1 as well as osteoclastogenesis in RAW264.7 preosteoclastic cells by MMCM or rRANK ligand. Finally, treatment with LLZ1640-2 potently suppressed MM growth in MM models with intratibial injection of murine 5TGM1 MM cells. Taken together, these results suggest that TAK1 plays a pivotal role in MM tumor growth and bone destruction, and that TAK1 may become an efficacious therapeutic target in MM.

The anti-diabetic drug Metformin reduces tumour burden and osteolytic bone disease in Multiple Myeloma in vivo. Siobhan Webb^{*}, Rosie Butler, Amanda Bacon, Ann Snaith, Sarah Gooding, Jessica Whitburn, Claire Edwards. University of Oxford, United Kingdom

Multiple myeloma (MM) is a fatal haematologic malignancy characterised by accumulation of malignant plasma cells in the bone marrow (BM), and severe lytic bone disease. Metformin is widely prescribed in diabetes, and recently associated with improved outcomes in diabetic patients with MM, suggesting a potential anti-myeloma effect of metformin. Our aim was to investigate the effect of metformin within the myeloma-bone microenvironment *in vitro* and *in vivo*. C57Bl/KaLwRij mice were inoculated with 5TGM1MM cells and treated with metformin either from time of tumour inoculation (met-cont) or from time of established tumour (met-delay). MM-bearing mice treated with metformin exhibited a decrease in myeloma-specific serum paraprotein as compared to control (Control; 4.29mg/ml \pm 0.3mg/ml, met-cont; 1.51mg/ml \pm 0.6mg/ml, $p<0.001$, met-delay; 0.7mg/ml \pm 0.7mg/ml $p<0.001$). MicroCT analysis demonstrated a significant decrease in osteolytic lesion number in MM-bearing mice treated with metformin (Control; 26 \pm 3.6, met-cont; 11.4 \pm 0.7 $p<0.001$, met-delay; 9 \pm 1.5 $p<0.01$). Histomorphometry revealed an increase in BV/TV of metformin mice compared to untreated MM (MM; 2.6% \pm 0.41, met-cont; 4.0% \pm 0.43 $p<0.05$, met-delay; 4.4% \pm 0.46 $p<0.05$). Metformin also increased osteoblast number (MM; 1.86/mm \pm 0.5, met-delay; 4.7/mm \pm 0.7, $p<0.01$, met-delay; 6.5/mm \pm 1.4 $p<0.01$) and decreased osteoclast number (MM; 2.86/mm \pm 0.4, met-cont; 1.6/mm \pm 0.1 $p<0.05$, met-delay; 1.2/mm \pm 0.2, $p<0.05$), as well as increasing trabecular thickness and decreasing trabecular separation compared to untreated MM. Interestingly, metformin had no significant effect on non-tumour mice, suggesting that the effect of metformin to reduce MM bone disease may be indirect, in response to the decrease in tumour burden. Metformin induced a dose-dependent decrease in MM cell viability. Metformin treatment of MM cells decreased IGF-1 gene expression and induced apoptosis, detected by increased cleaved caspase-3 and PARP. Metformin had no effect on BM stromal cell (BMSC) viability. BMSC-conditioned media (CM) had a protective effect against the anti-MM effects of metformin at 24h that was lost by 72h. In contrast, BMSC CM protected against the anti-MM effects of the proteasome inhibitor bortezomib at all time points. Our studies demonstrate a strong anti-tumour effect of metformin in the MM-bone microenvironment, suggesting that metformin may be effective for the treatment of MM and associated bone disease.

Long-term Safety of Denosumab Through Greater than 48 Doses in Giant Cell Tumor Patients. Susan Bukata¹, Madhuri Sudan², William Mendanha³, Neal Chawla³, Kamalesh Sankhala³, Sant Chawla³.¹UCLA, USA, ²Department of Epidemiology, UCLA School of Public Health, USA, ³Sarcoma Oncology Center, USA

Giant cell tumors of the bone (GCTB) are aggressive lytic tumors characterized by local invasion and limited non-surgical treatments. Stromal cells involved with GCTB express surface RANK ligand which is used to activate the osteolytic properties of the giant cells within the lesion. Denosumab is a RANK ligand inhibitor that has been shown to be effective in neutralizing this pathway, stopping the lytic destruction of the bone by the tumor. Because denosumab does not eliminate the stromal tumor cells, surgery is still required to clear the tumor.

In patients with unresectable tumors, long-term denosumab treatment has offered an opportunity to maintain tumor stability. We present a cohort of 42 such patients on 120 mg denosumab monthly (after 3 loading doses at 7 day intervals) who have received on average 48 doses of medication (Table 1). Safety, tumor stability, and patient comfort have been excellent. In addition, this cohort offers a unique opportunity to assess the long-term safety of multiple doses of denosumab, as they have now received more denosumab than osteoporosis patients would receive in a lifetime.

This patient population demonstrated a remarkably good safety profile on this medication. Myalgia (64%) and tooth pain (36%) were the most common complaints during treatment. Fourteen percent of patients complained of peripheral neuropathy, and other less common complications included eczema (10%), infection (10%), and cellulitis (10%). Osteonecrosis of the jaw (ONJ) also occurred in 10% of patients, and two patients developed atypical femur fractures. Only one case of ONJ was seen through the first 50 doses of medication (first case of ONJ occurred after 25 doses), with a notable increase in ONJ after 70 doses (Figure 1). Although tooth pain was seen frequently in patients with ONJ (75%), many patients without ONJ also complained of tooth pain (32%). Giant cell tumor suppression was maintained with rapid and sustained pain improvement with the therapy for all patients.

Conclusion: Long-term, high frequency dosing of denosumab in a population of giant cell tumor patients demonstrated a good safety profile and sustained tumor suppression. Complications did increase with prolonged dosing, but no complications occurred within the first 25 doses.

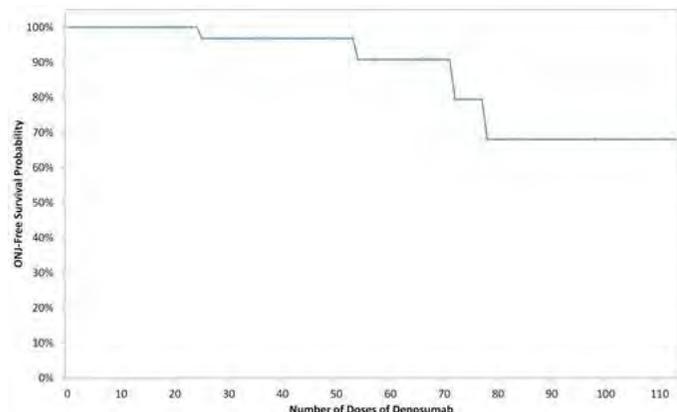

Figure 1. Probability of ONJ-free Survival by Total Number of Doses of Denosumab Administered

| | Total (n=42) |

A novel p53 isoform-dependent accelerated aging that causes osteoarthritis in mice. Yasuhiko Kawakami^{*}, Robyn Leary, Keianna Vogel, Hiroko Kawakami, Anindya Bagchi. University of Minnesota, USA

Purpose: Although aging is a major risk factor of osteoarthritis (OA), how aging affects OA is poorly understood. The goal of this proposal is to determine the role of the senescence-specific novel p53 isoform, found in our study, in OA development in mice. **Background:** We previously generated a mutant allele in mice, in which the D4Mit190-51 region on chromosome 4 is duplicated on one chromosome (duplicated allele: dp) and is deleted in another chromosome (deficiency allele: df). The df/dp alleles are a balanced chromosome and the mice are indistinguishable from wild type (WT) mice. However, dp/+ mice that harbor three copies of D4Mit190-51 region exhibited perinatal death with signs of cell senescence, a hallmark of aging. By following up this study, we succeeded in rescuing the dp/+ mice by genetically reducing p53 dosage, given that this locus indirectly regulates p53 on chromosome 11. This suggests that increased p53 activity caused the dp/+ mouse phenotype. **Methods:** By using collected tissue we examined knee joint tissue integrity by histological examination. We also performed RT-PCR with various primer sets and isolated a novel splice isoform of p53 from senesced dp/+ mouse embryonic fibroblasts (MEFs), which we termed as s-p53 (senescence-specific p53). Series of biochemical analyses were used to determine function of s-p53. **Results:** We found early lethality of df/dp; p53+/- mice (3-6 months of age) without tumor formation, compared to WT and p53+/- mice. The df/dp; p53+/- mice died by tumor, similar to p53+/- mice. By histological examination of the knee joint, we found early onset of joint cartilage degeneration of df/dp; p53+/- mice, compared to WT, p53+/- and p53+/- mice. Doxycycline-dependent inducible expression of s-p53 induced p21 expression and cell senescence in wild type cells, but not in p53+/- cells. By co-immunoprecipitation assays, we found that wild type p53 and s-p53 form a complex. In transmission electron microscopy analysis of MEFs, we found nuclear envelope blebbing in dp/+ cells, a characteristic of progeria. The blebbing phenotype was partially and completely rescued in dp/+; p53+/- and dp/+; p53+/- cells, respectively. **Conclusion:** Our results support the model that s-p53 forms complex with full length p53 and enhances p53 activity, which leads to cellular senescence, and that this process causes chondrocyte senescence and accelerated joint cartilage degeneration in mice.

Cartilage repair ability of scaffold-free tissue engineered construct(TEC) derived from osteoarthritis(OA) and rheumatoid arthritis(RA) patients' synovial mesenchymal stem cells(SMSC). Kota Koizumi*, Kosuke Ebina, Makoto Hirao, Takaaki Noguchi, Yukihiro Yasui, Norihiko Sugita, Hideki Yoshikawa, Norimasa Nakamura. Department of Orthopaedics, Osaka University Hospital, Japan

Purpose: We have developed scaffold-free TEC composed of SMSC and its cartilage-repairing efficacy in focal chondral defect of pig has been demonstrated. In addition, clinical trial of autogenic TEC in cartilage repair of the patients with traumatic knee injury (defined as control group; Ctrl) is on going in Osaka University Hospital. But autogenic TEC implantation have limitations such as multiple surgeries and cell culture period. Establishment of allogenic TEC bank may be useful in overcoming these problems. In this study, we evaluated the features and feasibility of SMSC and TEC derived from the patients with OA or RA, which can be obtained abundantly from routine surgeries compared with Ctrl.

Methods: 25 patients were divided into 4 groups (group name; female/total number, mean age = Ctrl; 2/6, 38.6, OA; 4/6, 71.2, RA without biologics (Bio-naive RA); 5/6, 67, RA with biologics (Bio RA); 6/7, 72.4). We analyzed the following items. 1:Proliferative ability of SMSC by WST-1 assay 2:Weight and volume of TEC composed of same cell number (1.52*10E6 / 6well dish) 3:Cytokine gene expression of TEC by qRT-PCR 4:Chondrogenesis of TEC by qRT-PCR and GAG component 5:Osteochondral repair at femoral trochlea groove (diameter1.5 × depth1mm) using TEC in nude rat (F344/NJcl/rnu, male, 12 week-old; evaluated by modified O'Driscoll score 8weeks after implantation)

Results: In every item, SMSC or TEC from OA and RA showed equivalent quality and quantity compared with Ctrl (mean ± SD, Ctrl / OA / Bio-naive RA / Bio RA). 1:Proliferation rate (Day3/Day1) 2.0 ± 0.16 / 1.8 ± 0.4 / 1.7 ± 0.3 / 1.7 ± 0.2, 2: Weight - Volume (mg - mm3); 5.9 ± 1.1 - 5.7 ± 1.2 / 6.1 ± 0.9 - 5.6 ± 0.7 / 6.5 ± 0.8 - 6.3 ± 0.8 / 5.7 ± 1.4 - 5.4 ± 1.3, 3: No significant difference in gene expression of IL1 β , IL6 and IL10 among all groups, 4: GAG component (%); 2.9 ± 0.4 / 3.1 ± 0.3 / 2.9 ± 0.75 / 3.2 ± 0.6, No significant difference in gene expression of SOX9, COL2 and ACAN, 5: All groups showed significantly better repair than defect group. (18.8 ± 0.8 / 18.8 ± 2.2 / 19 ± 1.0 / 20.0 ± 2.8 / Defect 11.5 ± 3.3)

Conclusions: Regardless of its higher age and inflammatory character, TEC derived from the patients with OA or RA showed similar quality and quantity compared with that from post-trauma patients. TEC from OA and RA patients may be promising source of cartilage repair and allogenic TEC bank, although further investigation with larger scale may be required.

Feasibility of TEC in cartilage repair

CK2.1, a novel BMP receptor mimetic peptide, induces cartilage formation *in vivo*. Hemanth Akkiraju*, Jonathan Avallone², Padma Srinivasan², Jeremy Bonor¹, Catherine Kirn Safran¹, Anja Nohe². ¹University of Delaware, USA, ²University of Delaware, Biological Sciences, USA

CK2.1 is a novel mimetic peptide based on the Bone Morphogenetic Protein (BMP) receptor type I sequence. Our research shows that this peptide CK2.1 induced chondrogenesis in C3H10T1/2 cells as well as in bovine chondrocytes. Here we demonstrate that systemic injection of the CK2.1 into the tail vein of 8 week old mice led to increased articular cartilage formation without chondrocyte hypertrophy. These

results are in sharp contrast to Bone Morphogenetic Protein 2 (BMP2) injections that led to increased trabecular bone and cartilage as well as chondrocyte hypertrophy. Fluorescence staining of articular cartilage shows that CK2.1 injected group had increased collagen type IX production but not collagen type X or MMP13. Furthermore second harmonic generation (SHG) imaging shows an increase in collagen fibrillar structure. CK2.1 acts by releasing Casein Kinase II (CK2) from the BMP receptor type I and activating the Smad signaling pathway. CK2.1 also induced COMP expression and upregulated *SOX9*, *CREB* and *NKX3.2* (genes associated with chondrogenesis). However, *ME2C*, *RUNX2* and *IHH* (genes associated with chondrocyte hypertrophy) were downregulated. These data show for the first time that CK2.1 induced chondrogenesis *in vitro* and enhance articular cartilage formation *in vivo* when injected systemically into mice. New therapeutics to treat Osteoarthritis or regenerate damaged cartilage are desperately needed and currently unavailable. Therefore CK2.1 maybe a new valuable treatment option for the restoration of cartilage defects in humans.

HIF1 α / β -catenin interaction prevents cartilage damage by inhibiting MMP13 expression in mice. Wafa Bouaziz*, Johanna Sigaux², Claire-Sophie Devignes¹, Thomas Funck-Brentano³, Hang-Korng Ea¹, Dominique Modrowski², Sylvain Provot², Martine Cohen-Solal¹, Eric Hay⁴. ¹INSERM U1132 University paris7, France, ²INSERM U1132, France, ³AP-HP, France, ⁴INSERMU1132 Université Paris 7, France

Purpose: Low oxygen tension (hypoxia) regulates chondrocyte differentiation and metabolism. HIF1 α is a crucial hypoxia factor for chondrocyte growth and survival. Few data focused on the role of hypoxia in the regulation of cartilage remodeling and maintenance in osteoarthritis (OA). Wnt/ β -catenin is a major chondrocyte regulator that might be down-regulated to preserve cartilage from damage. Here we investigated the role of HIF1 α and Wnt/ β -catenin to modulate MMP-13 and cartilage loss.

Methods: To determine the effect of HIF1 α in cartilage, we used mice with conditional deletion of HIF1 α in chondrocytes (Col2CreERT; fl/fl HIF1 α or ?HIF1 α chon) and WT (fl/fl HIF1 α) mice underwent destabilization of the medial meniscus (DMM) to induce OA. Hypoxia was monitored using Pimidazole probe in OA and undamaged cartilage. Cellular mechanisms were assessed using primary chondrocyte cultures of fl/fl HIF1 α mice. HIF1 α was modulated by siRNA strategy for the inhibition and by transduction of VHL resistant HIF1 α for stabilization.

Results: In WT mice, DMM decreased hypoxia levels in the articular cartilage along with a decrease HIF1 α expression. After DMM, ?HIF1 α chon mice showed increased cartilage breakdown and MMP-13 expression compared to WT mice. Chondrocytes cultured in hypoxic conditions (1%) showed that activation of Wnt/ β -catenin signaling was unable to induce the expression of the catabolic genes (Mmp-13, Mmp3), this effect being reversed by HIF1 α knock-down. Immunoprecipitation revealed decreased β -catenin/TCF4 complexes in hypoxia in favor of β -catenin/HIF1 α complexes. Moreover, chip assay and transactivation analysis demonstrated that HIF1 α inhibited the binding of β -catenin to Wnt responsive elements reducing the formation of β -catenin/TCF4 transcriptional activity, and thereby the expression of Mmp13. Finally, blockade of β -catenin/TCF4 direct interaction by PKF 118-310 alleviated the OA phenotype and Mmp13 downregulation.

Conclusions: We here demonstrated that HIF1 α is a negative regulator of MMP13 transcription and Wnt signaling through the direct interaction of HIF1 α / β -catenin. Our study sheds new light on the role of HIF1 α / β -catenin interaction in OA and brings new insights into the impact of hypoxia in regulating Wnt signaling in articular cartilage.

ADAMTS-12 protects against inflammatory arthritis through interacting with and inactivating proinflammatory CTGF. Jianlu WEI*, Wenyu Fu, Qingyun Tian, Chuanju Liu. Hospital for Joint Diseases of NYU, USA

It has been reported that ADAMTS-12 is a susceptibility gene for rheumatoid arthritis (RA) development (Nah et al, Mol. Med. Rep., 2012). In addition, we previously reported that ADAMTS-12 could directly bind to and degrade cartilage oligomeric matrix protein (COMP), and its level was significantly increased in RA patients (Liu, Nature Reviews Rheumatology, 2009; Liu et al, J Biol. Chem., 2006; Guo et al, Arthritis & Rheumatology, 2010). However, ADAMTS-12 was also reported to be required for normal inflammation (Angela et al, J Biol. Chem., 2012). These previous reports promoted us to determine whether ADAMTS-12 plays an important role in the pathogenesis of inflammatory arthritis, and if so what is the molecular mechanism involved. To address this issue, we established collagen-induced arthritis (CIA) model in ADAMTS-12 deficient mice and their control littermates. ADAMTS-12 deficient mice developed more severe inflammatory arthritis and exhibited increased bone and joint destruction when compared with their control littermates. Accelerated disease onset, significant increase in the arthritis severity score and arthritis incidence, were observed in ADAMTS-12 deficient mice. Histological analysis of whole ankle joints demonstrated a significant increase in synovitis, pannus formation and destruction of bone and cartilage in ADAMTS-12 deficient mice.

Furthermore, ADAMTS-12 deficient CIA mice exhibited higher level of ROR γ expression and lower level of Foxp3 expression, indicating the ratio of Treg/Th17 was reduced in ADAMTS-12 deficient mice. In addition, the isolated CD4+T cells produced more pro-inflammatory but less anti-inflammatory cytokines. Mechanistic studies revealed that ADAMTS-12 associated with connective tissue growth factor (CTGF), a molecule which is known to play a pro-inflammatory and pro-osteoclastogenesis role in the pathogenesis of inflammatory arthritis (Kazuhsa et al, Arthritis & Rheumatology, 2013). Yeast-Two-Hybrid (Y2H) assay with various ADAMTS-12 deletion mutants demonstrated that C-terminal mucin and TSP motifs of ADAMTS-12 were required and sufficient for binding CTGF. ADAMTS-12 digested and inactivated CTGF in the in vitro systems. In addition, elevated CTGF was observed in ADAMTS-12 deficient mice, and intra-articular injection of CTGF blocking antibody attenuated the enhanced inflammation seen in ADAMTS-12 deficient CIA model. Comparison of inflammation and bone loss between ADAMTS-12 deficient and ADAMTS-12/CTGF double deficient CIA models is ongoing. Collectively, ADAMTS-12 turns to be a critical regulator of inflammatory arthritis, through, at least in part, interacting with and inactivating CTGF. These findings not only provide novel insights into the role of ADAMTS-12 in the pathogenesis of inflammatory arthritis in vivo, but may also lead to the development of novel therapeutic intervention strategies for rheumatoid arthritis.

Retinoic Acid Receptor Gamma Agonists Promote Endochondral Ossification And Facilitate Cartilage-to-Bone Transition Together With beta-catenin-Lef/Tcf Signaling. Kenta Uchibe^{*1}, Agnese DiRocco², Matthew Johnson³, Sayantani Sinha², Colleen Larmour², Struan Grant³, Maurizio Pacifici², Motomi Enomoto-Iwamoto², Masahiro Iwamoto². ¹Okayama University Children's Hospital of Philadelphia, Jp, ²Translational Research Program in Pediatric Orthopaedics, The Children's Hospital of Philadelphia, USA, ³Divisions of Human Genetics & Endocrinology, The Children's Hospital of Philadelphia, USA

Chondrocytes in the growth plate undergo maturation and hypertrophy, regulate matrix remodeling, mineralization and blood vessel invasion, and promote endochondral bone formation. Previous studies have shown that the retinoic acid receptor gamma (RAR γ) functions as ligand-less form and maintains matrix homeostasis in prehypertrophic zone of growth plate. Expression level of RAR γ transcripts was high and rapidly decreased in hypertrophic zone (HZ) while RAR α and RAR β transcripts were detectable by RT-PCR but were less than 7% of RAR γ transcript. Surprisingly, immunostaining showed that RAR γ was present in HZ. Since the concentration of the endogenous active retinoid reaches to a physiological level at the chondro-osseous junction, RAR γ in HZ may bind to retinoids and regulate hypertrophic chondrocyte function. To address this question, we isolated mouse epiphyseal chondrocytes, treated them with a specific RAR γ agonist and performed RNAseq. Expression patterns of key growth plate genes were markedly altered by agonist treatment including: a reduction in cartilage matrix genes and their associated regulators Sox5, Sox6 and Sox9 as well as an induction of expression of genes encoding matrix proteases (ADAMTSs and MMPs), angiogenesis-inducing factors and mineralization-related factors. Interestingly, many genes up-regulated by the RAR γ agonist did not harbor typical RAR/RXR binding sites, suggesting that they were not direct targets but rather were indirectly impacted by cross-talk with other signaling pathways. Indeed, genes such as MMPs and VEGF are known to have binding sites for Lef/Tcf protein family members that act as gatekeepers for Wnt/ β -catenin signaling. To explore a possible relationship between RAR γ function and Wnt/ β -catenin signaling, we administered the RAR γ agonist NRX204647 from P10 to P16 to β -catenin conditional knockout mice (Col2CreER; floxed β -catenin CKO) and control (floxed β -catenin) littermates both receiving tamoxifen at P5 and P7. NRX204647 treatment accelerated replacement of growth plate to bone, leading to growth plate closure in control mice by 3 weeks of age, whereas 80% of treated CKO mutants did not show such a phenotype. The results indicate that stimulation of ligand bound RAR γ function promotes maturation in growth plate chondrocytes, thus facilitating cartilage to bone transition. The findings also suggest that RAR γ function is in part mediated by Wnt/ β -catenin signaling.

The role of macro-autophagy in cartilage homeostasis. Andrei Chagin^{*1}, Karuna Vuppalapati², Thibault Boudierlique², Phillip Newton². ¹Karolinska Institutet, Sweden, ²Karolinska Institute, Sweden

Macro-autophagy is a process of catabolic degradation of unnecessary intracellular material, which is encapsulated in a double-membrane vehicle called autophagosome and then delivered to lysosomes. The process of macro-autophagy is tightly controlled by mTOR (mechanical target of rapamycin) signaling pathway, which suppresses autophagy.

Here we explored the role of macro-autophagy in cartilage tissues by genetically inactivating indispensable autophagy genes Atg5 or Atg7 utilizing collagen2-driven Cre mouse strain and respected floxed strains.

Inactivation of autophagic process diminished chondrocyte survival in both epiphyseal growth plate and in articular cartilage. Accordingly, autophagy-deficient mice initially develop moderate growth retardation whereas osteoarthritis is developed with aging. Interestingly, surgery-induced osteoarthritis was autophagy-independent in this model. Diminished chondrocyte survival in the absence of autophagy led to cascade-dependent chondrocyte apoptosis associated with cytochrome C release by mitochondria. Finally, we also observed that pharmacological inhibitors of autophagy, in particular bafilomycin and chloroquine, unexpectedly activated mTOR signaling pathway in autophagy-independent manner and this activation is chondrocyte- but not osteoblast-specific. Summarizing, we demonstrated that macro-autophagy is an important mechanism supporting chondrocyte survival and facilitating cartilage homeostasis both at the growth plate level and at the articular surface.

Scleraxis cells contribute to the development of trauma-induced and genetic HO. Shailesh Agarwal^{*1}, Shawn Loder¹, Cameron Brownley¹, John Li¹, Hsiao Hsin Sung¹, Laura Mangiavini¹, Ammar Qureshi², Kristoffer Sugg¹, Shuli Li¹, Christopher Mendias¹, Nobuhiro Kamiya³, Bin Zhao⁴, Vesa Kaartinen¹, Thomas Davis², Jonathan Forsberg², Ernestina Schipani⁵, Yuji Mishina¹, Benjamin Levi¹. ¹University of Michigan, USA, ²Naval Medical Research Center, USA, ³Tenri University, USA, ⁴Albert Einstein College of Medicine, USA

Introduction: Heterotopic ossification is the pathologic development of ectopic bone. Two groups of patients are at risk for HO – those with trauma and burn injuries, and those with mutations in the type I BMP receptor, *ACVRI*. Despite the varying presentation of patients with HO and the differing etiologies, we hypothesize that the progenitor cells that develop into HO lesions are of the same cell lineage in all different settings. In this study, we tested this hypothesis.

Methods: Three different models of trauma-induced HO were used to identify HO progenitor cells: 1) mouse burn and Achilles' tendon transection (burn/tenotomy), 2) intramuscular BMP scaffold with cardiotoxin, and 3) rat muscle blast injury. Burn/tenotomy was additionally performed in *Scx-Cre/R26^{RFP}* mice, in which RFP marks the scleraxis-lineage. Additional genetic mouse models included Cre-induced constitutively active *Acvr1* transgenic mice (*ca-Acvr1^{floxWT}*) were bred with *Nfatc1-Cre*, *Ub-Cre-ERT*, *Ckmm-Cre*, and *Coll-CreERT*. All animals were euthanized at the appropriate time points and tissue sectioning was performed for histologic analysis. Pentachrome was used to identify cartilage, mature HO, and surrounding tissue. Immunostaining for pSmad 1/5, Scleraxis, Tenomodulin, and Sox9 was performed.

Results: All three models of trauma-induced HO, and *Nfatc1-Cre/ca-Acvr1^{floxWT}* mutant mice consistently developed HO lesions. Three weeks after burn/tenotomy, ectopic cartilage had robust presence of cells expressing scleraxis, tenomodulin, and SOX9 (Fig 1A). In *Scx-Cre/R26^{RFP}* mice, a vast majority of cells in mature HO expressed RFP. Cells along the periphery actively expressed SOX9, scleraxis, and tenomodulin. In the rat blast and intramuscular BMP scaffold models, cells forming HO lesions co-expressed scleraxis, tenomodulin, and SOX9. *Nfatc1-Cre/ca-Acvr1^{floxWT}* mice developed HO lesions exclusively in proximity to ligaments and tendons, despite recombination in tissues such as skin and muscle. HO lesions in mutants co-stained for scleraxis, tenomodulin, and SOX9 as well (Fig 1B). HO was not observed in mice expressing *ca-Acvr1* with muscle- or osteoblast-specific Cre drivers (*Ckmm-Cre* and *Coll-CreERT* respectively).

Conclusions: Our findings show that independent of etiology, scleraxis(+) cells contribute substantially to HO lesions. Furthermore, despite *ca-Acvr1* expression within multiple tissue types, only expression within tendons and ligaments appears to result in HO.

CNBP controls Chondrocyte Hypertrophy and Hypertrophic Chondrocyte Cell Size by Spatially and Temporally Regulating the Expression of Sox9 and Runx2. Yun Lu*, Wei Chen, Guochun Zhu, Yi-Ping Li. Department of Pathology, University of Alabama at Birmingham, USA

How chondrocyte hypertrophy and hypertrophic chondrocyte cell size are regulated is a fundamental question in bone biology. However, which factor(s) regulates the events still remains largely unknown. Cellular Nucleic acid Binding Protein (CNBP) is highly conserved among vertebrates. Functionally, CNBP binds single-stranded nucleic acids and may act as a molecular chaperone, thus regulating both transcription and translation. Recently, we found that CNBP cartilage specific knockout through the CNBP^{Loxp}/Loxp Col2a1-Cre (CKO) approach resulted in very large hypertrophic chondrocytes, which were about three-fold larger than that in wild type (WT) mice. Meanwhile, the immature chondrocytes of CNBP CKO mice experienced early hypertrophy. As a result, the limbs of CNBP CKO mice are extremely short, indicating the importance of normal chondrocyte hypertrophy and cell size. We hypothesized that CNBP regulates chondrocyte hypertrophy and controls hypertrophic chondrocyte cell size by spatially and temporally regulating the expression Sox9 and Runx2. To test this hypothesis and characterize the mechanism, we studied the function of CNBP at the histological, cell, and molecular levels respectively. Newborn IHC stain of Col X in the resting and proliferation zones confirms that the immature chondrocytes of CNBP CKO mice are undergoing hypertrophy. The expression of Sox9, which has been noted to block immature chondrocyte maturation into hypertrophic cells, was dramatically reduced in CNBP CKO mice. On the other hand, Runx2, as a vital transcriptional factor to trigger chondrocyte hypertrophy, is ectopically and highly expressed in the chondrocyte resting and proliferation zones, but poorly expressed in the pre-/hypertrophic zone of the growth plate in CNBP CKO mice. Surprisingly, IGF-1, which is essential for the third phase of the chondrocyte hypertrophy process, is highly expressed in CNBP CKO mice. Taken together, our study reveals that CNBP is a novel key negative regulator of chondrocyte hypertrophy initiation and cell size and spatially and temporally regulates the expression of Sox9 and Runx2 in chondrocytes. The insight of this study not only improved our understanding of the mechanism underlying how CNBP regulates chondrocyte hypertrophy and hypertrophic chondrocyte cell size, but it will also facilitate the design of novel treatment approaches for aging, congenital, degenerative skeletal and metabolic bone disorders and diseases by targeting CNBP.

Histone Deacetylase 3 Controls Extracellular Matrix Remodeling and Proinflammatory Signals in Chondrocytes. Lomeli Carpio*, Elizabeth Bradley¹, Amel Dudakovic¹, Andre van Wijnen¹, Meghan McGee-Lawrence², Jennifer Westendorf¹. ¹Mayo Clinic, USA, ²Georgia Regents University, USA

Histone deacetylase (Hdac) inhibitors are emerging epigenetic therapies for cancer, arthritis, and epilepsy; however, these drugs inhibit multiple Hdacs and have detrimental effects on the pre- and post-natal skeleton. Several Hdacs contribute to endochondral bone formation. In this study, we defined the cell autonomous role of Hdac3 in chondrocyte maturation by deleting it pre- and post-natally in type II collagen alpha 1 (Col2a1) expressing chondrocytes. Hdac3-CKOCol2 mice rarely survived embryogenesis. The few that survived birth were hypomorphic for Hdac3 expression, runted, and had severely reduced cancellous and cortical bone density. To overcome the prenatal lethality, postnatal Hdac3 deficiency was induced with a tamoxifen-inducible Col2a1 Cre model (Hdac3-CKOCol2ERT). At 4-weeks of age, these animals had residual hypertrophic cartilage and increased osteoclast activity in the primary spongiosa. By 8 weeks, these animals had compromised bone architecture, with significant decreases in trabecular bone, but greater cortical bone thickness, which is likely a compensation for disrupted growth plate maturation during development. Erk1/2 phosphorylation and matrix metalloproteinases (Mmp-3 and Mmp-13) were elevated in Hdac3-depleted immature mouse chondrocyte micromass cultures and the growth plates of the Hdac3-CKOCol2ERT mice. RNA sequencing was used to assess Hdac3-dependent global changes in gene expression. Functional annotation clustering for Hdac3-deficient IMCs showed increases in genes related to inflammatory and immune responses and reductions in genes related to the extracellular matrix, bone development and ossification. Among the differentially regulated proinflammatory cytokines, chemokines, and their respective receptors in Hdac3-depleted chondrocytes, interleukin-6 was significantly elevated. Downstream of this immune response mechanism, Stat3 phosphorylation was increased in Hdac3-deficient chondrocytes. These results show that chondrocyte-specific Hdac3 deletion alters gene expression in a number of cellular processes, including initiation of proinflammatory responses, which can increase Mmp expression. Altogether, these results indicate that Hdac3 controls the temporal and spatial regulation of gene expression and downstream signaling factors in chondrocyte maturation to ensure proper ossification during long bone development.

PRC2 controls chondrocyte proliferation, differentiation and hypoxic adaptation by suppressing aberrant activation of multiple signaling pathways. Fatemeh Mirzamohammadi*¹, Garyfallia Papaioannou², Erinn Rankin³, Huanfeng Xie⁴, Jennifer Inloes⁵, Stuart H. Orkin⁶, Ernestina Schipani⁷, Tatsuya Kobayashi⁸. ¹Massachusetts General Hospital & Harvard Medical School, USA, ²Massachusetts general hospital & harvard medical school, USA, ³Stanford cancer institute, USA, ⁴Dana-Farber Cancer Institute, USA, ⁵Endocrine Unit, Massachusetts General Hospital, USA, ⁶Boston Children's Hospital & Dana-Farber Cancer Institute, USA, ⁷University of Michigan, USA, ⁸Endocrine Unit, Massachusetts General Hospital & Harvard Medical School, USA

Histone modifications regulate gene expression through altering chromatin structure. Trimethylation on lysine residue 27 of histone 3 (H3K27me3), catalyzed by the polycomb repressive complex 2 (PRC2), controls cell fate determination and stem cell function by suppressing expression of genes that regulate cellular differentiation. However, the role of PRC2-mediated gene repression in somatic tissues remains largely unknown. To investigate the role of PRC2 in skeletal development, we genetically ablated PRC2 function in chondrocytes by deleting *Eed*, an essential component of PRC2. *Eed*-deficient mice exhibited a growth defect and kyphoscoliosis. *Eed*-deficiency led to decreased chondrocyte proliferation and accelerated differentiation, and caused ectopic cell death in the central area of the growth plate. Multiple signaling pathways, including the Wnt and TGF- β signaling pathways were upregulated in *Eed*-deficient chondrocytes. Suppression of the Wnt signaling using Wnt-C59, a Porcupine enzyme inhibitor, rescued accelerated chondrocyte differentiation and ameliorated kyphoscoliosis in mutants. We also found that *Eed*-deficient chondrocytes showed reduced expression of *Hif1a*, a critical transcription factor for hypoxia adaptation, which likely induced chondrocyte cell death in the hypoxic region of the growth plate. We found that the upregulation of TGF- β signaling in *Eed*-deficient chondrocytes was responsible for the *Hif1a* mRNA downregulation. In summary, our study demonstrates that PRC2 function is essential for normal skeletal development. PRC2-mediated gene regulation controls differentiation and proliferation, and hypoxic adaptation of chondrocytes by suppressing aberrant activation of multiple signaling pathways. Our study suggests a paradigm in which PRC2 continuously plays an essential role in lineage-committed, differentiated somatic cells.

Partial pharmacological repression of PPAR γ balances energy metabolism and increases bone mass. L.A. Stechschulte¹, P.J. Czernik², F. Tausi¹, C.A. Corzo³, A. Asteian³, M. Cameron³, T.M. Kamenecka³, P.R. Griffin³, B. Lecka-Czernik*¹. ¹Department of Orthopaedic Surgery, Center for Diabetes & Endocrine Research, University of Toledo, College of Medicine & Life Sciences, USA, ²Micro Tomografts Ltd., USA, ³Department of Molecular Therapeutics, The Scripps Research Institute, Scripps Florida, USA

The armamentarium to fight diabetes is constantly expanding into therapies targeting particular mechanisms controlling glucose levels; however treatments which increase cellular responsiveness to insulin are the most effective. Unfortunately, PPAR γ full agonists, TZDs, cause adverse effects including weight gain and bone fractures. Besides glucose metabolism, PPAR γ also regulates marrow mesenchymal stem cells (MSCs) commitment toward osteoblast and adipocyte lineage by either acting directly on MSCs or indirectly by changing milieu of marrow microenvironment. We have previously showed that PPAR γ anti-osteoblastic and insulin sensitizing activities can be separated by using ligands of different chemical structures. Recently, a new class of insulin sensitizers and selective modulators of PPAR γ activity has been developed in efforts to curb the adverse effect on weight gain, but their effect on bone remains unknown. Here, we demonstrate that SR10171 compound, a partial inverse agonist of PPAR γ , normalizes energy metabolism and increases bone mass by modulating directly osteocyte activities. Treatment of mice with SR10171 at the dose which normalizes glucose tolerance, results in increased trabecular and cortical bone mass due to increased bone formation and bone turnover. SR10171 decreases SOST and increases RANKL expression both *in vivo*, in osteocytes isolated from femora of treated mice, and *in vitro*, in treated MLO-A5 cells. At the same time, SR10171 is neutral for direct effect on osteoblast differentiation. Treatment of marrow MSCs does not have an effect on differentiation and expression osteoblast and adipocyte gene markers; however osteoblasts isolated from endosteal surface of femora of treated mice have increased activity of Wnt signaling and expression of osteoblast-specific gene markers. Beneficial effects on bone are independent of SR10171 metabolic activity. SR10171 increases energy metabolism and normalizes fat function in animals with diet induced obesity, but unlike rosiglitazone it is neutral in animals with balanced energy metabolism. Our data suggest that SR10171 modulates energy metabolism in an on-demand manner, while having sustained anabolic activity on bone regardless of animal metabolic status. These results demonstrate a possibility for developing a compound which may act as insulin sensitizer with simultaneous anabolic effect on bone.

PTHrP-derived Peptides Restore Bone Mass and Strength in Diabetic Mice: Additive Effect of Mechanical Loading. Marta Maycas^{*1}, Kevin A McAndrews², Amy Y Sato³, Gretel G Pellegrini³, Drew M Brown⁴, Matthew R Allen³, Lilian LI Plotkin², Pedro Esbrit⁵, Aranca Gortazar⁶, Teresita M Bellido⁷. ¹Anatomy & Cell Biology, Indiana University School of Medicine, USA, ²Department of Anatomy & Cell Biology, Indiana University School of Medicine; Roudebush Veterans Administration Medical Center, USA, ³Department of Anatomy & Cell Biology, Indiana University School of Medicine, USA, ⁴Department of Anatomy & Cell Biology, Indiana University School of Medicine, USA, ⁵Instituto de Investigación Sanitaria (IIS)-Fundación Jiménez Díaz, Universidad Autónoma de Madrid (UAM) & Red Temática de Investigación Cooperativa en Envejecimiento y Fragilidad (RETICEF), Spain, ⁶Universidad San Pablo-CEU School of Medicine Madrid Spain, Spain, ⁷Department of Anatomy & Cell Biology, Indiana University School of Medicine; Department of Medicine, Division of Endocrinology, Indiana University School of Medicine; Roudebush Veterans Administration Medical Center, USA

There is an unmet need to treat bone fragility in patients with diabetes mellitus. We examined herein the effectiveness of N- and C-terminal fragments of parathyroid hormone related peptide (PTHrP), in combination with mechanical loading, in counteracting skeletal deterioration in a mouse model of type 1 diabetes. Diabetes was induced in 4-month-old male C57BL/6 mice by 5 consecutive daily ip injections of streptozotocin (45 mg/kg). Four weeks after injections, glucose levels were significantly higher in streptozotocin-injected mice compared to non-diabetic control mice receiving saline (382±105 vs 179±27 mg/dL). At this time, diabetic mice were separated in 3 groups and received 3 consecutive daily sc injections of PTHrP(1-37) (50 µg/kg), PTHrP(107-111) (7 µg/kg), or vehicle, followed by loading of the right ulnae for 1 min at 120 cycles/day at 3 different magnitudes ranging from 1,995 to 2,500 g strain. All mice were sacrificed 12 days thereafter. Diabetic mice receiving vehicle exhibited a significant lower femoral BMD compared to non-diabetic controls (decreased by 14.9%). In contrast, diabetic mice treated with either PTHrP(1-37) or PTHrP(107-111) showed a gain of 3.4% and 3.5%, respectively, in femoral BMD, similar to non-diabetic controls. Moreover, the decrease in trabecular thickness in the distal femur and in cortical thickness at the mid-diaphysis exhibited by diabetic mice was reversed by both PTHrP peptides. Furthermore, diabetic mice exhibited significantly lower mechanical (ultimate force and stiffness) and material (ultimate stress and toughness) properties quantified by femoral 3-point-bending, which was restored to non-diabetic control levels by both PTHrP peptides. In addition, CTX, a bone resorption marker, was increased in diabetic mice and reversed to non-diabetic control levels by both PTHrP peptides. Higher magnitude loading was needed in diabetic mice to increase periosteal MAR and BFR/BS compared to non-diabetic controls. In addition, loading increased MAR and BFR/BS to higher levels in diabetic mice treated with either PTHrP peptide compared to diabetic mice receiving vehicle. In conclusion, these PTHrP peptides partially restored bone loss and strength, reversed increased resorption induced by diabetes, and worked additively with mechanical loading to enhance periosteal bone formation in the appendicular skeleton of diabetic mice. Thus, this short treatment with both PTHrP peptides reversed skeletal deterioration in diabetes.

Δ FosB in the ventral hypothalamus prevents the age-related dysregulation of metabolic homeostasis in mice. Kazusa Sato^{*1}, Anna Idelevich¹, Glenn Rowe², Francesca Gori¹, Roland Baron¹. ¹Harvard School of Dental Medicine, USA, ²Cardiovascular Institute, Beth Israel Deaconess Medical Center, Harvard Medical School, USA

Aging is associated with a high risk of developing osteoporosis and also impaired glucose tolerance. The hypothalamus plays a critical role in bone homeostasis as well as energy balance and glucose metabolism through endocrine and neuronal pathways that are only partially elucidated.

ΔFosB is a naturally truncated form of FosB that antagonizes AP-1 transcription. In mice, overexpression of ΔFosB under the control of the enolase 2 (ENO2) promoter, which drives expression in bone, adipose tissues, and the ventral hypothalamus (VHT), results in increased bone mass, decreased adipose mass due to increased energy expenditure, and favored glucose metabolism due to increased insulin sensitivity. Moreover, adeno-associated virus (AAV)-mediated expression of ΔFosB in the VHT phenocopies the bone, energy and glucose phenotypes of ENO2-ΔFosB mice, suggesting a dominant role of ΔFosB in the VHT.

The present study determined whether ΔFosB is implicated in the development of the age-related dysregulation of bone and glucose homeostasis, and evaluated the contribution of ΔFosB in the VHT to these regulation systems. To this end, we analyzed the bone and metabolic profiles of aged (40-50 weeks) ENO2-ΔFosB mice and C57BL/6 mice 35-40 weeks after stereotaxic injection of AAV encoding ΔFosB (AAV-ΔFosB) or GFP (AAV-GFP) as control exclusively in the VHT.

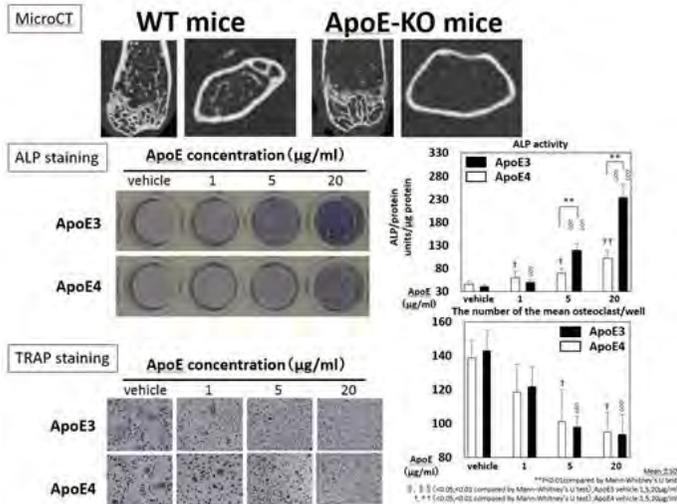

In comparison to control littermates, aged ENO2-ΔFosB mice had increased femoral BV/TV and Tb.Th by 28% and 39%, respectively, as well as increased energy expenditure and decreased abdominal adiposity. During glucose tolerance test, aged ENO2-ΔFosB mice maintained lower glucose levels (AUC 22.0±0.3 vs 16.1±1.5 *10³ mg/dl*min) with significantly lower insulin levels (AUC 1096±16 vs 54±5 ng/ml*min), due to markedly increased insulin sensitivity. This was in contrast to the glucose intolerance associated with severe hyperinsulinemia and exacerbated insulin resistance observed in aged control mice. Similarly, aged AAV-ΔFosB mice were protected from abdominal adiposity due to increased energy expenditure compared to aged AAV-GFP mice. Aged AAV-ΔFosB mice were more glucose tolerant (AUC 38.6±1.6 vs 30.1±1.3 *10³ mg/dl*min) with lower insulin response (AUC 456±64 vs 218±19 ng/ml*min) and increased insulin sensitivity as observed in aged ENO2-ΔFosB mice. Taken together, these results suggest that the VHT signaling downstream of ΔFosB has protective effects against age-related metabolic changes.

FR0091

Apolipoprotein E (ApoE) plays a crucial role in maintaining trabecular and cortical bone mass by promoting osteoblastic differentiation via ERK1/2 pathway and suppressing osteoclast differentiation by down-regulation of c-Fos and NFATc1. Takaaki Noguchi^{*1}, Kosuke Ebina², Makoto Hirao², Kota Koizumi², Hideki Yoshikawa². ¹Osaka University, Japan, ²Department of Orthopaedic Surgery, Graduate School of Medicine, Osaka University, Japan

It is well known that hyperlipidemia is tightly associated with osteoporosis, while its detailed mechanism remains unknown. ApoE plays a major role in the lipid metabolism and its deficiency leads to severe hyperlipidemia. The aim of this study is to clarify the effect of ApoE on bone metabolism. Females ApoE knockout mice (ApoE-KO) (n=8) and control C57BL/6 wild type mice (WT) (n=8) were fed with normal chow for 48-weeks and sacrificed. 3D trabecular structure of the femur was measured by microCT, and the number of osteoclasts was evaluated by TRAP staining in distal femur. ApoE-KO and WT mice calvaria were used to investigate osteoblastic differentiation, and murine bone marrow derived macrophages (BMDM) and human peripheral blood monocytes (PBMC) were used to investigate osteoclastogenesis under RANKL and M-CSF stimulation. The finding of microCT revealed that ApoE-KO mice showed severe osteoporosis compared to WT mice, which were evaluated by cancellous bone quantity (BV/TV: 3.3v.s.16.6%; P<0.001) and cortical bone quantity (Cv/Av: 31.8v.s.37.9%; P<0.01). ApoE-KO mice showed significantly larger number of osteoclasts per bone surface compared to WT mice (8.6v.s.4.5/mm; P<0.05). Recombinant human ApoE3 and ApoE4 protein (rh-ApoE3/E4) significantly promoted ALP activity (0→20µg/ml ApoE3: 40.5→233.7units/µg protein; P<0.01, 0→20µg/ml ApoE4: 46.0→102.2units/µg protein; P<0.01) and osteoblast-related mRNA (*ALP*, *osteocalcin*) expression in a dose dependent manner by using WT mice calvaria, and ApoE3 had significantly stronger effect compared with ApoE4. Western blot (WB) analysis showed that ApoE3 strongly down-regulated the phosphorylation of ERK1/2, which was up-regulated in ApoE-KO mice as compared with WT mice calvaria. On the other hand, rh-ApoE3/E4 significantly inhibited osteoclasts formation (0→20µg/ml ApoE3: 142.3→93.4/well; P<0.05, 0→20µg/ml ApoE4: 138.5→95.0/well; P<0.05) and osteoclast-related mRNA (*c-Fos*, *NFATc1*, *TRAP*, *Cathepsin K*) expression in a dose dependent manner by using BMDM. Furthermore, rh-ApoE3 significantly inhibited bone resorption activity by using PBMC (0→5µg/ml: 99692→2608µm²/well; P<0.05). WB analysis showed that ApoE3 suppressed c-Fos protein expression. Our findings revealed that ApoE plays a crucial role in bone metabolism by up-regulating osteoblastic differentiation and down-regulating osteoclastogenesis. Therapeutic strategy targeting ApoE may be a promising in treating both osteoporosis and lipid metabolism dysfunction.

Impaired Bone Accrual during Obesity occurs by a Neuropeptide Y-dependent Mechanism in the Osteoblast. Natalie Wee¹, Nikki Lee², Ronaldo Enriquez¹, Herbert Herzog², Paul Baldock¹. ¹Skeletal Metabolism, Osteoporosis & Bone Biology Program, Garvan Institute of Medical Research, Australia, ²Eating Disorders, Neuroscience Program, Garvan Institute of Medical Research, Australia

Diet-induced obesity (DIO) is detrimental to cancellous bone mass, the effect on cortical bone is less clear, as is the mechanisms involved.

Neuropeptide Y (NPY) is a powerful modulator of energy and bone metabolism. Central overexpression of NPY reduces bone formation and results in bone loss. In diet-induced obesity (DIO), NPY is upregulated, suggesting a potential inhibition of bone formation in obese mice. In this study, we aimed to determine the contribution of NPY to bone loss during DIO and to evaluate whether blocking osteoblastic Y1 receptors would be protective.

6-week old WT and NPYKO mice were fed either a chow or a HFD (23% fat) for 10 weeks. Obesity and bone mass was monitored by DXA. Post-cull, femurs were evaluated using microCT and histomorphometry. We also examined an osteoblastic-specific NPY, Y1 receptor KO mouse (Y1f3.6cre) using a high fat feeding model for 8 weeks.

WT mice on HFD had increased body weight compared to chow (by ~14%), due to increased fat mass (Chow ~3.3g; HFD ~ 7.3g of fat). NPYKO were less susceptible to DIO with no difference in body weight; however, fat mass was significantly increased (WT~3.0g; HFD~5.1g). In WT, HFD reduced the accrual of whole body BMC (WBBMC) over the 10 weeks compared to chow, with WBBMC reduced by ~ 26%. In contrast, NPYKO mice had greater WBBMC, and importantly, bone accrual was unaffected by HFD. Femoral cortical bone mass in HFD WT was reduced by 20%, independent of the positive effects of weight bearing, and again attributed to changes in fat mass. In NPYKO, cortical bone mass was not different between HFD and chow. Thus, suggesting that DIO affects bone mass via NPY-mediated mechanisms.

Additionally, NPYKO partially attenuated DIO-induced cancellous bone loss: HFD WT had 40% less BV/TV whilst HFD NPYKO had a 20% reduction in BV/TV compared to chow.

Bone from Y1f3.6cre mice was also unaffected by HFD, thus this effect can be directly regulated by NPY responses in the osteoblast.

In summary, we establish the critical role of NPY on inhibition of bone accrual during obesity. We also show that inhibition of osteoblastic NPY signalling using Y1f3.6cre is protective of DIO bone loss, highlighting the role of peripheral NPY signalling in this process and a potential therapeutic avenue.

Increased G_s Signaling in Osteoblasts Increases Metabolic Activity and Reduces Whole Body Adiposity. Corey Cain*, Joel Valencia, Kate Jordan, Edward Hsiao. University of California, San Francisco, USA

Purpose: Osteoblasts are thought to affect both systemic adiposity and metabolism through secreted factors. G_s-GPCR signaling is a potent regulator of both osteoblast and adipocyte development, but it is unclear if G_s-GPCRs in osteoblasts can have systemic effects beyond the bone. ColII(2.3)⁺/Rsl⁺ mice, which express the engineered G_s-GPCR receptor Rsl in ColII(2.3) expressing osteoblastic cells, have a 5-15 fold

increase in trabecular bone formation, a 2.8 fold reduction in total body fat, and a 11 fold reduction in tibial bone fat. The goal of this study is to use the ColII(2.3)⁺/Rsl⁺ mice to understand how changes in osteoblastic G_s-GPCR signaling regulate osteoblast metabolic activity and whole body adiposity.

Results: ColII(2.3)⁺/Rsl⁺ mice showed increased respiration (VO₂ and VCO₂) but a reduced respiratory exchange ratio (RQ) despite no changes in food intake and ambulatory movement. The mice had significant reductions in serum adipokines leptin and adiponectin, with increased serum GLA-osteocalcin and the metabolically active GLU-osteocalcin. Fasting blood glucose and insulin levels showed no alterations in ColII(2.3)⁺/Rsl⁺ mice. Glucose and insulin tolerance tests revealed that ColII(2.3)⁺/Rsl⁺ mice had increased insulin sensitivity that was independent of food intake in paired feeding experiments. 3T3-L1 pre-adipocytes differentiated with either control or ColII(2.3)⁺/Rsl⁺ serum showed comparable adipocyte differentiation. qPCR analysis of adipogenic genes in ColII(2.3)⁺/Rsl⁺ bones indicated a block in the development of mature adipocytes in the bone marrow, possibly resulting from increased Wnt signaling in ColII(2.3)⁺/Rsl⁺ bones. Seahorse glycolytic and mitochondrial stress tests, which measures cellular glycolytic and oxidative metabolism, of ColII(2.3)⁺/Rsl⁺ digested bone cells revealed increased glucose utilization but no significant alterations to the rate of oxygen consumption.

Conclusions: Our findings suggest that increased G_s-GPCR signaling in osteoblasts increases osteoblast metabolic activity and can reduce peripheral adiposity. Furthermore, osteoblast G_s-GPCR activity reduced mature adipocyte development in ColII(2.3)⁺/Rsl⁺ bones through Wnt signaling, however, the reduction in peripheral adipose tissues was most likely from increased GLU-osteocalcin by osteoblasts. These results suggest that targeting G_s-GPCR in osteoblasts can have potential non-skeletal advantages for treating obese patients with osteoporosis or bone fractures.

Mitochondrial Sirtuin-3 Regulates Skeletal Homeostasis. Linh Ho¹, Yong Pan², Emilie Besnard³, Theresa M. Roth⁴, Yuva Nishida³, Chia-Lin Tsou³, ChePing Ng³, Eric M. Verdin³, Robert A. Nissenson⁴. ¹UCSF, USA, ²Edison Pharmaceuticals, 350 North Bernardo Avenue, Mountain View, CA 94043, USA, USA, ³Gladstone Institutes, University of California San Francisco, San Francisco, CA 94158, USA, USA, ⁴Endocrine Research Unit, VA Medical Center & Departments of Medicine & Physiology, University of California San Francisco, San Francisco, CA, USA, USA

Among seven sirtuins in mammals, mitochondrial Sirt3 has been identified as an essential metabolic regulatory enzyme that plays an important role in metabolism, reducing oxidative stress and promoting efficient energy production with aging by the reversible deacetylation of mitochondrial proteins. However, the role of Sirt3 in skeletal homeostasis has yet to be studied. Using Sirt3 overexpression and Sirt3 knockout (Sirt3KO) mice in a C57BL/6 background, we now report that Sirt3 is a negative regulator of bone mass. Sirt3 transgenic (Sirt3Tg) male mice exhibited a significant reduction in cortical thickness at the tibio-fibular junction (TFJ) (0.201 ± 0.003 vs. 0.220 ± 0.004 mm in Sirt3Tg and WT mice, respectively, P=0.012). Osteoblastogenesis was unaffected by Sirt3 overexpression, but there was almost 2 fold decrease in osteoclastogenesis (P<0.05) by Sirt3KO bone marrow cells grown in the presence of macrophage colony-stimulating factor 1 (CSF1) and receptor activator of nuclear factor kappa-B ligand (RANKL). Accordingly, there was 2.5 fold increase in the number of tartrate resistant acid phosphatase (TRAP) positive cells/bone surface in Sirt3Tg mice compared with WT (P< 0.03). Upon histological analysis, Sirt3Tg mice exhibited an increased number of adipocytes in the tibia when compared to WT mice (92 ± 6.0 vs. 11 ± 0.1 in Sirt3Tg and WT mice, respectively, P<0.05). BMSCs from Sirt3Tg mice displayed an enhanced ability to differentiate into Oil Red O positive adipocytes compared to BMSCs from WT mice (adipocyte area per square millimeter of the Sirt3Tg is 1.274 ± 0.150 compared to the WT 0.642 ± 0.036, P=0.04). In contrast, BMSCs from Sirt3KO mice displayed reduced adipogenesis compared to BMSCs from WT mice (1.001 ± 0.073 adipocyte area per square millimeter of the Sirt3KO compared to 1.673 ± 0.077 of the WT, P<0.001). Interestingly, adipocytes differentiated from Sirt3KO bone marrow cells displayed reduced expression of macrophage colony-stimulating factor 1 (P<0.01), suggesting a role for Sirt3 in adipogenesis linked to induced osteoclastogenesis. In summary, Sirt3 promotes favorable metabolic effects in bone marrow cells and bone loss *in vivo*. The positive energetic effects of Sirt3 in bone marrow cells are associated with increased adipogenesis and increased osteoclastogenesis. These findings demonstrate that Sirt3 is an important regulator of skeletal homeostasis *in vivo*, and identify Sirt3 as a novel therapeutic target for the treatment of osteoporosis.

Metabolic Regulation of Osteoclast Differentiation by Hif1 α in Human Osteoclastogenesis. Koichi Murata*, Min Joon Lee, Seveon Bae, Sehwan Mun, Kyung-Hyun Park-Min, Lionel Ivashkiv. Hospital for Special Surgery, USA

Osteoclast differentiation is considered to be an energy-demanding process. However, molecular mechanisms regulating metabolic adaptation during osteoclastogenesis, to meet the increased demand for adenosine triphosphate, is not fully understood, especially in human. Hypoxia-inducible factor 1 (HIF1) is the major oxygen homeostasis regulator by low oxygen tensions. HIF1 stimulates glycolytic energy production by transactivating genes involved in extracellular glucose import (e.g. GLUT1) and enzymes responsible for glycolytic breakdown of intracellular glucose (e.g. PFK1). It also downregulates oxidative phosphorylation within the mitochondria by transactivating genes such as PDK1 and MX11. Although most knowledge regarding HIF-1 has been derived from studies following hypoxic stress, HIF1 stabilization has also been found in non-hypoxic settings. Here we show that Hif1 α is stabilized by RANKL stimulation and orchestrates metabolic adaptation during osteoclastogenesis even in normoxia.

We treated human osteoclast precursors (OCPs) with RANKL in a time-dependent manner and analyzed the expression of metabolic genes. Not only mTOR, which regulates growth and metabolism by integrating information on nutrient, energy, and oxygen levels, but also adenosine monophosphate (AMP)-activated protein kinase (AMPK), a sensor of increased AMP and adenosine diphosphate was induced and activated by RANKL stimulation, suggesting that RANKL promotes OCPs into energy-demanding and consuming status (Figure 1). RNA sequencing revealed 1761 genes were induced by more than 1.5 fold at 48 h after RANKL stimulation compared to 24 h time point of RANKL stimulation. We also found that 53 RANKL-induced genes were HIF1 α target. Immunoblotting showed the expression of HIF1 α protein could not be observed within 24 h of RANKL stimulation; however, it was detected at 48 h after RANKL stimulation in normoxia (Figure 2). Concomitantly, expressions of HIF1 α target genes, including GLUT1, GLUT3, VEGFA, PHD3 and LDHA, were induced at 48 h after RANKL treatment. Furthermore, siRNA-mediated knockdown of HIF1 α suppressed osteoclastogenesis, and osteoclast-related gene expression, including TRAP, CathepsinK, ITGB3, and DC-STAMP, supporting the important role of Hif1 α in osteoclastogenesis, even in normoxia (Figure 3).

In conclusion, Hif1 α is stabilized by RANKL stimulation and orchestrates metabolic adaptation during osteoclastogenesis even in normoxia.

Both phosphate replacement and high fat diet cooperatively improve survival and bone quality in Ebf1-deficient mice. Jackie Fretz*¹, Tracy Nelson², Ben-Hua Sun², Rose Webb², Nancy Troiano², Steven Tommasini². ¹Yale University School of Medicine, USA, ²Yale School of Medicine, USA

The transcription factor Early B Cell Factor 1 (Ebf1) is not only important for maturation of B lymphocytes, but has also been revealed to be integral for maturation of several cell lineages from mesenchymal progenitors. Whole body knockout mice have many problems including low bone mineral density and are severely runted. Our investigations have revealed that Ebf1-deficient mice have impaired renal maturation and function. The mice waste phosphate and calcium in urine, are hypophosphatemic, hypoalbuminuric, and exhibit alterations in proximal tubule and glomerular maturation in the peripheral cortex. Last year we reported that administration of a high phosphate diet (1.5%), high fat diet (45%), or combination diet in animals during the 6-12th weeks of life increased bone density and quality and improved survival of the KO mice. This year we report that administering specialized diets between the 3rd and 12th week of life improved survival from 10% in chow fed animals to 42.8% with high phosphate alone, 50% with high fat alone, and 75% with a combination high fat and phosphate diet. The extended time course provided an even greater improvement in linear growth with all modified diets (compared to chow fed mice) restoring the growth rate to that of WT and heterozygous littermates. Kidney health, as assessed through urine analysis, serology, histology, and circulating FGF23 were all improved with phosphate alone, and further enhanced by the addition of high fat. Biomechanical assessment of bone quality (by micro-CT, histology, and 4 point bending) revealed that phosphate alone provided significant improvement in bone quality, but that these parameters were also further enhanced by addition of high fat into the diet. These results demonstrate that dietary modification to counteract the renal insufficiency present in Ebf1-deficient mice: 1) significantly improves the overall health of the animals, 2) restores linear growth, 3) improves bone quality, and 4) slows

progression of renal failure. Furthermore, the results suggest that circulating lipids and possibly maintenance of adipose mass influences the severity of renal disease and associated renal osteodystrophy resulting from Ebf1-deficiency. These results provide novel insights into the mechanisms underlying the renal insufficiency present in Ebf1-deficient mice and provide intriguing evidence for an interaction of phosphate and circulating lipids to bone and kidney health.

Genetic keratin inactivation corrects the altered osteoblast function, bone formation and osteopenia in F508delta-Cftr mice, a murine model of cystic fibrosis. Carole Le Henaff^{*1}, Mélanie Faria², Aurélie Hatton², Danielle Tondelier², Caroline Marty¹, Mylène Zarka¹, Kurt Zatloukal³, Valérie Geoffroy¹, Aleksander Edelman², Isabelle Sermet², Pierre J. Marie¹. ¹INSERM UMR-1132 & University Paris Diderot, Sorbonne Paris Cité, France, ²INSERM U-1151, Faculté de Médecine Paris Descartes, France, ³Institute of Pathology, Medical University of Graz, Austria

Mice with the prevalent F508del mutation in the cystic fibrosis conductance regulator (Cftr) gene display reduced bone formation and osteopenia, but the underlying molecular mechanisms are unknown, which precludes the development of an efficient therapeutic strategy. In this study, we hypothesized that the microfilament keratin 8 (K8) which is known to interact with F508del-CFTR in epithelial cells, may play a role in osteoblast dysfunctions and bone loss induced by the F508del-Cftr mutation in mice. We found that osteoblasts isolated from wild type (WT) or F508del-Cftr mice express CFTR and the microfilament keratin 8 (K8) at the mRNA and protein levels. Analysis of bones of K8 null WT mice (K8^{-/-}) showed that inactivation of K8 led to long bone loss due to decreased bone mineral apposition rate (MAR) and bone formation rate (BFR) assessed by histomorphometric analysis. In marked contrast, K8 inactivation in F508del-Cftr mice fully rescued the decreased bone mass and altered microarchitecture induced by the mutation, as shown by bone histomorphometry and microCT analyses. The beneficial effect of K8 inactivation on bone mass in F508del-Cftr mice resulted from enhanced osteoblast activity as documented by the expression of phenotypic osteoblast genes (Runx2, Alp, Coll1a1, Oc) in bone and increased MAR and BFR, with no change in bone resorption parameters. Mechanistically, K8 inactivation in F508del-Cftr mice led to correct the overactive NF- κ B signaling and the decreased Wnt-beta-catenin signaling induced by the mutation in osteoblasts, as evidenced by Opg, Axin and Wisp1 expression in K8^{-/-}F508del-Cftr osteoblasts and by increased beta-catenin immunohistochemistry in vertebral bone of K8^{-/-}F508delta-Cftr mice. Knowing that the abnormal K8-F508del-CFTR interaction is a functional defect of F508del-CFTR in epithelial cells, we tested the effect of 407, a compound that binds to the F508del-NBD1 domain and acts as a protein-protein interaction inhibitor. We found that treatment with 407 corrected the abnormal NF- κ B transcription and Wnt-beta-catenin target gene expression and restored normal phenotypic gene expression in F508del-Cftr osteoblasts in vitro. In vivo, the injection of 407 for 4 days restored beta-catenin immunohistochemistry in vertebral bone and rescued long bone formation in F508del-Cftr mice, as indicated by correction of both MAR and BFR. Collectively, the data indicate that K8 plays a central role in the osteoblast dysfunctions induced by the prevalent F508del-Cftr mutation in mice, and suggests that K8 in relation with F508del-CFTR is a new target for therapeutics to correct the altered osteoblast bone formation and osteopenia in cystic fibrosis.

Matrix deposition and mineralization in heterozygous and homozygous mouse embryos with Gly610 to Cys substitution in the triple helical region of the α 2(I) collagen chain. Lynn Mirigian¹, Elena Makareeva¹, Shakib Omari¹, Anna Roberts-Pilgrim¹, Edward Mertz¹, Sergey Leikin^{*2}. ¹NICHHD, NIH, USA, ²National Institutes of Health, USA

Glycine substitutions in the triple helical region of type I collagen are the most common mutations resulting in severe forms of osteogenesis imperfecta (OI). The G610C mouse with a Gly610 to Cys substitution in the α 2(I) chain is the only model that produces moderately severe OI in heterozygous (het) and lethal OI in homozygous (hom) animals, as expected for dominant negative mutations. Here, we investigated extracellular matrix formation and mineralization in wild type (wt), het and hom G610C embryos and neonates on C57BL/6J background as well as in osteoblast and embryonic fibroblast cultures from these animals. At gestational day E18-19, we observed close to the expected 1:2:1 ratio of wt:het:hom embryos, all of which had similar size and appeared to be viable. Yet, all hom pups recovered within hours of birth were dead while most heterozygous and wild type pups survived to weaning. Skeletal staining and X-ray radiography of newborn hom animals revealed underdevelopment and undermineralization of calvaria, gross deformities of many other bones, and multiple fractures. Newborn het animals exhibited significant variability, ranging from severe bone malformations like in hom mice to almost normal bone appearance like in wt mice. In culture, heterozygous embryonic fibroblasts deposited 2-3 times less collagen/cell than their wt counterparts but approximately the same amount of collagen/cell as their hom counterparts.

Consistently, the skin of E18.5 het and hom embryos had similar reduced weight fraction of collagen and increased weight fraction of glycosaminoglycans compared to wt embryos. While het cells secreted equal number of molecules with and without the mutant α 2(I) chain, the matrix deposited by them in culture and skin of E18.5 embryos contained only 30% of mutant molecules. Deficient deposition of the latter into the matrix was at least in part caused by their reduced thermal stability and premature denaturation after secretion, before their incorporation and stabilization in collagen fibers. The amount of matrix deposited by cultured het osteoblasts was restored to almost wt level by treatment of the cells with rapamycin, suggesting that deficient matrix deposition was caused primarily by malfunction of the cells rather than secreted mutant molecules. Analysis of matrix mineralization *in vivo* and in culture also pointed to abnormal osteoblast differentiation and function as the primary cause of bone pathology.

MS-275 administration rescues cleidocranial dysplasia (CCD) phenotypes of Runx2+/- mice. Han-sol Bae^{*}, Won-joon Yoon, Young-dan Cho, Rabia Islam, Hye-rim Shin, Bong-soo Kim, Kyung-mi Woo, Jeong-hwa Baek, Hyun-mo Ryoo. Seoul National University, South Korea

Cleidocranial dysplasia (CCD) is an autosomal-dominant skeletal disorder caused by haploinsufficiency of Runx2, a key regulator of bone growth and differentiation. We previously reported that RUNX2 protein stability and its transcriptional activity require a serial post-translational modification process including phosphorylation, isomerization and acetylation. In the absence of the final acetylations, Runx2 undergoes perishing ubiquitination process. Aim of this study was to evaluate whether post-translational stabilization of Runx2 by an HDAC inhibitor (HDACi) could overcome phenotypes of genetic haploinsufficiency of Runx2. Runx2^{+/+} and Runx2^{+/-} mice were mated and MS-275, a Class I HDAC-specific inhibitor, was administered in pregnant mice at critical time points of bone development, then littermates treated with or without MS-275 were analyzed just after birth (P1). Systemic administration of MS-275 remarkably improved most of the skeletal deformities associated with Runx2^{+/-}; cranial bone development and clavicle maturation, spinal bone maturations, and mandible growth. In molecular level, MS-275 administration in Runx2^{+/-} mice stimulated Runx2 acetylation, thereby recovering hypomorphic expression of active Runx2 through enhanced stabilization of the protein so that Runx2 protein level was comparable that of wild-type mice. In addition, Runx2 transacting activity in Runx2^{+/-} calvarial osteoblasts was substantially recovered by the MS-275 treatment. On the other hand MS-275 neither caused pregnant mice to die, show toxic behaviors nor did it affect littermate numbers. Moreover, other class of HDACi, such as SAHA and valproic acid, didn't show any effects on Runx2^{+/-} bone defects. Conclusively, MS-275 could be applied for intervention of CCD phenotypes as a drug and its mechanism of action strongly suggested HDACi could open a new therapeutic regimen for diseases requiring bone regeneration.

Osteocyte-specific Overexpression of Human WNT16 Increases both Cortical and Trabecular Bone Density and Improves Bone Strength in Mice. Imranul Alam^{*1}, Austin Reilly¹, Charishma Kasipathi¹, Mohammed Alkhouli¹, Rita Gerard-O'Riley¹, Dena Acton¹, Amie Gray¹, Kyung-Eun Lim², Alexander Robling², Michael Econs¹. ¹Indiana University School of Medicine, USA, ²Anatomy & Cell Biology, USA

Several genome-wide association studies identified common variants in WNT16 gene that were associated with bone mineral density (BMD) and risk of fracture across multiple populations. In addition, studies involving both global and conditional knockout of Wnt16 in mice revealed that Wnt16 is a critical regulator for cortical BMD and strength. Recently, we demonstrated that osteoblast-specific overexpression of human WNT16 increased both cortical and trabecular bone mass and structure in mice. To further identify the cell-specific role of Wnt16 in bone homeostasis, we created transgenic (TG) mice over-expressing human WNT16 in osteocytes on B6 background using Dmp1 promoter. We compared bone density, micro-architecture and strength phenotypes between TG and wild-type (WT) mice at 6 and 12 weeks of age in both male and female. Compared to WT mice, Dmp1-WNT16 TG mice exhibited significantly higher ($p < 0.005$) whole body aBMD (9-16%) and BMC (11-21%) in both male and female (Figure 1). Spinal aBMD and BMC were also significantly greater (13-20%; $p < 0.005$ and 14-26%; $p < 0.05$, respectively) in the TG mice in both sexes. ρ CT analysis of trabecular bone at distal femur at 12 weeks of age revealed 2-fold (male) and 5-fold (female) higher ($p < 0.0005$) BV/TV, 29% (male) and 50% (female) higher Tb.N, 21% (male) and 50% (female) higher Tb.Th with 23% (male) and 35% (female) lower Tb.Sp in the TG mice compared to WT littermates (Figure 1). The cortical bone at midshaft femur showed 10-11% higher ($p < 0.001$) B.Ar/T.Ar and 4-6% higher ($p < 0.05$) cortical thickness in the TG mice. Femur biomechanics test at 12 weeks of age identified 12% higher ultimate force (UF), 7% higher stiffness (S) and 10% higher energy to UF in male TG mice compared to male WT littermates whereas female TG mice displayed significantly higher ($p < 0.05$) values for UF (17%), S (11%), energy to UF (35%) and energy to failure (16%)

compared to female WT mice (Figure 1). Our data indicate that overexpression of WNT16 in osteocytes increased both cortical and trabecular bone mass and improved bone strength, particularly in female. WNT16 has high potential for therapeutic interventions to treat osteoporosis or other low bone mass and high bone-fragility conditions.

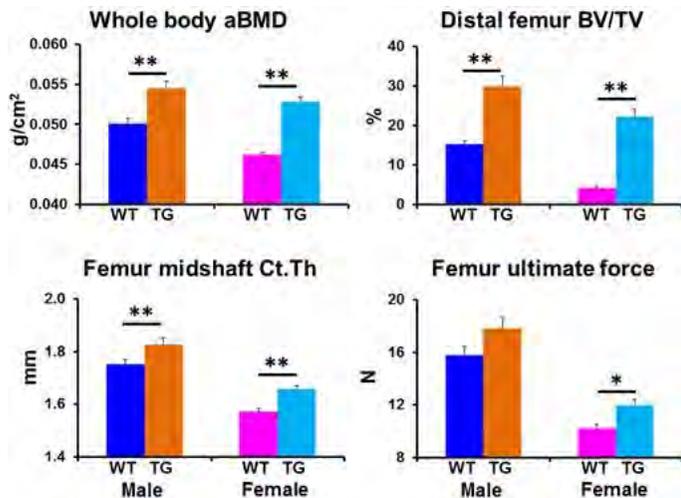

Figure 1. Bone mass and strength improved significantly in *Dmp1-WNT16* transgenic mice in both male and female. WT: wild-type; TG: Transgenic * $p < 0.05$; ** $p < 0.005$

PHOSPHO1 is Essential for Normal Bone Fracture Healing. Mina Morcos¹, Hadil Al-Jallad², Jose Luis Millan³, Reggie C Hamdy⁴, Monzur Murshed⁵. ¹McGill University, Canada, ²Division of Paediatric Orthopaedic Surgery, Shriners Hospital for Children, Montreal, Canada, ³Sanford-Burnham Medical Research Institute La Jolla, CA, USA, USA, ⁴Division of Paediatric Orthopaedic Surgery, Shriners Hospital for Children, Montreal. Department of Medicine, McGill University, Montreal, QC, Canada, Canada, ⁵Department of Molecular Genetics, Shriners Hospital for Children, Montreal. Department of Medicine, McGill University, Montreal, QC, Canada. Faculty of Dentistry, McGill University, Montreal, QC, Canada, Canada

Introduction: Bone fracture healing is regulated by a series of complex physicochemical and biochemical processes. One of these processes is bone mineralization, which is vital for normal bone development, its biomechanical competence and fracture healing. Phosphatase, orphan 1 (PHOSPHO1), a bone-specific phosphatase, has been shown to be involved in the mineralization of the extracellular matrix in bone. It can hydrolyze phosphoethanolamine and phosphocholine to generate inorganic phosphate, which is crucial for bone mineralization. *Phospho1*^{-/-} mice show hypomineralized bone and spontaneous fractures. All these data led to the hypothesis that PHOSPHO1 is essential for bone mineralization and its structural integrity. However, no study to our knowledge has shown the effects of PHOSPHO1 on bone fracture healing. In this study, we examined how PHOSPHO1-deficiency might affect the healing and quality of the fractured bones in *Phospho1*^{-/-} mice. **Materials and methods:** We performed rodded immobilised fracture surgery on the right tibia of control wild type (WT) and *Phospho1*^{-/-} mice (n=16 for each group) at 8 weeks of age. Bone was left to heal for 4 weeks and then the mice were euthanized and their tibias were analysed using Faxitron X-ray analyses, microCT, histology and histomorphometry. **Results:** Our microCT and X-ray analyses revealed that the appearance of the callus and several static parameters of bone remodeling at the fracture sites were markedly different in WT and *Phospho1*^{-/-} mice. We observed a significant increase of BS/BV, BS/TV and trabecular number and decrease in trabecular thickness and separation in *Phospho1*^{-/-} callus in comparison to the WT callus. These observations were further confirmed by histomorphometry. The increased bone mass at the fracture sites of *Phospho1*^{-/-} mice appears to be caused by increased bone formation as there is a significant increase of osteoblast number, while osteoclast numbers remained unchanged. There was a marked increase of osteoid volume over bone volume (OV/BV) in the *Phospho1*^{-/-} callus. Interestingly, the amount of osteoid was markedly higher at the fracture sites than that of normal trabecular bones. The mechanical properties of these fractured bones are currently being analyzed by 3-point bending tests. **Conclusion:** Our work suggests that PHOSPHO1 plays an integral role during bone fracture repair. PHOSPHO1 can be an interesting target to improve the fracture healing process.

Integrating genome-wide association and co-expression network data for novel BMD gene discovery. Gina Calabrese¹, Larry Mesner², Joseph Stains³, Steven Tommasini⁴, Mark Horowitz⁴, Clifford Rosen⁵, Charles Farber^{*2}. ¹University of Virginia, USA, ²University of Virginia, USA, ³University of Maryland, USA, ⁴Yale, USA, ⁵Maine Medical Research Institute, USA

Over the last seven years, genome-wide association studies (GWAS) have identified >70 associations for fracture, bone mineral density (BMD) and other fracture-related quantitative traits. While these data represent a treasure-trove of information on novel genes regulating bone strength, it has proven difficult to identify causal genes at associations using genetic data alone. Here, we hypothesized that analyzing GWAS data in the context of a co-expression network could identify putative regulators of BMD and causal GWAS genes. Our approach is based on the idea that groups of causal genes will influence BMD through the same process (e.g. osteoblast-mediated bone formation) and genes involved in the same process are often co-expressed. Therefore, we determined the module membership in a mouse bone co-expression network of 127 genes located in 64 BMD GWAS associations. We found that 25 of the 127 genes were members of two network modules (6 and 9; enrichment $P \leq 0.002$). We previously demonstrated that genes in modules 6 and 9 play key roles in the activity and function of osteoblasts. Of the 25 genes, 18 are well-known regulators of osteoblast activity and BMD, such as *Lrp5*, *Sp7* and *Tnfrsf11b*, demonstrating our ability to recover known BMD genes. To determine if the seven novel candidates were involved in the regulation of BMD, we queried BMD data collected on newly created mouse knockouts by the International Mouse Phenotyping Consortium. Knockout mice for two (*Tcf7l2* and *Spnb2*) of the seven had been characterized. Mice heterozygous for a null allele of *Tcf7l2* (*Tcf7l2*^{+/-}) had increased ($P=0.018$) BMD. In addition, BMD was decreased in female *Spnb2*^{+/-} mice and increased in male *Spnb2*^{+/-} mice (interaction $P=0.0002$). For an additional novel gene, *MARK3*, the network data predicted that it was involved in the regulation of osteoblast differentiation by altering the expression of module 9 genes. We showed that *Mark3* knockdown decreased osteoblast commitment, but increased osteoblast differentiation and mineralization. Additionally, *Mark3* knockout mice had increased femoral BMD, trabecular bone volume fraction (BV/TV) and cortical thickness and specifically altered the expression of module 9 genes. Together, our results identify *Tcf7l2*, *Spnb2* and *Mark3* as novel regulators of BMD and potential causal genes at their respective associations. Our results also highlight the power of using co-expression network data to inform human GWAS.

A Murine Model with Conditional FGF23 Deletion. Erica Clinkenbeard^{*1}, Taryn Cass², Julia Hum², Matt Allen³, Teresita Bellido³, Kenneth White². ¹Indiana University-Purdue University Indianapolis, USA, ²Department of Medical & Molecular Genetics Indiana University School of Medicine, USA, ³Department of Anatomy & Cell Biology Indiana University School of Medicine, USA

Phosphate homeostasis is maintained through FGF23 endocrine actions between bone and kidney. Characterized animal models involving FGF23 are highly informative, defining novel aspects of mineral metabolism. However, these models are limited by shortened life span, inability of fine FGF23 control, and infertility of the global knockout. To improve understanding of FGF23-mediated phosphate handling, a novel conditional-null mouse targeting deletion of FGF23 exon 2 was generated. Initial crosses of the floxed-FGF23 (*FGF23*^{fl/fl}) mice to ubiquitous *Ella*-cre mice were performed. Mice genotyped as fully recombined (*FGF23*^{Δ/Δ}) had undetectable serum intact FGF23 corresponding with elevated serum phosphate ($p < 0.05$) and increased kidney *Cyp27b1* ($p < 0.05$), thus recapitulating the global *FGF23*^{-/-} phenotype. To test functionality of this model, *FGF23*^{fl/fl} and *FGF23*^{Δ/Δ} first underwent targeted recombination with the early osteoblast 2.3kb *Col1a1* (2.3Col)-cre. After challenge with a high phosphate and low calcium diet, Cre⁺ mice had 2-2.4 fold increases in serum intact FGF23 ($p < 0.01$). At baseline, *FGF23*^{fl/fl} and *FGF23*^{Δ/Δ}/Cre⁺ mice exhibited ~50% lower intact FGF23 (133-144 pg/ml vs 75-66 pg/ml; $p < 0.05-0.02$). With dietary challenge, Cre⁺ mice had significantly elevated serum phosphates versus Cre⁻ mice ($p < 0.05-0.02$), whereas intact FGF23 remained restricted to below baseline, control-diet levels (63-88% reduction). *FGF23*^{Δ/Δ}/DMP1-Cre⁺ also had lower basal intact FGF23; however, Cre⁺ mice were less resistant to phosphate challenge (42-46% reduced; $p < 0.05-0.01$) consistent with recombination in more mature FGF23-producing cells. Next, the *FGF23*^{Δ/Δ}/Col2.3-cre was bred onto the Hyp background. As opposed to global *FGF23*^{-/-}/Hyp mice, which assume the biochemical and skeletal FGF23-null phenotype, *FGF23*^{Δ/Δ}/Col2.3-cre⁺/Hyp mice had 5% of the intact FGF23 versus Hyp mice and body and tail lengths comparable to WT. Additionally, μ CT analysis showed *FGF23*^{Δ/Δ}/Col2.3-cre⁺/Hyp had largely normal femur shape and increased metaphyseal trabecular BV/TV at 85+1.09% vs 3+0.9% in Hyp and 13.2+0.01% in WT. In summary, we developed a novel mouse model that undergoes conditional recombination of FGF23, and with bone-specific targeting this animal had reduced hormone levels that were resistant to phosphate challenge. Thus, the ability to suppress FGF23 non-lethally in vivo represents a useful genetic tool to address new questions isolating FGF23 bioactivity in normal and disease states.

Limb-specific Klotho Expression Is Required for FGF23 Production During Renal Failure. Jovana Kaludjerovic¹, Hirotaka Komaba¹, Tadatoshi Sato¹, Takenobu Ishii¹, Hannes Olausson², Tobias Larsson², Reinhold Erben³, Beate Lanske¹. ¹Harvard School of Dental Medicine, USA, ²Karolinska Institutet, Sweden, ³University of Veterinary Medicine, Austria

FGF23 has been proposed to be the initial adaptive response to development and progression of acute and chronic kidney disease. Since membrane Klotho (mKL) is expressed in osteoblasts and osteocytes – the major sites of FGF23 synthesis – we hypothesized that mKL may be required by FGF23 locally to induce an autocrine positive feedback loop. We conditionally deleted mKL from long bones in mice using Prx1-Cre and challenged these mice with renal failure by feeding them an adenine diet for 8 weeks. At 16 weeks of age, all mice fed adenine diet had reduced body weight, kidney atrophy, high urea concentrations (80-120 mg/dL) and hyperphosphataemia, confirming induction of renal failure. No differences in these parameters were seen between adenine fed *KL^{fl/fl}* and *Prx1-Cre;KL^{fl/fl}* mice. However, limbs of adenine fed *Prx1-Cre;KL^{fl/fl}* mice did not respond with an increase in *Fgf23* mRNA expression that was observed in adenine fed *KL^{fl/fl}* mice. As such, adenine fed *Prx1-Cre;KL^{fl/fl}* had significantly lower serum iFGF23 levels than adenine fed *KL^{fl/fl}* mice, higher expression of renal 1 α -hydroxylase, hypercalcaemia and severe kyphosis. To validate the results, findings were confirmed in 5/6 NTX *Prx1-Cre;KL^{fl/fl}* mice. Preliminary histomorphometric analyses of femurs (n=4-7/group) showed that *Prx1-Cre;KL^{fl/fl}* had increased number of trabecular osteocytes and osteocyte lacunae volume in response to uremia; but have significantly less mineralized volume, trabecular thickness and connectivity than uremic *KL^{fl/fl}* mice. Osteoblasts cultured from calvaria of newborn *KL^{fl/fl}* mice and stained with alizarin red showed that loss of mKL results in reduced bone mineralization. Therefore, our data is the first to show that limb-specific mKL plays an important role in regulating mineral ion homeostasis and more importantly FGF23 production. This novel data suggests that mKL expression in bone cells might provide a sensing mechanism for the need of FGF23.

Sustained expression of a soluble form of α Klotho prevents aortic calcification and disease phenotypes during chronic hyperphosphatemia. Julia Hum¹, Linda O'Bryan², Arun Tatiparthi³, Robert Johnson⁴, Jonathan Wilson⁴, Erica Clinkenbeard⁵, Tarvn Cass⁵, Rosamund Smith², Kenneth White⁵. ¹Indiana University School of Medicine, USA, ²Biotechnology Discovery Research, Eli Lilly & Company, USA, ³Lead Optimization Pharmacology & Toxicology, Covance Laboratories Inc., USA, ⁴Investigational Pathology, Eli Lilly & Company, USA, ⁵Department of Medical & Molecular Genetics, Indiana University School of Medicine, USA

α Klotho (α KL), the co-receptor for FGF23, is expressed as a membrane-bound protein (mKL) that forms heteromeric complexes with FGF receptors (FGFRs) to initiate intracellular signaling. A circulating form of α KL (cKL) also arises from endoproteolytic cleavage of mKL, however its role in phosphate handling remains unclear. The goal of the present study was to isolate cKL activity in the absence of native α KL, as renal α KL expression during CKD falls with disease progression. In WT mice, and in α KL-null mice where basal serum intact FGF23 levels are already high, 4-week delivery of adeno-associated virus (AAV2/8) carrying cKL (AAV-cKL) at 1011gc/20g mouse resulted in significantly elevated FGF23, compared to respective genotype controls (p<0.05). Consistent with these observations, AAV-cKL induced a >200-fold elevation of bone FGF23 mRNA in WT mice, and a 25-fold increase in already-elevated FGF23 mRNA in α KL-null mice. The α KL-null serum phosphate levels showed >20% reduction with cKL delivery (p<0.01 vs controls). This effect was independent of PTH, which remained suppressed in α KL-null compared to WT animals. Importantly, AAV-cKL prevented aortic calcification in α KL-null mice as tested by μ CT (74% less aorta mineral content, 72% reduced mineral volume; p<0.01), also confirmed by histology. In vitro, UMR-106 cells treated with cKL+FGF23 increased p-ERK1/2 activity, as well as FGF23 mRNA (12-fold; p<0.001), whereas cKL or FGF23 alone had minimal effects. EGFR1 mRNA, a marker for FGFR signaling activity, also responded with a 40-fold maximum increase (p<0.0001), and pretreatment with MEK (10 μ M; U0126) and FGFR inhibitors (80 μ M; PD173074) ablated p-ERK1/2 and EGFR1 responses. Additionally, a novel UMR-106 line with deletion of FGFR1 via CRISPR could not elevate FGF23 mRNA in response to cKL+FGF23. EGFR1 was similarly blunted in this line following treatment with cKL+FGF23 (78%), FGF2 (92%), and FGF8 (86%; all p<0.01). In summary, we demonstrated in a model of hyperphosphatemia and vascular calcification that sustained cKL expression reduced serum phosphate levels and prevented aortic calcification, in the absence of effects on PTH. cKL also stimulated FGF23 in an FGFR1-dependent manner in bone cells. Collectively, these findings support that stable cKL delivery may improve severe manifestations arising from alterations in phosphate homeostasis.

AMG 416 Prevented Cortical Porosity and Preserved Bone Strength in 5/6 Nephrectomized Rats with Established Secondary Hyperparathyroidism. Longchuan Yu¹, Frank Asuncion¹, Shawn Alexander¹, Kelly Hensley¹, Chun-Ya Han², Denise Dwyer³, Qing-Tian Niu¹, Marina Stolina¹, Charley Dean Jr¹, Michael Ominsky¹, William Richards¹, Xiaodong Li¹. ¹Amgen Inc., USA, ²Amgen, Inc., USA, ³Amgen, Inc, USA

Continuous elevation of parathyroid hormone (PTH) is catabolic to cortical bone, causing deterioration in cortical bone structure (eg, cortical porosity), and is a major factor for increased fracture risk in chronic kidney disease. AMG 416, a peptide agonist of calcium-sensing receptor, reduces PTH levels in patients on hemodialysis with secondary hyperparathyroidism (SHPT) in clinical studies. We hypothesized that AMG 416 would prevent the cortical bone deterioration by reducing PTH in a rat model of established SHPT. Twelve-week-old male 5/6 nephrectomized (5/6 Nx) rats were fed a special diet containing high phosphate (0.9%) and low calcium (0.6%) to further induce SHPT. Sham-operated rats were used as non-SHPT controls. Following 8 weeks on the special diet, rats were chosen with a baseline PTH level > 750 pg/mL (SHPT rats) and were subcutaneously injected daily with vehicle or AMG 416 for 6 weeks. Prior to treatment, SHPT rats had significant increases in serum creatinine (2-fold), blood urea nitrogen (BUN, 3-fold), PTH (5-fold), FGF-23 (13-fold) and osteocalcin (12-fold, a marker of bone turnover) compared with the non-SHPT controls. Serum creatinine and BUN continued to increase in both vehicle- and AMG 416-treated SHPT rats during the treatment period. PTH, FGF-23 and osteocalcin continued to increase in vehicle-treated SHPT rats, but were significantly reduced in AMG 416-treated SHPT rats (-96%, -64% and -38%, respectively at day 42). At the end of treatment, vehicle-treated SHPT rats had significantly increased cortical porosity (8.3% in SHPT vs 0.07% in non-SHPT) and lower energy to failure (-30%), a bone strength endpoint, compared with non-SHPT controls. In contrast, cortical porosity was significantly lower (-72%) and energy to failure was significantly greater (+54%) in the AMG 416-treated SHPT rats than in vehicle-treated SHPT rats. These results demonstrated that AMG 416 prevented cortical porosity and preserved bone strength by reducing PTH in 5/6 Nx rat model of established SHPT.

Continuous PTH Treatment Induces Bone Loss through G α S Signaling in T cells. Jau-Yi Li¹, Jerid W. Robinson², Abdul Malik Tyagi², Jonathan Adams², Neal M. Weitzmann², Roberto Pacifici². ¹Emory University School of Medicine, USA, ²Emory University, USA

Hyperparathyroidism in humans and continuous PTH treatment (cPTH) in mice stimulate bone resorption and cause bone loss by regulating RANKL production by osteocytes and osteoblasts. T cells markedly potentiate the bone catabolic effect of cPTH by secreting the osteoclastogenic cytokine TNF, a factor that potentiates the osteoclastogenic activity of RANKL. TNF produced by T cells is required for cPTH to expand Th17 cells and induce the production of the osteoclastogenic factor IL-17. IL-17 is an upstream cytokine that induces RANKL production by osteocytes and osteoblasts. PTH binding to its receptor PPR activates G protein α (G α S). Activation of G α S has been shown to induce the differentiation of Naive CD4+ cells into Th17 cells. Therefore, cPTH could further upregulate Th17 differentiation by activating G α S in naive CD4+ T cells. To investigate this hypothesis, we generated G α S^{ACD4,8} mice by crossing C57BL6 G α S fl/fl mice with C57BL6 CD4-Cre mice. The targeted genetic deletion of G α S with CD4-Cre occurs at the CD4+CD8+ double positive stage of T cell development. Consequently both CD4+ and CD8+ T cells from G α S^{ACD4,8} mice lack G α S expression. We found that in vivo cPTH treatment (80 μ g/kg/day subcutaneously for 2 weeks) increased the frequency of BM Th17 ~3 fold in control G α S fl/fl mice, but not in G α S^{ACD4,8} mice. μ CT measurements revealed that cPTH induced significant losses of femoral trabecular and cortical bone in G α S fl/fl mice but not in G α S^{ACD4,8} mice. Furthermore, cPTH increases serum CTX (a marker of bone resorption) in G α S fl/fl but not in G α S^{ACD4,8} mice. Conversely, cPTH increases serum PINP (a marker of bone formation) in all strains. Signaling events downstream of G α S include cAMP generation and activation of L-type calcium channels. The latter contributes to Th17 cell differentiation. To determine if Ca²⁺ influx is required for Th17 cell expansion induced by cPTH, we fed mice with water with or without the L-type calcium channel blocker diltiazem and infused them with vehicle and cPTH. Diltiazem blocked the increase in the number of BM Th17 cells, and the loss of cortical and trabecular bone induced by cPTH. Moreover, diltiazem blocked the increase in serum CTX levels but not the increase in serum PINP induced by cPTH. In summary, these findings demonstrate that cPTH causes bone loss by expanding Th17 cells via C α S/cAMP/Ca²⁺ signaling. Calcium channel blockers may thus represent novel therapeutic strategies for hyperparathyroidism.

CRISPR-mediated RUNX2 Deletion Delineates Mechanisms of Gene Expression throughout Osteoblast Differentiation and Mineralization. Mark Meyer*, Nancy Benkusky, J. Wesley Pike. University of Wisconsin-Madison, USA

RUNX2 (CBFA1) is a vital transcription factor for osteoblast maturation and function. RUNX2 forms complexes with transcription factors at enhancers located near essential osteoblast genes and contributes to their expression. Using a CRISPR/Cas9 deletion approach, we generated a unique cell culture knockout model of RUNX2 in UAMS-32P cells, a clonal osteoblastic line that stably expresses hPTH1R. Unlike its parental counterpart, these RUNX2 KO cells cannot differentiate or mineralize and exhibit retarded growth, all functions restored via lentivirus mediated re-expression of RUNX2. Many osteoblastic genes have distal enhancers that are RUNX2 dependent, as loss of RUNX2 greatly affects the binding of other factors to the same, or neighboring, enhancers as assayed by direct ChIP analysis. Accordingly, we see large reductions in the expression of genes that include *Enpp1/3*, *Bmp4*, and *Mmp13*; *Hdac4*, however, was only modestly reduced. Loss of RUNX2 prevents Osterix (*Sp7*), *Alpl*, *Igf1bp5*, and *Col2a1* expression, consistent with the cell's lack of differentiation. Finally, RUNX2 deletion had no effect on the expression of *Mgp*, *Cbs*, or several additional *Hdac* genes despite significant RUNX2 binding at major enhancers for these genes. The CRISPR approach was also used to prepare additional daughter cell lines containing mutations specifically within the *Mmp13* gene locus that permitted evaluation of the effects of 1,25(OH)₂D₃ on *Mmp13* expression. This enabled us to demonstrate a dual interplay between RUNX2 and the VDR at *Mmp13* and at sites across the UAMS-32P genome as well. These mutant lines have also allowed us to explore the impact of PTH and forskolin on the expression of *Mmp13* and other bone genes. PTH regulation of *Mmp13* is believed to be mediated through a region proximal to the promoter that is RUNX2 dependent and involves both HDAC4 and PKA signaling. However, deletion of this region in UAMS-32P cells had little effect on *Mmp13* expression induced by either PTH or the VDR. On the other hand, the activity of PTH at *Mmp13* was fully abrogated by deletion of a RUNX2-enriched enhancer located 30 kb up-stream of the *Mmp13* gene as well as through global deletion of RUNX2. Our CRISPR mouse model of *Mmp13* expression, now established, will allow us to confirm principles of *Mmp13* gene regulation *in vivo*, extend our understanding of *Mmp13* expression by RUNX2, and explore atherosclerotic disease models in which aberrant *Mmp13* expression may be involved.

LRP6 Is Required For PTH-Induced SOST Suppression. CHANGJUN LI*¹, Liang Xie², Xu Cao², Mei Wan². ¹Johns Hopkins University School of Medicine, USA, ²Department of Orthopaedic Surgery, Johns Hopkins University School of Medicine, Baltimore, MD 21205, USA, USA

Parathyroid hormone (PTH) suppresses the expression of a bone formation inhibitor sclerostin (SOST) in osteocytes by inducing nuclear accumulation of histone deacetylases (HDACs) to inhibit the myocyte enhancer factor 2 (MEF2)-dependent SOST bone enhancer. We previously demonstrated that lipoprotein receptor-related protein 6 (LRP6) mediates intracellular signaling activation elicited by PTH in osteoblastic lineage cells. Importantly, LRP6 is indispensable for PTH anabolic action on bone in mice. Here, we investigated whether LRP6 mediates the inhibitory effect of PTH on SOST using osteoblast-specific LRP6-knockout (LRP6 KO) mice, which were generated by crossing mice expressing the Cre recombinase driven by the human osteocalcin promoter (OC-Cre) with mice expressing loxP-flanked Lrp6 (*Lrp6^{fl/fl}*). Immunohistochemical analysis revealed that LRP6 expression was detected in most (approximately 75%) of the osteocytes in cortical bone of femora in wild type mice, but only in a small portion (about 23%) of osteocytes in femurs of the KO mice. Thus, LRP6 is deleted in most of the osteocytes in LRP6 KO mice. An increased level of SOST mRNA expression was detected in femur tissue from LRP6 KO mice relative to their wild type littermates. The number of osteocytes expressing sclerostin was also increased in bone tissue of LRP6 KO mice, indicating a negative regulatory role of LRP6 on SOST/sclerostin. We then examined the changes of SOST gene and sclerostin in osteocytes in femur tissue from WT mice and LRP6 KO mice after daily injection of either PTH(1-34) or vehicle for 4 weeks. Intermittent PTH treatment significantly suppressed SOST mRNA expression in femur tissue and the number of sclerostin+ osteocytes in WT mice relative to vehicle-treated mice, while this effect of PTH was much less significant in LRP6 KO mice. Thus, the suppressive effect of PTH on SOST/sclerostin in osteocytes was alleviated by LRP6 deficiency. It is known that HDACs interact with MEF2 transcription factor, and the MEF2-HDAC axis mediates the effect of PTH on SOST repression. In PTH-treated mice, MEF2C and 2D were down-regulated and the HDACs were also changed in osteocytes of femur tissue as detected by both immunohistochemical analysis and qRT-PCR. The changes of MEFs and HDACs were abrogated in LRP6 KO mice. Therefore, LRP6 mediates PTH effect on HDAC-MEF-SOST axis, providing an additional dimension to the current understanding of LRP6-mediated PTH bone action.

The large variant of the stimulatory G protein alpha-subunit XL α s mediates early postnatal regulation of renal phosphate handling by enhancing IP3/DAG signaling. Qing He*¹, Yan Zhu¹, Braden Corbin¹, Antonius Plagge², Murat Bastepe¹. ¹Massachusetts General Hospital, USA, ²University of Liverpool, United Kingdom

GNAS encodes the alpha-subunit of the stimulatory G protein (G α s), as well as its large variant XL α s. Through production of cAMP, G α s mediates the actions of multiple molecules, including parathyroid hormone (PTH), which promotes phosphate excretion and vitamin D activation in renal proximal tubules. PTH also activates G α _{q/11} signaling to regulate renal phosphate handling. XL α s can mimic the actions of G α s and mediate PTH-induced cAMP signaling when overexpressed. However, although alterations in XL α s level/activity are implicated in various diseases, its cellular roles have remained unclear. Here we determined that XL α s is expressed in renal proximal tubules early postnatally. At postnatal day 2 (P2) XL α s knockout mice (XLKO) exhibited hyperphosphatemia/hypocalcemia with elevated plasma PTH and 1,25 dihydroxyvitamin D. The level of sodium-phosphate co-transporter Npt2a was increased in renal brush border membranes, as well as the renal expression of vitamin D metabolizing enzymes Cyp27b1 and Cyp24a1. In addition, PTH-induced reduction of serum phosphate and downregulation of Npt2a were significantly blunted. Nevertheless, PTH-induced urinary cAMP excretion was modestly increased. Instead, XLKO pups showed repressed basal and PTH-stimulated G α _{q/11} signaling with diminished IP3 generation and reduced levels of certain PKC isoforms in proximal tubules. Hyperphosphatemia and elevated renal Cyp27b1 mRNA in XLKO pups, as well as reduced PKC levels in proximal tubules, were rescued by proximal tubule-specific overexpression of XL α s. Overexpression of XL α s in transgenic mice and in transfected HEK293 cells promoted G α _{q/11} signaling basally and in response to PTH. Thrombin, another agonist that stimulates G α _{q/11} signaling via its own endogenous receptor, also induced higher IP3 generation in HEK293 cells transfected with XL α s cDNA than in vector transfected cells. Moreover, XL α s expression recovered thrombin-induced IP3 generation in G α _{q/11}-/- HEK293 cells in which G α _q and G α ₁₁ were ablated through the use of CRISPR/Cas technology. Our findings indicate that XL α s mediates proximal tubular PTH actions during early postnatal development by mimicking, at least partly, the actions of G α _{q/11} to promote IP3/DAG signaling.

FR0124

Androgen receptor signaling in mesenchymal lineage cells suppresses soluble RANKL production, cancellous osteoclast number, and B lymphopoiesis. Semahat Serra Ucer*¹, Srividhya Iyer², Ha-neui Kim², Shoshana M Bartell², Aaron D Warren³, Li Han², Julie A Crawford², Charles A O'Brien², Maria Jose Almeida², Stavros C Manolagas². ¹University of Arkansas for Medical Sciences, USA, ²Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA, ³Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA

Androgens are critical for the acquisition and maintenance of bone mass in both the cortical and cancellous bone compartment, but the cellular and molecular mechanisms responsible for these effects remain poorly understood. It has been shown earlier that the anti-resorptive effects of androgens on cancellous bone result from androgen receptor (AR) signaling in cells of the mesenchymal lineage and a decrease in osteoclast numbers – but not from direct actions on osteoclasts. In addition, osteocyte-derived RANKL is critical for bone remodeling in the cancellous compartment in mice; the number of B lymphocytes increases in the bone marrow of rodents after loss of either estrogen or androgens; and B lymphocyte-derived RANKL contributes to the loss of cancellous bone caused by estrogen deficiency (OVX). In search of molecular mechanisms of the anti-resorptive effects of androgen on cancellous bone, male AR^{fl/y};Prx1-Cre mice and AR^{fl/y} littermates were euthanized at 16 weeks of age. In addition, C57BL/6 wild type mice were sham operated or orchidectomized at 20 weeks of age and euthanized 6 weeks later. In both experiments, bone marrow plasma was obtained at the time of harvest and soluble RANKL levels as well as the percentage of pre B (B220⁺/CD43⁺) and B (CD19⁺) lymphocytes were determined. Both AR deletion from cells of the mesenchymal lineage or orchidectomy (ORX) increased the levels of soluble RANKL by 85% and 248%, respectively. Similarly, AR deletion or ORX increased the percentage of pre B lymphocytes in the bone marrow by 32% and 161%, and the percentage of B lymphocytes by 27% and 133%, respectively. Nonetheless, RANKL mRNA levels on a per cell base was no different in B lymphocytes from either model. Collectively, our findings support the conclusion that androgen signaling via the AR expressed in cells of the mesenchymal lineage and their descendants, most likely osteocytes, restrains soluble RANKL production as well as the total number of B cells expressing RANKL rather than the expression level per B cell; and thereby restrains osteoclastogenesis. The greater increase in soluble RANKL and B lymphocyte percentage in the bone marrow of androgen deficient mice, as compared to mice with the targeted AR deletion in mesenchymal progenitors (AR^{fl/y};Prx1-Cre), raises the possibility that direct effects of androgens on other cell types, including B lymphocyte themselves, also contribute to their influence on RANKL and cancellous bone resorption.

FR0125

Conditional knockout of progesterone receptor in the osteoprogenitor cells, but not in the mature osteoblasts, increases trabecular bone formation. Zhendong Zhong^{*1}, Weihua Sun², Haiyan Chen², Yu-an Lay², Nancy Lane², Wei Yao². ¹University of California, Davis, USA, ²Musculoskeletal Research Unit, Department of Medicine, University of California Davis Medical Center, Sacramento, CA 95817, USA., USA

Sexual dimorphism in bone is well known; men tend to have higher peak bone mass than women. Our laboratory and another group previously reported that global progesterone receptor knockout (PRKO) mice displayed a high-bone-mass phenotype (Rickard, 2008; Yao, 2010). **Methods.** To further elucidate the role of progesterone receptor (PR) in osteoprogenitor cells and osteoblasts, bone-specific PR conditional knockout mice were generated in our laboratory by crossing PR-flox mice to either Prx1-Cre or Bglap-cre mice. Bone mass acquisition, bone turnover and bone mechanical properties were evaluated at the age of 2 and 6 months in both sexes. **Results.** We first used genetic fate-mapping approaches (PR-cre;tdTomato; Col1(2.3kb)-GFP) to demonstrate that the PR could be expressed by the cells on bone surface (primarily trabeculae) after 1 month of age, and these PR+ cells rarely expressed mature osteoblast marker Col1a1. PR protein measured by western blot was only detected at the femoral epiphysis and metaphysis, but not at the diaphysis. In line with the PR expression pattern in bone, no significant skeletal change was identified in Bglap-Cre-driven (mature osteoblast-specific) PR conditional knockout mice. In contrast, we observed 50-100% higher trabecular bone volume in distal femurs, as well as significantly higher serum osteocalcin levels, in Prx1-Cre-driven heterozygous/homozygous male and homozygous female PR knockout mice at 2 and 6 months of age. Bone size and femur length were similar between Prx1-Cre-driven mutant and WT controls. No significant phenotypic change was observed in cortical bone of femurs from 6-month-old Prx1-Cre;PR-flox mice by microCT analyses and 3-point bending tests, probably due to the lack of PR expression in the diaphyses. Mechanistically, we found ~40% higher MSC-like population (CD105+CD29+Scal+CD45-) in bone marrow stromal cells from male homozygous Prx1-Cre;PR-flox knockout mice at 2 and 6 months of age; and the PR-deficient BMSCs exhibited higher osteogenic differentiation in vitro. Further investigations are ongoing to decipher the PR signaling cascades involved in bone formation and attainment of peak bone mass. **Conclusions.** Inactivation of the PR in Prx1+ osteoprogenitor cells resulted in higher trabecular bone mass and bone formation in both sexes. Our results reveal PR in osteoprogenitor cells to be a potential target for bone mass augmentation.

FR0126

ER α Expression in T Lymphocytes is Dispensable for Estrogenic Effects in Bone. Karin Gustafsson^{*1}, Annica Andersson², Helen Farman², Vikte Lionikaite², Petra Henning², Jianyao Wu², Sara Windahl², Merja Nurkkala Karlsson², Angelina Bernardi², Ulrika Islander², Sofia Skrtic², Klara Sjögren², Claes Ohlsson², Marie Lagerquist². ¹University of Gothenburg, Sweden, ²Centre for Bone & Arthritis Research, Institute of Medicine, University of Gothenburg, Sweden

It is well established that estrogen withdrawal has deleterious effects in the skeleton and that estrogen signaling, via estrogen receptor alpha (ER α), counteracts this negative effect. ER α signaling in mesenchymal cells, including osteoprogenitor cells, is known to affect bone mass. However, T lymphocytes are implicated to be involved in bone loss caused by estrogen deficiency and we recently showed that ER α expression in hematopoietic cells affects the degree of bone response to estrogen treatment. The aim of this study was therefore to determine the role ER α expression in T lymphocytes both for ovariectomy (ovx)-induced bone loss and for the estrogen treatment response in bone.

Lck-ER $\alpha^{fl/fl}$ mice, lacking ER α expression in T cells, were generated by crossing Lck-Cre mice with ER $\alpha^{fl/fl}$ mice, carrying a floxed ER α exon 3, and compared to ER $\alpha^{fl/fl}$ littermates. The effectiveness of ER α gene deletion was demonstrated by an 84% (p<0.001) reduction in ER α mRNA levels in T lymphocytes (CD3-positive cells) in thymus. 12-week-old mice were sham-operated or ovx and treated with estradiol (E2; 167ng/mouse/day) or vehicle for 4 weeks. At termination the mice were subjected to a DEXA scan and the tibiae were dissected and analyzed using pQCT.

The total bone mineral density (BMD), measured by DEXA, did not differ between sham-operated Lck-ER $\alpha^{fl/fl}$ mice and ER $\alpha^{fl/fl}$ controls. OvX decreased total body BMD to a similar extent in both genotypes (Lck-ER $\alpha^{fl/fl}$; -4.2%, p<0.05, ER $\alpha^{fl/fl}$; -5.7%, p<0.05) and the estrogenic responses in total body BMD were equal (Lck-ER $\alpha^{fl/fl}$; +16%, p<0.001, ER $\alpha^{fl/fl}$; +18%, p<0.001). No significant difference in trabecular BMD, measured by pQCT, was detected between sham-operated mice Lck-ER $\alpha^{fl/fl}$ mice and ER $\alpha^{fl/fl}$ controls and the decrease was equal in both genotypes after ovx (Lck-ER $\alpha^{fl/fl}$; -35%, p<0.01, ER $\alpha^{fl/fl}$; -23%, p<0.001). Furthermore, the E2 response in trabecular BMD was similar in Lck-ER $\alpha^{fl/fl}$ mice (+281% p<0.001) and ER $\alpha^{fl/fl}$ controls (+338% p<0.001).

In conclusion, ER α expression in T lymphocytes is not required for ovx-induced bone loss or the estrogen treatment response in bone.

FR0127

The role of osteocyte estrogen receptor beta (ER β) in regulating skeletal growth, aging, and the skeleton's anabolic response to physical stimuli. Maxime Gallant¹, Haisheng Yang¹, Whitney Bullock², Teresita Bellido³, Russell Main^{*1}. ¹Purdue University, USA, ²Indiana University Purdue University Indianapolis, USA, ³Indiana University School of Medicine, USA

Sex hormones are key contributors to skeletal health. However, the effects of estradiol on skeletal anabolic pathways are still not well defined. While osteocytes are critical regulators of bone formation, osteocyte estrogen receptor alpha (ER α) has limited effects in the growing skeleton and response to mechanical load. These results call for a better understanding of skeletal ER β , which has been proposed as an inhibitor of skeletal mechanotransduction. Our goal is to characterize the role of osteocyte ER β in regulating bone structure during growth, aging, and the response to mechanical stimuli. Mice lacking osteocyte ER β were generated by Cre-LoxP recombination driven by DMP1-8kb-Cre. Male and female mice with osteocyte deletion of ER β (KO) and littermate control mice (LC) were (i) sacrificed at 4 or 7wks old or (ii) began 2wks of unilateral tibial loading at 10 or 26wks old (12 and 28wks old at sacrifice). Serum estradiol and testosterone analyses were conducted in 4, 7, and 28wks old. MicroCT analyses of the tibiae and L5 vertebrae were conducted and genotypic differences tested by t-test. Load-genotype interactions were tested by linear mixed model with repeated measures.

We found no genotype-related differences in serum hormones. There were few phenotypic differences between KO and LC mice at 4, 7, or 12wks of age. Osteocyte-specific ER β deletion had sex-dependent effects on bone mass at 28wks. Tibial midshaft Ct.Ar (+17%) and proximal cancellous BV/TV (+83%) were increased in male KO relative to LC mice. By contrast, cancellous BV/TV was reduced in 28wk female KO relative to LC mice (-38%). Similar cancellous patterns were seen in L5. While loading had an anabolic effect in the cancellous and cortical tissues in 12wk old tibiae, no interactive effect of genotype was found. 28wk female mice showed a strong midshaft response to load, but no genotypic interaction. At a site 37% of the tibia's length from the proximal end, 28wk female KO mice showed a greater load-induced increase in Ct.Ar than LC mice (+46% vs. +35%). Similarly, Tb.Th in the proximal tibia increased more in the 28wk female KO mice than in LC mice (+28% vs. +8%). 28wk old male mice did not respond strongly to tibial loading.

Osteocyte ER β plays an important role in regulating bone turnover in adult mice and the anabolic response to physical stimuli, especially in adult female mice. The cellular mechanisms underlying these structural outcomes are presently being investigated.

FR0128

Common polymorphism in Vitamin D 25-hydroxylase gene (CYP2R1) abrogates promoter activity and is associated with low serum 25OHD in a Caucasian pediatric cohort. Jeff Roizen^{*1}, Alex Casella², Jonathan Bradford², Meizan Lai², Hakon Hakonarson², Michael Levine². ¹The Childrens Hospital of Philadelphia, USA, ²The Children's Hospital of Philadelphia, USA

Optimal bone and mineral metabolism, as well as immune and cardiovascular function, depend on normal vitamin D metabolism. Ineffective sunlight exposure and inadequate dietary vitamin D each have well understood roles in the pathophysiology of vitamin D deficiency; however, the extent to which common variations or polymorphisms in genes encoding vitamin D metabolizing enzymes contribute to vitamin D homeostasis remains unknown. Several genome wide association studies (GWAS) have identified significant associations between serum [25(OH)D] and single nucleotide polymorphisms (SNPs) in or near the locus for CYP2R1, the gene encoding the principal vitamin D 25-hydroxylase enzyme. To examine whether SNPs in the CYP2R1 promoter alter transcriptional activity we introduced single base changes corresponding to the minor alleles of several SNPs into the 5 kb CYP2R1 promoter fragment that directs transcription of firefly luciferase in a hybrid reporter construct. Reporter constructs containing the wild type CYP2R1 promoter reporter or the minor allele of promoter SNPs (rs2060793, rs10741657, rs1562902, rs16930609 and rs7949459) plus a Renilla luciferase reporter were used to transfect LnCap cells, a human prostate carcinoma cell line that expresses CYP2R1 in a regulated fashion. The wild-type promoter showed significantly (p < 0.001 one way ANOVA) greater activity than a promoterless luciferase reporter (3.58 \pm 0.51 vs 1.00 \pm 0.00 (mean \pm SD)). Four of the five promoter polymorphisms (rs2060793, rs10741657, rs1562902 and rs16930609) showed similar luciferase activity compared to wild-type promoter (2.73 \pm 0.35 to 3.51 \pm 0.29 (mean \pm SD)). By contrast, the SNP rs7949459 showed an 85% reduction in luciferase activity compared to wild type promoter (0.58 \pm 0.07 vs 3.58 \pm 0.51, p < 0.001). This SNP is in high linkage disequilibrium with the commonly nearby SNPs identified in GWAS for 25(OH)D (for each of rs10500804, rs10741657, and rs10766192, D > 0.98). The 1000 Genomes database indicates that the minor allele of this SNP occurs in more than 10% of the population, however, it is not present on chips used for genotyping in GWAS. Therefore we used IMPUTE2 to determine the presence of this allele in a sample of 440 Caucasian children representing a population based cohort recruited by the Center for Applied Genomics at CHOP (info score of 0.933). Using logistic regression we tested for an association between allelic dosage and serum 25(OH)D levels expressed as quartiles. Presence of a

single rs7949459_T allele was associated as a continuous variable with 25(OH)D (beta= -0.35, SE=0.15, p=0.02). Our biochemical results provide evidence that this common genetic variation in *CYP27R1* has significant effects on transcription of *CYP27R1*, and our genetic studies provide a functional context for interpreting GWAS that show relationships between circulating 25(OH)D and *CYP27R1*.

FR0129

Conditional Knockout of Osteoblast Vitamin D Receptor and CYP27B1 Implicates Cell-Specific Receptor Signaling but Not Cell-Specific 1,25-dihydroxyvitamin D Production in the Maintenance of Trabecular and Cortical Bone Mass in Male and Female Mice. Tsui-Hua Chen, Amanda Herberger*, nathan liang, Alfred Li, daniel Bikle, wenhan chang, Dolores Shoback, UCSF, USA

Many tissues important in systemic calcium (Ca²⁺), phosphate, and bone homeostasis express both the vitamin D receptor (VDR) and CYP27B1 (1-alpha hydroxylase) and thus can locally produce and respond to 1,25-dihydroxyvitamin D [1,25-(OH)₂D] in an autocrine/paracrine manner. Such tissues include the parathyroid, kidney, and bone. Progress has been slow in understanding the role of locally produced 1,25-(OH)₂D on VDR actions in both local and distant endocrine actions of 1,25-(OH)₂D since global knockout (KO) mice show altered serum minerals and hormones as well as secondary bone and cartilage pathology. To test the role of the osteoblast (OB) VDR and of OB-produced 1,25-(OH)₂D, we generated OB-specific conditional KO's of VDR [^{OB}VDR(-/-)] and of CYP27B1 [^{OB}CYP27B1(-/-)] by crossing floxed VDR (gift of S. Kato) and floxed CYP27B1 (gift of R. St-Arnaud) with mice expressing Cre recombinase under control of the rat 2.3 kb Col1 promoter (gift of D. Rowe). We assessed mass and microstructure by computed tomography (CT) of trabecular (Tb) and cortical (Cort) bone at the distal femur and tibio-fibular junction, respectively, and mineral and hormonal parameters in male and female homozygous KO mice and control littermates at 12 weeks of age. Tb bone volume/tissue volume (BV/TV) was significantly greater in both female and male ^{OB}VDR(-/-) vs control mice – with increased connectivity and decreased structural model index (SMI) in females and increased Tb thickness in males (see Table; N=18-26 mice). Cort BV/TV and Cort thickness were significantly greater in both female and male ^{OB}VDR(-/-) vs control mice (see Table). In contrast, mice with deletion of CYP27B1 in OB's were not significantly different in their Tb and Cort bone parameters compared with their control littermates of the same sex (not shown; N=18-24 mice). Serum Ca²⁺, phosphate and alkaline phosphatase levels did not differ in ^{OB}VDR(-/-) vs control mice or in ^{OB}CYP27B1(-/-) vs control mice of either sex (data not shown, N=18-24 mice). Thus, the VDR expressed in OB's plays a key role in maintaining skeletal homeostasis in both male and female mice. Targeted inactivation of VDR produces mild osteopenia at both Tb and Cort bone sites. Local production of 1,25-(OH)₂D, however, is not required for maintenance of adult bone mass and structural properties in mice of either gender, supporting the dominance of endocrine vs paracrine/autocrine sources of 1,25-(OH)₂D in bone metabolism.

A transcriptomic analysis of cortical versus cancellous bone from mechanically-loaded murine tibiae reveals ERα-dependent differential changes in gene expression. Natalie Kelly*¹, John Schimenti¹, F Patrick Ross², Marjolein van der Meulen¹. ¹Cornell University, USA, ²Hospital for Special Surgery, USA

In postmenopausal osteoporosis decreased estrogen signaling, in part via the receptor ERα, contributes to reduced bone mass. Mechanical loading increases bone mass differentially in cortical (Ct) and cancellous (Cn) bone at the tissue level. We recently showed that mice lacking ERα in osteoblasts and osteocytes (pOC-ERαKO) had an increased adaptive response to mechanical loading in Cn bone [1], but little is known about the molecular mechanisms. Here we used RNA-seq to identify molecular changes during Ct and Cn adaptation to tibial loading in pOC-ERαKO and littermate control (LC) mice.

Tibiae from LC and pOC-ERαKO mice (10-wk female) underwent one session of mechanical loading with the contralateral tibia as control [3]. Three hours (LC, n=4; pOC-ERαKO, n=2) and 24 hours (LC, n=4) after loading a Cn core was removed from the Ct shell of the metaphysis, and RNA was isolated (LC: Ct and Cn; pOC-ERαKO: Cn only) [2]. mRNA was processed for RNA-seq (100bp, single-end). Sequences were aligned (TopHat), and differential expression determined by a paired design (DE >1.5-fold, EdgeR). Enriched pathways were determined (DAVID).

Ct and Cn bone respond differently at 3 and 24h in LC: More genes were DE in Ct than Cn bone at 3h (43 vs 18), with only 11 genes common to both sites (fig 1A). In both sites, a majority of genes were upregulated. Wnt signaling was enriched in Ct and Cn bone, while hedgehog signaling was enriched only in Ct. At 24 hours, more genes were DE in Ct than Cn (57 vs 32), with 12 shared genes (fig 1B). More genes were upregulated in Ct (60%) and downregulated in Cn (66%). Enriched pathways included melanogenesis in Ct and tight junction in Cn. Loaded Ct bone shared 4 genes between time points (*Wnt1*, *Wnt10b*, *Prgs2*, *Mt2*), while loaded Cn bone shared 1 gene (*Timp1*).

pOC-ERαKO response increased in Cn bone over LC at 3h: More genes were DE in Cn bone of pOC-ERαKO mice than LC (71 vs 18). The fold-change of the 12 shared genes was 1.3-4.2X higher in pOC-ERαKO than LC mice (figure 2).

The increased gene expression in Cn bone of pOC-ERαKO agrees with our previous tissue-level data showing enhanced response to loading [1]. RNA-seq analysis of *in vivo* mechanical loading response in Ct and Cn bone separately provides transcriptome level data to identify new research targets and identify estrogen's role in mechanotransduction.

Inhibition of BMP 2/4 Signaling Reduces Enhanced Cancellous Bone Response to Mechanical Loading in Female ERα-Deficient Mice. Katherine Melville¹, Gina Surita¹, Natalie Kelly¹, R Scott Pearsall², John Schimenti¹, F Patrick Ross³, Marjolein Van Der Meulen*¹. ¹Cornell University, USA, ²Accelaron Pharma, USA, ³Hospital for Special Surgery, USA

Estrogen and BMPs regulate bone homeostasis and adaptation to mechanical loading. Cortical and cancellous bone mass decreased in female mice lacking ERα in mature osteoblast [1]. In contrast, blocking signaling through BMPRIA increased bone mass in a time- and dose-dependent manner in mice [2]. These pathways interact *in vitro* and are implicated in adaptation to loading, but have not been studied *in vivo*. Our goal was to examine whether blocking BMP signaling affected (a) skeletal

phenotype and (b) the response to mechanical loading *in vivo* and whether ER α modulated the response.

We bred female osteoblast-specific ER α KO (pOC-ER α KO) and littermate control (LC) mice [1]. At 10 weeks of age, *in vivo* mechanical loading was applied to the left tibia daily for 2 weeks (7N peak load [1], n=20 mice/gp). We administered either placebo or a soluble BMPRI1 Fc ligand trap (RAP-661, 5 mg/kg ip, 2x/wk) to each genotype during the loading period (n=10/gp). Cortical and cancellous morphology of tibiae, femora and vertebrae were analyzed by microCT. Sections were stained for TRAP (osteoclasts, N.Oc/BS) and pro-collagen I (osteoblast activity, N.Ob/BS). Femora and L5 vertebrae were failed in 3-point bending or compression, respectively. Data were analyzed by ANOVA; p<0.05 was significant.

In both genotypes, inhibiting BMP 2/4 signaling increased bone mass in the cortical and cancellous vertebra but not in the femur. In the vertebra, blocking BMPRI1A increased cortical bone mass more in LC than in ER α KO mice, but strength was increased similarly.

At the tibial metaphysis, inhibiting BMP signaling attenuated the loading response in cortical and cancellous bone in both genotypes. However, the increased response to loading in pOC-ER α KO was eliminated when BMPRI1A was blocked. Tb.Th increased 18% in LC and 29% in pOC-ER α KO placebo mice, but only 3% in LC and 9% in pOC-ER α KO without BMP signaling. In the cancellous metaphysis, blocking BMP signaling suppressed bone formation with loading but did not alter resorption. In the diaphysis adaptation to loading was not altered by blocking BMP signaling.

Blocking BMPRI1A signaling increased bone mass site- and genotype-specifically. Inhibition of BMP signaling dramatically increased bone mass in the vertebra and cancellous tibial metaphysis along with increased strength in the vertebra, but did not affect the diaphysis. BMP 2/4 signaling appears to be needed for the cancellous response to loading.

Low Magnitude Mechanical Loading Regulates Repair Events in Cortical Bone Defect Healing. Robert Carrera¹, Vittoria Flamini², Benson George³, Daniel Hunter³, Bo Liu³, Gurpreet Singh³, Jill Helms³, Philipp Leucht⁴, Alesha Castillo⁵. ¹Department of Bioengineering, Stanford University, USA, ²Department of Mechanical & Aerospace Engineering, New York University, USA, ³Department of Surgery, Stanford University School of Medicine, USA, ⁴Departments of Orthopaedic Surgery & Cell Biology, New York University School of Medicine, USA, ⁵Departments of Mechanical & Aerospace Engineering & Orthopaedic Surgery, New York University, USA

Introduction: The purpose of this work was to (1) develop an *in vivo* murine model to study the influence of mechanical loading on bone regeneration, and (2) to use this model to determine the effects of loading on cellular events during repair. Early postoperative weight-bearing is an important aspect of orthopaedic rehabilitation, though its effects on cellular and molecular events in bone regeneration are not completely understood¹. We describe a novel *in vivo* system consisting of a mechanically loaded, stable cortical defect injury in the mouse tibia, and present data showing the influence of early loading on proliferation and cellular differentiation. **Methods:** Bilateral mono-cortical tibial defects were created in B6 adult mice (n=40); this defect typically heals via intramembranous ossification². Tibiae were subjected to 4 consecutive days of *in vivo* axial compressive loading (4 N, 2 Hz, 60 cycles)(Fig. 1A) beginning on post-surgical day (psd) 2. Non-loaded tibiae served as controls. *In vivo* μ CT images of defects were acquired on days 2, 5, 8, 10, and 14. The ROI included the regenerate and surrounding cortices. Percent change in bone volume (% Δ BV) at each time point, relative to psd 2, was calculated for each tibia. Mice were euthanized on days 5, 10, and 14. Longitudinal sections were assessed for proliferation and differentiation. A linear elastic FE model at psd 2 was developed and strains were computed for a 4 N point load. **Results:** Highest compressive strains (700-1100 μ ε) were observed at the posteromedial edge of the defect, with strains reaching ~300 μ ε in tension at the anterior edge (Fig 1). % Δ BV was significantly lower in loaded versus control tibiae at psd 8 and 10 relative the first day of loading (psd 2) (Fig 2) by a T-test (α =0.05). Loaded defects displayed increased proliferation (Fig 3) and greater amounts of cartilage (Fig 4) at the periosteum and within the regenerate at psd 10 and 14. **Conclusion:** Low magnitude loading in the inflammatory phase (psd 2) delays mineralization and remodeling by prolonging the proliferative phase and initiating a robust endochondral response. The primary advantage of this model is that it combines a well-described and tightly regulated sequence of repair events with a highly controlled mechanical stimulus, a system amenable for studying effects of physical signals on distinct components of the regenerative cascade. Mechanical unloading sensitive miR-138 targets MACF1 to regulate bone formation. [Airong Qian](#)*¹, [Zhihao Chen](#)², [Yasir Arfat](#)², [Lifang Hu](#)², [Peng Shang](#)³, [Ge Zhang](#)⁴. ¹Northwestern Polytechnical University, Peoples republic of china, ²Key Laboratory for Space Bioscience & Biotechnology, Institute of Special Environmental Biophysics, School of Life Sciences, Northwestern Polytechnical University, Xi'an 710072, China, China, ³Key Laboratory for Space Bioscience & Biotechnology, Institute of Special Environmental Biophysics, School of Life Sciences, Northwestern Polytechnical University, China, ⁴nstitute for Advancing Translational Medicine in Bone & Joint Diseases, School of Chinese Medicine, Hong Kong Baptist University, Hong Kong, China, China

MicroRNAs (miRNAs) are an abundant class of evolutionarily conserved, short (about 22 nt long), single-stranded RNA molecules that have emerged as important post-transcriptional regulators of gene expression. Computational predictions indicate that more than 50% of all human protein-coding genes are potentially regulated by miRNAs. miRNAs play critical roles in diverse biological and cellular processes including metabolism, differentiation and apoptosis. Reportedly, miRNAs have been identified as indispensable regulators of osteoblasts differentiation and bone formation.

This study aimed to identify specific miRNAs and their regulatory roles in the process of MACF1-induced osteogenic differentiation. We investigated specific miRNAs and their regulatory roles in hind limb unloading (HLU) mice. Eight week old male BALB/c mice underwent HLU and their femur and tibia were harvested to extract total bone RNAs after four weeks of suspension. We have identified thirteen up regulated and one down-regulated miRNAs to be differentially expressed and their expression was verified by quantitative real time PCR. Especially, elevated levels of miR-138 correlated with a lower degree of bone formation in whole bone samples of HLU mice were presented (Fig 1).

Target prediction analysis tools were used to predict MACF1 as a direct target of miR-138. To investigate the effects of role of miR-138 in regulating the bone formation, specific inhibitors antagomir-138 and antagomir-NC is designed. Then Transfect antagomir to preosteoblast MC3T3-E1 by lipofectamine 2000, researching miRNA function on bone formation in vitro. MACF1 is specially higher with using

antagomir-138 than antagomir-NC and control by qPCR analysis. Staining of calcium deposition by Alizarin red in MC3T3-E1 cells after treatment with antagomir-138 shows that miR-138 downregulate bone formation (Fig 2). Further, *in vitro* analysis confirmed the osteoblasts activity and matrix mineralization were enhanced by antagomir-138. Predominantly, we found an inhibitory role of miR-138 in regulating the bone formation in HLU mice and *in vivo* pretreatment with antagomir-138, partly recovered the bone loss caused by HLU. Taken together, these results suggest that *in vivo* inhibition of miRNA by anti-miR could represent a potential therapeutic strategy for ameliorating bone loss.

Pre-exercise through Moderate Treadmill Running Enhances Healing of Wounded Tendons in Aging Rats. Jianying Zhang*, Ting Yuan, James H-C Wang. University of Pittsburgh School of Medicine, USA

Aging leads to degenerative changes in tendons, while appropriate exercise enhances their mechanical strength. In young mice (2.5 months) tendons, we previously showed that moderate treadmill running (MTR) induces anabolic changes such as increasing tendon stem/progenitor cell (TSC) numbers and collagen production. It is known that adult stem cells play a vital role in tissue homeostasis, remodeling and repair. Therefore, in this study we aimed to test the hypothesis that MTR enhances tendon healing potential in aging rats through TSC-based mechanisms.

In this study, we used 24 rats (20 months), which were divided into MTR and control groups. Rats in the MTR group ran 5 days/week at the speed of 13 meter/min for 15 min/day in the first week and for 30 min/day for the next 4 weeks. Control rats freely roamed in cages. After MTR, a 2mm window defect was created in the patellar tendons of all rats and TSCs were isolated from the excised tendons for *in vitro* culture. Then, the effect of MTR on aging rat tendons was tested both *in vitro* and *in vivo*.

Our results showed that *in vitro* culture of TSCs from rats in the MTR group formed larger colonies with higher TSC numbers when compared to the controls (Fig. 1). Besides, flow cytometry revealed that MTR significantly increased the expression of stem cell markers, SSEA-1 and Stro-1 (Fig. 2), and qRT-PCR showed the up-regulation of Nanog and OCT-4 by MTR (Fig. 3). Gross morphology of patellar tendons revealed high vascularization and unhealed wounds in the controls after 4 weeks (Fig. 4A) while defects in the MTR group appeared 50% healed (Fig. 4B). After 8 weeks, the wound was still visible in the controls (Fig. 4C) while the tendon was completely healed in the MTR group (Fig. 4D). Moreover, H&E staining showed better collagen fiber organization in the MTR group while in the controls the collagen fibers were disorganized and had large holes (Fig. 5).

These findings indicate that pre-exercise in the form of MTR can enhance healing of injured aging tendons by inducing anabolic effects such as increasing TSC proliferation and stemness, which may improve tendon function and quality of tendon repair after an injury. This study reveals the TSC-based mechanisms behind the beneficial effects of pre-exercise on tendons and may help devise clinical rehabilitation protocols to treat tendon injuries in aging patients.

Preosteoclasts Mediate Bone Modeling by Secretion of PDGF-BB and Induction of CD31^{hi}Emcn^{hi} Vessels. Hui Xie¹, Zhuying Xia², Weicheng Xu³, Genevieve Brown⁴, Mei Wan³, X. Edward Guo⁴, Xu Cao³. ¹Johns Hopkins Medical Institution, USA, ²Xiangya Hospital, Central South University, China, ³Department of Orthopaedic Surgery, Johns Hopkins University School of Medicine, USA, ⁴Department of Biomedical Engineering, Columbia University, USA

Bone is modeled in adaptation of mechanical loading changes. The molecular and cellular mechanism is still under investigation. We have found that preosteoclasts secrete platelet-derived growth factor-BB (PDGF-BB) to induce cortical bone formation and CD31^{hi}Emcn^{hi} vessels, a specific vessel subtype that couples angiogenesis and osteogenesis essential for new bone formation during bone modeling and growth. Here we report that mechanical loading and unloading regulate bone modeling by modulating the formation of preosteoclasts and consequently the PDGF-BB secretion and CD31^{hi}Emcn^{hi} vessel formation. In brief, the number of preosteoclasts and CD31^{hi}Emcn^{hi} endothelial cells in periosteum, periosteal bone formation and cortical bone mass were dramatically increased after four weeks of mechanical loading in wild-type mice, whereas CD31^{hi}Emcn^{hi} vessels, periosteal bone formation and cortical bone mass were not changed in osteoclast lineage-specific PDGF-BB conditional knockout mice. Interestingly, the number of preosteoclasts

was also increased in osteoclast lineage-specific PDGF-BB conditional knockout mice, indicating that PDGF-BB secreted by preosteoclasts regulates bone modeling. Conversely, following three weeks of hind-limb unloading, wild-type mice experienced substantial decline in preosteoclast number in both periosteum and trabecular bone. Bone marrow PDGF-BB level, CD31^{hi}Emcn^{hi} endothelial cell number, trabecular and periosteal bone formation, trabecular and cortical bone mass were decreased accordingly. The alterations in hind-limb unloading mice were partly rescued by a cathepsin K inhibitor, which has been shown to stimulate formation of preosteoblasts and subsequent formation of CD31^{hi}Emcn^{hi} vessels by secretion of PDGF-BB. Taken together, mechanical loading-modulated formation of preosteoclasts mediates bone modeling by secretion of PDGF-BB and induction of CD31^{hi}Emcn^{hi} vessels.

Simulated Space Radiation: Murine Skeletal Responses during Recovery and with Mechanical Stimulation. Yasaman Shirazi-Fard*¹, Ann-Sofie Schreurs¹, Tiffany Truong¹, Candice Tahimic¹, Joshua Alwood¹, Alesha Castillo², Ruth Globus¹. ¹NASA Ames Research Center, USA, ²New York University, USA

Simulated space radiation at doses similar to those of solar particle events or a round-trip sojourn to Mars (1-2Gy) may cause skeletal tissue degradation and deplete stem/progenitor cell pools throughout the body. We hypothesized that simulated space radiation (SSR) causes late, time-dependent deficits in bone structure and bone cell function reflected by changes in gene expression in response to anabolic stimuli. We used a unique sequential dual ion exposure (proton and iron) for SSR to investigate time-dependence of responses in gene expression, cell function, and microarchitecture with respect to radiation and an anabolic stimulus of axial loading.

Male 16-wk C57BL/6J mice (n=120 total, n=10/grp) were exposed to 0Gy (Sham), ⁵⁶Fe (2Gy, positive control dose), or sequential ions for SSR (1Gy ¹H/⁵⁶Fe/¹H) by total body irradiation (IR), and the tissues were harvested 2 or 6 mo. later. ⁵⁶Fe caused a significant reduction in BV/TV compared to Sham (-38%) and SSR (-29%); however BV/TV for SSR group was not different than Sham 2-mo post-IR. Both ⁵⁶Fe and SSR caused significant reduction in Tb.N compared to Sham (-38% and -12%, respectively). Tb.N for ⁵⁶Fe was also significantly lower than SSR (-30%). To assess the response to anabolic stimuli, we subjected subsets of Sham and SSR groups to rest-inserted axial loading 1-month post-IR (-9N, 60 cycles/day, 3 days/wk, 4 wks). There were main effects of both mechanical loading and radiation to reduce BV/TV, and a main effect of mechanical loading to reduce TbTh, and a main effect of radiation to reduce TbN. Axial loading increased BV/TV by 19% and 17%, Tb.Th by 20% and 15% in Sham and SSR groups, respectively, and Tb.N remained unchanged. *Ex vivo* culture of marrow cells to assess growth and differentiation of osteoblast lineage cells 6 months post-IR showed that both ⁵⁶Fe and SSR exposures significantly impaired colony formation compared to Sham (both by ~84%), as well as nodule mineralization (-75% and -51% respectively). Additional analyses of cancellous bone microarchitecture (6 mo) and gene expression (2&6 mo) post-IR are in progress.

Results indicate that SSR caused persistent impairment of osteoblast colony formation and nodule mineralization 6-mo post-IR. Sequential ¹H/⁵⁶Fe/¹H exposure (1Gy) was not as detrimental on bone microarchitecture compared to a maximal dose (2Gy ⁵⁶Fe) for damaging HZE particles. Contrary to hypothesis, SSR did not suppress the ability of the bone to respond to mechanical stimuli.

Sirtuin 1's Role as a Negative Regulator of the Anabolic Response to Mechanotransduction in Mature Osteoblasts. Elizabeth Rendina-Ruedy*¹, Nicole Fleming², Rashmi Pandey¹, Guillaume Vignaux², Heather Durai², Daniel Perrien³. ¹Vanderbilt University Medical Center, VA Tennessee Valley Healthcare System, USA, ²Vanderbilt University Medical Center, USA, ³VA Tennessee Valley Healthcare System, Vanderbilt University Medical Center, USA

Disuse experienced by astronauts/cosmonauts and bedridden patients leads to rapid and dramatic bone loss or osteoporosis, predisposing these populations to an increased risk of fracture. Moreover, bone mineral density upon return to normal loading is slow, possibly incomplete, and the mechanisms controlling this anabolic response are poorly understood. Sirtuin 1 (Sirt1) is a NAD⁺-dependent deacetylase originally described for its role in prolonging life. Female mice that are globally hemizygous for Sirt1 or with osteoblast-conditional deletion of Sirt1 using Col1a1-Cre or Osr-Cre have a low bone mass phenotype and treatment with the Sirt1 activators, resveratrol or SRT2104, reduces bone loss during hindlimb suspension (HS) in mice. However, the role of Sirt1 in disuse osteoporosis and/or recovery of bone remains unclear. This study tested the hypothesis that Sirt1 reduces disuse-induced bone loss and promotes recovery of bone upon return to normal ambulation. Fourteen (14) wk-old, male *Sirt1*^{fl/fl} and *2.3kbCol1a1-Cre;Sirt1*^{fl/fl} mice (*Sirt1*^{Ob-/}) underwent HS or normal ambulation (Con) for 3 wks. At the end of this period, a cohort of the HS mice were released from tail suspension and allowed to recover/reambulate (HSRA) for an additional 3 wks. Trabecular and cortical bone volume and structure in the femur were assessed by *ex vivo* μ CT. The *Sirt1*^{fl/fl}-Con and *Sirt1*^{Ob-/}-Con mice had a

similar bone phenotype; and following disuse, they experienced similar, significant decreases in trabecular bone volume (-37%) as well as deterioration of trabecular architecture within the respective genotype. Interestingly, however, the *Sirt1*^{Ob-/}-HSRA mice had a higher trabecular bone volume (~24%) compared to the *Sirt1*^{fl/fl}-HSRA mice, demonstrating a hypersensitive anabolic response during reambulation. These data suggest that the endogenous activity of Sirt1 does not play a role in disuse-induced bone loss, but Sirt1 may function as a negative regulator of the anabolic responses of osteoblasts and osteocytes during recovery from disuse. Continued investigation is underway to explore the mechanism by which Sirt1 exerts this effect which could lead to the development of novel therapeutic targets capable of enhancing the recovery from disuse osteoporosis.

FR0139

β -catenin deletion in osteocytes does not prevent load-induced bone formation. Kyung Shin Kang*, Alexander Robling, Indiana University, USA

Osteocytes are the major mechanosensory cell type in bone. Wnt/Lrp5 signaling in osteocytes is essential for modulating mechanotransduction. The putative downstream cascade for this receptor/ligand complex involves activation of β -catenin (β -cat); thus β -cat might be essential for the response to loading, much like the upstream mediator Lrp5 is required. Alternatively, other downstream mechanisms might transduce mechanical information originating from Lrp5 that do not require β -cat. We sought to understand whether osteocytic β -cat regulates mechanotransduction in bone by deleting both copies of β -cat from ^{10kb}Dmp1-expressing cells. Because β -cat^{fl/fl} mice that harbor the ^{10kb}Dmp1-Cre transgene do not survive beyond 8-12 wks, and mechanotransduction studies are most informative when conducted after the growth phase is completed (16 wks of age), we chose an inducible Cre model (^{10kb}Dmp1-CreERT2) which allows for postnatal activation of Cre to recombine the floxed β -cat alleles (β -cat^{fl/fl}). We injected tamoxifen (TAM; 20 mg/kg IP) or corn oil (OIL; vehicle) into 16-wk old transgenic (TG) and non-transgenic (NTG) mice 6 and 3 days prior to the first loading bout, and again 3 and 9 days after loading began. All mice underwent ulnar loading (2 Hz, 2.85 N; 180 cyc.) of the right arm 3 dy/wk for 1 wk. Fluorochrome labels were injected 5 and 12 dy after loading began for use in histomorphometry. BMD was measured pre-induction and at sacrifice to monitor skeletal changes due to β -cat loss. TAM-treated TG mice exhibited significantly reduced whole body (9-12% decrease; p<0.05) and spinal (32-24% decrease; p<0.05) BMD, compared to control mice (TAM-treated NTG mice, and OIL-treated TG and NTG mice). In the nonloaded control ulna, β -cat mutation resulted in a 65-73% (p<0.05) reduction in MS/BS, compared to the control groups, but MAR was unaffected by β -cat deletion. TAM-treated TG mice exhibited a significant response to mechanical loading. Load-induced bone formation (226 μ m³/ μ m²/yr) in TAM-treated TG mice was significantly less (p<0.05) in absolute terms that that exhibited by the control groups (380-490 μ m³/ μ m²/yr), but when normalized to the nonloaded control ulna (i.e., rBFR/BS), TAM-treated TG mice were equally responsive to loading as control mice. Our data indicate that the osteogenic response to loading can occur in the absence of osteocytic β -cat, suggesting that other downstream mediators of Lrp5 might participate in transducing load induced Wnt signaling.

FR0140

β -catenin gainofunction mutation in osteocytes confers protective effects from disuse-induced bone loss. Whitney Bullock*, Alexander Robling, Indiana University, USA

Wnt signaling is a key modulator of bone metabolism, including response to the mechanical environment. Although portions of the extracellular and transmembrane components of Wnt signaling, such as Sost and Lrp5, have been explored in the bone mechanotransductive response, the intracellular downstream signaling molecules, such as β -catenin, have received only cursory investigation. In the canonical Wnt pathway, activation of downstream mediator β -catenin by Wnt co-receptors Lrp5/6 leads to stabilization of β -catenin and changes in gene expression. Activating mutations in Lrp5 or genetic deletion of Sost in mice leads to an osteoprotective phenotype when mechanical stimulation is removed by disuse models (tail suspension or Botox-induced muscle paralysis). To date, it is unclear what downstream molecular mechanisms are altered in this mechanotransductive response, or if increased levels of β -catenin would generate the same osteoprotective phenotype. We hypothesized that the constitutive activation of β -catenin would have an osteoprotective effect and would diminish disuse-induced bone loss. β -catenin gain-of-function mutant mice (floxed exon 3) were crossed with the tamoxifen-inducible ^{10kb}Dmp1-CreERT2 transgenic mice to selectively activate β -catenin postnatally in osteocytes. Mice were given tamoxifen (20 mg/kg) or corn oil (vehicle) at 12 weeks of age to induce recombination/deletion of the floxed 3rd exon, and consequent stabilization of β -catenin. These mice were then subjected to disuse by hind limb suspension or by unilateral Botox-induced muscle paralysis (Botox; 20 U/kg) of the right lower limb for four weeks. As expected, control mice (oil-treated TG mice) subjected to disuse by tail-suspension and muscle paralysis lost a significant amount of femoral BMD (13.1 \pm 4.1% and 22.3 \pm 6.2% reduction, respectively [p<0.05]), whereas ground or saline control mice maintained femoral BMD (5.8 \pm 4.0 and 1.1 \pm 9.1% increase [NS], respectively), over the 4 week experiment. However, mice with transgene-induced activation of β -catenin did not lose bone mass in the hind limbs (3.8 \pm 6.9% decrease in

tail suspended and $13.0 \pm 11.0\%$ decrease in Botox treated [NS]). In summary, constitutive activation of β -catenin in osteocytes of adult mice had osteoprotective effects during disuse in both muscle paralysis and tail suspension models, suggesting that β -catenin might be a therapeutic target for bone wasting conditions caused by mechanical disuse.

Actin Cytoskeletal Structure Influences MSC Lineage through Balanced Activity of LARG GEF and ARHGAP18. William Thompson¹, Sherwin Yen², Zhihui Xie², Gunes Uzer², Buer Sen², Maya Styner², Keith Burridge², Janet Rubin². ¹Indiana University, USA, ²University of North Carolina Department of Medicine, USA

The quantity and quality of bone depends on mesenchymal stem cell (MSC) differentiation, where adipogenic commitment depletes the available pool for osteogenesis. Cell architecture influences lineage decisions, as the cytoskeleton aligns critical elements that regulate responses to the physical environment. Disruption of the actin cytoskeleton, and RhoA activity, tip MSC fate in favor of adipogenesis. Mechanical strain suppresses MSC adipogenesis by cytoskeletal enhancement through activation of RhoA via Fyn/mTORC2/AKT signaling. Two distinct protein families direct RhoA activity, GEFs (RhoA activators) and GAPs (RhoA deactivators). In fibroblasts, ARHGAP18, a little studied GAP, suppresses RhoA leading to decreased stress fiber formation and motility, while the GEF LARG regulates RhoA activation in response to force. We hypothesized that ARHGAP18 and LARG influence MSC commitment by regulating cytoskeletal structure through control of RhoA. Knockdown of LARG resulted in accelerated adipogenesis and repression of basal RhoA activity. Importantly, mechanical activation of RhoA was almost entirely inhibited following LARG depletion and the anti-adipogenic effects of strain were prevented. This implicates LARG as the GEF responder to substrate strain in MSCs, controlling both RhoA activity and mechanical biasing against adipogenic lineage. In contrast, shRNA knockdown of ARHGAP18 increased basal RhoA activity and actin stress fibers; yet, no synergistic enhancement of RhoA was observed following mechanical strain. As the actin cytoskeleton modulates MSC fate, we reasoned that ARHGAP18 should affect MSC differentiation. In ARHGAP18 null MSCs adipogenesis was suppressed, as assessed by Oil-Red-O staining and Western blot of fat markers. Moreover, ARHGAP18 knockdown enhanced osteogenic commitment, confirmed by alkaline phosphatase staining and PCR of *Osx* and *Ocn*. This suggests that ARHGAP18 is a critical tonic inhibitor of MSC cytoskeletal assembly, returning RhoA to an "off state". In contrast, LARG is recruited during dynamic mechanical strain, and as such its absence has less effect on the resting RhoA state. In summary, control of RhoA cycling between on and off states is determined by ARHGAP18 when quiescent, with LARG playing a dominant role in the actin remodeling resulting from active mechanical input. Thus, both of these GTP exchangers converge on RhoA to regulate the MSC response to static and dynamic physical factors, influencing lineage allocation.

Disruption of nucleo-cytoskeletal connectivity increases intranuclear actin and enhances MSC differentiation. Gunes Uzer¹, Buer Sen¹, Zhihui Xie¹, William Thompson², Guniz Bas¹, Maya Styner¹, Janet Rubin¹. ¹University of North Carolina, USA, ²Indiana University, USA

The cell cytoskeleton (CSK) not only modulates cell signaling and differentiation, but also - through LINC (Linker of Nucleoskeleton and Cytoskeleton) connections - distributes force into the nucleus thus altering gene expression by mechanisms currently unknown. We recently showed that disconnecting the nucleus from the CSK by disrupting the LINC complex limits the ability of mesenchymal stem cells (MSCs) to respond their mechanical environment. As similar disruptions in LINC underlie clinically significant premature aging and muscle wasting disorders, and these are associated with increased fat infiltration in bone, we hypothesized that nucleocytoskeletal connectivity as facilitated by LINC would affect MSC fate selection. Using murine MSC, we first showed that dislocation of the actin binding element of LINC complex -Nesprin with siRNA targeting the Nesprin anchoring proteins SUN1 and 2 (siSUN) - increased adipogenic differentiation as represented by increased fatty acid binding protein (150% of to control siRNA, $p < 0.001$) and Adiponectin (250%, $p < 0.001$). Decreased β catenin is associated with adipogenesis; indeed, siSUN treatment decreased nuclear β catenin (68%, $p < 0.001$). Surprisingly, when siSUN treated cells were cultured under osteogenic conditions; we found increased osteocalcin mRNA (500%, $p < 0.001$) and protein (390%) compared to control siRNA. This suggested that mechanically isolating the nucleus from the CSK by disrupting LINC connectivity might generally enhance ongoing gene expression. Increased nuclear actin is known to enhance gene expression; in fact, we recently showed that cofilin-mediated influx of nuclear G-actin strongly promotes osteogenesis in MSCs. Thus, we next considered if disconnecting F-actin from the nuclear envelope by disrupting LINC might result in increased free monomeric G-actin which could be translocated into the nucleus. We found that siSUN treatment was associated with actin accumulation in the cell nucleus (220% compared to control siRNA, $p < 0.001$). We are currently investigating whether the increased bicameral differentiation of LINC deficient cells

requires the cofilin-dependent nuclear transport of actin. Further, we are interested in how actin might alter the nucleoskeleton, potentially leading to activation of heterochromatin associated genes, such as osteogenic *Runx2*. These findings suggest novel mechanisms by which cytoskeletal cues regulate MSC lineage decisions.

Distinct subcellular activation patterns of Src and FAK by interstitial fluid flow and cytokines. Qiaoqiao Wan¹, Hiroki Yokota², Sungsoo Na³. ¹Department of Biomedical Engineering, Purdue University, USA, ²Department of Biomedical Engineering, Indiana University Purdue University Indianapolis, USA, ³Indiana University-Purdue University Indianapolis, USA

In the chondrocytes of patients with osteoarthritis (OA), the elevated level of inflammatory cytokines such as interleukin 1 β (IL1 β) and tumor necrosis factor α (TNF α) have been reported. These cytokines contribute to degrading cartilage matrix. Therefore, blocking the action of these cytokines is a potential strategy to prevent cartilage degradation. Accumulating evidence suggests that mechanical loading contributes to the regulation of cartilage homeostasis. However, the underlying mechanisms are not clear as to how varying magnitudes of mechanical loading trigger differential intracellular signaling pathways at sub-cellular levels.

Tyrosine kinases such as Src and FAK are known to play a crucial role in OA progression. To investigate activation patterns of Src and FAK at sub-cellular microdomains, we used lipid raft-targeting (Lyn-FAK and Lyn-Src) and non-lipid raft-targeting (KRas-FAK and KRas-Src) biosensors based on fluorescence resonance energy transfer (FRET). The C28/I2 human chondrocytes were grown in a three-dimensional (3D) cell culture system using collagen-coupled agarose gels to mimic the physiologically relevant cell environment. The activities of Lyn-Src, KRas-Src and Lyn-FAK were up and down regulated by high (>10 μ /min) and moderate (5 μ /min) interstitial fluid flow, respectively (Fig. 1A-C), but KRas-FAK did not respond to the flow (Fig. 1D). We also found that Src regulation by fluid flow was blocked by inhibition of FAK (Fig. 1E, F), while inhibition of Src did not affect FAK activities (Fig. 1G, H), suggesting that FAK is necessary for flow-induced Src activity. In contrast, Src was necessary for inflammatory cytokine-induced FAK activation (Fig. 2). Furthermore, we developed a 3D ex vivo system that uses bovine and murine cartilage explants. This system in conjunction with 3D FRET imaging allowed us to visualize sub-cellular signaling activities of Src and FAK that closely mimic in vivo conditions. We found that intermediate loading can inhibit inflammatory cytokine-induced activities of Lyn-Src, KRas-Src and Lyn-FAK, but not KRas-FAK (Fig. 3).

In summary, our findings of the distinct sub-cellular activation patterns of FAK and Src suggest the different mechanisms of mechanical loading- and cytokine-induced signaling. By selectively regulating Src and FAK activities, moderate fluid flow appear to interact with Src/FAK signaling and contribute to cartilage health.

Ectopic Tendon Mineralization After Injury Is Progressive, Deteriorates Tendon Biomechanical Properties And Involves BMP Signaling. Kairui Zhang¹, Shuji Asai², Michael Hast³, Louis Soslowsky³, Motomi Enomoto-Iwamoto^{*1}. ¹Children's Hospital of Philadelphia, USA, ²Nagoya University, Japan, ³University of Pennsylvania, USA

Heterotopic ossification (HO) is ectopic bone formation occurring outside of the normal skeleton, and may limit range of motion and cause pain. HO can be caused by traumatic events (acquired HO) or genetic disorders (hereditary HO). The former is generally self-limited while the latter is progressive and life threatening. Ectopic tendon mineralization can be found as a sequel to tendon injuries. Clinical retrospective studies have reported that mineralization is found in 14–62% of cases following percutaneous or open repair of the Achilles tendon. In this study, we utilized a mouse tendon injury HO model to determine whether ectopic tendon mineralization affects biomechanical property and whether BMP signaling is also involved in this condition as previously suggested in other HO. A complete transverse incision was made at the midpoint of the right Achilles tendon in 8-week-old female CD-1 or C57/BL6 mice and the gap was left open. Ectopic cartilaginous mass formation was found in the injured tendon by 4 weeks after surgery and ectopic mineralization was detected by radiographical and histological inspections at 8–10 weeks postsurgery. Ectopic mineralization grew over time and volume of the mineralized materials of 6 months postsurgery samples was about 2.5 fold bigger than that of 10 weeks samples, indicating that injury-induced ectopic tendon mineralization is progressive. In vitro mechanical testing showed that mid-substance modulus in the 6-months samples was significantly lower than that in the 10-weeks samples. The 6-months samples showed a higher circular variance of collagen alignment than the 10-weeks samples, indicating that collagen fibers in injured tendons became more disorganized over time. To determine the signaling pathway involved in ectopic tendon mineralization, we analyzed gene expression in injured tendon one week after surgery. We found huge increases in expression levels of various TGF β /BMP signaling related genes. Immunohistochemical analysis revealed that both phospho-Smad1/5/8 and phospho-Smad2/3 were highly up-regulated in ectopic chondrogenic lesion. Treatment with the BMP receptor kinase inhibitor (LDN193189: 3 mg/kg daily IP injection for 2 weeks) significantly inhibited injury-induced tendon mineralization. These findings indicate that injury-induced ectopic tendon mineralization is progressive and detrimental to tendon biomechanical properties, and involves BMP signaling.

Low Intensity Pulsed Ultrasound Can Promote Stem Cell Proliferation during Fracture Healing but Varied by the Acoustic Wave Patterns. Yi-Xian Qin¹, Hua Yue^{*2}, Guoxian Feng², Li Huang², Jingyu Wang², Devi Zhang², Jingbo Liu², Kartik Grover². ¹State University of New York at Stony Brook, USA, ²Stony Brook University, USA

Recent studies have shown that low intensity pulsed ultrasound (LIPUS) has effects on acceleration of fresh fracture healing. Ultrasound exposure has mechanotransductive properties that allow inducing mechanical stimulation in bone cells and activate osteogenesis leading to bone formation. The objective of this study was to evaluate the effect of plain and focus ultrasound in fracture healing under hindlimb suspension (HLS) in a rat model, and MSC activations.

76 Sprague-Dawley rats (Female, 12 weeks old, 350–400g) were randomly divided into 4 groups (n=18 per group): 1) Fracture+HLS+Focused Ultrasound (FUS), 2) Fracture+HLS+Plain Ultrasound (PUS), 3) Fracture+HLS, and 4) Fracture+FUS. All the animals underwent surgeries on mid-shaft of right femur, and an accurate 2mm defect was made. LIPUS of 3 MHz, pulse width of 200ms, and intensity of 100mW/cm² for 20 min/day and 5 days/week. Immediately sacrificed the animals, the bone marrow was flushed out from the fracture area by dulbecco's modified eagle medium (DMEM) and then centrifuged and washed by sterilized phosphate buffer solution (PBS). The surface marker expression of MSCs, including CD29, CD90.1, CD11b, CD45 and CD49e, was analyzed by flow cytometry assay. The mid-shaft and the callus part of the right femur were scanned at 18 microns resolution using microCT (μ CT40, Scano Medical). Turnover Markers were analyzed by Serum/Plasma ALP, PINP, TRACP level by an Elisa Kit or EIA kit (Biovision or IDS). Three-point bending was performed to determine the stiffness and strength of right femur for all 4 groups. All results were statistical analyzed with One-way ANOVA on Tukey's protocol, with significance set at $p < 0.05$.

MSCs numbers and percentage in the bone marrow after 2 weeks ultrasound therapy were varied from 131, 503, 115, and 169 (Group 1-4), indicating PUS has most effective on MSC numbers (Fig. 1a), while the MSC numbers changed at week 4, 224, 153, 114, and 161 (Group 1-4) (Fig. 1b). There is no significant difference of mechanical stiffness between PUS and FUS in femurs, but both significantly higher than fracture plus LIPUS and fracture alone groups (Fig. 2).

This study suggested that both PUS and FUS has positive effects on accelerating MSCs recruitment in bone fracture area during the fracture healing process under disuse condition. However, PUS played an important role in the early phase of bone regeneration, whereas FUS had an effect on MSCs recruitment after 4 weeks of stimulation.

Diminished Mechanoresponsiveness with Skeletal Maturation occurs via a Sclerostin-Independent Pathway. Laia Albiol^{*1}, Annette I. Birkhold², David Pflanz², Tobias Thiele², Ina Kramer³, Michaela Kneissel², Georg N. Duda², Sara Checa², Bettina M. Willie². ¹Julius Wolff Institut, Charit \ddot{e} – Universit \ddot{a} tsmedizin Berlin, Germany, ²Julius Wolff Institute, Charit \ddot{e} Universit \ddot{a} tsmedizin, Germany, ³Novartis Pharma, Switzerland

An apparent loss in mechanoresponsiveness with maturation and aging may contribute to bone loss observed already in adulthood. We reported female C57Bl/6 adult mice had a reduced cortical bone formation response to loading (1200 μ c tibial midshaft) compared to young mice. Loading reduces SOST/sclerostin expression, however sclerostin independent pathways have been shown to be involved in the cortical bone formation response to loading in young mice. Thus, we hypothesized that reduced mechanoresponsiveness with skeletal maturation occurs through sclerostin independent pathways. Female 10 and 26 week old SOST knockout (KO) and littermate wild-type (WT) C57Bl/6 mice underwent 2 weeks of cyclic compressive loading of the left tibia (right tibia=control, n=7/genotype/age, 216 cycles/d, f=4 Hz, emax=900 μ c). In vivo microCT of the midshaft was performed at days 0 and 15. Images were registered and voxels were labeled as newly formed, quiescent or resorbed bone. 3D dynamic in vivo morphometry was used to quantify mineralized and eroded normalized volume (MV/BV, EV/BV), normalized surface area (MS/BS, ES/BS) and thickness/depth (MTh, ED) (Fig.1a). ANOVA assessed within-subject, between-subject and interaction effects for absolute values and interlimb differences (?interlimb=loaded - control limb). Age affected (re)modeling: MV/BV and MTh were lower ($p < 0.001$ and $p = 0.046$) and all resorption parameters were higher in adult compared to young mice ($p < 0.001$). Genotype affected MTh, ES/BS, ED ($p < 0.018$). Loading increased MV/BV and MS/BS ($p < 0.001$) and decreased ES/BS ($p = 0.003$). The formation (MV/BV) response to loading was reduced with skeletal maturation in WT (young: 142%, adult 38%) and SOST KO mice (young: 206%, adult 81%; %?= (loaded - control)/control \times 100); all formation parameters had a greater response to loading in 10 than 26 week old SOST KO and WT mice (loading and age interaction, < 0.010). Similar results were observed for interlimb differences; 10 week old had a greater formation response to loading compared to 26 week old mice (< 0.010). SOST KO had a greater ?MS/BS ($p < 0.016$) in response to loading than WT mice. Our study indicates sclerostin independent pathway(s) contribute to the reduced bone formation response at maturation in mice. Our data suggest the anabolic and catabolic benefits of loading in combination with sclerostin inhibition are age-specific. Studies are required to confirm this in humans and identify signaling pathways contributing to reduced mechanoresponsiveness with skeletal aging.

In conclusion, in aged, as in young mice, mechanical loading alone is osteogenic in both cortical and trabecular bone compartments. iPTH is also osteogenic in cortical bone but, unlike its effects in young mice, it acts independently of the mechanostat. In trabecular bone iPTH does not have the dramatic osteogenic effect seen in young mice (1) and appears to reduce rather than enhance the positive effects of the mechanostat. The mechanism of this age-related dislocation of the effects of iPTH and mechanical loading needs to be determined.

Risedronate and Mechanical Loading Have Additive Effects Increasing Bone Mass in Cortical, but Not Cancellous, Bone in Aged Mice. Peter Delisser*¹, Henry Todd¹, Lee B Meakin¹, Gabriel L Galea¹, Lance E Lanyon¹, Sara H Windahl², Joanna S Price³. ¹School of Veterinary Sciences, University of Bristol, United Kingdom, ²Centre for Bone & Arthritis Research, Institute of Medicine, Sahlgrenska Academy, Gothenburg, Sweden & School of Veterinary Sciences, University of Bristol, United Kingdom, ³School of Veterinary Sciences, University of Bristol, United Kingdom

In young adult mice the osteogenic response to artificial mechanical loading is unaffected by bisphosphonates suggesting that it primarily involves adaptive osteogenic modelling without accompanying resorption [1]. The aim of the present study was to use bisphosphonates to determine whether the mechanically adaptive response is similar in aged mice.

Female 19-month-old C57BL/6J mice were administered vehicle (saline) or the bisphosphonate Risedronate (15µg/kg) by daily subcutaneous injections from day zero. From day four, the right tibiae were subjected to loading every second day for two weeks, with the left limb as an internal non-loaded control. Mice were killed on day 21. Cortical and trabecular bone was analysed by µCT.

Loading resulted in greater trabecular thickness (Tb.Th) and increased cortical bone mass in the proximal tibia (37% site) by increasing cortical area (Ct.Ar), cortical thickness (Ct.Th), total tissue area (Tt.Ar) and polar moment of inertia (PMI) despite an increase in medullary area (Ma.Ar). As expected, loading had no significant effect on cortical bone in the distal tibia (75% site). Risedronate reduced trabecular structure model index (SMI), increased Ct.Th in both cortical sites and increased PMI in the

Parathyroid hormone’s enhancement of bones’ osteogenic response to loading in young mice is lost in the cortical bone of old mice, and reversed in their trabeculae. Lee Meakin, Henry Todd, Peter Delisser, Alaa Moustafa, Gabriel Galea, Sara Windahl, Lance Lanyon, Joanna Price*. University of Bristol, United Kingdom

Decreased effectiveness of bones’ adaptive response to mechanical loading contributes to age-related bone loss. Thus therapies that enhance the effectiveness of “the mechanostat” could stimulate structurally appropriate increases or maintenance of bone mass and so reduce the incidence of fragility fractures. In cortical bone of young mice, intermittent administration of parathyroid hormone (iPTH) and loading interact synergistically to increase bone mass (1). This interaction could be particularly valuable in the elderly. Here we assessed the effects of loading and iPTH in cortical and trabecular bone of old mice.

19-month-old female C57BL/6 mice (n=32) were administered 0, 25, 50 or 100µg/kg iPTH by daily subcutaneous injection for 4 weeks. Their tibiae were examined at 37% of the bone’s length from the proximal end. Histological and mCT analysis revealed potent iPTH dose-related effects on cortical (re)modelling; periosteally-enclosed area, cortical area and porosity were increased and cortical thickness decreased. iPTH had no effect of loading-related strain measurements at the same site. 30 similar mice were given the medium, submaximal, 50 µg/kg iPTH dose or vehicle daily for 6 weeks with concurrent minimally osteogenic non-invasive axial mechanical loading (40 cycles, 10s rest period, peak strain 1750µε on the medial aspect of the tibia, three times weekly) of the right tibia for the final 2 weeks of iPTH treatment. In trabecular bone of the proximal tibia iPTH alone had no effect, however, it abrogated the load-related increase in BV/TV by reducing the increase in trabecular number, with no effect on the increase in trabecular thickness. In cortical bone at the 37% site loading reduced the iPTH-associated increase in porosity. The osteogenic effects of iPTH and loading on periosteally-enclosed area and cortical area were additive but not synergistic.

37% site. The combination of risedronate and loading did not alter the loading-related increase in Tb.Th but additively increased Ct.Ar, Ct.Th and PMI in the proximal tibia. Risedronate pre-treatment prevented the loading-related increase in Ma.Ar observed at the 37% cortical site. Loading did not alter the increase in Ct.Th due to risedronate treatment in the distal tibia.

In conclusion, the lack of any observed effect of risedronate on trabecular bone mass in these old mice differs from that reported in young mice [1], demonstrating that observations in the young cannot necessarily be extrapolated to the old. To the extent that the situation in old mice can be extrapolated to old humans, it appears that in cortical bone, risedronate treatment potentially confers the clinical benefit of increased bone mass. This benefit is increased when risedronate treatment is combined with loading since there is an additive positive increase in a number of cortical bone parameters, due to increased periosteal expansion unaccompanied by endosteal resorption.

A Natural Antibody Against Oxidized Phospholipids Causes Bone Anabolism. Elena Ambrogini^{1*}, Shuling Wang², Xuchu Que², Fumihiko Yamaguchi², Annick Deloose¹, Kanan Vyas¹, Michela Palmieri¹, Stuart B Berryhill¹, Robert S Weinstein¹, Sotirios Tsimikas², Stavros C Manolagas¹, Joseph L Witztum², Robert L Jilka¹. ¹Center for Osteoporosis & Metabolic Bone Diseases, University of Arkansas for Medical Sciences & the Central Arkansas Veterans Healthcare System, USA, ²Department of Medicine, University of California, San Diego, USA

Oxidation of LDL is thought to be a fundamental mechanism of atherogenesis. Oxidized phospholipids (OxPL) in oxidized LDL (OxLDL) serve as ligands mediating the uptake of OxLDL by macrophage scavenger receptors and promoting inflammatory gene expression in endothelial cells and macrophages. E06 is an IgM natural antibody that recognizes the phosphocholine moiety of OxPL in OxLDL and on apoptotic cells. E06 prevents both the uptake of OxLDL by macrophage scavenger receptors and the pro-inflammatory activity of OxPL. We generated LDL receptor-KO (LDLR-KO) mice expressing a single chain variant of E06 (E06-scFv) as a transgene under the control of the ApoE promoter (LDLR-KO;E06-Tg mice). The E06-scFv is expressed in liver and macrophages, and leads to atheroprotection in LDLR-KO mice fed a high fat diet (HFD). Mouse models of atherosclerosis caused by HFD also exhibit decreased bone mass. We therefore studied LDLR-KO mice and LDLR-KO;E06-Tg mice to determine if OxPL play a role in bone homeostasis. At two months of age, male LDLR-KO;E06-Tg mice were placed on HFD containing 0.5% cholesterol and 21% milk fat; LDLR-KO mice were fed either HFD or normal chow. At 6.5 months, LDLR-KO mice on HFD had lower femoral bone mass as compared to LDLR-KO mice fed chow, as determined by DXA BMD. LDLR-KO;E06-Tg mice, however, were protected from the adverse effect of HFD on femoral BMD observed in the LDLR-KO mice. At 7.5 months, mice were euthanized and vertebrae and femurs were analyzed by micro-CT. LDLR-KO mice on HFD had decreased cortical diaphyseal thickness resulting from a decrease in periosteal perimeter. Strikingly, LDLR-KO;E06-Tg mice did not exhibit a decrease in cortical thickness. This, however, resulted from a decrease in the endosteal perimeter due to increased bone formation (determined by tetracycline labeling) – not a reversal of the suppressive effect of the HFD on periosteal apposition. Cancellous bone mass in the femur and vertebra was indistinguishable in LDLR-KO mice fed HFD vs chow. More surprisingly, LDLR-KO;E06-Tg mice exhibited a profound increase in femoral cancellous bone mass as compared to the other two groups. E06-scFv does not possess antibody effector functions other than the ability to neutralize OxPL. Therefore, our data suggest that OxPL - generated from a variety of sources, including inflammatory and apoptotic cells - restrain bone formation. Hence, neutralization of OxPL with an antibody could be a novel strategy for bone anabolism.

Activation of Protein Kinase A in Mature Osteoblasts Promotes a Remarkable Bone Anabolic Response. Liana Tascou¹, Thomas Gardner¹, Hussein Anan², Charlie Yongpravat¹, Christopher Cardozo³, William Bauman³, Francis Lee¹, Daniel Oh¹, Hesham Tawfeek^{3*}. ¹Columbia University, USA, ²SacredHeart Hospital/Temple University, USA, ³James J Peters VA Medical Center, USA

Protein kinase A (PKA), a major serine/threonine kinase, is directly activated by cAMP after G-protein alpha S (Gs) or Gs-coupled receptor stimulation. This study determined whether PKA activation in the osteoblast cells is sufficient to mediate a bone anabolic response. Thus, a constitutively active form of the PKA (CA-PKA) catalytic subunit was conditionally expressed in the osteoblast lineage cells of mice (CA-PKA-OB mouse) by crossing 2 mouse lines, a 2.3-kb alpha1(I)-collagen promoter-Cre mouse (Coll-Cre mouse) with a floxed-CA-PKA mouse (FF-CA-PKA mouse). Primary osteoblast cells from the CA-PKA-OB mice exhibited higher basal PKA activity than that of the osteoblast cells from control mice. Micro CT analysis revealed that constitutive PKA activation in osteoblast cells of female mice

led to a more than 10-fold increase in femur (p=0.0001) but only 20% increase in L5 vertebral (p=0.009) bone volume/total volume (BV/TV) compared to control littermates. Femur cortical thickness and volume were also higher in the CA-PKA-OB mice. Interestingly, the three-dimensional structure model index (TRI-SMI) was significantly reduced both in femur (-8 ± 6 vs 3 ± 0.4, p=0.0008) and L5 (-0.6 ± 0.3 vs 0.4 ± 0.1, p=0.0001) of the CA-PKA-OB mice, reflecting an increase in the number of plates vs rods. In agreement with improved bone micro-architecture, femurs from the CA-PKA-OB mice had a 55% greater load to failure (p<0.001) and were 45% stiffer (p<0.001) compared to those of control mice. Furthermore, the CA-PKA-OB mice had enhanced bone turnover with a predominance of bone formation (serum PINP, 35 ± 5 vs 13 ± 4, p=0.001) over that of resorption (serum CTX, 23 ± 4 vs 16 ± 2, p=0.007). In summary, these findings demonstrate that constitutively activated PKA in mature osteoblasts is sufficient to increase bone mass and improve bone architecture and mechanical properties. PKA in osteoblasts is, therefore, an important target for designing new bone anabolic drugs for treating osteoporosis and diseases that are associated with bone loss.

Gpr39 deficient mice have increased bone mass during aging as a result of accelerated osteoblast differentiation. Noam Levaot^{1*}, Milena Pesic², Gail Guterman-Ram², Avelet Orenbuch². ¹Ben-Gurion University of the Negev, Israel, ²Department of Physiology & Cell Biology, Ben-Gurion University of the Negev, Israel

G coupled protein receptors (GPCRs) are a diverse group of receptors that play a pivotal role in regulation of both resorption and formation of bone. Recently, a novel GPCR, GPR39 was shown to be expressed in osteoblast cell lines, but the role of GPR39 in the regulation of bone homeostasis was not explored. In order to elucidate the role for GPR39 in bone metabolism we investigated the bone phenotype of GPR39 deficient mice (GPR39^{-/-}).

These mice had normal body length, weight and bone mass at the age of 12 weeks when the skeleton reach maturation. However, micro CT analysis of trabecular bone in the femurs of aging six month old mice revealed a significant increase of 32% in the trabecular bone fraction, compared to wild type littermates. Increased trabecular bone in these mice was a result of higher trabecular numbers and thickness. In order to test whether increased bone mass was a result of attenuated resorption by osteoclasts we analyzed the serum levels of CTX-1 peptide. No significant difference in the levels of CTX-1 was observed. In addition, histomorphometric analysis showed normal numbers and distribution of TRAP stained osteoclasts in GPR39^{-/-} bone sections. On the other hand, serum levels of PINP-1, a marker for bone formation, showed significant increase in GPR39^{-/-} mice indicating bone formation is higher in these aging mice. In vitro, isolated bone marrow mesenchymal stem cells (BMSCs) from GPR39^{-/-} mice formed mineralization nodules as early as 7 days, a time point were no mineralization nodules were observed in cultures of wild type BMSCs. This enhanced mineralization was unlikely a result of increased osteoprogenitor numbers as colony-forming-unit fibroblasts and expression of the early osteoprogenitor markers Runx2 and Osterix showed no difference between GPR39^{-/-} and wild type BMSCs. However, mRNA expression analysis showed ordered but early and much higher expression of osteoblast and osteocytes regulating genes, suggesting that the osteoblast differentiation program is accelerated in the absence of GPR39. Thus our data suggest an inhibitory role for GPR39 in regulation of osteoblast differentiation. This assumption was further supported by our observation that GPR39 mRNA levels drop significantly during osteoblast differentiation of BMSCs in vitro.

Our data reveal a novel role for the receptor GPR39 in regulation of bone homeostasis and suggest that its absence leads to accelerated osteoblast differentiation and bone formation.

Intermittent Parathyroid Hormone Enhances Osseointegration of a Physiologically Loaded Tibial Implant in Ovariectomized Mice. Xu Yang^{1*}, Aleksey Dvorzhinskiv¹, Vinicius Ladeira Craveiro¹, Caroline Briat¹, Benjamin Ricciardi¹, F. Patrick Ross¹, Marjolein van der Meulen², Mathias Bostrom¹. ¹Hospital for Special Surgery, USA, ²Cornell University, USA

Introduction: Cementless total knee replacements primarily rely on cancellous bone for their initial stability and long term fixation. With a novel physiologically-loaded mouse tibial implant model, we have previously demonstrated that intermittent parathyroid hormone (iPTH) enhances osseointegration and strength of the bone-implant interface in intact mice. In the current study, we used this model to determine the effects of ovariectomy (OVX) and post-implantation iPTH on peri-implant cancellous bone mass and fixation strength.

Methods: Study Design: The titanium implant manufactured by 3-D printer has a smooth surface of the proximal side of the plateau to articulate with the native femur and a roughened surface of the stem to facilitate bone on-growth and initial stability. The implant was pressed fit into the medullary canal of the mouse tibia (Fig 1). The mice tolerated the implant well and started weight bearing immediately after surgery.

Female C57BL/6 mice received OVX or sham surgery (n=20/group) at age of 12 weeks and an implant in right tibia at 16 weeks. From day 1 post-implantation, the mice were given PTH (S.Q., 40 µg/kg/day) or vehicle (n=10/treatment/group), 5 days/week, until euthanasia 4 weeks post-implantation. **Microcomputed Tomography (microCT):** Both tibiae of each mouse were scanned by microCT. Bone volume fraction (BV/TV) was measured in the left tibial metaphysis and two regions in the right tibia (Fig 2). **Mechanical Testing:** The implant was pulled out of the tibia under displacement control to failure. Maximum load was calculated from the load-displacement curve. **Statistical Analyses:** The differences with surgery and treatment were assessed with two-way ANOVA. The alpha was 0.05.

Results: OVX decreased BV/TV of cancellous bone in left tibiae 8 weeks post surgery. iPTH did not affect BV/TV in OVX or sham mice (Fig 3A). OVX decreased cancellous mass in both the peri-implant and distal to implant regions of the right tibiae 4 weeks post-implantation. PTH enhanced cancellous mass in both of these two regions of both OVX and sham mice (Fig 3B and C). OVX lowered the maximum load of pull out testing. PTH enhanced the maximum load of both OVX and sham mice (Fig 4).

Discussion: OVX decreased peri-implant cancellous bone mass and fixation strength post-implantation. iPTH rescued bone mass and fixation strength. These results will lead to translational studies and may eventually benefit patients receiving cementless joint replacements.

Figure 1. Dimension and use of a novel titanium tibial implant. The implant was manufactured using three-dimensional metal printing. Top left: Implants shown in top, front, and side views. Implants were placed on a dime for size comparison. Bottom left: Secondary electron microscopy image of the implant showing the roughened surface. Right: Lateral radiograph of the knee with tibial implant in situ.

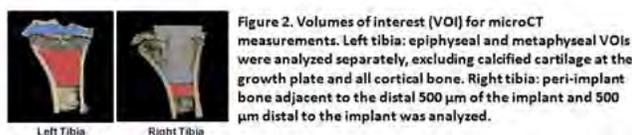

Figure 2. Volumes of interest (VOI) for microCT measurements. Left tibia: epiphyseal and metaphyseal VOIs were analyzed separately, excluding calcified cartilage at the growth plate and all cortical bone. Right tibia: peri-implant bone adjacent to the distal 500 µm of the implant and 500 µm distal to the implant was analyzed.

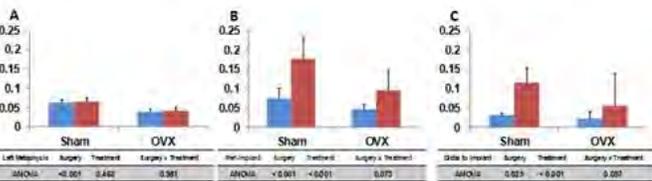

Figure 3. Bone volume fraction measured by microCT in: A. left metaphysis, B. right peri-implant region, and C. right distal to implant region. p values of ANOVA are shown in the table below each graph.

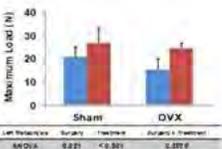

Figure 4. Maximum load of pull-out testing. p values of ANOVA are shown in the table below each graph.

Overexpression of Bmi1 in Mesenchymal Stem Cells Mediates Intracrine Actions of PTHrP in Regulating Skeletal Growth and Development. Guangpei Chen^{*}, Ying Zhang¹, Wanxin Qiao¹, Andrew Karaplis², Xiang-Jiao Yang², David Goltzman², Dengshun Miao³. ¹Nanjing Medical University, China, ²McGill University, Canada, ³Nanjing Medical University, Peoples republic of china

We previously demonstrated that Bmi1 deficiency resulted in an osteoporotic phenotype by inhibiting bone marrow mesenchymal stem cell (BM-MSC) proliferation and differentiation into osteoblasts. To investigate whether overexpression of Bmi1 in BM-MSCs can stimulate osteogenesis, we generated a transgenic mouse model overexpressing Bmi1 in BM-MSCs (Prx1-Bmi1^{Tg}). The expression levels of Bmi1 were significantly higher in skeletal tissue and BM-MSCs of Prx1-Bmi1^{Tg} mice than in those of wild-type mice, and body weight and size, skeletal size, cortical and trabecular bone volume, osteoblast number, ALP-positive and type I collagen-positive areas, total numbers of CFU-f and ALP⁺ CFU-f were all significantly increased in the Prx1-Bmi1^{Tg} mice. We then crossed Prx1-Bmi1^{Tg} with Bmi1^{-/-} mice and found that Bmi1 overexpression in BM-MSCs in the Bmi1^{-/-} background not only largely rescued

the osteoporotic phenotype of Bmi1^{-/-} mice, but also significantly prolonged their lifespan. In PTHrP (1-84) knockin (Pthrp KI) mice, Bmi1 expression is reduced and premature osteoporosis occurs. We demonstrated that Bmi1 and PTHrP were colocalized to cellular nuclei and interacted physically; therefore we crossed Prx1-Bmi1^{Tg} mice with Pthrp KI mice. BM-MSC overexpression of Bmi1 in the Pthrp KI background resulted in a longer lifespan, increased body weight, and improvement in skeletal growth and osteoblastic bone formation in the Pthrp KI mice, although the defects were not completely rescued. Levels of anti-oxidative enzymes including SOD1 and 2, catalase, glutathione reductase and glutathione peroxidase 1 were up-regulated in bony tissues of the Prx1-Bmi1^{Tg} mice, but down-regulated in the Pthrp KI mice, and importantly, Bmi1 overexpression in the Pthrp KI mice rescued this down-regulation. In contrast, the tumor suppressor genes p16, p19, p53 and p21 were down-regulated in bony tissues of the Prx1-Bmi1^{Tg} mice, but up-regulated in the Pthrp KI mice and Bmi1 overexpression in the Pthrp KI mice rescued their up-regulation. Taken together, these results demonstrate that overexpression of Bmi1 in BM-MSCs partially rescues the defects in skeletal growth and osteogenesis in the Pthrp KI mice by inhibiting oxidative stress and inactivating p16 and p19 signaling pathways. These studies therefore indicate that the PTHrP-Bmi1 signaling axis plays an essential role in regulating skeletal growth and development.

Pyk2-Deletion Enhances Bone Mass through Estrogen Signaling in Osteoblasts and Osteoclasts. Sumana Posritong^{*}¹, Pierre P. Eleniste², Evan R. Himes², Melissa A. Kacena², Angela Bruzzaniti¹. ¹Indiana University School of Dentistry, USA, ²Indiana University School of Medicine, USA

An imbalance between osteoclast (OC) and osteoblast (OB) activity can lead to low bone mass and osteoporosis. The activity of the proline-rich tyrosine kinase 2 (Pyk2) is important for bone remodeling. Pyk2-deficient mice (Pyk2-KO) exhibit high bone mass which is due to both increased OB activity and decreased OC function. We found that Pyk2-KO mice are protected from ovariectomized (OVX) induced bone loss and that estrogen (E2)-supplemented Pyk2-KO OVX mice exhibit a greater increase in bone mass than wild-types (WT). To determine if Pyk2-deficiency promotes the anti-resorptive or bone-promoting actions of E2, we performed several *in vitro* studies. Calvarial OBs were cultured in osteogenic media with or without E2 for up to 28 days. E2-stimulation led to an increase in Pyk2 protein levels in WT OBs. On the other hand, ER α (but not ER β) was lower in Pyk2-KO than WT OBs. Further, QPCR studies revealed significantly higher c-fos mRNA levels in Pyk2-KO OBs, consistent with increased OB proliferation, which remained high after E2 treatment. Alkaline phosphatase (ALP) activity was also significantly higher in Pyk2-KO OBs (13.8 ± 1.7 nM/ml) than WT OBs (6.8 ± 0.7). Importantly, E2-treatment further increased ALP activity in Pyk2-KO OBs (28.1 ± 1.8) but had no effect on WT OBs. Similarly, calcium deposition (mineralization) was higher for Pyk2-KO OBs (7.4 ± 1.1 µg/ml Ca²⁺) than WT OBs (2.5 ± 0.1) and E2 further increased calcium deposition by Pyk2-KO OBs (12 ± 0.3) but not WT OBs. Next, we examined the effects of E2 on RANKL and OPG which control OC differentiation. In the absence of E2, Pyk2-KO OBs showed a higher RANKL/OPG ratio (1.5-fold) than WT OBs, which was reduced to 0.9-fold in E2-treated Pyk2-KO OBs. Finally, E2 decreased the survival of mature Pyk2-KO OCs (-38%) to a greater extent than WT OCs (-24%). Together, these results suggest that Pyk2 plays an important role in the E2/ER α -signaling pathways to regulate both bone formation as well as OC number *in vitro* and *in vivo*.

Skeletal Anabolism By Concurrently Targeting the PTH1R and CaSR. Christian Santa Maria^{*}¹, Alfred Li², Zhiqiang Cheng², Fuqing Song², Dolores Shoback³, Chia-Ling Tu², Wenhan Chang². ¹UCSF, USA, ²San Francisco Veterans Affairs Medical Center, USA, ³University of California, San Francisco, USA

Intermittent parathyroid hormone, PTH(1-34) is the only approved osteoanabolic therapy for osteoporosis. However, its use is limited to a short-term with a relatively low dose due to adverse hypercalcemic effects and oncogenic potential in bone. A better understanding of the mechanisms underlying the actions of PTH(1-34) is required to enhance this therapy. Our recent studies have shown that increases in local [Ca²⁺] activate the extracellular Ca²⁺-sensing receptor (CaSR) in osteoblasts (OBs) to promote bone accrual and maturation. To determine whether the calcium-mobilizing effects of PTH(1-34) activate OB CaSRs to produce osteoanabolic responses, we tested whether co-injecting a calcimimetic, an allosteric CaSR agonist that can stimulate OB CaSRs directly, enhances the anabolic effects of PTH(1-34) and whether ablating CaSRs in early OB lineage blocks the effects in OBCaSR-KO mice. We found that treatment with PTH(1-34) or calcimimetic alone produced hypercalcemia or hypocalcemia, respectively, 3 hrs after injections in wild-type (Wt) C57/B6 mice. Co-injections with calcimimetics normalized the hypercalcemic effects of PTH(1-34) (p<0.01). Skeletal analyses by μ CT showed that PTH(1-34) alone increased trabecular bone mass and thickness by \approx 8% (p<0.05) in distal femurs compared to vehicle-injected controls. When a calcimimetic was co-injected with PTH(1-34), there were robust increases in trabecular bone mass (\approx 21% or 2.5 fold

over PTH(1-34) treatment alone, $p < 0.05$) and in thickness ($\approx 17\%$, $p < 0.05$). Co-injections of calcimimetic with PTH(1-34) also significantly increased cortical bone size, volume, and thickness at tibiofibular junction by 8-10% ($p < 0.01$), and bone strength as indicated by a 10% increase in failure load ($p < 0.01$) in 3-point bending tests, all which were absent with PTH(1-34) treatment alone. In OBCaSR-KO mice, the osteoanabolic effects of combined PTH(1-34)/calcimimetic treatment were completely abrogated, supporting our hypothesis that OB CaSRs play an essential role in mediating skeletal responses to the treatment. Our findings suggest novel synergistic actions of PTH(1-34) and of Ca^{2+} itself in producing skeletal anabolism and may inform preclinical regimens to restore osteoporotic skeleton and augment healing of injured bones.

The Effects of Systemic Hedgehog Pathway Modulation on Fracture Healing. Jennifer McKenzie*, Evan Buettmann, Matthew Silva, Michael Gardner. Washington University in St. Louis, USA

The role of the Hedgehog (Hh) pathway in regulating skeletal development has been extensively studied; however its role in skeletal repair is less well understood. In this study we sought to determine the effects of pharmacological Hh pathway activation on fracture repair in a healing-challenged model. It has been shown that older rodents demonstrate less robust fracture healing, characterized by delayed periosteal bridging and a downregulation of hedgehog related gene expression. Expression of *Ihh*, *Gli1* and *Ptch1* during fracture healing of aged mice (18mo) is diminished when compared to younger mice (10 wk). Specifically, *Ihh* expression in older mice was reduced to less than 50% of expression in young mice at both 3 and 7 days post fracture. Therefore, we hypothesized that Hh pathway activation will overcome the age-related decline in Hh signaling and improve radiographic and histologic aspects of fracture healing. Using the *Gli1-Cre-ERT2;Ai14* mice we were able to localize Hh signaling in the fracture callus at 5 and 7 days post fracture. Strong Hh activity was seen in the woven bone and the periphery of the cartilaginous area of the callus. Daily dosing of Hh agonist (Hh-Ag1.5) or vehicle for 28 days was well-tolerated by the mice and demonstrated sustained activation of the Hh pathway (*Gli1*, *Ptch1* upregulation by qPCR by >200 and 300% , respectively). In addition, 28 days of treatment with Hh agonist increased trabecular bone formation compared to vehicle treated group (60% increase in BV/TV). This demonstrated the potent bone anabolic effect of enhanced Hh signaling. Assessment of microCT at 2 weeks post fracture in aged (18mo) mice demonstrated improved callus BMD in the Hh agonist treatment group (Figure 1). In summary, the Hh pathway is important in regulating fracture healing and pharmacological modulation may lead to enhanced healing.

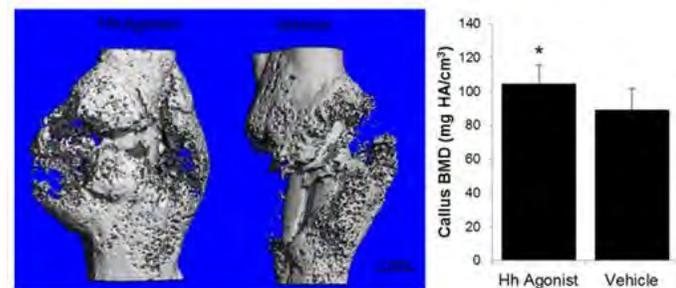

Figure 1. Daily systemic treatment with Hh agonist improved fracture healing.

Crosstalk between Sensory Neuropeptides Regulating Heterotopic Ossification in Tendon. Ceren Tuzmen*, Phil Campbell, Lee Weiss. Carnegie Mellon University, USA

Heterotopic ossification (HO) of soft tissues is a costly medical problem with no effective cure. It is usually predisposed by neurogenic and musculoskeletal trauma, where systemic release of certain factors leads to overexpression of bone morphogenetic proteins (BMPs). BMP-2, one of the most studied of the BMPs, has been shown to be involved in most common cases of HO by promoting osteogenic differentiation of primitive stem cells into osteocytes at an anatomical site ectopic to bone. Despite advances in understanding the pathophysiology of HO, the associated cellular and molecular mechanisms are not well understood. The peripheral nervous system acting via specific neuromediators plays an active role in regulation of cellular and extracellular changes observed in ossified tendons. Sensory neuropeptides, including substance P (SP) and calcitonin gene-related peptide (CGRP), are upregulated in patients with injured or degenerative tendons, as well as in animal disease models and they are known to be involved in BMP-2 induced osteogenic differentiation *in vitro*. In this study, we assessed the effect of SP and/or CGRP on BMP-2 induced osteogenic differentiation *in vitro* and on tendon HO *in vivo*. Unique

to this study is to deliver SP and/or CGRP using biopatterning technology which enables spatial control of the tendon microenvironment.

Our *in vitro* and *in vivo* data suggest a possible connection between SP and CGRP pathways and the BMP-2 pathway. *In vitro*, neither of the treatments had significant effect on BMP-2 induced alkaline phosphatase activity (Fig1). However, SP alone significantly enhanced while CGRP had no effect on BMP-2 induced mineralization (Fig2). *In vivo*, SP promoted HO but CGRP had no effect on tendon HO (Fig3). Remarkably, when SP and CGRP are delivered together, both *in vitro* and *in vivo*, CGRP was able to counteract the effect of SP on BMP-2-induced mineralization and bone formation in tendon (Fig2,3). In conclusion, we were able to spatially promote and further reverse HO in Achilles tendons using biopatterning as delivery system. To our knowledge there is no other study reported that involves administration of SP and/or CGRP in tendon to elucidate the effect of these neuropeptides in tendon HO as well as the interaction between SP and CGRP related to tendon HO.

LRP4 in osteoblasts suppresses bone formation and promotes osteoclastogenesis and bone resorption. Wen-Cheng Xiong*, Lei Xiong, Georgia Regents University, USA

LRP4 (low-density lipoprotein receptor related protein 4) is a member of the LDL receptor family, whose mutations have been identified in patients with high bone-mass such as sclerosteosis and Van Buchem diseases. However, it remains unknown how LRP4 regulates bone-mass homeostasis in vivo. Here we provide evidence that LRP4 null mutation or specific mutation in osteoblast-lineage cells increased cortical and trabecular bone-mass, which was associated with elevated bone formation and impaired bone resorption. This phenotype was not observed in osteoclast-selective LRP4 knock-out mice. Mechanistic studies indicate that loss of LRP4 function in osteoblast-lineage cells increased serum levels of sclerostin, a key factor for bone mass homeostasis that interacts with LRP4, but abolished the inhibition of Wnt/ β -catenin signaling and osteoblastic differentiation by sclerostin. Concomitantly, sclerostin-induction of RANKL (receptor activator of nuclear kappa B ligand) was impaired, leading to a lower ratio of RANKL over OPG (osteoprotegerin) (a key factor for osteoclastogenesis). Taken together, these results support the view for LRP4 as a receptor of sclerostin to inhibit Wnt/ β -catenin signaling and bone formation, and identify LRP4 as a critical player in bone-mass homeostasis.

Milk fat globule-epidermal growth factor 8 (MFG-E8) is a novel anti-inflammatory factor in rheumatoid arthritis in mice and men. Martina Rauner*¹, Elise Albus², Kathrin Sinnigen², Maria Winzer², Sylvia Thiele², Anke Hannemann³, Sylvia Grossklauss⁴, Triantafyllos Chavakis⁴, Mark Udey⁵, Lorenz Hofbauer². ¹Medical Faculty of the TU Dresden, Germany, ²Department of Medicine III, Technische Universität Dresden, Germany, ³University of Greifswald, Germany, ⁴Department of Clinical Pathobiochemistry & Institute for Clinical Chemistry & Laboratory Medicine, Technische Universität Dresden, Germany, ⁵Dermatology Branch, Center for Cancer Research, National Cancer Institute, USA

Milk fat globule-epidermal growth factor 8 (MFG-E8) mediates the clearance of apoptotic cells and is implicated in the pathogenesis of autoimmune and inflammatory diseases. As MFG-E8 has recently also been shown to influence bone metabolism, we investigated its role in the pathogenesis of rheumatoid arthritis (RA) and the subsequent bone destruction. The regulation of MFG-E8 by inflammation was assessed in osteogenic cells *in vitro*, in arthritic mice and in patients with RA. K/BxN arthritis was applied to MFG-E8 knock-out mice to assess its role in the pathogenesis of arthritis. Stimulation of osteoblasts with LPS and TNF- α down-regulated the expression of MFG-E8 by 30-35% in a receptor-dependent manner. MFG-E8-deficient osteoblasts responded to LPS with a stronger production of the pro-inflammatory cytokines TNF and IL-6. *In vivo*, MFG-E8 mRNA levels were 52% lower in paw extracts of collagen-induced arthritic mice and 24-42% lower in the serum of arthritic mice using two different arthritis models. Similarly, patients with RA ($n=93$) had lower serum concentrations of MFG-E8 (-21%) as compared to healthy controls ($n=186$). In a subgroup of patients who had a moderate to high

disease activity at the time of measurement ($n=21$), serum concentrations of MFG-E8 rose when remission or low disease activity had been achieved after successful treatment (+49%). Finally, MFG-E8-deficient mice subjected to K/BxN arthritis exhibited a stronger disease burden, an increased number of neutrophils and CD3-positive T cells in the joints, and a more extensive local and systemic bone loss, which was associated with an increased number and activity of osteoclasts. Thus, MFG-E8 is a relevant factor in the pathogenesis of RA and subsequent bone destruction. Whether MFG-E8 qualifies as a novel biomarker or therapeutic target for the treatment of RA needs to be addressed in further studies.

Tanshinol reverses the impaired bone formation of Glucocorticoid-induced osteoporosis in rats: a role for KLF15. Liao Cui¹, Yajun Yang*², Yanjie Su², Yahui Chen², Yuyu Liu², Tie Wu². ¹Guangdong Medical College, Peoples republic of china, ²Department of Pharmacology, Guangdong Key Laboratory for R & D of Natural Drugs, Guangdong Medical College, China

Objective: Decreased bone formation is responsible for the pathogenesis of glucocorticoid-induced osteoporosis (GIO), while the mechanism remains to be elucidated. Krueppel-like factor 15 (KLF15), a direct GR target gene, exerts an extensive role in pathophysiologic progression of diverse diseases. This study aims to investigate the action of Tanshinol (termed D(+)- α -3,4-dihydroxyphenyl lactic acid), a botanical antioxidant, on bone metabolism involving in KLF15-dependent regulation of Wnt/FoxO pathway in GIO rats. Methods: KLF15 mRNA level of bony tissue were detected in 4-month-old female Sprague-Dawley rats administered prednisone acetate (GC, 5mg/kg), GC plus Tanshinol (Tan, 16mg/kg) and GC plus Resveratrol (Res, 5mg/kg, positive control) for 14 weeks. Micro-CT, histomorphometry, biomechanical assay, serum biomarkers of bone turnover, and gene or protein expression analysis in bone tissue were investigated. Cell viability, cell apoptosis, capacity of bone formation, oxidative stress level, Wnt signaling and FoxO3a pathway were measured in C2C12 cells and MC3T3-E1 cells exposed to dexamethasone (Dex, 1 μ M) in the presence or absence of KLF siRNA or overexpression of KLF15. Results: Tanshinol exerted a preventive effect on impairment of bone formation and bone architecture, and the following decreased bone mass (%BV/TV) and bone quality in association with inhibition of the increased KLF15 mRNA level in GIO rats. Furthermore, Tanshinol maintained bone homeostasis involving in up-regulation of Wnt signaling and counteracted osteoblastic apoptosis elicited by oxidative stress via down-regulation of FoxO3a pathway in GIO rats. Further evidence *in vitro* confirmed that Tanshinol counteracted the GR-dependent activation of KLF15 cascade pathway, contributing to activation of Wnt signaling and the subsequent bone formation, and to inhibition FoxO3a pathway and the following caspase 3-dependent apoptosis in the two cell lines treated with Dex in a synergistic manner with KLF15 siRNA. In addition, transcription activity of Tcf-luc was stimulated by KLF15 siRNA and suppressed by overexpression of KLF15 in the two cell lines treated with Dex, especially in the presence of Tanshinol, which were adverse to the alterations of FoxO3a-Luc. Conclusion: Tanshinol attenuates reduction of Wnt-mediated bone formation and FoxO3a-triggered osteoblastic apoptosis in GIO via inhibition of KLF15-dependent pathway. The study may provide a novel target to treat GIO.

Annexin A5 inhibits bony outgrowth at tendon/ligament insertion sites. Akemi Shimada*¹, Yoshinori Arai², Satoshi Wada³, Hisashi Ideno⁴, Taichi Kamiyunt³, Kazuhisa Nakashima⁴, Koichiro Komatsu⁴, Teruhito Yamashita⁵, Yoichi Ezura⁶, Norio Amizuka⁷, Ernst Pöschl⁸, Bent Brachvogel⁹, Yoshiki Nakamura³, Akira Nifuji⁴. ¹Tsurumi University School of Dental Medicine, Japan, ²Nihon University, School of Dentistry, Japan, ³Department of Orthodontics, Tsurumi University School of Dental Medicine, Japan, ⁴Department of Pharmacology, Tsurumi University School of Dental Medicine, Japan, ⁵Division of Hard Tissue Research, Institute for Oral Science, Matsumoto Dental University, Japan, ⁶Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical & Dental University, Japan, ⁷Department of Developmental Biology of Hard Tissue, Division of Oral Health Science, Graduate School of Dental Medicine, Hokkaido University, Japan, ⁸School of Biological Sciences, University of East Anglia, Norwich Research Park, Norwich, United Kingdom, ⁹Experimental Neonatology, Department of Pediatrics & Adolescent Medicine, Center for Biochemistry, Medical Faculty, University of Cologne, Germany

Formation and remodeling of insertion sites of tendon/ligament to bone (enthesis) has remained unclear. Annexin a5 (Anxa5), which belongs to the annexin family of calcium-dependent phospholipid binding proteins, is known to have many functions as mechanical sensor in osteoblast, signal molecule in cell apoptosis, and regulator of

cell membrane repair. Previous studies suggested that Anxa5-deficient mouse in which lacZ was inserted into Anxa5 gene (*Anxa5^{lacZ}*) displayed no obvious changes in skeletal development by 3 months of age. In the present study, we analyzed skeletal phenotypes in detail in adult *Anxa5^{lacZ}* mice. We observed that Anxa5 was strongly expressed at articular cartilage, periosteum, and tendon/ligament insertion sites to bone by lacZ staining. At 4 weeks of age, there were no obvious difference in bone morphology between wild and *Anxa5^{lacZ}* mice. After 7 weeks of age, however, increase of bony outgrowth at enthesis in *Anxa5^{lacZ}* mice was observed, while there were no obvious differences in morphology of long bones. These phenotypes were commonly observed in long bones as well as mandibular bones. To examine the contribution of muscle movements on the bony outgrowth at enthesis, we performed tenotomy in mice in which movement of anterior tibial muscle was impaired by surgical releasing muscle from enthesis at 12 weeks of age. In the tenotomy mice, bony outgrowth of tibial bone in *Anxa5^{lacZ}* mice were decreased to comparable levels to that of wild mice after 8 weeks of operation. These results suggest that Anxa5 inhibits the bony outgrowth at enthesis which depends on mechanical stimuli brought by muscle movements.

Fusion Induced Hypertrophy of Skeletal Muscle Is Modulated By Pin1 through the Smad3 Pathway. Rabia Islam*, Won-joon Yoon, Young-dan Cho, Woo-Jin Kim, Han-sol Bae, Hye-rim Shin, Bong-soo Kim, Kyung Mi Woo, Jeong-Hwa Baek, Hyun-Mo Ryoo. Seoul National University, School of Dentistry, Department of Molecular Genetics, South Korea

The regulation of skeletal muscle fusion is necessary for normal embryo development as well as for the repair of damaged muscle in adult life. We had previously observed that the enzyme Peptidyl-prolyl cis-trans isomerase NIMA-interacting 1 (Pin1) is involved in osteoclast fusion. The objective of this study was to find out if Pin1 is also involved in the fusion induced hypertrophy of myoblasts. *Pin1^{-/-}* mice have neurodegenerative features so we selected the *Pin1^{+/-}* mice as a genetic model to analyze the effect of Pin1 in muscle fusion. Different hind limb muscles from *Pin1^{+/+}* and *Pin1^{+/-}* mice were collected and processed for histological analysis. In vitro studies were carried out with the common model for muscle, C2C12 myoblast cell line. We compared the *Pin1^{+/+}* and *Pin1^{+/-}* muscle cross sections and found that *Pin1^{+/-}* muscles had increased bulk as indicated by the weight and distribution of the muscle fiber CSA (cross sectional area). *Pin1^{+/-}* mice had complete recovery of muscle weight and myofiber size in an earlier time point than *Pin1^{+/+}* mice after muscle injury was inflicted by injecting cardio toxin from *Naja mossambica*. The number of nascent myofibers formed after muscle injury was also higher in *Pin1^{+/-}* mice. We found that overexpression of Pin1 suppressed myoblast fusion in vitro also. Low dose of Pin1 inhibitor, DTM (0.01 μ M) treatment actually caused more enhanced fusion than higher dosage (1 μ M). With very high concentration of DTM (10 μ M) treatment fusion was reduced even in the absence of cytotoxicity. The R-Smads 1, 2 and 3 are well known targets of Pin1. In muscle we found only p-Smad3, a key signaling mediator for the major regulators of skeletal muscle hypertrophy Tgf- β and myostatin pathway, was decreased with minimal inhibition of Pin1. With low dose of Pin1 inhibitor treatment total Smad3 expression level was decreased in vitro and in *Pin1^{+/-}* muscle in vivo. We observed that Pin1 is crucial for maintaining the stability of Smad3 and preventing Smad3 ubiquitination. Our results show that the dosage of Pin1 protein is very critical for regulation of the Smad3 signaling pathway to maintain the muscle bulk. This knowledge of the basic molecular mechanism behind myoblast fusion can contribute to the development of therapeutics for muscle repair in debilitating diseases.

Identification of Muscle-derived Mesenchymal Stem Cells in Traumatic Heterotopic Ossification. Zijun Zhang*, Reed Michell², Lew Schon². ¹Union Memorial Hospital, USA, ²MedStar Union Memorial Hospital, USA

Heterotopic ossification (HO) is a pathological condition that muscles calcify. Local muscle damage and fracture/osteotomy are often associated with the development of HO. The source of cells in the muscle that contribute to the HO develop is unclear. In muscles, there are two types of progenitor cells that are potent in differentiation: satellite cells and mesenchymal stem cells (M-MSCs). Both of them have been demonstrated are capable of osteogenic differentiation. This study was designed to differentiate the source of cells that participate in the development of HO.

HO surgical model: Surgery that included osteotomy of great trochanter and muscle injury (O+M) was performed on the right hip of mice to simulate the tissue condition for HO formation. Muscle injury was done by clamping the gluteus maximus and gluteus medius for 5 min. For controls, either osteotomy of great trochanter (O) or muscle injury (M) was performed on mice. Mice in groups O+M, O and M, were euthanized at days 1, 3, 5 and 10. Gluteus maximus and gluteus medius were collected for muscle digestion. The isolated cells were cultured in an osteogenic medium for 3 weeks and osteogenesis was examined with gene expression of type I collagen, osteocalcin and Runx2.

For cells harvested on 1 day post surgery, gene expression of type I collagen, osteocalcin and Runx2 was not significantly different among groups M, O and M+O. In group O, muscle cells that harvested on days 3, 5 and 10 moderately increased the

expression of type I collagen over the time, comparing with the corresponding time-points in group M. Other osteogenic genes such as Runx2 and osteocalcin, however, were not up-regulated in the cells of both groups O and M. Notably, the expression of type I collagen, Runx2 and osteocalcin by the cells of group M+O harvested on days 3, 5 and 10 was significantly increased, compared with the corresponding ones in groups M and O. Furthermore, the expression of type I collagen, Runx2 and osteocalcin by the cells of group M+O was gradually increased from day 1 to day 10.

Flow cytometry was performed on cells isolated from groups M, O, and M+O (day 10) for the expression of CD73, CD90, CD105, CD56 and PDGFR-alpha (CD140). In general, M-MSCs isolated from groups M, O and M+O (day 10) had similar expressions profiles of common MSC surface markers, except the expression of CD90 was lower in the groups O and M+O than in group M. CD56, representing myogenic progenitors, was highly expressed in M-MSCs isolated from group M (day 10), as compared with groups O and M+O (day 10) ($p < 0.05$). CD140, also known as platelet-derived growth factor receptor α (PDGFR-alpha), is a specific marker of M-MSCs. Among the three experimental groups, CD140 was expressed the highest in group M+O (day10), followed by group O and group M ($p < 0.05$).

The data indicate that M-MSCs, rather than muscle satellite cells, participate in HO formation in the muscles.

Increased Glycolytic Fast-twitch Skeletal Muscle Growth in Mice has Beneficial Effects on Both Loaded and Non-loaded Skeletal Sites. Joshua Farr*, Glenda Evans¹, Thomas White¹, Daniel Fraser¹, Kenneth Walsh², Sundeep Khosla¹, Nathan LeBrasseur¹. ¹Mayo Clinic, USA, ²Boston University, USA

In addition to mechanically loading bone, skeletal muscle may stimulate bone formation via secreted factors, or "myokines". To advance this concept, we examined the skeletal phenotype of a unique skeletal muscle-specific conditional transgenic mouse expressing a constitutively active form of Akt1. Activation of the Akt1 transgene by administration of doxycycline (DOX) results in hypertrophy of glycolytic fast-twitch muscle fibers (Cell Metab 7:159-72, 2008).

Akt1 transgenic mice (4 week-old female) were administered either DOX (n = 14) or vehicle (n = 11) for 6 weeks. All mice underwent *in vivo* pQCT scanning of the tibia at baseline and end of study. μ CT scans were performed on excised femurs and lumbar spines following sacrifice. Quadriceps and gastrocnemius weights were recorded and lean and fat mass were quantified by EchoMRI. At the study midpoint, physical activity was monitored over a 48-hour period using a Comprehensive Laboratory Animal Monitoring System.

At baseline, the two groups of mice were of similar weight with no differences any bone or soft tissue parameters. Physical activity levels did not differ between the groups. DOX-mediated transgene activation caused a doubling in both quadriceps and gastrocnemius weights ($p < 0.001$). These increases in muscle mass contributed to a modestly greater gain in total body lean mass in DOX- compared to vehicle-treated mice (+39% vs +23%, $p = 0.09$) and an attenuated accrual of fat mass (+14% vs +44%, $p < 0.05$). At the end of the study, pQCT analysis of the tibia revealed that DOX-treated mice had significantly thicker cortices than vehicle-treated mice (+7.2%, $p < 0.05$), resulting mainly from periosteal expansion (+3.2%, $p < 0.05$). μ CT analysis of the femur confirmed that DOX-treated mice had thicker cortices than vehicle-treated mice (+5.6%, $p < 0.05$). Finally, DOX-treated mice had significantly (all $p < 0.05$) better trabecular microarchitecture at the lumbar spine compared to vehicle-treated mice (i.e., increased trabecular number [+12.0%] and thickness [+6%]; decreased trabecular separation [-10.9%] and SMI [-15.3%]).

Collectively, these results suggest that glycolytic fast-twitch skeletal muscle growth has beneficial effects on the skeleton at both loaded (femur and tibia) and non-loaded (spine) sites. Future studies utilizing this model may provide new insights into the "crosstalk" between skeletal muscle and bone, and ultimately lead to the identification of novel musculoskeletal therapeutic targets.

Free Fatty Acid Induced Insulin Resistance in Human Synovocytes: A Potential Link Between Obesity and Osteoarthritis. Eric Schott*, Daisuke Hamada², Robert Maynard¹, Michael Zuscik¹, Robert Mooney³. ¹Center for Musculoskeletal Research, University of Rochester Medical Center, USA, ²Department of Orthopedics, Tokushima University Hospital, Japan, ³Department of Pathology, University of Rochester Medical Center, USA

Obesity-induced type 2 diabetes (T2D) is an established major risk factor for the development of osteoarthritis (OA). To address the molecular basis of this comorbid interaction, we previously demonstrated high-fat (HF) diet-induced T2D in mice leads to increased pro-inflammatory cytokine expression, including TNF and IL-6, in the synovium of the knee. Consistent with this, we also showed that TNF expression is increased in the synovium from obese/T2D OA patients compared to non-obese control subjects. Importantly, synovium from obese/T2D patients is insulin resistant, evidenced by decreased insulin-induced phosphorylation

of Akt compared to the non-obese synovium. Moreover, we have established that synovial insulin resistance may promote OA since TNF-induced catabolic enzyme and pro-inflammatory cytokine expression in human fibroblast-like synoviocytes (FLSs) is significantly blunted by insulin. It is known that in the obese state, increased free fatty acid (FFA) levels lead to upregulation of pro-inflammatory cytokines and insulin resistance. Therefore, we hypothesize that the accelerated progression of OA in obesity is, in part, due to elevated saturated FFA levels leading to increased cytokine expression and impaired insulin signaling in the synovium. To address this hypothesis *in vitro*, FLSs from non-diabetic patients were treated with palmitic acid (PA), the most abundant saturated FFA in the circulation. PA induced an inflammatory response with expression of IL-6 and MMP13 increasing in a dose dependent manner. Importantly, PA also induced insulin resistance in FLSs in less than 60 min, as demonstrated by a 75% blunting of phosphorylation of Akt in response to insulin. Toll-like receptor 4 (TLR4), the receptor for lipopolysaccharide (LPS), has been implicated as a mediator of PA-induced insulin resistance in various cells. When FLSs were treated with LPS, insulin signaling was impaired as reflected by decreased insulin-dependent pAkt levels, though the effect was less than that of PA, suggesting more than one pathway mediates the effect of PA on FLSs. Taken together, these data demonstrate that PA increases the expression of pro-inflammatory cytokines and induces insulin resistance. This may be an important mechanism mediating the increased OA risk in obesity.

Therapeutic effects of a novel FGFR1 inhibitor on osteoarthritis. Yangli Xie^{*1}, Wei Xu², Siru Zhou², Zuqiang Wang², Junlan Huang², Xianding Sun², Wanling Jiang², Xiaolan Du², Lin Chen². ¹Third Military Medical University, Peoples republic of china, ²Center of Bone Metabolism & Repair, Department of Rehabilitation Medicine, State Key Laboratory of Trauma, Burns & Combined Injury, Trauma Center, Institute of Surgery Research, Daping Hospital, Third Military Medical University, China

Objective. Fibroblast growth factors (FGFs) and their receptors (FGFRs) play important roles in articular cartilage homeostasis. Our previous study revealed that genetic inhibition of Fibroblast growth factor receptor 1 in knee cartilage attenuates the degeneration of articular cartilage in adult mice, suggesting that FGFR1 may be a potential therapeutic target for treating osteoarthritis. This study aims to investigate whether a novel FGFR1 inhibitor, GL-141 (screened through molecular docking approach by collaborators) has therapeutic effects on osteoarthritis.

Methods. Human articular chondrocytes were incubated with FGFR1 inhibitor followed by IL-1 β for 24 hours, then the expression levels of adams-5, mmp-13 and aggrecan were detected by real-time PCR, the protein level of MMP-13 were detected by western blot. Surgical destabilization of the medial meniscus (DMM) was performed to induce experimental murine OA. Intra-articular injections of 10 μ l of GL-141 were administered twice weekly for 4 and 8 weeks. Articular cartilage damage was analyzed by histology using the OARSI histologic scoring system at 4 and 8 weeks after surgery. MMP-13, type II collagen, type X collagen expressions were analyzed by immunohistochemistry.

Results. The mRNA levels of adams-5 and mmp-13 were increased and the mRNA level of aggrecan was decreased in human articular chondrocytes after IL-1 β treatment, as compared to those in vehicle-treated human articular chondrocytes. Treatment with GL-141 resulted in a remarkable reduction in the IL-1 β stimulated mRNA levels of adams-5 and mmp-13 and a marked increasing of aggrecan mRNA level in human articular chondrocytes. MMP-13 protein level was increased after IL-1 β treatment in articular chondrocytes. In the presence of FGFR1 inhibitor, the degree of increase in the protein level of MMP-13 was attenuated in IL-1 β treated chondrocytes. Intra-articular injection of GL-141 attenuated the DMM-induced cartilage destruction and matrix loss in mice knee joints. Inhibitor-treated mice showed higher Type II collagen expression and lower MMP-13 and type X collagen expression in articular cartilage than that in mice that underwent vehicle treatment.

Conclusion. GL-141 treatment reduced the catabolic events induced by IL-1 β in human articular chondrocytes. Intra-articular injection of GL-141 attenuates the degeneration of articular cartilage in mice.

Communication of Cyclic AMP by Connexin43 Gap Junctions Influences Osteoblast Signaling and Gene Expression. Aditi Gupta^{*}, Hidayah Anderson, Margaret Ren, Joseph Stains. University of Maryland School of Medicine, USA

While connexin43 (Cx43) containing gap junctions play an important role in bone modeling and remodeling, very little is known about the biologically relevant second messengers communicated by Cx43 in bone. In this study, we have used MC3T3-E1 mouse osteoblast and UMR106 rat osteosarcoma cells to test the hypothesis that cyclic AMP (cAMP) is a second messenger communicated by bone cells that impacts osteoblast function. Overexpression of Cx43 in these cells enhanced the responsiveness of a cAMP-response element driven transcriptional reporter (CRE-luc) and enhanced phospho-CREB levels following treatment with prostaglandin E2 (PGE2), forskolin

or expression of a constitutively active Gs-alpha. In addition, activation of cAMP-dependent signaling led to an increase in ERK1/2 activation, an effect that was also enhanced by Cx43 expression. The protein kinase A (PKA) inhibitor H89 blocked the increase in phospho-CREB levels and CRE-luc transcriptional activity, as well as the activation of ERK1/2. Notably, the enhancement of signaling caused by Cx43 expression in PGE2 treated cells was not accompanied by a further increase in cAMP levels as determined by an ELISA assay, suggesting that the cAMP was shared between cells rather than Cx43 enhancing cAMP production. In support of this point, using a novel assay in which one set of cells express a constitutively active Gs-alpha (donor cells) were co-cultured with a second set of cells expressing a cAMP-response element driven transcriptional reporter (acceptor cells), we showed that when both the donor cells and acceptor cells express Cx43, then we could detect robust activation of the CRE-luc reporter in the acceptor cells, indicating communication of the cAMP-dependent signal. This stimulation was not seen when the donor and acceptor cells were co-cultured in a transwell chamber where cell-to-cell contacts were not formed between the donor and acceptor cell populations, nor when the cells did not both express Cx43. Finally, we showed that Cx43 increased the cAMP-dependent expression of RANKL in UMR-106 cells in culture and enhanced the repression of Sost, implying a potential mechanism for the modulation of tissue remodeling. In total, these data demonstrate that Cx3 can communicate cAMP to impact signal transduction cascades and the expression of key bone effector molecules.

Intravital imaging of coupling between osteoblasts and osteoclasts by using multiphoton microscopy. Masayuki Furuya^{*1}, Junichi Kikuta², Hiroki Mizuno², Shigeto Seno³, Hiroki Maeda⁴, Kazuya Kikuchi⁴, Hideo Matsuda³, Hideki Yoshikawa¹, Masaru Ishii². ¹Department of Orthopaedics, Graduate School of Medicine, Osaka University, Japan, ²Department of Immunology & Cell Biology, Graduate School of Medicine & Frontier Biosciences, Osaka University, Japan, ³Department of Bioinformatic Engineering Graduate school of Information Science & Technology, Osaka University, Japan, ⁴Department of Material & Life Sciences, Graduate School of Engineering, Osaka University, Japan

Background/Purpose: Bone is constantly remodeled by bone-resorbing osteoclasts (OCs) and bone-forming osteoblasts (OBs). Although it has long been believed that bone homeostasis is tightly regulated through communication between OBs and OCs ('coupling'), the fundamental process and the dynamics have remained elusive. Previously we originally established an intravital bone imaging system with multiphoton microscopy and reported the dynamics of OCs and osteoclast precursor monocytes *in vivo*. This study aimed to reveal the mechanism of coupling and investigate the effects of parathyroid hormone (PTH) on coupling in living bone tissues by using an intravital bone imaging system.

Methods: For visualizing coupling between OBs and OCs, we generated the double fluorescently-labeled mice (Col2.3-ECFP/TRAP-tdTomato mice) by crossing Col2.3-ECFP mice where ECFP was expressed in Col1a1⁺ OBs with TRAP-tdTomato mice where tdTomato was expressed in TRAP⁺ OCs. We observed calvaria bone tissues of Col2.3-ECFP/TRAP-tdTomato mice by using an advanced intravital bone imaging system with multiphoton microscopy that we have previously reported. We investigated the function of OCs by means of a pH-sensing fluorescent chemical probe which we previously developed to detect the acidification by bone-resorbing OCs *in vivo*. In addition for examining the effects of PTH, teriparatide (40 μ g/kg/day) was administered by subcutaneous injections 5 days a week. 0, 1, 3, or 6 weeks after the initiation of the treatment, images were acquired.

Results: We succeeded in visualizing the interaction of OBs with OCs in live bone tissues. In normal condition we could observe some clusters of OBs and OCs respectively. In boundary areas between OBs and OCs, there were a few interaction areas, where OCs had some synapse like projections to OBs. We also found that treatment of PTH increased bone volume by the anabolic effect of PTH, the number of OBs and OCs, and the number of interaction areas *in vivo*. Furthermore we could demonstrate that OCs interacting with OBs have lower ability of bone resorption than non-interacting OCs in live bone tissues. **Conclusion:** By visualizing *in vivo* behaviors of OBs and OCs simultaneously, we found a few areas with interaction of OBs with OCs in normal condition. In addition, we revealed that PTH could not only increase the number of OBs and OCs, but also the number of interaction areas and inhibit bone resorption in live bone tissues.

Matrix Vesicles Mediate the Cell-to-Cell Transmission of MicroRNA-125b as an Inhibitor of Osteoclastic Bone Resorption. Yuichiro Takei^{*1}, Yuko Nakao², Tomoko Minamizaki¹, Yasumasa Irie², Faisal Ahmed², Hiroataka Yoshioka¹, Shumpei Niida³, Kotaro Tanimoto¹, Yuji Yoshiko¹. ¹Hiroshima University Institute of Biomedical & Health Sciences, Japan, ²Hiroshima University Graduate School of Biomedical & Health Sciences, Japan, ³Biobank, National Center of Geriatrics & Gerontology, Japan

Matrix vesicles (MVs) play a key role during the initial stages of bone mineralization. MVs bud off from the osteoblast plasma membrane and located at the osteoid matrix. Mineralization regulatory molecules are accumulated in MVs, and initial hydroxyapatite crystals form within these microstructures. Additionally, MV-derived TGF- β and IGF-I are released from the matrix during bone resorption and contribute to bone formation. In our global analysis of microRNAs (miRs) in osteoblasts, we identified that miR-125b and let-7c are selectively transported into MVs. Because these miRs may be targeted to genes involved in bone formation and resorption, we investigated whether MV mediates osteoblastogenesis and/or osteoclastogenesis by a miR-dependent mechanism. We examined the effects of MVs on mouse osteoblastic MC3T3-E1 cells and mouse macrophage RAW-D cells. MVs were isolated by collagenase and ultracentrifugation from human and rodent osteoblasts. MVs had no obvious effects on proliferation and osteogenic differentiation in MC3T3-E1 cells. The vesicles, however, suppressed RANKL-dependent osteoclast (OC) formation from RAW-D cells. In accordance with this, cells with MVs expressed reduced levels of OC marker genes including *Acp5*, *Ctsk* and *Destamp*. These effects were mimicked in primary mouse macrophages. We confirmed that MVs are incorporated relatively quickly and accumulated in RAW-D cells but not MC3T3-E1 cells. Treatment of MVs increased levels of miR-125b but not let-7c in RAW-D cells. Besides being a suppression of RANKL-dependent OC formation, transfection of miR-125b decreased the expression of its predicted target gene, *Prdm1*, and OC marker genes in RAW-D cells. To determine whether miR-125b affects bone resorption in vivo, we used a mouse lipopolysaccharide (LPS)-induced calvarial osteolysis model. miR-125b partially inhibited LPS-dependent osteoclastic osteolysis, when administered subcutaneously over the calvaria. These findings suggest MV-mediated miRs transfer from osteoblasts to osteoclasts, which provides new insights into the importance of MVs for cell-to-cell interactions in bone.

New Insight into Collagen Assembly Dynamics in Osteoblasts by Live Cell Imaging. Michael Grillo^{*1}, LeAnn Tiede-Lewis², Lora McCormick¹, Charlotte Phillips³, Hong Zhao¹, Sarah Dallas¹. ¹University of Missouri - Kansas City, USA, ²University of Missouri-Kansas City, USA, ³University of Missouri - Columbia, USA

Type I collagen, the major bone matrix protein, consists of heterotrimers of two $\alpha 1(I)$ chains and one $\alpha 2(I)$ chain, encoded by the COL1A1 and COL1A2 genes. Although the collagen biosynthetic pathway is well understood, the dynamic process by which collagen is assembled into extracellular fibers is less clear. We previously generated transgenic mice expressing GFP-tagged $\alpha 2(I)$ collagen driven by the 3.6kb-COL1A1 promoter. To gain new insight into collagen assembly dynamics we have developed immortalized osteoblast-like cell lines. One cell line expresses GFP-tagged collagen. Another co-expresses GFP-collagen and RFP-actin (p^{cmv}LifeAct-TagRFP). The third co-expresses GFP-collagen and a membrane-targeted TdTomato. Widefield and confocal live-cell imaging was performed on these cell lines with or without transfection of an endoplasmic reticulum imaging probe (CellLightER-RFP) or golgi probe (CellLight Golgi-RFP). Dual imaging of GFP-collagen and ER-RFP showed that prior to addition of ascorbate GFP-collagen was localized in the ER. After ascorbate addition, collagen condensed into intracellular vesicle-like structures that continued to co-localize with ER-RFP. A small proportion of GFP-collagen co-localized with the golgi-RFP probe. These findings were confirmed by immunostaining for ER and golgi markers on fixed col-GFP osteoblasts and immunostaining for wild-type collagen and ER in primary osteoblasts. The collagen-containing vesicles showed extensive intracellular movement to localized regions in the cell, followed by formation of extracellular fibers. Collagen assembly was highly dynamic, with motile cells exerting considerable forces on the fibers, resulting in stretching and distortion. Time-resolved confocal imaging suggested that thicker collagen fibers formed by cell-mediated stretching of smaller "mesh-like" fibers to condense them into rope-like structures. Dual imaging of GFP-collagen/ActinRFP cells seeded at low density on wild-type cells allowed visualization of collagen deposition by individual cells and showed assembly in a circular/perinuclear arrangement that appeared to be due to cell rotation/centrifugal collagen placement. Collagen was deposited only in areas where the cell body or processes had been, suggesting active cell placement. Our data show that collagen assembly is highly dynamic and involves internal movement of collagen-containing vesicles to localized regions of the cell and physical molding of fibers via cell-generated forces.

Structure-Function Analysis of Connexins as Active Regulators of Signal Transduction in Osteoblasts. Megan Moorer^{*}, Carla Hebert, Joseph Stains. UMB, USA

Gap junctions allow signaling between osteoblasts and osteocytes, coordinating bone remodeling. While gap junctions are generally thought of as passive conduits for small molecules to be shared between cells, we hypothesize that connexins actively contribute to downstream signaling by assembling a specific subset of effectors to the gap junction. We propose that, in addition to having unique permeability (e.g., Cx43 forms a pore permeable to <1kD molecules, and Cx45 forms a pore permeable to <0.3kD molecules), each connexin can assemble a unique "interactome" that can affect downstream signaling and bone cell function. In support of this hypothesis, several studies show that the unconserved, C-terminal domain (or tail) of connexins can associate with a variety of signaling complexes. Here, we examine the influence of this C-terminal tail on osteoblast signaling and function. We look at the function of two connexins, Cx43 and Cx45, which generally have opposing function in osteoblast biology. In addition, we have generated chimeric connexins, which fuse the Cx43 pore with the Cx45 C-terminal tail (Cx43pore-Cx45tail) and vice versa (Cx45pore-Cx43tail), to test the function of the C-terminus on osteoblastic signaling and function. Luciferase reporter assays performed in UMR106 or MC3T3 cells showed that expression of an intact Cx43 increased the transcriptional activity of a beta-catenin reporter (TOPflash), a Runx2 reporter (pOSE2-Luc), a cAMP-response element reporter (CRE-luc), a MAPK sensitive serum response element luciferase reporter (SREluc) and an NFkB sensitive reporter. In contrast, expression of an intact Cx45, or a Cx43pore-Cx45tail or Cx45pore-Cx43tail chimera either inhibited or had minimal impact on the transcriptional activity from these reporters. These results were confirmed by immunoblots from transfected cells. In addition, an intact Cx43 stimulated the expression of Sp7/Osterix, bglap/osteocalcin, coll1a1, lox, axin2 and excl12. In contrast, Cx45 attenuated the expression of most of these genes, while the chimeras were generally intermediate between the two. In total, these data suggest that both the pore and tail of Cx43 and Cx45 are required for their ability to affect osteoblast signaling and gene expression, implying that gap junctions need to not only pass signals back and forth, but also must be able to recruit the appropriate effector molecules in order to affect cell function.

A Novel Role of miR-150 in Bone Homeostasis. Fouad Moussa^{*1}, Gregory Sondag¹, Thomas Mbimba¹, Kimberly Novak², Scott McDermott³, Favez Safadi². ¹Kent State University, USA, ²NEOMED, USA, ³SUMMA Health System, USA

MicroRNA is a small non-coding RNA that consists of about 22 nucleotides, which targets mRNA and triggers its degradation or repress translation. MiR-150 is highly expressed in immature B cell stage, and targets c-Myb, a transcription factor that is important for lymphocytes development. However, the role of miR-150 on bone has not been documented. Our laboratory shows that miR-150 is expressed in mouse long bone and calvaria, and its expression is increased with age, thus, suggesting that miR-150 might play a role in bone homeostasis. Here, we show a novel role of miR-150 in osteoblast differentiation and function, where miR-150 gene expression is maximum at early stage (cell proliferation) and decreases at later stage (matrix mineralization) of osteoblastogenesis in vitro. To further determine the role of miR-150 in osteoblast function in vivo, we obtained the miR-150 knockout mice (miR-150 KO) and characterized their skeletal phenotype. MiR-150 KO mice have decreased bone mass associated with less bone volume to tissue volume ratio; decreased trabecular number associated in increased trabecular separation. This phenotype was evident as early as 4-weeks of age. Furthermore, we observed a significant reduction of ex vivo bone marrow-derived mesenchymal stem cells (MSCs) proliferation. Interestingly, there was an increase in osteoblast differentiation and function compared to wild type (WT) MSCs. We further examined osteoclast-mediated bone resorption in vivo and found that CTX1 levels was significantly reduced in miR-150 KO compared to WT mice. To determine the mechanism by which miR-150 plays in regulating bone cell differentiation and function, osteoactivin/gpmb, a bone anabolic factor is regulated by miR-150 through its 3'-UTR. OA expression was increased in miR-150 KO compared to WT bone cells. These results explained, at least in part, the mechanism of miR-150 in regulating bone cell differentiation and function. Taken together, these data suggest that miR-150 is a novel target for bone-related genes that might play a role in bone homeostasis and regulating MSCs proliferation, osteoblast and osteoclast differentiation and function. In addition, miR-150 can also be utilized as a therapeutic potential to treat osteoporosis, or used as a diagnostic tool for bone-related diseases.

Disclosures: Fouad Moussa, None.

FR0187

Alternative NF- κ B as a Regulator of Osteogenesis. Jennifer Davis^{*1}, Deborah Novack². ¹Washington University in St. Louis, USA, ²Washington University School of Medicine, USA

The alternative (alt) NF- κ B pathway has been shown to regulate both osteoblasts (OB) and osteoclasts (OC), complicating interpretation of bone phenotypes in global KO animals. In order to support the hypothesis that alt NF- κ B is a cell-intrinsic regulator of osteogenesis, we used transgenic mouse models to modulate alt NF- κ B in the OB lineage. NIK and IKK α are both critical upstream kinases for alt NF- κ B activation. We generated Osx-Cre:IKK α ^{fl/fl} (cKO) mice to ablate alt NF- κ B signaling in the OB lineage. NIKDT3 (NT3) is a constitutively active, lox-Stop-lox allele of NIK placed in the ROSA26 locus. Osx-Cre:NT3^{+/+} (cACT) mice were generated to activate alt NF- κ B signaling in the OB lineage. Recombination of alleles was induced by doxycycline withdrawal at weaning, and controls (CON) were Cre negative littermates.

As expected based on global KO studies, levels of collagen Ia and osteocalcin were higher in OB cultures from cKO animals, while OB from cACT animals had severely blunted levels. However, *in vivo* microCT analysis revealed no significant difference in trabecular or cortical bone parameters between cKO mice and CON at ages up to 6 months. 16 week old cACT mice showed an increase in cortical parameters (Ct.Th and Ct.BV, but no change in TV), not apparent at 6 and 12 weeks, a finding opposite to the expected decrease in bone mass. We next used *in vivo* axial tibial compression (2000 μ e; 4 Hz, 1200 cycles/day, 5 days/week, 2 weeks) to examine responses to mechanical anabolic stimulus between cKO, cACT, and CON animals at 16 weeks of age. Dynamic histomorphometry at the tibial mid-shaft in cKO mice showed no increase in Ps.BFR/BS, Ps.MAR, or Ps.MS/BS compared to CON. Surprisingly, cACT animals displayed an enhanced response to loading with increased Ps.BFR/BS and Ps.MS/BS.

In summary, the *in vitro* OB phenotype of cKO and cACT animals is consistent with reports in the alt NF- κ B global KO mice. However, we observe no difference in cKO bone phenotype either basally or after anabolic stimulus suggesting that loss of alt NF- κ B is not critical for OB differentiation and/or function *in vivo*. The finding that cACT animals have increased cortical bone mass and bone formation after *in vivo* loading suggests that pathological alt NF- κ B activation may impact osteogenesis. Taken together, our results indicate that the role of this pathway *in vivo* is complex and potentially context and/or age-dependent.

Collagen production of osteoblasts revealed by ultra-high voltage electron microscopy. Rumiko Hosaki-Takamiya¹, Mana Hashimoto¹, Tomoyo Tanaka¹, Takashi Yamashiro², Hiroshi Kamioka^{*3}. ¹Department of Orthodontics, Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sciences, Japan, ²Department of Orthodontics & Dentofacial Orthopedics, Graduate School of Dentistry, Osaka University, Japan, ³Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sciences, Jp

In the bone, collagen fibrils form a lamellar structure called "twisted plywood-like model." For this unique structure, the bone can withstand various mechanical stresses. But the formation of this structure has not been elucidated due to the difficulty in observing collagen fibrils production of the osteoblasts via currently available methods. This is because the formation occurs in the very limited space between the osteoblast layer and bone matrix. In this study, we used ultra-high voltage electron microscopy (UHVEM) to observe collagen fibrils production three-dimensionally. UHVEM has 3 MV acceleration voltage and enables us to use thicker sections. We observed collagen fibrils that were beneath the cell membrane of osteoblasts elongated to outside of the cell. We also observed that osteoblasts produced collagen fibrils with polarity. By using AVIZO software, we observed collagen fibrils produced from osteoblasts along the contour of the osteoblasts towards the bone matrix area. Immediately after releasing from the cell, the fibrils run randomly and sparsely. But as they recede from the osteoblast, the fibrils began to run parallel to the definite direction and became thick and we observed a periodical stripe at that area. Furthermore, we also observed membrane structures wrapped around filamentous structures inside the osteoblasts. The filamentous structures had densities similar to the collagen fibrils and a columnar form and diameter. Our results suggested that collagen fibrils run parallel and thick, which may be related to the lateral movement of the osteoblasts. UHVEM is a powerful tool for observing collagen fibrils production.

Double knockout of CLC3 and CLC5 in murine osteoblasts eliminates all mineralization. Quitterie C. Larrouture^{*1}, Deborah J. Nelson², Paul H. Schlesinger³, Peter A. Friedman⁴, Irina Tourkova⁵, Li Liu⁶, Harry Blair⁷.

¹Department of Pathology University of Pittsburgh, USA, ²Dept of Neurobiology, Pharmacology & Physiology, University of Chicago, USA, ³Department of Cell Biology, Washington University, USA, ⁴Department of Pharmacology & Chemical Biology, University of Pittsburgh, USA, ⁵Department of Pathology, University of Pittsburgh, & Pittsburgh Veteran's Affairs Medical Center, USA, ⁶Department of Pathology, University of Pittsburgh, USA, ⁷University of Pittsburgh, USA

Bone formation is mediated by a tight epithelium-like layer of secretory osteoblasts. The new bone matrix is separated from the extracellular fluid by tight junctions. The osteoblasts, and deeper layers of osteocytes of a bone forming osteon, are connected by gap junctions that couple the unit functionally. The osteon makes osteoid, mainly type I collagen, and then mineralizes it. Mineral formation, in a sealed space, liberates massive amounts of acid:

By removing the acid, mineralization can be driven to completeness efficiently over a wide range of interstitial fluid variations. This effectively mirrors osteoclast acidification of the resorption compartment to solubilize mineral. In both cases we envision multiple coordinated transporters moving protons across the osteoblast or osteoclast cell body at neutral pH. Previously, we showed that sodium hydrogen exchangers 1 and 6 (NHE1 and 6) move massive amounts of acid out of active osteoblasts at the *basolateral surface*. The pdz organizing protein, sodium hydrogen exchange regulatory factor 1 (NHERF1), also at the basolateral surface, is essential for efficient of bone formation and for phosphate transport via the neutral phosphate transporter-2 (Npt2). The unresolved central activity, crucial to active mineral deposition, was hypothesized to be *high capacity transporter(s) moving protons from the extracellular matrix space into the osteoblast cytoplasm*. We studied proton transport in membrane vesicles of mineralizing osteoblasts, which was consistent with Cl⁻ dependent H⁺ uptake. Matching these results with the identity of pumps, channels and exchangers significantly expressed in mineralizing osteoblasts we identified the chloride-proton exchangers as probable candidates. CLC3 and 5 expression is increased by large amounts (20-100 fold) in mineralizing osteoblasts. These transporters occur at the apical secretory surface as well as in the canalicular system. The CLC3 KO has mildly disordered mineralization with increased CLC5 expression compensating. We isolated mesenchymal stem cells from CLC3 ko mice, and used lentiviral CLC5 shRNA expression to create double KO MSCs. Phenotypes were validated by Western blots and PCR. In the double KO, no extracellular mineral is produced (Figure). Thus, osteoblast apical Cl⁻/H⁺ exchange imports acid from mineral formation. This acid is removed by basolateral Na⁺/H⁺ exchange to maintain osteoblast cytosolic pH.

Normal alk phos but no mineral in CLC3/5 double KO osteoblasts

Multi-Modal High-Content Imaging Reveals Relationships Between Cell Signaling and Mineralization in Zebrafish. Claire Watson*, Edith Gardiner, Werner Kaminsky, Ronald Kwon. University of Washington, USA

The generation of new bone requires activation of specific signaling cascades in a temporally and spatially distinct manner. However, until recently, a direct comparison between the dynamics of these signaling events and the formation of mineralizing bone has been precluded by the lack of strategies to simultaneously visualize these relationships *in vivo*. The optical clarity of the zebrafish caudal fin allows for high content imaging of cell signaling in real time by taking advantage of fluorescent reporter strains. Previously, we demonstrated the potential to measure crystalline mineral accrual during fin regeneration using quantitative birefringence imaging (Rotopol microscopy [1]). Building on these findings, in this study, we developed a high-content, multi-modal imaging system for tandem imaging of fluorescent reporters and bone mineralization within the same tissue. The system consisted of a motorized rotating polarizer integrated into a fully motorized Zeiss Axio Imager.M2 high-content fluorescence microscope, with custom software enabling interfacing between systems. We applied this imaging strategy to directly examine the relationships between canonical Wnt signaling and *sp7* (*osterix*) expression (using the Tg(7xTCF-Xla.Siam:GFP)ia4 and Tg(sp7:EGFP) reporter fish, respectively) with changes in cell metabolism (indicated by NADH autofluorescence) and mineralization (via Rotopol acquired birefringence) during bone formation and maturation in the regenerating zebrafish fin (Fig 1A). The first segment of bone distal to the amputation plane was analyzed for each of these parameters during the first 8 days post amputation (dpa) to examine early bone maturation (Fig 1B). We find that acute activation of NADH is followed by Wnt signaling and subsequent expression of *sp7* at this site. Interestingly, increases in mineralization coincide with second and third peaks in NADH autofluorescence. Furthermore, we find that mineralization is not complete even at 26 dpa in some fish. Using Rotopol imaging in concert with high resolution fluorescent imaging for the first time, we demonstrate that this system can be used to examine relationships between core bone formation events and maturation into fully mineralized bone.

Regulation of matrix mineralization and bone vascularization by pigment epithelium-derived factor (PEDF). Heeseog Kang*, Joan C. Marini. NIH/NICHD, USA

Pigment epithelium-derived factor (PEDF), encoded by SERPINF1, is a potent anti-angiogenic and neurotropic factor. Null mutations in SERPINF1 cause recessive type VI osteogenesis imperfecta (OI), a progressive deforming OI characterized by broad bands of unmineralized osteoid and a fish-scale pattern of bone under polarized light. Serpinfl (-/-) mice were reported to have delayed *in vitro* mineralization and increased mineral-to-matrix ratio, giving rise to decreased trabecular bone mass and brittle bone. However, it remains to be elucidated how PEDF contributes to bone matrix mineralization. Furthermore, we recently reported a novel connection of PEDF and the transmembrane protein BRIL, expressed during osteoblast mineralization. A loss-of-function BRIL mutation (IFITM5 (c.119C>T; p.S40L)) causes atypical type VI OI with decreased SERPINF1 expression, while the type V OI gain-of-function IFITM5 mutation (c.-14C>T) increased SERPINF1 expression and PEDF secretion. Here, we investigated the differentiation of murine serpinfl (-/-) calvarial osteoblasts. We show that serpinfl expression increases during early osteoblast differentiation and then decreases in terminally differentiated osteoblasts. Osteoblasts from serpinfl (-/-) mice exhibited delayed nodule formation and mineralization, compared with WT osteoblasts. We examined expression of osteogenesis marker genes during differentiation of calvarial osteoblasts by real-time PCR. Serpinfl (-/-) osteoblasts exhibited lower expression of ifitm5, demonstrating a mutual feedback loop regulating transcription of these proteins. Several osteoblast differentiation markers (colla1, osteocalcin, and phex) were significantly lower than in WT cells during matrix mineralization. The delayed mineralization was accompanied by the reduced expression of mineralization markers, such as alkaline phosphatase and phospho1, while expression of the mineralization inhibitor, osteopontin, was increased. Moreover, the absence of PEDF significantly decreased expression of sost (sclerostin), an antagonist of the canonical wnt signaling. The reduced sost expression was consistent with the elevated expression of vegfa and ptgs2 (COX-2), the wnt target genes. The resultant increase in VEGF-to-PEDF ratio may underlie the increased bone vascularization previously in serpinfl (-/-) mouse bones. Taken together, these results suggest that PEDF plays a role in coordinating bone matrix mineralization and bone vascularization.

Loss of galectin-3 leads to retention of bone mass in aging female mice. Kevin Maupin*¹, Kevin Weaver², Carol Flegler³, Stanley Flegler³, Tao Yang², John Wang³, Bart Williams². ¹Van Andel Institute Graduate School, USA, ²Van Andel Research Institute, USA, ³Michigan State University, USA

Osteoporosis is a growing health concern in the United States due to an aging population. Thus, there is a need to identify novel targets to control bone homeostasis. Galectin-3 (Gal3) is a chaperone protein which functions in numerous cell processes both intracellularly via protein-protein interactions and extracellularly by binding specific glycans on glycoproteins. Gal3-deficient mice have normal reproduction and lifespan, but are protected against fibrosis. Because Gal3 is highly expressed by bone cells and regulates the deposition of collagen in fibrosis models, we hypothesized that Gal3-deficient mice would have altered bone matrix deposition.

When we compared the femurs of aging (12, 24, 36, and 48wks) Gal3-deficient mice to their wildtype littermates by microcomputed tomography (μ CT), we found that Gal3-deficient mice had a sex-dependent bone phenotype. While males showed no difference in measured bone parameters, Gal3-deficient females had increased trabecular bone volume fraction (BV/TV) and were protected against age related loss of trabecular bone mineral density (BMD). At 36wks, there was an increase in the polar moment of inertia (MMI) of female Gal3-deficient femurs, which suggested an improvement in cortical bone strength. Mechanical testing by 4-point bending revealed that the Gal3-deficient bones had no changes in absolute strength or stiffness. However, there was a decrease in the maximum strain and Young's modulus of elasticity, which meant that there was a decrease in the quality of the bone matrix. We used scanning electron microscopy to observe the collagen of the cortical bone and found that despite normal cortical BMD, there was abnormal mineralization of the collagen fibrils. We also wanted to know whether the bone phenotype is dependent upon abnormal osteoblast function, so we made an osteoblast conditional knockout mouse line by crossing mice with floxed Gal3 alleles (*Lgals3-flox*) to mice expressing cre-recombinase driven by the human osteocalcin promoter (*OCN-cre*). Consistent with the globally Gal3-deficient mice, the *OCN-cre;Lgals3-flox* mice also showed a sex-dependent increase in trabecular bone mass and mineralization. The results of this study identify a novel sex-dependent regulation of the extracellular matrix by Gal3 in bone. While further experimentation is necessary, our data provides support for the development of Gal3 targeted therapies to prevent bone loss during aging.

microRNA Regulation of Circadian Rhythm in the Osteoblastic Lineage. Spenser Smith*, Neha S. Dole, Tiziana Franceschetti, Anne M. Delany, UConn Health, USA

Disruption of circadian rhythm is associated with many diseases, including cancer, metabolic syndrome and bone loss. In bone, genes critical for normal homeostasis display circadian rhythm. Rhythm is maintained by clock genes, including *Bmal1* and *Per1-3*, which interact in a series of transcriptional and post-transcriptional feedback loops. In non-skeletal tissues, microRNAs (miRNAs) were shown to be important for controlling circadian rhythm; however, miRNAs maintaining rhythm in bone have not been determined. Here, we identify miR-433 as a regulator of rhythmic gene expression in the osteoblast lineage.

Hif1 α and *Igf1* are critical osteoblast genes displaying circadian rhythm. Using Luciferase reporter-3'UTR assays, we demonstrated that these genes are novel miR-433 targets. *In vivo*, we saw that miR-433 displays robust rhythmicity in mouse calvaria. Its expression pattern was anti-phasic in relation to *Bmal1*, peaking after light removal. However, in primary mouse mesenchymal cells synchronized with a short pulse of dexamethasone, miR-433 did not display rhythmicity. This suggests that a systemic factor establishes miR-433 rhythm *in vivo*.

miR-433 was recently shown to target the glucocorticoid receptor (Riester et al.), and rhythmic secretion of glucocorticoids is critical for synchronizing local clocks in peripheral tissues by activating transcription of *Per* genes. Moreover, as circulating glucocorticoid levels fluctuate diurnally, so does the sensitivity of tissues to glucocorticoids. We hypothesized that miR-433 helps maintain circadian rhythm in osteoblasts by regulating glucocorticoid signaling. To determine if miR-433 regulates circadian rhythm *in vitro*, its activity was inhibited using a doxycycline-inducible competitor (miR-433 tough decoy) in stably transduced C3H10T1/2 cells. Although miR-433 inhibition did not affect *Bmal1* rhythm, it dramatically altered *Per2* amplitude, period length, and phase. miR-433 inhibition also dampened rhythmicity of *Runx2* mRNA. Inhibiting miR-433 activity amplified the dexamethasone-stimulated expression of glucocorticoid responsive genes *Dusp1* and *Per2*, demonstrating increased glucocorticoid sensitivity. Overall, we found that miR-433 displays a circadian rhythm in calvaria, targets mRNAs with rhythmic expression and regulates sensitivity to glucocorticoid signaling. We speculate that miR-433 can modify responsiveness of peripheral tissues to variations in circulating glucocorticoids and alter bone metabolism.

Osteoblast-specific deletion of Sclerostin rescues ovariectomy-induced bone loss, in adult female mice, but does not significantly improve bone parameters in adult males. Cristal S. Yee¹, Nicole M. Collette¹, Deepa K. Muruges¹, Aris N. Economides², Alexander G. Robling³, Gabriela G. Loots⁴. ¹Lawrence Livermore National Laboratories, USA, ²Regeneron Pharmaceuticals, USA, ³Indiana University, USA, ⁴Lawrence Livermore National Laboratory, USA

Estrogen deficiency causes rapid bone loss followed by skeletal fragility and ovariectomy (OVX) in rodents can effectively recapitulate these osteoporotic phenotypes. Sclerostin (Sost) is a negative regulator of bone formation and blocking its function *via* antibodies has shown great therapeutic promise by increasing both bone mass in humans and animal models. Sclerostin deletion in *Sost* knockout mice (*Sost*^{KO}) causes high bone mass (HBM) similar to Sclerosteosis patients. Both 3- and 6- month old *Sost*^{KO} mice have >150% and >300% more bone volume/total volume (BV/TV), respectively, than aged matched controls, and it has been postulated that the main source of skeletal Sost is the osteocyte. To examine temporal and cell-type specific contributions of Sost to bone metabolism, we investigated the skeletal phenotypes of mice with conditional *Sost* (*Sost*^{KO}) deletions initiated (1) in the limb mesenchyme (*Prx1-Cre*); (2) in embryonic osteoblasts (*Coll-Cre*); or (3) in adult osteoblasts (*Coll-ER-Cre*). *Prx1-Cre* deletes alleles in the early limb bud mesenchyme, between E9.5-E10.5. These cells represent the osteochondral progenitors (chondrocytes, adipocytes, osteoblasts, osteocytes) of the appendicular skeleton, and *Prx1-Cre* leaves the axial skeleton unperturbed. At 16 weeks of age, microCT (mCT) analysis of *Sost*^{KO}; *Prx1-Cre* distal femurs showed 200% more BV/TV than controls. The lumbar vertebrae, region of the skeleton where *Sost* alleles should remain intact, also showed a significant increase (60%) in BV/TV compared to controls. *Sost*^{KO}; *Coll-Cre* femurs displayed 75% more BV/TV than controls, while *Sost* deletion initiated by tamoxifen (TMX) injection at 22- weeks of age in *Sost*^{KO}; *Coll-ER-Cre* male mice caused no significant changes in the bone mass in 28- weeks old femurs compared to PBS or TMX treated *Sost*^{KO}; *Coll-ER-Cre* controls. However, *Sost* deletion initiated at 22- weeks of age significantly improved the bone parameters of *Sost*^{KO}; *Coll-ER-Cre* females that were ovariectomized at 16 weeks of age, and indicated a complete rescue from the effects of ovariectomy on bone mass. We found osteoblast deletion of *Sost* after OVX in females to significantly increase BV/TV by 130%, suggesting that the high bone turnover in OVX may rapidly propagate *Sost* deletion from osteoblasts to osteocytes, rescuing the LBM phenotype.

Serum Amyloid A3: A Novel Means by Which Preosteoclasts Inhibit the Anabolic Effects of PTH. Shilpa Choudhary*, Sui-Pok Yee, Renata Rydzik, Estus Thomas, Douglas Adams, Joseph Lorenzo, Carol Pilbeam, University of Connecticut Health Center, USA

Absence of cyclooxygenase 2 (*Cox2*), the major enzyme regulating prostaglandin production, enhances the bone formation response to PTH infusion in mice without affecting resorption. We identified Serum amyloid a3 (*Saa3*) as a *Cox2*-dependent inhibitor of PTH-stimulated cAMP production and osteoblast (OB) differentiation *in vitro* and showed that *Saa3* is secreted by preosteoclasts (POCs). We generated *Saa3* knockout (KO) mice using the CRISPR/Cas9 approach in a CD1 background and confirmed by PCR and sequencing. The goal of this study was to determine if *Saa3* knockout enhanced osteogenic responses to PTH *in vitro* and anabolic responses to PTH *in vivo*. In primary OB cultures, conditioned media from WT but not *Saa3* KO POCs inhibited PTH-stimulated cAMP production and cAMP-regulated *Ramp3* expression. In bone marrow stromal cell cultures, PTH stimulated markers of OB differentiation only in *Saa3* KO cultures. Male WT and KO mice (n=3/group; 3 month old) were infused with vehicle or hPTH 1-34 (40 μ g/kg/d) via ALZET pump for 12 days. Bone mineral density (BMD) was measured at the beginning and end of infusion. PTH decreased BMD in WT mice but increased BMD in KO mice. μ CT analysis of vehicle-infused WT and KO distal femur showed no differences. PTH infusion increased trabecular BV/TV, Conn.Dens and Tb.N and decreased Tb.Sp in KO femurs relative to WT. There were no differences in cortical parameters with PTH infusion. PTH increased serum PINP, a marker of bone formation, only in KO mice but increased serum CTX, a marker of resorption, equally in WT and KO mice. Gene expression was performed on whole tibiae. *Saa3* was undetectable in vehicle-infused tibiae and markedly induced by PTH in WT tibiae. Other members of the serum amyloid family, *Saa1* and 2, were unchanged by PTH infusion. PTH increased expression of the cAMP-regulated gene, *Ramp3*, only in KO tibiae but increased expression of *Rankl* and *Cox2* similarly in both WT and KO tibiae. PTH increased the bone formation-related genes—*Runx2*, *Osteocalcin*, *Igf1* and the Wnt family gene, *Wnt10b*—only in KO tibiae. PTH infusion decreased expression of the Wnt antagonists, *Sost* and *Dkk1*, only in KO tibiae. These results demonstrate that the effects of *Saa3* knockout on responses to PTH appear to mimic the effects previously seen with *Cox2* knockout. Thus, it seems likely that *Cox2*-dependent production of *Saa3* is a novel mechanism by which osteoclast lineage cells regulate the anabolic responses of osteoblast lineage cells to PTH.

Constitutive Activation of NF- κ B, Mimicking Inflammation, Inhibits Osteoblast Function by Inducing Glycolysis and mTORC2. Gaurav Swarnkar¹, Tim (Hung-Po) Chen¹, Gabriel Mbalaviele¹, Yousef Abu-Amer². ¹Washington University School of Medicine, USA, ²Washington University in St. Louis School of Medicine, USA

Inflammatory signals elicit bone catabolic responses through increased bone resorption by osteoclasts (OC) coupled with decreased bone formation by osteoblasts (OB), resulting in net bone loss. Whereas the mechanisms underlying inflammatory OC activity have been well-studied, those governing OB function remain elusive. The transcription factor NF- κ B which is considered as the centerpiece mediator of inflammation and essential for normal bone development, has also been shown to regulate cellular metabolism. Hence, this study was designed to investigate if IKK2/NF- κ B activation, an index of inflammation, cellular metabolism and function of OB. To this end, we conditionally deleted or constitutively activated IKK2 (IKK2ca) during OB differentiation using Sp7cre (early stage), Coll1cre and DMP1cre (late stage) mice. micro-CT analysis indicates that deletion of IKK2 using Sp7cre results in increased basal level of bone volume. In contrast, mice expressing IKK2ca under Sp7cre show a decrease in bone volume compared with WT, suggesting that IKK2 activation in OB mediates inflammation-induced catabolic effect. However, deletion using DMP1cre did not change bone parameters, yet activation with DMP1cre resulted in a moderate decrease in bone mass and connectivity density compared with WT controls. Analysis of Coll1cre-induced regulation of NF- κ B is ongoing. These results suggest that NF- κ B is more important in early stage of OB differentiation. Mechanistically, we found that expression of IKK2ca but not IKK2-Kinase dead in calvarial OB changed cellular metabolism towards increased aerobic glycolysis and decreased OB function. We found increased expression of glycolytic enzymes, including Hexokinase 2 and Lactate dehydrogenase in OB expressing IKK2ca compared to control cells. These cells also showed increased glucose uptake and consumption with increase in lactate production. IKK2ca expression also resulted in increased expression of sclerostin, DKK1, and RANKL along with decreased expression of OB genes (ALP, OCN). Further, consistent with reports that suggest that IKK2 regulates mTORC1/2 signaling, we found that IKK2ca expression in OB upregulates mTORC2 signaling evident by increase in expression of mTOR/Rictor. Further details of the mechanism underlying IKK2 mediated regulation of mTOR and OB metabolism are under investigation. Our study highlights the mechanism by which inflammation alters OB metabolism leading to impaired osteoblastogenesis

Effects of Osteoblast-Specific Gαs Over-Expression on Skeletal Development using a Transgenic Mouse Model. Lucia Zhang*¹, Kim Sugamori¹, Colin Claridge¹, Ariana Dela Cruz¹, Marc Grynpas², Jane Mitchell³. ¹University of Toronto, Canada, ²Lunenfeld-Tanenbaum Research Institute of Mount Sinai Hospital, Canada, ³Department of Pharmacology & Toxicology, University of Toronto, Canada

Gαs is a heterotrimeric G protein that transduces signals from activated G protein-coupled receptors on the cell surface to stimulate intracellular signaling cascades. In bone cells, Gαs is known to play a central role in mediating processes that regulate skeletal development, maintenance, and repair. Clinically, alterations in Gαs activity are associated with many bone disorders. Constitutive activity of Gαs results in McCune-Albright syndrome and fibrous dysplasia, while a 50% reduction in Gαs activity results in pseudohypoparathyroidism and Albright hereditary osteodystrophy. Our lab has previously found there is a 2.4 fold variation in Gαs protein levels in lymphocytes from children suggesting there is significant variability in Gαs levels in human cells. To examine the effects of increased osteoblastic Gαs expression on bone *in vivo*, we have created a transgenic mouse model of Gαs over-expression in osteoblasts (Gs-Tg mice) driven by the 3.6 kb Col1A1 promoter.

At both the RNA and protein levels, expression of total Gαs was significantly increased specifically in bone and teeth of Gs-Tg mice compared to wild-type (WT) mice. MicroCT assessment of bone microarchitecture showed cortical bone from 9-week old Gs-Tg mice had a modest reduction in volumetric bone mineral density (vBMD) compared to age-matched WT mice. Conversely, trabecular bone displayed significantly increased vBMD in Gs-Tg mice, accompanied by increased trabecular number and bone volume. Furthermore, static and dynamic histomorphometry analyses were conducted to examine differences at the cellular level. Static histomorphometry revealed gross abnormalities in the growth plates of 9-week old Gs-Tg mice compared to WT mice, with loss of the normal organization of growth plate chondrocytes. In concordance, dynamic histomorphometry displayed calcin green labelling that could not be quantified as it was both disorganized and diffuse. Follow-up analyses in female Gs-Tg mice revealed there is some disruption of the growth plate present at 3-weeks of age, progressed at 9 weeks, and was not resolved after skeletal maturity at 26-weeks of age. In summary, our findings suggest that osteoblastic Gαs over-expression leads to aberrant skeletal development in which cortical bone and trabecular bone are differentially affected.

Promotion of osteoblast differentiation and nodule formation through Ucm a as a direct transcriptional target of Runx2 and Osterix. Yeon-Ju Lee*¹, Seung-Yoon Park², So-Jeong Lee¹, Eun-Hye Lee¹, Soon-Young Kim¹, Je-Yong Choi³, Yeo Hyang Kim⁴, Jung-Eun Kim⁵. ¹Dept. of Molecular Medicine, CMRI, BK21 Plus KNU, Kyungpook National University School of Medicine, South Korea, ²Dept. of Biochemistry, School of Medicine, Dongguk University, South Korea, ³Dept. of Biochemistry & Cell Biology, CMRI, BK21 Plus KNU, Kyungpook National University School of Medicine, South Korea, ⁴Dept. of Pediatrics, Kyungpook National University Hospital, South Korea, ⁵Kyungpook National University School of Medicine, South Korea

Runx2 and Osterix (Osx) are the master transcription factors in bone formation. Nonetheless, genes acting downstream of both Runx2 and Osx have yet to be fully characterized. Here, we investigate the downstream targets of both Runx2 and Osx in osteoblasts. In DNA microarray analysis using Runx2/Osx double heterozygous embryos, the expression of unique cartilage matrix-associated protein (Ucm a) was significantly decreased. In contrast, Ucm a expression was increased in osteoblasts overexpressing both Runx2 and Osx. Ucm a expression was initiated mid-way through osteoblast differentiation and continued throughout the differentiation process. Transcriptional activity of the Ucm a promoter was increased upon transfection of the cells with both Runx2 and Osx. Runx2- and Osx-mediated activation of the Ucm a promoter was directly regulated by Runx2- and/or Sp1-binding sites within its promoter. During osteoblast differentiation, the formation of mineralized nodules in Ucm a-overexpressing stable clones occurred earlier and was more enhanced than that in the mock-transfected control. In contrast, osteoblast differentiation and nodule formation were significantly reduced in Ucm a-knockdown cells. Mineralized nodule formation was strongly augmented in osteoblasts or partially rescued in Ucm a-knockdown cells cultured in a medium containing Ucm a proteins. Collectively, our data demonstrate that Ucm a is a novel downstream gene regulated by both Runx2 and Osx and it stimulates osteoblast differentiation and nodule formation.

Runx2 Gene Deletion in Odontoblast Fails to Disrupt Dentin Synthesis. Mitra Adhami*¹, John C. Clarke¹, Haiyan Chen¹, Harunur Rashid¹, Kayla King¹, Mohammad Hassan¹, Yang Yang², Amjad Javed³. ¹School of Dentistry, University of Alabama at Birmingham, USA, ²Department of Pathology, University of Alabama at Birmingham, USA, ³University of Alabama at Birmingham, USA

Runx2 transcription-factor is essential for lineage commitment of undifferentiated oral mesenchyme toward odontoblast. Global deletion of Runx2 results in arrested tooth development prior to the bell stage. Runx2 deficient dental-mesenchyme fails to commit to the odontoblast lineage and lack morphological features characteristic of differentiated odontoblast. However, due to early lethality of global null mice, the specific role of Runx2 for development of functional odontoblast remains unknown. Here we determine Runx2 requirement during odontogenesis. Runx2 gene was deleted in committed odontoblast using 2.3kbCol1a1-Cre transgene which is turned on in dental-mesenchyme during embryonic development. We confirmed specific deletion of Runx2 in committed odontoblast by two independent reporter lines. To our surprise, Runx2^{CKO} mice were born alive and were similar to wild-type littermates in size and body-weight. Newborn heads sectioned sagittally showed normal tooth morphogenesis in homozygous mutants. Incisors and multi-cusped 1st and 2nd molar were noted in wild-type and Runx2^{CKO} littermates. Consistent with normal tooth-morphogenesis, both odontoblasts and ameloblasts were polarized and well differentiated in Runx2^{CKO} mutants at birth. Expression levels of dentin matrix genes were similar in tooth organs of WT and Runx2^{CKO} littermates. Thus Runx2 activity in committed odontoblast is not essential for embryonic tooth development. We also evaluated molars after eruption. The size, length and width of crowns and roots of molars in Runx2^{CKO} mice were comparable to wild-type mice. Furthermore, a well-defined predentin, dentin and cementum layer was present in both wild-type and Runx2^{CKO} mice. Equal number, spacing and thickness of odontoblast tubules were noted in both littermates. Finally, the periodontal ligament was integrated into surrounding alveolar-bone in both wild-type and Runx2^{CKO} mice. In sharp contrast, Runx2 mutants exhibited significantly low bone mass by 1 month of age. Decreased bone formation was associated with decreased gene expression of osteoblast markers and impaired collagen assembly in the extracellular matrix. We further show that osteoblast function, and not number, is disrupted in Runx2^{CKO} mice. Taken together our data demonstrate that despite critical requirement during lineage commitment of dental mesenchyme, Runx2 is not essential in odontoblasts for tooth development.

Disclosures: Mitra Adhami, None.

Dividing Growth Plate Chondrocytes Transdifferentiate into Osteoblasts and Provide a Major Source of De Novo Osteoblasts throughout Postnatal Growth in Mice. Patrick Aghajanian*¹, Shaohong Cheng¹, Catrina Alarcon¹, Subburaman Mohan². ¹Jerry L Pettis VA Medical Center, USA, ²Jerry L. Pettis Memorial VA Medical Center, USA

It has long been believed that during endochondral ossification osteoblast progenitors are delivered via the vasculature to form bone matrix that replaces the cartilage. In contrast to this model, we recently demonstrated that epiphyseal chondrocytes transdifferentiate into bone forming osteoblasts during the early postnatal growth period in mice. To determine if transdifferentiation of chondrocytes represents a major source of De Novo osteoblasts at different bone forming sites, we genetically labeled proliferating chondrocytes with tamoxifen-induced Col2-CreERT2 using Tomato (Tom) expression and followed the fate of labeled cells over a period of 16 weeks. Col2-Cre-ERT2; ROSA-tdTomato mice were administered a single dose (100 ug) of tamoxifen at postnatal day 3 and were euthanized at weeks 1, 2, 3, 6, 12 and 16. Immunohistochemistry of frozen bone sections were performed using chondrocyte and osteoblast markers. Our data show that many proliferating chondrocytes originating in the growth plate (physis) have the potential to transdifferentiate into osteoblasts which populate both the primary and secondary spongiosa during postnatal growth. Similarly, proliferating chondrocytes in the epiphysis predominantly contribute to bone forming osteoblasts at the secondary ossification center (SOC). Co-expression studies using osteoblast markers indicate colocalization of Tom with matrix proteins, bone sialoprotein II (BSP) and alkaline phosphatase (ALP), as well as osterix (OSX), all of which are indicators of osteoblast differentiation, in both the SOC and in trabecular bone. These events occur as early as 7 days after tamoxifen injection and continue to occur until at least 16 weeks of age. As early as 3 weeks of age, Tom labeled cells can be seen composing populations of trabecular bone and trabecular lining cells as far as 2.2 mm deep from the growth plate and 3.5 mm from the growth plate in 16 week mice. Quantitative studies indicate that 50% or more of OSX and BSP-positive osteoblasts in the primary and secondary spongiosa regions as well as epiphysis contained Tom. Taken together, our data show that dividing chondrocytes can transdifferentiate into bone matrix producing osteoblasts throughout postnatal growth and represent a major source of osteoblasts at different skeletal sites. Therefore, mechanisms that promote the chondrocyte-osteoblast transdifferentiation process should provide novel therapeutic opportunities towards development of anabolic skeletal therapies for osteoporosis.

Histone H2B Monoubiquitination is Required for Bone Development. Zeynab Najafova^{*1}, Peng Liu², Dominik Saul³, Hiroaki Saito⁴, Wanhua Xie⁵, Simon Baumgart⁵, Ahmed Mansouri⁶, Eric Hesse⁴, Stephan Sehmisch³, Jan Tuckermann², Steven A. Johnsen⁵. ¹University Medical Center Goettingen, Germany, ²Institute for General Zoology & Endocrinology, University of Ulm, Germany, ³Department of Trauma Surgery & Orthopedics, University Medical Center Goettingen, Germany, ⁴Department of Trauma-, Hand- & Reconstructive Surgery, University Medical Center Hamburg, Germany, ⁵Clinic for General, Visceral & Pediatric Surgery, University Medical Center Goettingen, Germany, ⁶Max Planck Institute for Biophysical Chemistry, Molecular Cell Differentiation Group, Germany

The complexity of lineage-specific transcriptional regulation is controlled by an intricate network of tissue-specific transcription factors and epigenetic regulatory mechanisms. Perturbation of these epigenetic mechanisms frequently leads to developmental defects and/or cancer. Thus, therapeutic strategies which specifically target these mechanisms offer an ideal approach for a number of clinical conditions such as aging-related bone loss. Histone H2B monoubiquitination (H2Bub1) is carried out by the obligate heterodimeric Rnf20/40 E3-ligase complex and is associated with transcriptional elongation on active genes. Surprisingly, despite its global correlation with active gene transcription, we previously demonstrated a specific role for H2Bub1 and its upstream regulatory pathway in controlling osteoblast (OB)-specific gene transcription during OB differentiation of mesenchymal stem cells (Karpiuk et al., 2012, Mol Cell). To address the significance of H2Bub1 for bone development *in vivo*, we generated a bone-specific Rnf40 conditional knockout (KO) mouse model. *Ex vivo* differentiation studies confirmed a role for Rnf40 and H2Bub1 in OB differentiation as revealed by decreased alkaline phosphatase activity/expression, mineralization and expression of Runx2 and Sp7 in KO OBs. Surprisingly, γ CT analysis revealed increased bone mass in homozygous OB-specific KO mice while bone histomorphometry demonstrated a decreased bone formation rate. Consistently, biomechanical loading studies showed reduced bending parameters (Stiffness, Yield load, Fmax (Strength) and Failure Load). Thus, these findings suggest that while H2Bub1 is required for OB differentiation, its absence results in increased bone mass associated with reduced bone strength and formation, a finding frequently associated with decreased osteoclast activity. Consistently, Rnf40-deficient OBs showed significantly reduced Rankl expression. Altogether, these data suggest that H2Bub1 is a defining epigenetic regulator of osteoblast-osteoclast coupling *in vivo* and provide a basis for future studies to investigate the potential of its regulatory pathway for the treatment of conditions such as aging-related osteoporosis.

miR-322 and Its Target Protein Tob2 Modulate Osterix mRNA Stability. Beatriz G3mez Molina^{*}, Edgardo Rodr3guez-Carballo, Francesc Ventura. University of Barcelona, Spain

The aim of our study was to perform a miRNA expression profile in BMP-treated cells and to analyze the biological impact of their modulation in osteoblast differentiation. We performed a screening of BMP-regulated miRNAs in C2C12 cells and focused on miR-322, a down-regulated miRNA. miR-322 was also repressed in MC3T3-E1 and BM-MSCs after BMP treatment. We also carried out miR-322 gain- and loss-of-function experiments in C2C12 and MC3T3-E1 in order to determine whether miR-322 affects osteoblast differentiation. Overexpression of miR-322 significantly increased *Osx*, *Runx2* and *Msx2* mRNA at basal levels and after BMP-2 stimulation. Concordantly, miR-322 increased OSX protein levels, revealing that miR-322 enhances the BMP-2 response. Furthermore, we confirmed the regulation of *Osx* mRNA by miR-322 in differentiated BM-MSCs using a lentiviral approach.

Putative targets of miR-322 were analyzed *in-silico* and *Tob2* was identified as a potential target. The characterization of the specific *Tob2* 3'-UTR sequence bound by miR-322 was possible due to the generation of *Renilla* luciferase reporter plasmids carrying wild-type or mutant *Tob2* 3'-UTR. Only wild-type construct was significantly inhibited after cotransfection with miR-322 in C2C12 and MC3T3-E1 cells, allowing us to demonstrate that miR-322 acts as an inhibitor of *Tob2*.

Previous studies identified *Tob* not only as a general regulator of mRNA decay but also as a specific regulator through its binding to CPEB2-4 (cytoplasmic polyadenylation element-binding protein) and further recruitment of the Cnot7 deadenylase to the target mRNAs. mRNA decay assays in C2C12 and MC3T3-E1 cells evidenced that ectopic expression of *Tob2* reduced the half-life of *Osx* transcripts. Moreover, accumulation of miR-322 led to significant stabilization of *Osx* mRNA.

To further prove direct binding of *Tob2* and CPEB2-4 to *Osx* prior to specific decay, we developed RNA pulldown assays using oligonucleotides corresponding to *Osx* 3'-UTR sequences found to form secondary stem-loop structures compatible to those shown to bind CPEB2-4. Either expressed alone or in combination, ectopic CPEB4 and *Tob2* were able to bind specifically to *Osx* RNA.

In conclusion, our results demonstrate a new molecular mechanism controlling osteogenesis through the miR-322/*Tob2* regulation of specific target mRNAs. This

regulatory circuit provides a clear example of a complex miRNA-transcription factor network for fine-tuning the osteoblast differentiation program.

Osteoblast-derived FGF9 Regulates Skeletal Homeostasis. Liping Wang^{*1}, Marcia Abbot², Theresa Roth³, Linh Ho³, Lalita Wattanachanya³, Rebecca Hayden³, Robert Nissenon⁴. ¹VA Medical Center, San Francisco, USA, ²Endocrine Unit, San Francisco VA Medical Center, Canada, ³Endocrine Unit, San Francisco VA Medical Center, USA, ⁴Endocrine Unit, San Francisco VA Medical Center; Department of Medicine & Physiology, University of California, USA

FGF9 has complex and important roles in skeletal development and repair. We have previously observed that FGF9 expression in osteoblasts (OBs) is regulated by G protein signaling and therefore the present study was done to determine whether OB-derived FGF9 was important in skeletal homeostasis. To directly test this idea, we deleted functional expression of FGF9 in OBs using a 2.3kb collagen type I promoter-driven Cre transgenic mouse line. Both FGF9 knockout (KO) and wild type (WT) mice were maintained in an FBV/N background. μ CT revealed that 3 month old male FGF9 KO mice displayed a 26% ($p < 0.001$) decrease in cancellous BV/TV, an 11% ($p < 0.001$) decrease in trabecular thickness in the distal femur and a 5.9% ($p = 0.05$) decrease in cortical thickness (Ct.Th) at the tibiofibular junction, compared to age and sex matched WT mice. Strikingly, FGF9 deficiency in OBs did not affect bone mass in female mice (KO vs. WT: cancellous %BV/TV, 13.8 ± 0.6 vs. 12.9 ± 0.5 ; Ct.Th, 236 ± 5.6 vs. $232 \pm 4.1 \mu\text{m}$). Histomorphometry of the distal femur confirmed that significant changes were seen in male KO mice only. There was a 39% ($p < 0.01$) decrease in cancellous BV/TV and a 52.7% ($p < 0.05$) decrease in bone formation rate at the distal femur in male KO mice. Continuous treatment of mouse BMSCs with FGF9 (5 ng/ml) from day 0 to day 20 inhibited mouse BMSC mineralization while acute treatment (5 ng/ml) on BMSC cultures at day 3 for 24h increased the progenitor cell proliferation, as determined by BrdU incorporation. Strikingly, BMSCs from male mice were more responsive to FGF9 than were BMSCs from female mice. There was a 209% ($p < 0.01$) increase in BrdU labeled male cells and a 76% ($p < 0.05$) increase in BrdU labeled female cells, when compared to sex matched, vehicle treated control cells. In a previous study, heterozygous loss of Akt1 was shown to be deleterious to OB precursor development, leading to lower bone mass in male (but not female) mice (Mukherjee A et al., PLoS One. 2014, 9: e93040). In the present study, we found that inhibition of Akt activity by adding an Akt inhibitor, MK-2206 ($1 \mu\text{M}$) completely prevented the stimulatory effect of FGF9 (5 ng/ml) on OB precursor proliferation *in vitro*. Our results demonstrate that mature OBs are a biologically important source of FGF9, positively regulating skeletal homeostasis in male mice. Osteoblast-derived FGF9 may serve a paracrine role to maintain the osteogenic progenitor cell population through activation of Akt signaling.

Ablation of a mitochondrial stress sensor, cyclophilinD, increases osteogenicity of MSCs and reduces bone degeneration. Roman Eliseev^{*}, Jerry Madukwe. University of Rochester, USA

The goal of this project was to elucidate the effect of genetic ablation of a mitochondrial stress sensor, cyclophilin D (CypD), in CypD knock-out (KO) mice on bone marrow mesenchymal stromal (a.k.a. stem) cells (MSC) and on bone degeneration. MSCs are precursors of osteoblasts, adipocytes and chondrocytes. Our data and the literature indicate that MSC osteogenic function is highly dependent on the ability of these cells to activate mitochondria and maintain high levels of oxidative metabolism. Under the conditions of oxidative stress observed in aging and upon loss of hormone stimulation, mitochondria become less functional leading to cell demise and whole tissue dysfunction. Opening of the mitochondrial permeability transition (MPT), a large non-selective pore gated by CypD, is the major mechanism of such a mitochondrial dysfunction. Our previous data indicated improved bone quality and biomechanical properties and preservation of oxidative metabolism in 13-month old CypD KO mice when compared to the age-matched wild type mice. We are now presenting our new data indicating that genetic ablation of CypD prevented aging-associated decline in MSC CFU's and increased their osteogenic potential while reducing MSC adipogenic potential. On a tissue level, in 13-month old CypD KO mice we observed reduced bone loss, absence of bone marrow fat, no change in osteoblast numbers but improved osteoblast function measured with bone formation rate, and higher osteocyte numbers when compared to the age-matched wild type mice. Overall, our data indicate that protecting and enhancing mitochondrial metabolism by targeting CypD/MPT and de-sensitizing mitochondria for stress, improves MSC osteogenic function and prevents adipogenic shift leading to reduced bone degeneration in aging.

Disclosures: Roman Eliseev, None.

Identification of a Subpopulation of Periosteal and Endosteal Prx1-Expressing Cells in Postnatal Long Bones and Their Contribution to Fracture Repair. Alessandra Esposito^{*1}, Ye Ping², Tieshi Li³, Joe Temple³, Anna Spagnoli³. ¹Rush University Medical School, USA, ²UNC of Chapel Hill, USA, ³Rush University Medical Center, USA

The regenerative ability of bones after fracture implies the existence of adult progenitors. However, the nature of these progenitors is still elusive. Although it is evident that the periosteum is critical to fracture repair, the cell population(s) that govern its regenerative ability are largely unknown. Furthermore, there is evidence that the endosteum contributes to the intramembranous callus by providing progenitor(s) derived from the bone marrow interfacing the bone. To identify potential adult skeletal progenitors, we used Prx1CreERGFPRosaLacZ mice in which Tamoxifen (TAM) induces Prx1Cre-driven recombination resulting in bGal expression. For early postnatal study, TAM was given at P3 and tibias obtained at P6, P9, P12, P19, P15, P18 and P21. We found that at P6 and P9, most of the Prx1-bGal cells localized in the endosteum. By P12, in addition to endosteum, Prx1-bGal cells were detected in the periosteum. By P15 and P21, Prx1-bGal cells were found in the periosteum, endosteum, within the cortical bones, growth plates and secondary ossification centers as osteoblasts, lining cells, and chondrocytes. In older mice (16-18 weeks) 4OHTAM was given for 5 days and mice sacrificed either 6 or 28 days later. At both chasing times, we found Prx1-bGal cells within the periosteum (mostly) and the endosteum. In the longer term chasing study, we also found Prx1-bGal cells within the cortical bones and growth plates. We next evaluated Prx1-bGal+ pattern in fracture repair using two timelines for TAM administration. Study 1 was aimed at labeling cells that express Prx1 during repair (4OHTAM 3 days before and 2 days after fracture), Study 2 at tracing cells that express Prx1 before fracture and their progenies (4OHTAM for 5 days starting 33 days before fracture). Mice were euthanized 7 days post-fracture. In both studies, we found a large number of Prx1-bGal cells within the periosteum and endosteum facing the fracture line. Differently from Study 1, Study 2 showed Prx1-bGal cells within the callus as bone and cartilaginous cells. At the periosteal and endosteal sites in unfractured as well as fractured mice, Prx1-bGal cells, were perivascular, surrounding PECAM+ and vWF+ endothelial cells, and co-expressed the pericyte markers aSMA and NG2. Our studies indicate that we have identified a population of periosteal and endosteal Prx1+ pericytes that seem to contribute to fracture repair. Studies are in progress to further characterize the nature of Prx1+ cells.

Large-scale Bone Regeneration by Cells Intermediate between Chondrocytes and Osteocytes. Gage Crump^{*}, Sandeep Paul, Simone Schindler, Sofia Bougioukli, Jay Lieberman, Francesca Mariani, University of Southern California, USA

The repair of extensive bone injuries remains a clinical challenge. While bone repair often involves a cartilage intermediate, the role of chondrocytes in this process has remained unclear. We have found that the adult lower jawbone of zebrafish can undergo extensive regeneration following resection, and that it does so through an unusual skeletal cell type with properties intermediate between chondrocytes and osteoblasts. During jawbone regeneration, these cells initially produce cartilage matrix while expressing genes associated with both chondrocyte and osteoblast development. Shortly thereafter, regenerating chondrocytes directly produce mineralized matrix and become embedded in mature bone. By analyzing adult viable *ihha* mutants, we find that *Ihh* signaling causes periosteal progenitors to shift from making osteoblasts during bone homeostasis to making chondrocyte-like cells during bone regeneration. Together, our studies highlight that jawbone regeneration utilizes a progenitor program distinct from endochondral development. Moreover, we observe a remarkably similar process during mouse rib bone regeneration, and we are testing if rib periosteal cells are able to heal critical sized bone defects in other parts of the mouse. We therefore propose periosteal-derived hybrid cartilage/bone cells as a novel therapeutic for critical sized bone defects in patients.

Mesenchymal Progenitors Promote Vasculogenesis to Initiate the Formation of Secondary Ossification Center in the Epiphyseal Cartilage. Wei Tong^{*1}, Motomi Enomoto-Iwamoto², Haoruo Jia³, Ling Qin³. ¹Perelman school of medicine, USA, ²Department of Surgery, The Children's Hospital of Philadelphia, USA, ³Department of Orthopaedic Surgery, University of Pennsylvania, USA

Endochondral ossification in long bones proceeds via the development of a diaphyseal primary ossification center (POC) in embryo and an epiphyseal secondary ossification center (SOC) after birth. While POC formation has been extensively studied, the initiation and expansion of SOC are largely uncharacterized. Tomato (Td)+ cells of Col2-Cre Rosa-Td mice were recently identified as mesenchymal

progenitors that constantly replenish osteoblasts and osteocytes in POC. At P4, while most epiphyseal chondrocytes were Td+, those located at cartilage surface had much higher Td signal than those inside cartilage and were termed Td^{high} cells. Since later all osteoblasts, osteocytes, and osterix+ osteoprogenitors within SOC were Td^{high}, those Td^{high} cells at cartilage surface are likely mesenchymal progenitors responsible for subchondral bone formation. At P5, using a whole mount staining with 3D image reconstruction (100 um thickness), we observed that Td^{high} cells started to penetrate into cartilage at discrete surface sites, followed by endothelial progenitor cells. At P6, cartilage canals were initiated at these sites. The canal wall, which consists of Td^{high} cells, endothelial progenitors, and chondrocytes, was again preceded by VEGF+ Td^{high} cells leading the front edge. Inside the canal, there was a cone-shaped and dense cell cluster, including Td^{high} cells, vessels, and CD45+ cells, with the base at the cartilage surface. Those Td^{high} cells were proliferative and they migrated either as perivascular cells or as single cells. Interestingly, there was a space about 30 um long between the canal wall and the cell cluster where only erythrocytes were detected. The canal wall was distinctly labeled by an antibody against the aggrecan-degraded product (VIPEN). The unique initiation and structure of cartilage canal strongly suggest that mesenchymal progenitors play a leading role in promoting vasculogenesis, a de novo vessel formation process, and together with chondrocytes creating a path for canal protrusion. In vitro, mesenchymal progenitors greatly stimulate migration and vessel assembly of endothelial progenitors. After P8, the expansion of SOC was led by blood vessel growth followed by Td^{high} progenitors, the same mechanism by which the growth plate is remodeled into bone. In summary, using a powerful 3D imaging approach, we discovered a novel crosstalk between mesenchymal progenitors and endothelial progenitors that initiates SOC formation.

Notch Signaling Mediates Skeletal Sex Differences. Stefano Zanotti^{*}, Ernesto Canalis, UConn Health, USA

Women attain a lower peak bone mass and are more prone to cancellous bone loss than men. Similarly, maturing female mice have less cancellous bone volume than male littermates. The skeletal disadvantage suffered by female rodents is explained by a decrease in osteoblastogenesis due to a suppressed capacity of progenitor cells to become osteoblasts. However, the mechanisms responsible for sex differences in skeletal microarchitecture and osteoblastic cell maturation are not known. Since Notch activation in immature osteoblasts suppresses their differentiation and decreases bone mass, we asked whether sensitization of female mice to the effects of Notch in osteoblast precursors mediates sex-dependent skeletal effects. To answer this question, we generated dual Notch1/Notch2 conditional null C57BL/6 mice in Osterix-expressing cells and compared them to Notch1/Notch2 conditional littermate controls of the same sex. Postnatal Notch1 and Notch2 inactivation in osteoblast precursors precluded the influence of sex on cancellous bone volume and microarchitecture, indicating that Notch receptors are responsible for sex differences in skeletal microarchitecture. To establish whether Notch mediates the impact of sex on osteoblastogenesis, bone marrow stromal cells from conditional Notch1/Notch2 mice were infected with an adenoviral vector where the cytomegalovirus (CMV) promoter governs Cre expression (Ad-CMV-Cre), or a control vector (Ad-CMV-GFP). Notch downregulation enhanced osteoblastogenesis in cells from female, but not from male, mice. Moreover, suppression of Notch activity in cells from wild-type mice confirmed these findings, indicating that Notch signaling mediates sex differences in osteoblastogenesis. To determine whether canonical Notch signaling, which requires the DNA-binding protein Rbpjk, is responsible for the sex differences, we assessed the capacity for osteoblastogenesis of bone marrow stromal cells from conditional Rbpjk mice. Rbpjk downregulation following infection with Ad-CMV-Cre did not change the influence of sex on osteoblast differentiation. These results suggest that Rbpjk-independent, or non-canonical, Notch signaling mediates sex differences in osteoblastogenesis. In conclusion, Notch1 and Notch2 determine skeletal sexual dimorphism, and the effect on osteoblastogenesis is mediated by non-canonical mechanisms.

A Novel Interferon Regulatory Factor-8 (IRF8) Mutation is Associated with Osteoclast-Mediated Idiopathic Tooth Root Resorption. Vivek Thumbigere Math^{*1}, Brian Foster², Anthony Neely³, Hiroaki Yoshii⁴, Keiko Ozato⁴, Martha Somerman². ¹National Institutes of Health, USA, ²National Institute of Arthritis & Musculoskeletal & Skin Diseases (NIAMS), USA, ³University of Detroit-Mercy School of Dentistry, USA, ⁴National Institute of Child Health & Human Development, USA

Multiple idiopathic root resorption is a form of periodontal disease often noted in middle age with unknown etiology. Previous case reports of familial pattern suggest a genetic susceptibility to the disease. Following IRB approval from the University of Detroit Mercy School of Dentistry and the National Institutes of Health (NIH), dental/medical histories, x-rays, saliva samples, and extracted teeth were collected from a kindred (3 affected and 3 unaffected members) exhibiting idiopathic root resorption. On examination, the proband and the affected son and daughter exhibited severe root resorption of multiple teeth, but no other significant medical history.

Micro-CT of exfoliated teeth revealed a unique pattern of severe cervical root resorption distinct from tooth decay. Whole exome sequencing performed using saliva identified SNPs in twenty-three candidate genes that co-segregated with the resorption phenotype, including a novel autosomal dominant missense mutation in IRF8. Primarily expressed in immune cells, IRF8 is a key regulator of inflammation and bone metabolism, and its repression mediates osteoclastogenesis by enhancing nuclear factor of activated T cells c1 (NFATc1) activity. The identified amino acid change (G388S) in IRF8 was localized to a highly conserved C-terminal motif, leading to altered serine phosphorylation motifs and phosphoserine binding domains, and is predicted to cause a large shift in 3D protein folding. These data suggest that the G388S mutation would impair IRF8 heterodimerization with other transcription factors including NFATc1, thereby producing overactive osteoclasts that target the periodontia. Consistent with these predictions, we noted *Irif8^{-/-}* mice, when compared to WT mice, exhibited increased osteoclast activity in the periodontia, widened periodontal ligament (PDL) space and alveolar bone loss. Following induction of periodontal inflammation, these findings were exacerbated including irregularities in tooth root surfaces. In conclusion, this study identifies a novel mutation associated with multiple idiopathic root resorption and results indicate that IRF8 is a key factor in maintaining periodontal tissue homeostasis.

Osteoclastic miR-214 targets PTEN to increase bone resorption. Jin Liu*¹, Defang Li², Baosheng Guo², Lei Dang², Aiping Lu², Ge Zhang^{2,1}, Hong kong, ²Institute for Advancing Translational Medicine in Bone & Joint Diseases, Hong Kong Baptist University, Hong kong

Introduction: Emerging evidences indicate the unique role of microRNAs in regulating bone resorption. Our preliminary study showed that elevated osteoclastic miR-214 associated with increased bone resorption in both postmenopausal osteoporosis and osteolytic bone metastasis, suggesting a potential role of osteoclastic miR-214 in regulating bone resorption. It was documented that miR-214 could target PTEN in cancer cells (Yang et al. 2008). Moreover, PTEN was shown to participate in regulating osteoclast function (DeMambro et al. 2012). Thus, we postulated that osteoclastic miR-214 could target PTEN to regulate bone resorption.

Objectives: To investigate whether osteoclastic miR-214 could target PTEN to regulate bone resorption.

Methods: We performed qPCR, TRAP staining, western blotting and luciferase reporter assays to determine the role of osteoclastic miR-214 during osteoclast differentiation *in vitro*. We applied qPCR, ELISA, western blotting, microCT and bone histomorphometric analysis to examine the role of osteoclastic miR-214 in regulating bone resorption in our established osteoclast-specific miR-214 knock-in (OC-miR-214) mice.

Results: In the *in vitro* study, we found that the miR-214 level gradually increased during osteoclast differentiation (Fig. 1). The mRNAs level of *TRAP* and *CTSK* and the area of TRAP+ cells could be suppressed by antagomiR-214 and promoted by agomiR-214 during osteoclast differentiation (Fig. 2). Moreover, a series of *in vitro* experiments showed that miR-214 could functionally target the 3'UTR of *PTEN* mRNA to promote osteoclast activity (Fig. 3). In the *in vivo* study, we found that the intrasosseous mRNA level of osteoclast marker genes and serum bone resorption biomarker were all higher in OC-miR-214 mice when compared to WT mice (Fig. 4 a, b). The intrasosseous PTEN protein level was lower in OC-miR-214 mice when compared to WT mice (Fig. 4c). Micro-CT imaging revealed poorly organized trabecular architecture at distal femur in OC-miR-214 mice when compared to WT mice (Fig. 4d). Bone histomorphometry analysis showed higher level of bone resorption-related parameters in OC-miR-214 mice when compared to WT mice (Fig. 4e). In addition, the above bone phenotype in OC-miR-214 mice could be markedly attenuated after treatment with antagomir-214 encapsulated by our established osteoclast-targeting delivery system (Liu et al. 2015) (Fig. 4f, g).

Conclusions: Osteoclastic miR-214 could target PTEN to increase bone resorption.

Ostm1 expression in mature osteoclasts is both necessary and sufficient to prevent osteopetrosis. Jean Vacher*¹, Monica Pata², Marie Solange Mutabaruka^{2,1} Institut De Recherches Cliniques De Montréal, Canada, ²IRCM, Canada

Autosomal recessive malignant osteopetrosis is an inherited bone disorder resulting from defective hematopoietic derived osteoclasts. We have characterized the *Ostm1* gene (*Ostm1*) responsible for the spontaneous recessive murine osteopetrotic *gl* mutation and functional rescue of hematopoietic defects in myeloid and lymphoid lineages including osteoclast, B and T cells, was attained in *gllgl*-PU.1-*Ostm1* BAC transgenic mice. Characterization of *gllgl* hematopoiesis showed that *gllgl* multipotent cells can differentiate into all lineages and that the osteoclast lineage is significantly stimulated. In contrast the mature *gllgl* osteoclasts are poorly functional and display cytoskeletal defects. To definitively establish the osteoclast autonomous role of *Osm1*, first we targeted *Ostm1* expression specifically to mature osteoclasts under the control of the CathepsinK (*Ctsk*) promoter in transgenic mice. Several transgenic lines with differential expression levels of the *Ctsk-Ostm1* transgene were established and *gllgl* *Ctsk-Ostm1* transgenic mice were generated. Phenotypic rescue of osteopetrosis in these progenies was demonstrated as dosage dependent and correlated with transgene expression levels. However, these *gllgl* transgenic mice did not thrive normally and died prematurely with a lifespan of 8-9 weeks due to neuronal degeneration. Second, we generated a conditional *Ostm1* floxed allele that reproduces the first *OSTM1* mutation we described resulting from *OSTM1* exon 5 skipping. The potential of the floxed allele to reproduce a complete *Ostm1* loss of function was validated with the ubiquitously expressed *Meox-Cre* deleter mice. *Ostm1^{lox/lox}* *Meox-Cre⁺* progenies compared to control littermates exhibited smaller size, severe osteopetrosis with major increase of bone mass and die ~3 weeks. This result demonstrates that the *Ostm1^{lox}* allele we generated can recapitulate, under systemic ablation, an osteopetrotic phenotype similar to the spontaneous *Ostm1* null mutation in *gllgl* mice. Specific mature osteoclast conditional ablation was induced using the CathepsinK-Cre deleter mouse. Ablation of *Ostm1* in *Ostm1^{lox/lox}* *Ctsk-Cre⁺* was concomitant with osteoclast maturation and reached ~100% efficiency in fully mature OCLs produced *ex vivo*. *In vivo*, loss of *Ostm1* in mature osteoclasts resulted in severe osteopetrosis with massive increased bone mass, inefficient bone resorption and early death ~3 weeks of age. All these features closely recapitulate the skeletal phenotypes that we characterized in the spontaneous osteopetrotic *Ostm1*-null *gllgl* mouse mutant. Together our studies demonstrate that the *Ostm1* expression in mature osteoclasts is necessary and sufficient to prevent osteopetrosis.

Conditional abrogation of *Atm* in osteoclasts leads to reduced bone mass in mice. Toru Hirozane*, Takahide Tohmonda, Masaki Yoda, Yoshiaki Toyama, Morio Matsumoto, Hideo Morioka, Keisuke Horiuchi, Masaya Nakamura. Keio University School of Medicine, Japan

Introduction Ataxia-telangiectasia mutated (ATM) plays a major role in response to DNA damage. We previously found that ATM is activated during osteoclastogenesis (Fig1); however, the potential function of ATM in bone metabolism is not well-understood.

To address this issue, we generated mutant mice in which ATM is specifically disrupted in osteoclasts (*Atm-Ctsk* mice).

Methods

Atm floxed mice were crossed with Cathepsin K-Cre recombinase transgenic mice to specifically inactivate ATM in osteoclasts. Bone morphometric analysis and μ CT analysis were done using the femur collected from 3-week-old and 9-week-old male *Atm-Ctsk* and their littermate control mice. In vitro osteoclast formation assay was performed using bone marrow cells harvested from 9-week-old male *Atm-Ctsk* and control mice. The number of multinucleated osteoclasts was enumerated and the pit formation assay was performed. The expression levels of osteoclast-related transcripts and proteins were evaluated by quantitative PCR and western blotting, respectively.

Results and Discussion

Bone morphometric analysis and μ CT analysis showed reduced cancellous bone mass in *Atm-Ctsk* mice compared to control mice (Fig2). However, there was no increase in the osteoclast number or resorption activity in *Atm-Ctsk* mice compared to control mice. Of note, we found that the expression of the osteoclast-derived coupling factors, including *Wnt10b* and *Bmp6*, was reduced in ATM-deficient osteoclasts compared to control cells, and that RANKL-induced NF κ B signaling was suppressed in ATM-deficient osteoclasts. These observations indicate that the decreased bone volume in *Atm-Ctsk* mice was in part derived from the defect in producing coupling factors that are involved in stimulating osteoblastic bone formation in osteoclasts lacking ATM.

Conclusion

Atm-Ctsk mice exhibited reduced bone mass possibly due to the defects in producing coupling factors that are involved in stimulating bone formation following bone resorption by osteoclasts.

Correlating RANK Ligand/RANK Binding Kinetics with Osteoclast Formation and Function. Julia Warren^{*1}, Steve Teitelbaum², Wei Zou², Nidhi Rohatgi², Corinne Decker², Christopher Nelson², Daved Fremont². ¹Washington University in St. Louis School of Medicine, ²Washington University in Saint Louis, USA

The interaction between Receptor Activator of NF- κ B Ligand (RANKL) and its receptor RANK is essential for the differentiation and bone resorbing capacity of the osteoclast. Osteoprotegerin (OPG), a soluble homodimer, acts as a decoy receptor for RANKL and thus inhibits osteoclastogenesis. An imbalance in the RANKL/RANK/OPG axis, with decreased OPG and/or increased RANKL, is associated with diseases that favor bone loss, including osteoporosis. Recently, we established a yeast surface display system and screened libraries of randomly mutated RANKL proteins to identify mutations that abolish binding to OPG while preserving recognition of RANK. These efforts yielded several RANKL variants possessing substantially higher affinity for RANK compared to their wild-type (WT) counterpart. Using recombinant RANKL mutant proteins, we find those with increased affinity for RANK produce more robust signaling in osteoclast lineage cells and have greater osteoclastogenic potential. Our results are the first to document gain of function RANKL mutations. They indicate that the physiological RANKL/RANK interaction is not optimized for maximal signaling and function, perhaps reflecting the need to maintain receptor specificity within the tumor necrosis factor superfamily (TNFSF). Instead, we find, a biphasic relationship exists between RANKL/RANK affinity and osteoclastogenic capacity. In our panel of RANKL variants, this relationship is driven entirely by manipulation of the kinetic off-rate. Our structure-based and yeast surface display-derived insights into manipulating this critical signaling axis may aid in the design of novel anti-resorptive therapies as well as provide a paradigm for design of other receptor-specific TNF superfamily ligand variants.

Sirtuin1 (Sirt1) activation suppresses osteoclastogenesis by deacetylating FoxOs. Ha-Neui Kim^{*1}, Li Han², Srividhya Iyer¹, Serra Ucer², Aaron Warren², Haibo Zhao², Rafael de Cabo³, Charles O'Brien², Stavros Manolagas², Maria Almeida². ¹Univ. Arkansas for Medical Sciences, Central Arkansas VA Healthcare System, USA, ²University of Arkansas for Medical Sciences & the Central Arkansas Veterans Healthcare System, USA, ³National Institute on Aging, USA

Activation of Sirt1 – an NAD⁺ dependent deacetylase – by natural or synthetic compounds like resveratrol, SRT2104, and SRT3025 attenuates the loss of bone mass caused by ovariectomy, aging, or unloading in mice. Conversely, Sirt1 deletion in osteoclast progenitors increases osteoclast number and bone resorption. Sirt1 deacetylates FoxO1, 3, and 4 and thereby modulates their activity; and FoxO1, 3, and 4 restrain osteoclastogenesis and bone resorption. Here, we tested the hypothesis that the anti-resorptive effects of Sirt1 activators require FoxO deacetylation. We report that FoxO1 acetylation was increased by knocking-down Sirt1 or adding RANKL to bone marrow macrophages (BMM) from C57BL/6J mice; this effect of RANKL was prevented by SRT3025. Further, transduction of a wild-type (WT) FoxO1 construct into BMM from mice lacking FoxO1,3,4 reversed the increased cyclinD1, macrophage proliferation, and osteoclastogenesis. In contrast, transduction of a FoxO1 mutant in which all six acetylation sites could not be de-acetylated (KQ-FoxO1), had no effect. In line with this result, SRT2104 or SRT3025 decreased cyclinD1 levels, proliferation, and osteoclast number in BMM from FoxO replete control mice. All the effects of the Sirt1 activators were absent in cells from littermate mice lacking FoxOs. Additionally, SRT3025 increased the expression of the FoxO-target genes catalase and heme oxygenase-1 in control BMMs, but this effect was greatly attenuated in cells lacking FoxOs. Furthermore, transfection of WT-FoxO1 into Raw264.7 macrophages increased the activity of a FoxO-luciferase reporter while KQ-FoxO1 had no effect, strengthening the evidence that deacetylation promotes FoxO-mediated transcription. Finally, SRT3025 decreased the protein levels of components of mitochondrial complex II (Sdhb), III (Uqcrc2), IV (Cox1) and V (Atp5a1), as well as ATP production in BMM from control mice, but not in BMM from mice lacking FoxOs, suggesting that the anti-osteoclastogenic effects of Sirt1 activation result from impaired mitochondria activity. These results, along with earlier findings that the osteoblastogenic effects of Sirt1 are also mediated by FoxOs, demonstrate that the dual anti-osteoporotic efficacy of Sirt1 stimulators (i.e. decreasing bone resorption and promoting bone formation) is indeed mediated via FoxO deacetylation.

Alternative NF- κ B Regulates RANKL-induced Osteoclast Differentiation and Mitochondrial Biogenesis via Independent Mechanisms. Rong Zeng*, Roberta Faccio, Deborah Novack, Washington University in St. Louis, USA

Mitochondrial biogenesis, the generation of new mitochondrial DNA and proteins, has been linked to OC differentiation and function. In this study we used mutations in key alternative NF- κ B pathway proteins, RelB and NIK, to dissect the complex relationship between mitochondrial biogenesis and osteoclastogenesis. In precursors lacking either NIK or RelB, RANKL is unable to increase mitochondrial DNA or expression of proteins in the oxidative phosphorylation chain, associated with lower oxygen consumption rates. Transgenic OC precursors expressing constitutively active NIK showed normal RANKL-induced mitochondrial biogenesis compared to controls, but had larger mitochondrial dimensions and increased oxygen consumption rates, suggesting increased mitochondrial function in the mutant cells. To deduce the mechanism for mitochondrial biogenesis defects in NIK- and RelB-deficient precursors, we examined expression of several genes known to control this process. PGC-1 β , but not PGC-1 α , PPRC1 or ERR α , were significantly decreased in RelB-/- and NIK-/- cells. Because PGC-1 β has been reported to positively regulate both mitochondrial biogenesis and differentiation in OCs, we retrovirally overexpressed PGC-1 β in RelB-/- cells. Surprisingly, exogenous PGC-1 β did not affect differentiation, nor restore RANKL-induced mitochondrial biogenesis. Thus, while downstream of RelB, PGC-1 β is not the key mediator of RANKL-induced mitochondrial biogenesis in OCs. To determine whether the blockade in osteoclastogenesis in RelB-deficient cells precludes mitochondrial biogenesis, we rescued RelB-/- differentiation with overexpression of NFATc1. Mitochondrial parameters were unaffected by retrovirus-driven NFATc1 in either WT or RelB-/- cultures, and bone resorption in the latter was not restored. Our data demonstrate that alternative NF- κ B regulates mitochondrial biogenesis in response to RANKL stimulation in OC precursors, but this process is independent of NFATc1. Furthermore, the inability of PGC-1 β to drive mitochondrial biogenesis in the absence of RelB indicates that there is cell type-specificity in the regulation of mitochondria.

Function of novel splicing variant of receptor activator of NF- κ B. Riko Kitazawa*¹, Ryuma Haraguchi², Yosuke Mizuno³, Yasuhiro Kobayashi⁴, Sohei Kitazawa². ¹Department of Diagnostic Pathology, Ehime University, Japan, ²Department of Molecular Pathology, Ehime University Graduate School of Medicine, Japan, ³Department of Diagnostic Pathology, Ehime University Hospital, Japan, ⁴Institute of Oral Science, Matsumoto Dental University, Japan

Receptor activator of NF- κ B (RANK) is a member of the tumor necrosis factor receptor (TNFR) family expressed in osteoclast precursors, and RANK-RANK ligand (RANKL) signaling is a key system for differentiation, activation and survival of osteoclasts. We have identified a novel alternative splicing variant of mouse and human RANK gene (vRANK) that contains an intervening exon between exons 1 and 2 of full-length RANK (fRANK) mRNA. Since this novel exon contains a stop codon, vRANK encodes short truncated amino acids that have a portion of the signal peptide of fRANK and additional amino acids that show no homology to previously reported domains. By transient transfection of RAW264.7 cells with vRANK-GFP and -Flag expressing constructs, vRANK was found localized mostly in the cytoplasm and partly in the cell membrane, but was not secreted into the culture supernatant. In the HL60 human myelomonocytic leukemic cell line, vRANK expression was induced by PMA or TGF- β in the presence of Vitamin D3 in an ERK-dependent manner. The presence of Sam68 binding sites located around intervening exon-intron junctions also signifies the importance of the ERK pathway in vRANK expression. When overexpressed *in vitro*, vRANK in mouse pre-osteoclastic RAW264.7 cells decreased the formation of TRACP-positive multinucleated giant cells and negated the anti-apoptotic effect of sRANKL. When systemically overexpressed *in vivo*, the CAGCre+/vRANK mouse showed high fatality before weaning; a 13-week survivor displayed severe cardiac dilatation with cardiomyopathy and bronchopneumonia. When selectively overexpressed among the RANK-positive monocyte-macrophage lineage *in vivo*, the RANKCre+/vRANK mouse displayed reduced bone mass with almost normal osteoclastic activity. Taken together, these results suggest that vRANK is a novel bioactive peptide that not only reduces the number of RANKL-induced mature osteoclasts, but also exhibits profound systemic cytopathic effects. We are now creating CTSKCre+/vRANK mice to analyze the effects of vRANK on mature osteoclasts.

Loss of PARP1 Poly-ADP-ribosylating Function is Necessary for Osteoclast Differentiation. Chao Qu*¹, Chun Wang¹, Gaurav Swarnkar¹, Jacqueline Kading¹, Michael Hottiger², Yousef Abu-Amer¹, Roberto Civitelli¹, Gabriel Mbalaviele³. ¹Washington University School of Medicine, USA, ²University of Zurich, Switzerland, ³Washington University in St. Louis School of Medicine, USA

Poly(ADP-ribose) polymerase 1 (PARP1) catalyzes the formation of poly-ADP-ribose (PAR) polymers by transferring several ADP-ribose units from nicotinamide adenine dinucleotide (NAD⁺) onto acceptor proteins, a post-translational modification termed PARylation. Emerging evidence implicates PARP1 in cell differentiation, but its role in bone metabolism remains unknown. We find that M-CSF induces massive PARylation of proteins, including PARP1, in mouse bone marrow macrophages (BMM), an effect that is PARP1-dependent as silencing or selective inhibition of this enzyme decreases protein PARylation by >95%. Our other *in vitro* findings indicating that retroviral-mediated PARP1 overexpression inversely correlates with the survival of BMM suggest that attachment of PAR units to PARP1 in response to M-CSF may be a survival signal that restrains the action of this enzyme in the osteoclast (OC) lineage. Consistent with this view, and the overall prediction that PARP1 negatively regulates OC formation, we find that PARP1 protein abundance is completely suppressed in BMM cultures after 3-day exposure to RANKL, via increased protein degradation without interference with mRNA expression. Mechanistically, we established a sequence of biological events during RANKL-driven osteoclastogenesis whereby PARP1 is highly PARylated in BMM, cleaved in OC lineage-committed BMM by caspase-1, a component of the intracellular NLRP3 inflammasome complex, and finally degraded in late OC precursors, thus enabling OC maturation. Notably, genetic or pharmacological blockade of the inflammasome, not only preserve PARP1 protein abundance, but also inhibits OC formation induced by M-CSF and RANKL, strengthening the notion that PARP1 negatively affects OC differentiation. Consistent with these results, knock-in mice (2-week-old and 8-week-old) globally expressing an uncleavable PARP1 mutant (gain-of-function) consistently exhibit 30-40% higher bone mass compared to wild-type littermates, owing to decreased OC differentiation and bone resorption, while bone formation is unaffected. Conversely, in states of pronounced PARP1 degradation and reduced PARylation responses such as those associated with inflammasome hyperactivation, OC development is accelerated. These results indicate that protein PARylation is one of the mechanisms through which PARP1 inhibits OC differentiation, and reveal an important role of this post-translational modification in modulating bone resorption and homeostasis.

Lineage Tracing of Cathepsin-K in Bone and Other Tissues. Farzin Takyar*¹, Ryan Berry², Lynda Bonewald³, John J Wysolmerski⁴, Mark C Horowitz². ¹Yale University, School of Medicine, USA, ²Department of Orthopaedics & Rehabilitation, Yale School of Medicine, USA, ³School of Dentistry, University of Missouri-Kansas City, USA, ⁴Section of Endocrinology & Metabolism, Yale School of Medicine, USA

The cathepsin K inhibitor, Odanacatib, has been shown to increase periosteal bone formation through unknown mechanisms. Using *CatKCre;R26R* mice we recently showed that some periosteal cells express CatK. To determine the origin of these cells, we performed lineage tracing using fluorescent *mTmG* reporter mice bred to *CatKCre* mice. The *mTmG* model is useful for lineage tracing because expression of Cre-recombinase in progenitor cells results in the permanent expression of eGFP in both progenitor and daughter cells. 10 day-old *CatK-Cre;mTmG* mice show eGFP (CatK expression) within osteoclasts at the primary spongiosum and along the endosteal surface of the cortex. We also observed scattered CatK expression within the periosteum. In 6-wk-old mice, an almost continuous layer of periosteal cells at the bone surface express CatK with scattered eGFP+ osteoclasts along the endosteum and trabeculae. Chondrocytes and bone marrow (BM) cells are CatK-negative at either age. There is also a prominent eGFP+ population of cells with a stellate appearance in the skin and smaller numbers of cells in skeletal muscle, the medulla of the kidney and in some fat depots. In order to identify if eGFP+ periosteal cells arise from hematopoietic stem cells in the BM, *mTmG* mice were lethally irradiated and reconstituted with BM from *CatK-Cre;mTmG* mice. eGFP+ osteoclasts were readily detected in the BM of reconstituted mice but no GFP+ cells were present along the periosteum, showing that CatK+ BM-derived cells do not home to the periosteal surface. Isolation of periosteal cells followed by flow cytometry characterized GFP+ cells as predominantly negative (75.7%) for the common leukocyte marker, CD45. A minor population of GFP+ cells (14.3%) was positive for CD11b (which is a monocyte/macrophage marker), while just over half of the GFP+ cells (53.3%) were Ly6C+, a monocyte marker. These findings indicate that periosteal catK+ cells are not likely to be derived from the bone marrow macrophage/osteoclast lineage. Finally, ovariectomy of 10-week-old *CatK-Cre;mTmG* mice did not change the numbers or distribution of GFP+ cells on the periosteum suggesting that these cells are not affected by estrogen withdrawal. Furthermore, neither unloading nor loading altered CatK expression in periosteal cells. In summary, our data suggest that the periosteum contains a resident population of CatK+ cells that may be a target of Odanacatib's periosteal effects.

STAT5 is a key transcription factor for IL-3-mediated inhibition of RANKL-induced osteoclastogenesis. Semun Seong^{*1}, Jongwon Lee², Jung Ha Kim², Kabsun Kim², Inyoung Kim², Lothar Hennighausen³, Nacksung Kim². ¹Chonnam National University Medical School, South Korea, ²Department of Pharmacology, Medical Research Center for Gene Regulation, Chonnam National University Medical School, South Korea, ³Laboratory of Genetics & Physiology, National Institute of Diabetes & Digestive & Kidney Diseases, National Institutes of Health, USA

Among diverse cytokines involved in osteoclast differentiation, IL-3 has been known to inhibit RANKL-induced osteoclastogenesis. However, the mechanism underlying IL-3-mediated inhibition of osteoclast differentiation has not fully understood. In the present study, we demonstrated that STAT5 activated by IL-3 inhibited RANKL-induced osteoclastogenesis through induction of Id genes. Over-expression of STAT5 inhibited RANKL-induced osteoclastogenesis. However, RANKL regulated neither STAT5 expression nor activation during osteoclast differentiation. STAT5 deficiency prevented IL-3-mediated inhibition of osteoclastogenesis, suggesting that STAT5 plays an important role in IL-3-mediated inhibition of osteoclast differentiation. In addition, IL-3-induced STAT5 activation upregulated expression of Id1 and Id2 genes, negative regulators of osteoclastogenesis. Over-expression of ID1 or ID2 in STAT5-deficient cells reversed osteoclast development recovered from IL-3-mediated inhibition. Moreover, micro-computed tomography and histomorphometric analysis revealed that STAT5 conditional knockout mice had reduced bone mass with increased number of osteoclasts. Furthermore, STAT5 conditional knockout mice showed that IL-3 less effectively inhibited RANKL-induced osteoclast differentiation than wild-type mice in RANKL injection model. Taken together, our data suggest that STAT5 activation is a key transcription factor for IL-3-mediated inhibition of RANKL-induced osteoclastogenesis through Id gene expression.

Analysis of an in Vitro Reconstitution System of Bone Cell Network by Two-Photon Microscopy. Atsuhiko Hikita^{*1}, Tadahiro Iimura², Yusuke Oshima², Shin Yamamoto², Takeshi Imamura². ¹Graduate School of Medicine, The University of Tokyo, Japan, ²Ehime University, Japan

[Purpose] To establish a system to reconstitute cellular network of osteoblasts, osteoclasts and osteocyte with matrices synthesized by osteoblast lineage cells, and to capture cellular events in bone metabolism. [Methods] Calvarial osteoblasts were harvested from newborn C57BL/6J mice and cultured under osteoblast differentiation condition for 4 weeks. Bone marrow macrophages from Ctsk-Cre x flox-tdTomato mice were co-cultured with differentiated osteoblasts for 3 weeks under co-culture condition, followed by a culture again in osteoblast differentiation condition. During the culture period, cells were observed using a multiphoton confocal microscopy system (A1R+MP, Nikon). Collagen fibers of matrices were also detected by second harmonic generation without labeling. Acquired images were processed and analyzed by NIS-Elements (Nikon) and IMARIS (Bitplane AG). [Results] Inside the nodule formed in osteoblast differentiation culture, cells with many processes were observed. By immunofluorescence staining, expression of DMP-1 and sclerostin was detected, which suggested these cells were osteocytes. During the osteoblast differentiation culture, increase of matrices and appearance of osteocytes were observed. Osteoblasts on the nodule changed their shape from cuboidal to flat, which was quantitatively demonstrated by image analysis. When bone marrow macrophages were co-cultured in this system, most of osteoclasts were formed on the nodule, suggesting the presence of supporting cells for osteoclasts in the nodule. Increase of osteoclasts and progression of matrix destruction were observed during the co-culture condition. Flat osteoblasts were found in the resorption pits formed by osteoclasts. When culture medium was changed again to osteoblast differentiation condition, flat osteoblasts became cuboidal, and newly synthesized matrices filled the resorption pits almost completely, which suggest the coupling of matrix resorption and formation occurred in this system. [Conclusion] A novel reconstitution system of bone cell network was established. By analyzing this system using two-photon microscopy, cellular events in bone modeling and remodeling such as coupling of matrix resorption and formation were observed.

Characterization of a New Cre Model Targeting Osteocytes. Delphine Maurel^{*1}, Mark L Johnson², Stephen E Harris³, Marie A Harris³, Lynda F Bonewald². ¹Department of Oral & Craniofacial Sciences, USA, ²Oral & Craniofacial Sciences, USA, ³UT Health Science Center at San Antonio, USA

Transgenic mice are widely used to delete or overexpress genes in a cell specific manner to advance bone biology. While numerous Cre models exist to target gene recombination in osteoblasts and osteoclasts, there are few that target osteocytes. Our goal was to create a spatial and temporal conditional Cre model using tamoxifen to induce Cre expression in osteocytes using the Sost Bac construct containing the 5' and 3' regions of the Sost gene (Sost ERT2 cre).

Using RP24-178J4 BAC (157Kb) with the Sost gene, recombineering was used to replace the ATG region with the CreERT2 cassette, and the frt-neo-frt cassette was then removed with l-arabinose inducible flip recombinase. Four founder lines were created by pronuclear injection of the SostBAC-CreERT2 construct. The founder lines were crossed with the td tomato reporter mice (AI9, Jackson Laboratory). CreERT2 + and CreERT2 - male and female mice were injected at 2 or 5 mo of age with tamoxifen diluted in corn oil (53 to 555mg/kg, divided in 5-6 injections in consecutive days) or vehicle (corn oil). Tail vertebrae were taken at baseline before tamoxifen injection and the mice were sacrificed 1 month later. Bones and organs (28 total) were fixed and cryosectioned (10um) in order to image and quantitate the red signal using fluorescent microscopy and to identify any off target effects.

Out of the four founder lines, only one showed specific and strong signal in osteocytes (See figure below). No signal was observed in any surface bone cell, nor in bone marrow or in muscle. While no expression was observed in the 2 day old pup, by 2 months of age some osteocytes were positive, and the osteocyte expression became more 'leaky' with age. The percentage of positive osteocytes was increased following tamoxifen injection, especially in males (40-90% positive cells versus 20-37% in females). No expression was observed in any other organ, however with tamoxifen injection, a few positive cells were observed in kidney, eye, lung, heart and brain. Many of the positive cells were associated with blood vessels, but very few blood vessels contained these positive cells. All the other organs analyzed were negative (28 organs in total).

To conclude, this model is a useful tool to delete targeted genes in osteocytes as well as to image potential changes in the osteocyte network under various conditions.

Gene Expression and Local in vivo Environment (LivE) Imaging of Osteocyte Subpopulations in trabecular mouse bone. Andreas Truesse^{*1}, Felicitas Flohr², Gisela Kuhn², Ralph Müller². ¹ETH Zurich, Institute for Biomechanics, Switzerland, ²ETH Zurich, Institute for Biomechanics, Switzerland

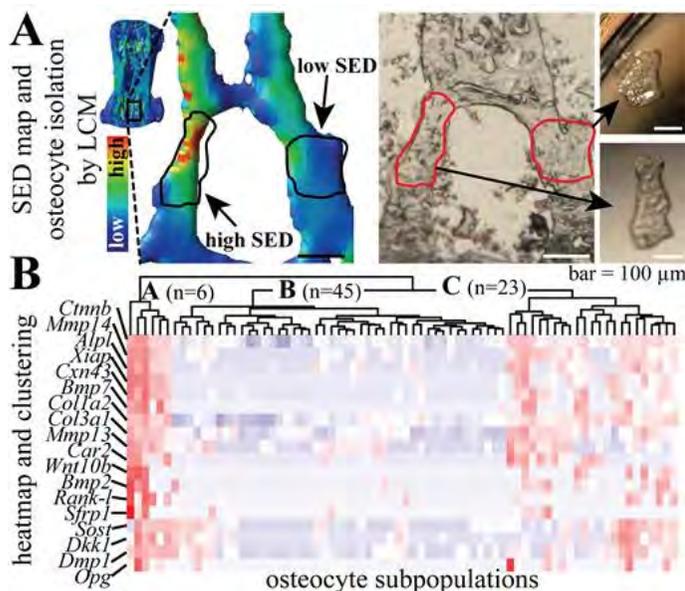

Bone constantly remodels itself to adapt to changes in its physiological environment. Osteocytes (Ot) are thought to coordinate this remodeling process with cellular signals that result in increased or decreased bone formation or resorption activity on nearby marrow-bone interfaces. To investigate these signaling events, we have developed a local in vivo environment (LivE) imaging technique based on in vivo micro-computed tomography (microCT) imaging and micro finite element (microFE) analysis in combination with laser capture microdissection (LCM) and high throughput gene expression assays. LivE imaging allows us to quantify the mechanical and remodeling microenvironment of hundreds of individual Ots over several weeks. Here, we used LivE imaging in trabecular mouse bone to show that the Ot's microenvironment is locally linked to its gene expression pattern.

To do so, the 6th caudal vertebrae of adult female C57BL/6 mice (n=9) were imaged 2 weeks prior and again 24h prior to sacrifice by in vivo microCT. 3D dynamic morphometric parameters were assessed and local strain energy density (SED) was simulated by microFE analysis. Cryosections were cut and registered into 3D microCT data. In these cryosections, Ots were identified, mapped into the microCT coordinate system and grouped according to their local SED values (high or low) and according to the past remodeling activity on the nearby marrow-bone interface

(forming, quiescent or resorbing). By LCM, Ots ($n = 689$) were then isolated in subpopulations ($n = 74$, figure A) containing nine Ots on average and their gene expression was analyzed using a microfluidic platform. Ot subpopulations were clustered according to their expression patterns (consisting of 18 individual gene expression levels) using unsupervised hierarchical clustering.

Three cluster (A, B, C) were distinguished (figure B), Ots from cluster A had a 3.3x increased chance to be found in the resorbing group and Ots from cluster C had a 1.8x higher chance to be found in the high SED group. Furthermore, Live imaging showed that Ots of the resorbing group blocked bone formation activities by Sfrp1, a WNT antagonist and increased perilacunar matrix resorption by MMPs (Mmp13, Mmp14). Ots in areas of high SED increased WNT signaling related gene expression (β -catenin and connexin43) to enhance bone formation. Additionally, genes involved in perilacunar matrix remodeling (Alpl, Colla2, Dmp1, Mmp14) were upregulated, indicating active remodeling of Ot's perilacunar matrix. Finally, the expression levels of bone morphogenic growth factors (Bmp2, Bmp8) were increased in these Ots, thus indicating an anabolic effect within the high SED group.

In conclusion, Live imaging helps to understand how Ots contribute to the dynamic remodeling of trabecular bone on the molecular level.

A) Osteocyte isolation from high & low SED. B) Gene expression heatmap & hierarchical clustering.

Reduction in microRNA21 promotes apoptosis and increases RANKL in osteoblastic cells and with aging. Hannah Davis^{*1}, Emily Atkinson¹, Julia Harris¹, Rafael Pacheco-Costa², Arancha Gortazar³, Mircea Ivan¹, Angela Bruzzaniti⁴, Teresita Bellido¹, Lillian Plotkin¹. ¹Indiana University School of Medicine, USA, ²Federal University of Sao Paulo School of Medicine, Brazil, ³San Pablo-CEU University School of Medicine, Spain, ⁴Indiana University School of Dentistry, USA

Mice lacking connexin (Cx) 43 in osteocytes exhibit apoptotic osteocytes preferentially located near endocortical bone surfaces containing osteoclasts. However, the mechanism by which osteocytes lacking Cx43 undergo apoptosis and the potential consequences for osteoclast development are unknown. Silencing Cx43 in MLO-Y4 osteocytic cells increased cell death about 3-fold, which was abolished by the caspase3 inhibitor DEVD demonstrating death by apoptosis. Apoptosis of Cx43-deficient osteocytes was accompanied by reduced levels of the microRNA (miR) 21, which promotes survival in various cell types but of unknown function in osteoblastic cells. Similar to silencing Cx43, reduction of miR21 expression by transfecting a specific oligonucleotide inhibitor induced apoptosis of control osteocytes. Conversely, transfection of an oligonucleotide miR21-mimic reversed the increased apoptosis of Cx43-deficient osteocytes. These results demonstrate that reduction of miR21 is sufficient to increase osteocyte apoptosis and that apoptosis of Cx43-deficient osteocytes is due to reduced miR21 expression. Earlier evidence showed that Cx43-deficient osteocytes express increased RANKL and decreased OPG levels in vivo and in vitro. We now found that soluble (s) RANKL was increased 4-fold in conditioned media (CM) from Cx43-deficient osteocytes compared to control osteocytes. In addition, 12-fold more osteoclasts were induced by CM from Cx43-deficient osteocytes compared to control osteocytes, under suboptimal concentrations of sRANKL (40ng/ml) and MCSF (10ng/ml). Moreover, 5-fold more osteoclasts developed from non-adherent bone marrow precursors co-cultured with Cx43-deficient osteocytes compared to control osteocytes. Further, inhibition of apoptosis with DEVD prevented the increase in RANKL, but not the decrease in OPG

expression in Cx43-deficient osteocytes. Similar to Cx43-deficient mice, old mice exhibit increased osteocyte apoptosis and elevated endocortical bone resorption. Consistent with these similarities, bones from 24-month-old C57BL/6 mice exhibit reduced expression of both Cx43 and miR21 compared to 4-month-old mice. We conclude that miR21 lies downstream of Cx43 in the control of osteocyte apoptosis; and that the increased osteoclastogenic potential of Cx43-deficient osteocytes is a consequence of osteocyte apoptosis. Our findings reveal a novel Cx43/miR21/RANKL pathway in osteocytes that could be targeted to treat bone fragility with aging.

Bone microarchitecture anomalies and vascular expression of osteocytes markers in low serum parathormone CKD rats with vascular calcification.

Sarah-Kim Bisson¹, Roth-Visal Roth², Sylvain Picard², Richard Larivière², Mohsen Agharazi², Fabrice Mac-Way^{*3}. ¹CHU de Québec Research Center, l'Hôtel-Dieu de Québec Hospital, Laval University, Quebec, CANADA, Canada, ²CHU de Québec Research Center, l'Hôtel-Dieu de Québec Hospital, Division of Nephrology, Department of Medicine, Laval University, Quebec, CANADA, Canada, ³CHU de Québec Research Center, l'Hôtel-Dieu de Québec Hospital, Division of Nephrology, Faculty & Department of Medicine, Laval University, Quebec, CANADA, Canada

INTRODUCTION: The mechanisms underlying bone and vessels anomalies are poorly understood in chronic kidney disease (CKD). Vascular calcification is a tightly regulated process involving the transdifferentiation of vascular smooth muscle cells into "osteoblasts-like" cells. The aim of this study is to determine the anomalies of bone microarchitecture in CKD rats with vascular calcification and to evaluate whether if calcified vessels express osteocytes markers.

METHODS: CKD, low serum parathormone (PTH) level and vascular calcification in Wistar rats were induced by 5/6 nephrectomy and high calcium, phosphate and vitamin D (Ca/P/VitD) supplementation. These rats were compared to CKD and normal rats fed with a normal diet. Tibia bones and thoracic aortas were harvested 4-6 weeks after CKD induction. The markers of vascular remodeling and osteoblastic differentiation (RunX2, BMP-2, α -SMA and osteocalcin) were analyzed by qPCR and immunofluorescence on thoracic aortas. The expression of osteocytes markers (sclerostin, DMP-1, DKK-1) was performed on the thoracic aortas by immunofluorescence and western-blot. Serum levels of sclerostin were also determined. Cortical and trabecular bone microarchitecture assessment were performed by Micro-Ct and histomorphometry analysis.

RESULTS: CKD rats given a Ca/P/Vit D supplementation developed vascular calcification and induced low serum PTH level as compared to control and CKD rats fed a normal diet. In the thoracic aortas, markers of osteoblastic differentiation (RunX2, BMP-2, osteocalcin) were increased only in CKD rats with vascular calcification while α -SMA was significantly reduced. Sclerostin, DMP-1 and DKK-1 were all highly expressed in areas of calcification from thoracic aortas (Figure 1). Furthermore, serum levels of sclerostin were increased only in rats with vascular calcification. Cortical bone mineral content and thickness were significantly decreased in CKD rats with vascular calcification as compared to control while trabecular thickness, osteoid volume and surface were dramatically increased (Table 1).

CONCLUSIONS: In this CKD model of vascular calcification and low serum PTH levels, there is increased expression of osteocytes markers in calcified vessels. Furthermore, cortical and trabecular bone compartments are differently affected. These results emphasize the central role of bone metabolism and osteocytes in the development of vascular calcification in CKD.

EphrinB2 acts differently in osteoblasts and osteocytes to control bone strength and matrix composition. [Christina Vrahnas](#)¹, [Ingrid Poulton](#)², [Huynh Nguyen](#)³, [Mark Forwood](#)³, [Keith Bamberg](#)⁴, [Mark Tobin](#)⁴, [T John Martin](#)², [Natalie A Sims](#)². ¹St. Vincent's Institute, Australia, ²St. Vincent's Institute of Medical Research, Australia, ³Griffith University, Australia, ⁴Australian Synchrotron, Australia

Deletion of ephrinB2, a receptor tyrosine kinase stimulated by parathyroid hormone, in osteoblasts and osteocytes (*OsxCre.EfnB2^{fl/fl}*) delayed bone mineralization, resulting in osteoid-rich compliant bones that broke at a lower force in 3-point

bending tests. Deletion of ephrinB2 in osteocytes (*Dmp1Cre.EfnB2^{fl/fl}*) also resulted in bones that broke at a lower force, however they were more brittle with a 30% reduction in toughness, energy absorbed at failure and a 40% reduction in ultimate strength. Their phenotype was not associated with a change in cortical tissue mineral density or bone formation rate. To determine the cause of altered strength in these two mouse models, we have used synchrotron-based Fourier-Transform Infrared Microscopy (sFTIRM) to assess cortical bone composition.

Tibial sections from 12 week old female *Dmp1Cre.EfnB2^{fl/fl}*, *OsxCre.EfnB2^{fl/fl}* mice and littermate *Cre+* controls (*w/w*) (n = 13/ group) were analyzed 1.5mm below the growth plate starting at the periosteal edge of the lateral cortex, in three 15µm² regions, concluding in the more mature bone.

While cortical composition was unchanged in *OsxCre.EfnB2^{fl/fl}* bones, sFTIRM revealed that the *Dmp1Cre.EfnB2^{fl/fl}* bones had a 12% higher mineral:matrix (p<0.05) and 37% higher carbonate:mineral (p<0.05) ratio than *w/w* controls, even in newly formed bone at the periosteal edge. This suggests that the brittleness relates to altered primary mineralization, and not prolonged secondary mineralization. *Dmp1Cre.EfnB2^{fl/fl}* bones also had altered collagen orientation (13% lower amide I:amide II, p<0.001) that may underlie their high mineral content. Regression analysis with 3-point bending data showed that while the energy absorbed to failure correlated with amide content of *w/w* bones (r² = 0.40, p<0.05), this relationship failed in *Dmp1Cre.EfnB2^{fl/fl}* mice. Instead, ultimate strength of *Dmp1Cre.EfnB2^{fl/fl}* bones was determined by the carbonate:mineral ratio (r² = 0.50, p<0.05); an abnormal relationship that was not upheld in *w/w* controls.

While ephrinB2 deletion in the entire osteoblast lineage delayed bone mineralization but retained normal cortical composition, its absence in osteocytes promoted carbonate deposition within the bone matrix, leading to increased brittleness. These data highlight two stage-specific roles of ephrinB2 during osteoblast/osteocyte differentiation: in osteoblasts ephrinB2 promotes osteoid maturation while in osteocytes ephrinB2 limits the carbonate content of the matrix.

Disclosures: Christina Vrahnas, None.

FGF9 Potently Induces Dmp1 Expression and Early Osteocyte Markers in a Cell Model of Osteocyte Differentiation. [Lora McCormick](#)^{*}, [Kun Wang](#), [LeAnn Tiede-Lewis](#), [Hong Zhao](#), [Yixia Xie](#), [Lynda Bonewald](#), [Dallas Sarah](#). University of Missouri-Kansas City, USA

In humans and in rodent models aging is associated with a dramatic loss in osteocyte connectivity and dendricity, which has features in common with age-related neurodegeneration. We therefore hypothesized that the molecular mechanisms controlling osteocyte dendrite formation, maintenance and dendrite degeneration may overlap with mechanisms regulating neurogenesis/neurite formation and neurodegeneration. To investigate this a recently generated cell line, OmGFP66, was used, which expresses a membrane-targeted GFP driven by the *Dmp1* promoter. When differentiated over a 21 day timecourse this cell line expresses early then late osteocyte markers. It also forms "mini-bone" structures with a highly organized bone-like appearance and dendritic GFP-positive osteocytes embedded in clearly defined lacunae. Using a neurotrophin/receptor targeted qPCR array, OmGFP66 cells were shown to robustly express 33 genes related to neurogenesis/neurite formation, 17 of which were enriched in "mini-bone" structures compared to the undifferentiated cell monolayer. FGF9, which plays key roles in glial cell development/repair, neuronal cell differentiation/survival, sex determination and chondrogenesis, was enriched 18 fold in "mini-bone" structures compared to the cell monolayer in day 15 cultures. qPCR showed that FGF9 expression in OmGFP66 cells and IDG-SW3 cells, another model of osteocyte differentiation, increased over a 28 day timecourse by 33 and 94 fold, respectively, with FGF9 highly enriched in OmGFP66 "mini-bones" compared to the cell monolayer at every time point. Treatment with recombinant FGF9 potently induced *Dmp1*-GFP expression in early undifferentiated or late differentiated OmGFP66 cells and also in IDG-SW3 cells. qPCR analysis confirmed a 12 fold upregulation of *Dmp1* expression with FGF9 treatment and a 2 fold upregulation of PHEX in early differentiating OmGFP66 cells. Alkaline phosphatase was down-regulated. Live cell imaging showed a rapid induction of *Dmp1*-GFP after only 3 hrs of FGF9 treatment in OmGFP66 cells, that the FGF9-induced cells were highly polymorphic and that in differentiated cultures the induced cells were localized around the "mini-bones". Live cell imaging also suggested that FGF9 stimulated extension and retraction of dendrites in embedded osteocytes. These data identify the glial cell differentiation factor FGF9 as a potent inducer of *Dmp1* expression that may play a role in initiating the transition from osteoblast to osteocyte.

To measure or not to measure? Vitamin D and parathyroid hormone in patients with clinical risk factors for osteoporosis. [Oliver Bock](#)^{*}¹, [Silke Nicklisch](#)¹, [Christiane Weinberg](#)², [Ute Dostmann](#)¹. ¹Promedio - Integrated Medicine, Germany, ²German Osteoporosis Screening Center, Germany

Background: Vitamin D deficiency is associated with higher incidence of falls and fractures and plays a role in the pathophysiology of many chronic diseases. Despite the large amount of studies published on vitamin D, the threshold for a sufficient serum 25(OH)D concentration remains subject to a considerable debate. There has also been no clear consensus on the assessment and treatment of vitamin D deficiency.

Objective: To examine the prevalence of vitamin D deficiency or insufficiency and its impact on calcium/phosphate homeostasis as well as on bone turnover in a major German cohort of individuals with defined clinical risk factors (CRF) for osteoporosis and fractures (acc. to German DVO Guideline 2009, and QFracture Score 2013).

Results: In 2014 we examined a total of 7,253 patients (mean age = 62.6 yrs (SD 13.9); women 64.4%, men 35.6%) with CRF for osteoporosis and fractures. The prevalence of 25(OH)D serum levels <75 nmol/l was 87.7%. 25(OH)D serum levels below 50 nmol/l (deficiency) and 25 nmol/l (severe deficiency) have been detected in 55.0% and 15.7% of patients, respectively. Elevated PTH levels (>65 ng/l) have been found in 20.9% of 5,119 samples tested - with an inverse correlation to 25(OH)D serum levels (p<0.05) and positive relationship to increased bone turnover markers (B-AP, OC, DPD). The prevalence of secondary hyperparathyroidism (sHPT) was highest in patients with severe Vitamin D deficiency (35.3%) but common also in patients with 25(OH)D serum levels between 50 and 75 nmol/l (13.5%). In 29 further cases elevated PTH levels were attributed to primary hyperparathyroidism (pHPT). Five patients had mild hypercalcemia of (formerly unknown) malignancy, uncovered by PTH serum levels <2.5 ng/l. **Conclusion:** In our opinion the high prevalence of vitamin D deficiency or insufficiency with or without secondary hyperparathyroidism in a major cohort of patients at risk for osteoporosis demonstrates the importance of measurements of 25(OH)D and PTH serum levels for differential diagnostic and therapeutic purposes. The results put into question the approach adopted in various national guidelines which do not recommend 25(OH)D routine measurements. Furthermore, additional consideration of PTH serum levels may contribute to a more adequate estimate of individual vitamin D supplementation needs.

Improved Risk Assessment Using Lumbar Spine Trabecular Bone Score (TBS) to Adjust Fracture Probability: The Manitoba BMD Cohort. William Leslie^{*1}, Helena Johansson², Anders Oden², Eugene MCloskey², Didier Hans³, John Kanis². ¹University of Manitoba, Canada, ²University of Sheffield Medical School, United Kingdom, ³Lausanne University Hospital, Switzerland

Background: Lumbar spine trabecular bone score (TBS), a DXA-derived image texture measurement, is a risk factor for osteoporotic fracture independent of FRAX clinical risk factors and femoral neck BMD. Our aim was to determine whether applying a TBS adjustment to fracture probability was beneficial in terms of risk reclassification and treatment qualification.

Methods: Using a registry containing all clinical DXA results for Manitoba, Canada, we identified 34,316 women age 40-100 years (mean 64 years) with baseline spine and hip DXA (Prodigy, GE Healthcare), FRAX input variables, blinded lumbar spine TBS measurement (TBS iN Sight[®] version 2.1, Med-Imaps), and minimum 5 years of observation (to March 31, 2013). Population-based health services data were used to identify non-trauma major osteoporotic fractures (MOF) and hip fractures (HF). MOF and HF probability were estimated using FRAX with femoral neck BMD (Canadian tool) without and with the TBS adjustment. Risk re-categorization was assessed using net reclassification improvement (NRI) for individual FRAX-based intervention criteria (fixed MOF 20%, fixed HF 3%, age-specific MOF) and three national clinical practice guidelines (CPGs) (Osteoporosis Canada, US National Osteoporosis Foundation [NOF], UK National Osteoporosis Guideline Group [NOGG]).

Results: Overall proportions of women reclassified with the TBS adjustment to FRAX were small (less than 5%). However, for women close to an intervention cut-off (MOF 20%+5% [absolute], HF 3%+1% [absolute], age-specific+20% [relative]) reclassification rates were much higher (17.5%, 17.9%, 25.3%, respectively); reclassification rates were <1% otherwise. During mean 8.8 years of follow up, 3503 (10.2%) women experienced an incident MOF and 945 (2.8%) women experienced an incident HF. There was a small but significant improvement in overall NRI for all individual FRAX-based intervention criteria (range 0.7-1.8%) and all three national CPGs (range 0.5-1.1%). NRI was greater in women younger than age 65 years compared with women age 65 years and older.

Conclusion: A small but significant improvement in MOF and HF risk assessment was seen by using lumbar spine TBS to adjust FRAX probability. The improvement in risk classification was not specific to a particular CPG, and was observed for CPGs from three different countries. Almost all of the benefit in terms of risk re-categorization was seen in individuals close to the intervention threshold.

Proportion reclassified and NRI for individual FRAX intervention criteria and three national CPGs.

Contribution of Lumbar Spine BMD to Fracture risk in individuals with T-score discordance. Dunia Alarkawi^{*}, Dana Bliuc, Tuan Nguyen, John Eisman, Jacqueline Center. Garvan Institute of Medical Research, Australia

Context Bone mineral density (BMD) is an important predictor of fracture risk. Risk estimates are usually based on femoral neck (FN) BMD. However it is unclear how to address T-score discordance, where lumbar spine (LS) T-score is lower than FN T-score.

Objectives To examine the impact of LS BMD on fracture risk, specifically in individuals with lower LS T-score than FN T-score.

Design Prospective cohort from the Dubbo Osteoporosis Epidemiology Study of community-dwelling women and men aged 60+ years that had had both LS and FN BMD measured at their first visit, followed from April 1989 to December 2014.

Results Of 2270 women and 1373 men, 988 women and 264 men had lower LS T-score than FN T-score. Of those, 364 women and 60 men had a LS T-score lower than FN T-score by ≥1 SD (discordant group). In women with lower LS than FN T-score, each 1 SD lower LS T-score was associated with a 30% increase in fracture risk (HR 1.30, 95% CI 1.19-1.41, P<0.0001). However, there was no further increase in fracture risk for men with lower LS T-score than FN. Discordant women had a greater fracture risk than the rest of the women for all levels of FN T-score. This increased fracture risk was more apparent for lower levels of FN T-score and in older age groups. For example, with FN T-score -2, discordant women aged 60-69 had a 3% higher five-year absolute fracture risk than non-discordant women. In the 70-79 yr age group this risk was 11% higher and in the >80 group, it was 31% higher. Furthermore, an osteoporotic LS T-score increased ten year absolute fracture risk for women with either normal or osteopenic T-score by ~15%.

Conclusion This study demonstrates the significant contribution of lower LS BMD to fracture risk in individuals, over and above FN BMD. Women with lower LS T-score by ≥1 SD than FN T-scores had consistently higher absolute fracture risks regardless of their FN T-scores. However the risk increased exponentially with lower FN BMD and increasing age. The findings clearly indicate that a LS BMD lower than FN BMD should be incorporated into fracture risk calculation algorithms at least for women.

Net Reclassification Improvement with FRAX Versus a Simpler Risk Assessment System: More is More. William Leslie^{*1}, Suzanne Morin², Sumit Majumdar³, Lisa Lix¹, Helena Johansson⁴, Anders Oden⁴, Eugene MCloskey⁴, John Kanis⁴. ¹University of Manitoba, Canada, ²McGill University, Canada, ³University of Alberta, Canada, ⁴University of Sheffield Medical School, United Kingdom

Background: There is much debate regarding the value of complex fracture risk assessment tools over simpler more intuitive tools. Indeed, Canadian clinical practice guidelines (CPG) go so far as to endorse both complex (WHO FRAX) and simple (Canadian Association of Radiologists and Osteoporosis Canada [CAROC]) tools. CAROC uses age, sex, femoral neck BMD and two clinical risk factors (prior fracture and prolonged glucocorticoid use) to assign semi-quantitative 10-year risk (low <10%, moderate 10-20%, high >20%). We compared net incremental benefit of using the complete FRAX tool vs CAROC tool. **Methods:** Using a registry with all clinical DXA results for Manitoba, Canada, we identified women and men age = 50 years undergoing baseline DXA in years 1996-2011. Population-based data were used to identify FRAX/CAROC covariates and incident major osteoporotic fractures (MOF). Net reclassification improvement (NRI) was used to quantify the differences between FRAX vs CAROC. **Results:** The study population included 54,493 women and men (mean age 67 years [SD 10], 90% female) among whom 4,508 (8.3%) sustained an incident MOF during mean follow up 6 years. FRAX and CAROC both provided good risk stratification and calibration (observed 10-year MOF with FRAX = low 6.6%, moderate 15.4%, high 30.4%; CAROC = low 6.7%, moderate 15.4%, high 28.7%), with identical risk categorization in 82.3% (FRAX higher 6.7%, CAROC higher 11.0%). NRI for FRAX vs CAROC was no different in those who experienced an incident MOF (-0.7%, P=0.23) but it was significantly greater for those who did not (+4.6%, P<0.001) as well as for the entire cohort (+3.9%, P<0.001). Subgroup analyses in 10,880 patients with prior fracture showed lower risk concordance (64.9%) and overall NRI was again significantly better with FRAX vs CAROC (+14.9%, P<0.001). Similar improvements in NRI with FRAX (all P<0.001) were seen in the following subsets of prior fracture patients: age < 65 (+17.1%), age = 65 (+8.4%), women (+10.9%), men (+22.1%). The NNF ("Number Needed to FRAX") to improve fracture prediction was 26 overall and 7 in those with a prior fracture. **Summary:** Both FRAX and CAROC provide good risk stratification and are well calibrated to the Canadian population, but FRAX provides a more accurate quantitative assessment of risk, particularly in those with prior fracture, compared with simpler semiquantitative systems.

Statistical Shape and Appearance Models and Statistical Parameter Mapping for Hip Fracture Discrimination: Not Better Than BMD or Less Robust. Oleg Museyko¹, Valérie Bousson², Jean-Denis Laredo², Judith Adams³, Andreas Friedberger⁴, Klaus Engelke⁵. ¹Inst of Med Physics, Univ of Erlangen, Germany, ²Service de Radiologie OstéoArticulaire, Hôpital Lariboisière, France, ³Clinical Radiology, The Royal Infirmary, Univ. of Manchester, United Kingdom, ⁴Inst of Med Physics, Univ. of Erlangen, Germany, ⁵University of Erlangen, Germany

Purpose: To investigate whether statistical parameters describing the 3D shape (SSM) of the proximal femur and its local BMD distribution (SAM: statistical appearance model) can discriminate subjects with and without acute osteoporotic hip fractures.

Methods: QCT datasets of the femur from 98 pm women (46 with acute hip fx) were used. SSM and SAM models were built by non-rigid registration of randomly selected segmented femurs to one femur. Models included unfractured subjects (ctrl) and fractured subjects (fx). SSM/SAM consisted of principal components (PC) of the registration displacement vectors (BMD values) for the whole sample set. SSM/SAM parameters that discriminated sig. between the two groups after adjust. for age, height, and weight were included into binary logistic regression to obtain odds ratios (OR) and AUC of the ROC curve. A stratified validation was performed by means of random partitioning of the whole sample into k partitions with k=1, 2, and 5. Then 1. The discrimination of SSM/SAM and int. BMD were compared. 2. A combined SSM-SAM model was compared with the combination of trochanteric trabBMD (TrTrabBMD) + neck cort. thickness (NeckCortTh). 3. In addition, statistical parameter mapping models (SPM) were built to find voxels on the normalized femur shape which were significantly different between ctrl and fx, forming a new analysis VOI.

Results: For both SSM and SAM, only one significant PC was found. The discriminative performance of SSM and SAM for k=1 is shown in the table. Performance of the combined shape-appearance model was sig. worse (AUC 0.71 [0.61,0.81]) than TrTrabBMD+NeckCortTh (AUC 0.79 [0.70,0.88]). SPM on shapes did not find any voxels with sig. difference between ctrl and fx; for BMD, 3% of voxels were sig. different forming a VOI which discriminated fracture with AUC 0.82 [0.74,0.91], but reduced to 0 and 1% voxels when analyzing to halves of the sample (k=2, see Fig).

Conclusions: The performance of SSM/SAM was not superior to BMD. Intersubject variations of shape not related to fracture were much larger than those related to fracture, indicating that sig. parameters in femur shape models may be quite "noisy". The observed discrimination may be just by chance. SPM on BMD discriminated best but was instable to subset-based validation due to the small number of significant voxels found, which may indicate that much more accurate registration is needed. BMD was a more stable discriminator for hip fractures.

Multiple GWAS-Implicated Adult Height Loci Operate in the Context of Pediatric Bone Mineral Density and Content Determination. Alessandra Chesni^{*1}, Jonathan Mitchell², Kevin Basile³, Shana McCormack³, Sani Roy³, Heidi Kalkwarf⁴, Joan Lappe⁵, Vicente Gilsanz⁶, Sharon Oberfield⁷, John Shepherd⁸, Andrea Kelly³, Babette Zemel³, Struan Grant⁹. ¹Children's Hospital of Philadelphia, USA, ²University of Pennsylvania, USA, ³Children's Hospital of Philadelphia, USA, ⁴Cincinnati Children's Hospital Medical Center, USA, ⁵Creighton University School of Medicine, USA, ⁶University of Southern California, USA, ⁷Columbia University Medical Center, USA, ⁸University of California, USA, ⁹Children's Hospital of Philadelphia / University of Pennsylvania, USA

Height is a complex trait influenced by environmental and genetic factors operating in a number of biological pathways, including those related to hormone activity and bone accretion. The most recent meta-analysis of genome-wide association studies of adult height identified 697 variants corresponding to 423 distinct genomic loci, which collectively account for up to one-fifth of this trait's heritability. However, the physiological route by which these genetic variants influence an individual's overall height is not known.

Stature reflects skeletal size, which is achieved by bone mineral accretion during childhood growth. Thus, we investigated the effects of genetic variants known to associate with adult height on pediatric bone mineral content and density. We leveraged a prospective observational study of 691 participants of European ancestry enrolled in the Bone Mineral Density in Childhood Study (52% female), then sought further support from an additional cohort of 472 Caucasian subjects (51% female). Bone mineral content (BMC) and areal bone mineral density (aBMD) of the radius, hip, spine and total body (to estimate head and whole body BMC/aBMD) were assessed by dual energy X-ray absorptiometry (DXA) and expressed as age and sex-specific Z-scores. We further tested bone Z-scores adjusted for height-for-age Z-score to account for known effects of size on DXA outcomes. DNA was extracted from blood/saliva and genotyped using high-throughput technology. Genotyping of subjects was performed at the Children's Hospital of Philadelphia using the Illumina InfiniumTM II OMNI Express plus Exome BeadChip technology.

Three of the loci previously linked to adult height yielded Bonferroni-corrected significance for association with pediatric bone accretion at specific skeletal sites. These loci were rs3750972 at *TPCN2* for head aBMD in males ($P=5.48 \times 10^{-2}$; $\beta=-0.241$), rs6952113 at *C7orf58* (also known as *CPED1*) for both BMC and aBMD at the distal radius in females ($P=1.63 \times 10^{-5}$; $\beta=-0.250$ and $P=6.30 \times 10^{-8}$; $\beta=-0.317$, respectively), and rs2781373 at *MAX* with aBMD at the distal radius in females ($P=3.22 \times 10^{-5}$; $\beta=0.243$). These loci did not show any degree of significant association with height Z-score, nor did height adjustment of BMC/aBMD outcomes dramatically alter the significance of association of these loci to their respective skeletal phenotypes. Additionally, 19 other adult height loci demonstrated at least a nominally significant, directionally consistent association in both the discovery and replication cohorts for a variety of other skeletal phenotypes.

These results indicate that at least some of the genetic variants associated with adult height may be exerting their influence via alterations in pediatric bone accretion. Additionally, our data have implicated *TPCN2* and *MAX* as novel pediatric bone density loci.

Single Nucleotide Polymorphisms Are Associated with Circulating Bone Biomarkers in Young Adults undergoing Initial Military Training. Erin Gaffney-Stomberg^{*1}, Anna Shcherbina², Darrell Ricke³, Martha Petrovick², Laura Lutz⁴, Thomas Cropper⁵, Sonya Cable⁶, James McClung⁴. ¹USARIEM, USA, ²Massachusetts Institute for Technology Lincoln Laboratory, USA, ³Massachusetts Institute for Technology Lincoln Laboratory, Lexington, MA 02420, USA, ⁴US Army Research Institute of Environmental Medicine, USA, ⁵Lackland Air Force Base, USA, ⁶Initial Military Training Center of Excellence, USA

Initial military training (IMT) is associated with increased risk of stress fracture. Previous studies demonstrated that supplemental calcium (Ca) and vitamin D (vit D) provided daily throughout IMT reduced stress fracture incidence, suppressed PTH, and improved some measures of bone health compared to placebo. The purpose of this study was to determine whether previously identified single nucleotide polymorphisms (SNPs) in Ca and vit D related genes are associated with circulating biomarkers of bone metabolism in young adults entering IMT, and whether responses to Ca and vitamin D supplementation during IMT are modulated by genotype. Baseline associations between SNPs including the following genes: vit D receptor (VDR; n=6), vit D binding protein (VDBP; n=2), and 1-alpha-hydroxylase (CYP27B1), and circulating biomarkers were measured in fasting blood samples from volunteers (n=778) starting IMT. Volunteers were block randomized by race and sex to receive a Ca and vit D fortified food product (2000 mg Ca and 1000 IU vit D per day) or placebo throughout Army or Air Force IMT (7-9 wk). Habitual food intake during IMT was estimated using a food frequency questionnaire. Total Ca and vit D intakes were calculated as the sum of supplemental intake based on compliance

and dietary intake. Relationships between SNPs, Ca and vit D intake tertile, and change in biomarkers were evaluated in those who completed the trial (n=391). At baseline, circulating 25(OH)D was positively associated with the presence of the minor allele of a VDR gene SNP (rs1544410, B=1.39, p=0.02) and in a VDBP gene SNP (rs7041, B=3.65, p=2.82x10⁻¹⁴). In addition, presence of the minor allele of a second VDR SNP (rs2228570) was associated with lower circulating P1NP (B=-4.81, p=0.02), while presence of the minor allele in the CYP27B1 gene (rs10877012) was associated with higher CTX (B=2.99, p=0.03). In black/African American volunteers, those homozygous for the T allele of a VDR SNP (rs11568820) had greater increases in BAP with higher Ca and vit D intake (B=15.8, p<0.01) compared to volunteers carrying the C allele. These data suggest that VDR, VDBP and CYP27B1 SNPs are associated with 25(OH)D status and bone turnover and that a VDR SNP conferred a greater anabolic response to Ca and vit D intake in Black/African American volunteers.

Prevention of osteoporotic fractures by black tea consumption. Richard Prince¹, Gael Myers², Jonathan Hodgson³. ¹Sir Charles Gairdner Hospital, Australia, ²Curtin University, School of Public Health, Australia, ³University of Western Australia, School of Medicine & Pharmacology, Australia

Previous studies, including our own, have demonstrated a beneficial effect of tea, a major source of dietary flavonoids, on bone structure. The association of black tea and flavonoid intake with the risk of fractures leading to hospitalization or death was examined in a prospective cohort study of women mean age over 80 years.

At baseline 1,188 women had their dietary intake assessed by a food frequency and beverage questionnaire. Complete ascertainment of 10 year, incident, verified osteoporotic fracture hospitalisation or death was determined through the Western Australian Hospital Morbidity Data system. Multivariate-adjusted Cox regression was used to examine the hazard ratios (HR) for incident fracture. Flavonoid intake was calculated using United States Department of Agriculture flavonoid databases.

Any osteoporotic fractures occurred in 288 (24.2%) women. Compared to women consuming £1 cup/week, for each 1 cup/day increase in tea intake there was a 9% decrease in the risk of any serious osteoporotic fracture (fully-adjusted HR 0.91; 95% CI:0.84, 0.99; P=0.027), the relationship was not significant after adjustment for BMD. Major osteoporotic fracture occurred in 212 (17.8%) women and hip fracture in 129 (10.9%) women Tea accounted for 75% of the total flavonoid intake. Compared to the lowest tertile of flavonoid intake, women in the highest tertile of flavonoid intake had a lower risk of serious osteoporotic fracture (HR: 0.65; 95% CI: 0.47, 0.88, actual risk 21.0% and 28%); major osteoporotic fracture (HR: 0.66; 95% CI: 0.45, 0.95; actual risk 15% versus 20%) and hip fracture (HR: 0.58; 95% CI: 0.36, 0.95, actual risk 8% versus 12%).

Women who drink black tea, a major dietary flavonoid, have a substantial lower fracture risk. The health benefits of tea may extend to the skeletal system.

The Effect of Vitamin K1 and Vitamin D on Muscle Composition and Muscle Function: the ECKO RCT. Andy Kin On Wong¹, Marvam Hamidi², Lianne Tile², George Tomlinson³, Hanxian Hu², Judy Scher², Yuna Lee⁴, Lilian Thompson³, Reinhold Veith⁵, Robert Josse⁴, Sophie Jamal³, Gillian Hawker⁶, Angela M. Cheung². ¹University Health Network, Ca, ²UHN, Canada, ³University of Toronto, Canada, ⁴St. Michael's Hospital, Canada, ⁵Mount Sinai Hospital, Canada, ⁶Women's College Hospital, Canada

Objectives: 1) to determine the effect of vitamin K1 on changes in muscle function; 2) to evaluate how vitamin K modulates the relationship between muscle function and composition. Study design: A randomized double-blind placebo-controlled trial of vitamin K1 with prospective follow-up for 48 months. Outcomes: Muscle function was measured at 0, 24 and 48 months. Myotendinous density (MyD) was assessed at the distal tibia using HR-pQCT at the last study visit. Percentage undercarboxylated osteocalcin (%UCOC), serum vitamin K and triglyceride levels were measured at baseline, 12, 24, 36 and 48 months. Yale Physical Activity Energy Expenditure Summary Index (EESI) was determined at these same visits. Analyses: Effect of treatment on changes in muscle function variables was assessed using a general linear model (GLM). Factor analysis identified latent muscle constructs, which were also subjected to GLM. All GLMs adjusted for serum vitamin K/triglyceride ratio, EESI, serum vitamin D at 24 months, as well as age and body mass index (BMI). Latent growth curve models measured the effect of %UCOC at 24 months on trajectories of muscle function. The effect of treatment on how MyD relates to function was evaluated as an interaction term in linear regression analyses. Results: Among 428 (Vitamin K, N=211, Placebo, N=217) postmenopausal women, serum vitamin K was higher (p<0.001) in the vitamin K-treated group (23.4 ± 21.4 ng/mL) at 24 months compared to placebo (2.1 ± 2.3 ng/mL) (upheld after adjusting for age, BMI and triglycerides). Factor analyses yielded a locomotor function construct, and a balance construct. There was a non-significant trend towards maintained static balance in the vitamin K-treated group over 48 months compared to placebo (Fig 1). A smaller

%UCOC at 24 months was associated with a significantly faster rate of improved balance (construct) but not locomotor function (construct), which was preserved after adjusting for EESI and serum vitamin D (Table I). Higher serum vitamin D at 24 months was associated with increased locomotor function (construct) but not balance (B=0.001, SE(B)=0.0003, Beta=3.17, p<0.001, effect = 0.08%). MyD correlated with muscle function constructs more strongly in those treated with vitamin K than with placebo (Table II). Conclusions: Those with superior vitamin K status have mildly improved balance. Taking vitamin K may improve the ability to use muscle that is already present.

Table I. Effect of % undercarboxylated osteocalcin (%UCOC) at 24 months on the rate of change in the locomotor function (LMF) construct and the balance construct. Regression coefficients are expressed as unit rate per 1% increase in UCOC. Models are adjusted for age, BMI and the baseline value for the latent construct at minimum (Model A), plus concurrent changes in energy expenditure (Model B) and plus serum vitamin D at 24 months (Model C) cumulatively.

| N | | Model | B | SE(B) | Beta | P-Value | Effect (% of mean) |
|-----|---------|-------|---------|--------|-------|---------|--------------------|
| 427 | LMF | A | 0.0010 | 0.0004 | 2.35 | 0.009 | 0.08 |
| 426 | LMF | B | 0.0025 | 0.0018 | 1.42 | 0.078 | 0.19 |
| 378 | LMF | C | -0.0003 | 0.0006 | -0.47 | 0.317 | -0.02 |
| 427 | Balance | A | -0.0036 | 0.0018 | -2.05 | 0.020 | -0.68 |
| 426 | Balance | B | -0.0008 | 0.0004 | -2.26 | 0.011 | -0.16 |
| 378 | Balance | C | -0.0040 | 0.0020 | -2.03 | 0.021 | -0.74 |

Does Vitamin D Metabolism Differ by Race? Evaluation of Vitamin D Metabolites in American Indians and Caucasian Americans Prior to and Following Vitamin D₃ Supplementation. Neil Binkley¹, Ellen Fidler², Gretta Borchardt², Diane Krueger². ¹University of Wisconsin, Madison, USA, ²University of Wisconsin, USA

Objective: Serum 25(OH)D levels differ between races. It is often assumed that this is due to pigmentation with dark skinned individuals at higher risk for low 25(OH)D levels. However, whether racial differences exist in other circulating vitamin D metabolite levels, e.g., cholecalciferol (D₃) and/or 24, 25(OH)₂D (24,25D), or whether race affects the change in these metabolites following supplementation has received little study. Recently, liquid chromatography tandem mass spectrometry (LC-MS/MS) methodology has made measurement of D₃ and 24,25D more available. This report describes serum levels of these metabolites in American Indian (AI) and Caucasian American (CA) postmenopausal women and to evaluate change in these metabolites following oral vitamin D₃ supplementation.

Materials and Methods: Serum D₃, 25(OH)D and 24,25D were measured by LC-MS/MS in a study of 99 postmenopausal AI mean (SD) age 61.2 (7.3) years and a second study of 88 postmenopausal CA women mean (SD) age 64.2 (8.7) years. Inclusion/exclusion criteria for both studies were similar. The AI volunteers were randomly assigned to receive either 400 IU or 2500 IU of vitamin D₃ daily for six months; the CA women received 2300 IU of daily vitamin D₃ for four months. Vitamin D metabolites were measured at baseline and study conclusion.

Results: At baseline, mean serum 25(OH)D did not differ between AI (27.6 ng/mL) and CA (26.2 ng/mL) women. Baseline 24,25D was lower ($p < 0.0001$) in AI than CA (2.0 and 2.9 ng/mL respectively). Serum 24,25D was positively correlated ($p < 0.001$) with 25(OH)D in both AI and CA women. Following supplementation with 2300 or 2500 IU daily, a greater ($p < 0.001$) increase in 25(OH)D was observed in AI than CA women (18.1 vs. 11.9 ng/mL). After this supplementation, 24,25D increased similarly in AI and CA women. Serum D₃ was detectable (≥ 5 ng/mL) in only 9% of AI and 4% of CA women at baseline.

Conclusion: When compared to Caucasian postmenopausal women, serum 24,25D is lower, and the response to daily vitamin D₃ supplementation greater, in a cohort of postmenopausal AI women. This differing response suggests that reported racial differences in vitamin D status may reflect not only skin pigmentation, but also differences in vitamin D metabolism. It is possible that vitamin D intake and status recommendations should be race specific. Further study of potential racial differences in vitamin D metabolism is needed.

The Association between Maternal and Fetal 25OHD and Infant Size and Adiposity at Birth, 6 Months and 2 Years of Age. Mary Horan¹, Jean Donnelly¹, Malachi McKenna², Brenda Crosbie², Mark Kilbane², Fionnuala McAuliffe¹. ¹National Maternity Hospital, Ireland, ²St. Vincent's University Hospital, Ireland

Background: While the effects of vitamin D in pregnancy and offspring bone health are well established, there remains a dearth of knowledge on the effect of maternal vitamin D status on offspring size and adiposity. The aim of this study was to examine the association of early and late pregnancy and fetal 25-hydroxyvitamin D (25OHD) on offspring size and on adiposity at birth, at 6 months and at 2 years of age in a cohort from the ROLO (Randomised cOntrol trial of LOw glycaemic index diet versus no dietary intervention to prevent recurrence of fetal macrosomia study).-
Methods: 272 mother and infant pairs from the ROLO study were included in this analysis at 20 weeks gestation, 290 at 34 weeks gestation, 292 at birth, 160 at 6 months postpartum and 287 at 2 years postpartum. 25OHD was measured in mothers in early (13 weeks) and late (28 weeks) gestation, and in fetal umbilical cord blood samples at delivery. **Results:** According to Institute of Medicine 2011 Report, 30% in early pregnancy and 38% in late pregnancy were at risk of vitamin D deficiency (25OHD < 30 nmol/L). Birthweight was negatively associated with early pregnancy 25OHD ($p < 0.001$) and with fetal 25OHD ($p < 0.001$). Birth length was not associated with early, late or fetal 25OHD. Neonatal sum of all skinfolds and sum of subscapular and triceps skinfolds, which are measures of overall adiposity, were negatively associated with fetal 25OHD (respectively, $p = 0.001$, and $p = < 0.001$). At 2 years of age there was a negative association between weight-for-age z-score and early pregnancy 25OHD ($p < 0.041$). **Conclusion:** Maternal and fetal 25OHD were negatively associated with offspring size and adiposity at birth, at 6 months, and 2 years of age in a cohort at risk of macrosomia in whom risk of vitamin D deficiency was high. Improvement of vitamin D status in pregnancy remains a public health concern.

A neuronal action of Sirtuin 1 Suppresses Bone Mass in young and aging mice. Na Luo¹, Ioanna Mosialou¹, Aruna Kode¹, Mattia Capulli², Stavroula Kousteni¹. ¹Columbia University Medical Center, USA, ²University of L'Aquila, Italy

The histone deacetylase Sirtuin 1 (Sirt1) has emerged as a regulator of several brain-dependent functions that are compromised with aging. We explored a potential role of Sirt1 in the neuronal control of bone mass through regulation of the activity of the sympathetic nervous system (SNS). We show that a modest increase in *Sirt1* expression in transgenic (*TgSirt1*) mice, compromised bone mass by suppressing bone formation and promoting bone resorption. The opposite effects of Sirt1 on the two compartments of bone remodeling correlated with an increase in SNS activity as indicated by increased expression of *Ucp1* in brown fat and elevated levels of urinary epinephrine and norepinephrine in *TgSirt1* mice. Decreased bone mass was observed at 1.5 month-old *TgSirt1* mice and persisted at 3, 6 and 12 months of age. The decrease in osteoblast numbers was more pronounced at 12 months of age indicating a progressive effect of Sirt1 functions with aging. High sympathetic tone in *TgSirt1* mice accounted for the decrease in bone mass as pharmacological inhibition of SNS signaling by daily administration of the beta adrenergic receptor inhibitor propranolol to *TgSirt1* mice for 4 weeks fully restored osteoblast and osteoclast numbers and rescued the low bone mass phenotype of these animals. To examine whether Sirt1 regulates bone mass through a central action, we generated mice lacking *Sirt1* in the brain by crossing mice carrying an allele of *Sirt1* in which exon 4 is floxed with *Synapsin-Cre* mice (*Sirt1^{brain}-/-* mice). Inactivation of *Sirt1* in the brain decreased SNS activity and increased bone mass by increasing bone formation and suppressing bone resorption in 3 month-old *Sirt1^{brain}-/-* mice. More directly related to Sirt1 biology, whereas the loss of bone mass in 3-month old *Sirt1^{+/+}* mice occurs only in female mice and only in the femur, we found that brain inactivation of *Sirt1* increased bone mass in both genders at this age. Likewise, whereas 7-month old female or male *Sirt1^{+/+}* mice do not have a bone phenotype, brain inactivation of *Sirt1* increased bone mass at 8 months of age. Collectively, these observations suggest that, in addition to its cell autonomous effects in osteoblasts and osteoclasts, Sirt1 controls bone mass by upregulation of SNS signaling. The neuronal effects of Sirt1 in the regulation of bone mass persist and become more pronounced during aging.

Glucocorticoids attenuate bone formation independently of FoxOs. Srividhya Iyer¹, Elena Ambrogini², Li Han², Shoshana Bartell², Ha-Neui Kim³, Aaron Warren², Julie Crawford², Stuart Berryhill², Stavros Manolagas², Maria Almeida². ¹Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA, ²Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA, USA, ³Center for Osteoporosis & Metabolic Bone Diseases, University of Arkansas for Medical Sciences, USA, USA

Administration of glucocorticoids causes rapid bone loss and increases the risk of fractures. Endogenous or exogenous glucocorticoid excess severely decrease the number of osteoblast and bone formation due to reduced production of new osteoblast precursors as well as premature apoptosis of mature osteoblasts. However, the molecular mechanisms responsible for these deleterious effects remain unclear. In vitro studies have suggested that glucocorticoids activate members of the FoxO family of transcription factors and thereby attenuate Wnt signaling in cultured osteoblast progenitors. Based on this and in vivo evidence that FoxOs suppress bone formation by sequestering β -catenin and preventing Wnt/TCF transcription in osteoprogenitors, we examined here whether FoxOs mediate the deleterious effects of glucocorticoids on bone formation. To this end, 5-month-old male mice lacking FoxO1, 3 and 4 in *Osx1-Cre* targeted cells (designated FoxO1,3,4^{*ΔOx1-Cre*}) and their littermate controls (FoxO1,3,4^{*fl/fl*}) were administered placebo or prednisolone (2.1 mg/kg/day) for 28 days, using slow-release pellets. Consistent with earlier evidence, prednisolone did not alter the cancellous bone volume at the spine or the distal femur in the control mice. Prednisolone administration, however, severely decreased mineralizing surfaces and bone formation rate (38% and 40%, respectively) as determined by dynamic histomorphometry in vertebral bone sections. As seen also before, the FoxO1,3,4^{*ΔOx1-Cre*} mice had increased cancellous bone at the spine and at the femoral metaphysis compared to the FoxO1,3,4^{*fl/fl*} littermates. Nevertheless, the decrease in mineralizing surface and bone formation caused by glucocorticoids in FoxO1,3,4^{*ΔOx1-Cre*} mice was indistinguishable from the controls. In agreement with the adverse effects on bone formation, prednisolone decreased the mRNA and protein levels of osteocalcin in both genotypes, measured in tibia shafts and serum, respectively. Taken together, these results demonstrate that the deleterious effects of glucocorticoids on bone formation do not result from the activation of FoxOs in cells of the osteoblast lineage.

Sost/sclerostin deficiency protects the murine skeleton from glucocorticoid-induced bone loss by inhibiting bone resorption. Amy Y. Sato*, Meloney Cregor, Jasmine Tzeggai, Kevin McAndrews, Jesus Delgado-Calle, Alexander G. Robling, Lilian I. Plotkin, Teresita Bellido. Indiana University School of Medicine, USA

The bone weakening effects of glucocorticoids (GC) oppose those promoted by activation of the Wnt/beta-catenin signaling pathway. Based on this evidence, we investigated here whether mice lacking the gene encoding the Wnt antagonist Sost (KO) are protected from the bone loss induced by GC excess. Female 4-month-old KO and wild type (WT) littermate controls (10 mice/group) were implanted with slow-release pellets containing placebo or prednisolone at two doses 1.4 or 2.1 mg/kg/day, for 4 weeks. Consistent with the previously demonstrated bone anabolism with Sost/sclerostin deficiency, KO mice displayed higher bone mineral density (BMD) compared to WT controls (+42, +55, and +64% for total, femoral, and spinal BMD); increased MS/BS (+32%), MAR (+44%), and BFR (+101%), increased circulating bone formation markers ALP (+43%) and P1NP (+72%), but no changes in bone resorption markers CTX or TRAP5b. GC induced the expected dose-dependent decrease in BMD in WT mice (total: -2.1 and -2.7% and spinal: -4.4 and -5%, $p < 0.05$). Both GC doses also reduced significantly trabecular thickness, cortical bone area (BA/TA) and cortical thickness in WT mice, quantified by micro-CT in L6 vertebra. In contrast, GC failed to decrease BMD at any site, or BA/TA, or reduce trabecular or cortical thickness in KO mice, demonstrating bone preservation. Unexpectedly, however, both doses of GC decreased MAR and BFR similarly in WT and KO mice (MAR: -38 vs -31% and BFR: -33 vs -34%, for WT and KO, respectively). Further, GC lowered circulating bone formation markers to a similar extent for both doses in WT and KO mice (ALP, 2wks: -36% vs -33% and P1NP, 2 and 4wks: -61% vs -67%, for WT and KO mice respectively). In contrast, GC raised circulating bone resorption markers (CTX: +32% and TRAP5b: +77%) and increased osteoclast number and surface (+40% and +80% for low and high dose, respectively) in WT mice, but not in KO mice at any dose or time point. Moreover, both GC doses increased Sost (1.6- and 2.2-fold) and decreased OCN (0.44- and 0.36-fold) and OPG (0.70- and 0.67-fold) expression in WT mice. In contrast, in the KO mice, GC decreased OCN expression (0.44- and 0.20-fold), but did not affect OPG expression. These findings demonstrate that the absence of Sost/sclerostin protects from GC-induced bone loss not by reversing the inhibition of bone formation, but instead by preventing downregulation of OPG and the consequent increase in bone resorption induced by GC.

NR2C2 gene regulated osteoblasts bone formation activity through mir34a TGF β signaling pathway. Eric Beier*¹, Hsin-chu Ho², Shen-chin Hsu³, John Holz⁴, Tzong-Jen Sheu⁵, I-Hui Su⁶, Edward Puzas⁵. ¹Rutgers, USA, ²Wan-Chuan Clinics, Fangliao General Hospital, Taiwan, ³Chung Shan Medical University Hospital Dept of Pharmacy, Taiwan, ⁴D'Youville College Department of Math & Natural Sciences, USA, ⁵University of Rochester, USA, ⁶Fangliao General Hospital, Taiwan

Nuclear receptor subfamily 2, group C, member 2 (NR2C2) belongs to a nuclear receptor superfamily without an identified ligand. The expression of NR2C2 is found in virtually all tissue types including cerebellum, skeletal tissue, pancreas, reproductive system. NR2C2^{-/-} mice have severe osteopenia. Its role within the skeletal system and signaling mechanisms are currently unknown.

To study how NR2C2 regulates skeletal integrity, we first characterized NR2C2-deficient mice compared with wild type mice. The mutant mice showed significantly lower bone density (50% compared to wild type mice) at 4 wks, and remained lower beyond 6 months. Flexure testing of femurs revealed a 30-50% decrease in stiffness and resistance to load in mutant mice. Trabecular bone properties in the femur (BV/TV, trabecular number, connection density) showed the same magnitude of decrease when comparing the deficient mice to wild type mice. Excessive bone resorption was ruled out as the major contributor to the osteopenia as osteoclast markers TRAcP5b, NTX, and CTX levels remained unchanged. However, serum osteocalcin (OC) levels were significantly lower in the mutant, and furthermore the remaining OC was primarily in the inactive gamma-carboxyglutamic form (Gla-OC). Therefore we hypothesize that the observed bone loss is predominantly a function of insufficient osteoblast bone formation activity. In support of this, dynamic histomorphometry by calcein-alizarine double labeling showed that the mineral apposition rate and bone formation rate were 65% and 50% lower respectively in deficient mice compared to wild type. Next, we isolated primary osteoblasts from the calvaria of NR2C2-KO and wild type mice. miRNA screening and RNA-Seq techniques demonstrated a reduction of transforming growth factor-beta (TGF-beta) signaling activity in deficient osteoblasts. Concordantly, we generated several TGF-beta luciferase reporter transgenic osteoblasts comprised of pBabe-NR2C2, pBabe-NR2C2 RNAi, and pBabe GFP, which similarly confirmed a link between NR2C2-deficiency and an impingement of TGF-beta signaling. On the other hand, over-expression of NR2C2 showed a consistent three-fold induction of TGF-beta luciferase activity compared to the control group (pBabe-GFP). In addition, the expression of miR-34a was increased and the corresponding miR-34a target TGF-beta-induced factor (TGIF) was decreased in mutant mice. This novel characterization of NR2C2 regulation of the

TGF-beta signaling pathway offers new mechanistic insights on NR2C2 regulation of osteoblast activity, in which NR2C2 insufficiency can produce a bone loss phenotype.

Conclusion: NR2C2 regulates TGF-beta signaling through the microRNA miR-34a, which subsequently reduces its downstream target TGIF. TGIF has been linked to lipid metabolism, a long-suspected ligand candidate for NR2C2. This data uncovers a new signaling axis that may help to understand how the NR2C2 orphan receptor regulates skeletal integrity.

Skeletal Health in Healthy Postmenopausal Women Treated with Exemestane for the Primary Prevention of Breast Cancer: 3-year data from the nested bone strength substudy of the MAP.3 trial (MAP3BSS). Miranda Boggild*¹, Lianne Tile¹, George Tomlinson¹, Natasha Gakhal², Sandhya Pruthi³, John Robbins⁴, Shail Rawal¹, Sharmila Majumdar⁵, Sundeep Khosla³, James Ingle³, Harriet Richardson⁶, Paul Goss⁷, Angela Cheung¹. ¹University of Toronto, Canada, ²Women's College Hospital, Canada, ³Mayo Clinic, USA, ⁴UC Davis Health System, USA, ⁵UCSF University of California, San Francisco, USA, ⁶Queen's University, Canada, ⁷Harvard University, USA

Purpose: Exemestane is an oral steroidal aromatase inhibitor that lowers circulating estrogen levels and prevents breast cancer in postmenopausal women. Previously published data from a nested non-inferiority bone strength substudy of the MAP.3 trial (MAP3BSS) showed that exemestane had negative effects on bone at 2 years. In this analysis, we assessed the effect of exemestane on bone after 3 years of treatment.

Methods: Postmenopausal women in the MAP.3 trial (a placebo-controlled randomized trial of exemestane 25 mg/day for the primary prevention of breast cancer) who did not have osteoporosis (T-score > -2.0 at all sites), were not on bone medications, and have never had fragility fracture were recruited from 5 centres (2 US and 3 Canadian). Primary outcome was change from baseline to 3 years in total volumetric bone mineral density (BMD) at the distal radius as measured by HRpQCT. For all outcomes, we compared the percent change over time between groups with the Kruskal-Wallis test.

Results: Three hundred and sixty-two women (171 in the exemestane group, 191 in the placebo) participated in the MAP3BSS. Seventy-nine participants crossed over from the placebo to the exemestane group after unblinding at 2 years. This analysis included women who have taken up to 3 years of exemestane as compared to placebo. At baseline, median age was 61.2 years and median areal BMD T-scores at the lumbar spine and total hip by DXA were -0.41 and 0.12, respectively. From baseline to 3 years, the mean percent change in total volumetric BMD at the distal radius was -8.53% (95% CI -9.35 to -7.72) in the exemestane group, -7.59% (95% CI -8.71 to -6.47) in the women who crossed over from placebo to exemestane, and -2.33% (95% CI -3.93 to -2.04) in the placebo group ($p < 0.0001$). The decline in secondary bone outcomes continued to the third year of treatment and was significantly different compared to the placebo group (Table 1 and Figure 1).

Conclusions: Three years of exemestane for the prevention of breast cancer continued to have progressive negative effects on bone despite calcium and vitamin D supplementation. Further studies with long-term follow-up, including fracture risk, are needed to weigh the risks and benefits of using exemestane for the primary prevention of breast cancer.

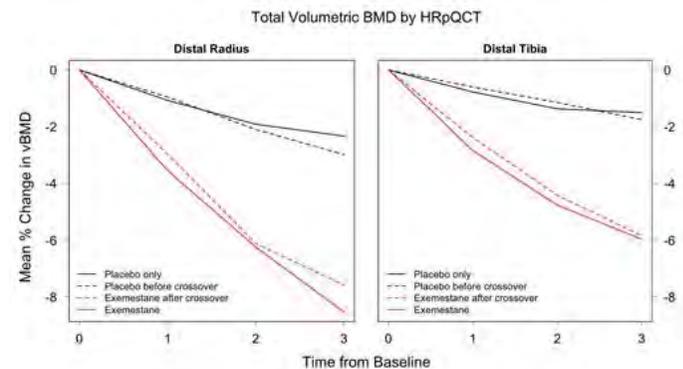

Figure 1

| Table 1. Mean percent change in secondary bone outcomes from baseline to 3 years | | | |

Bone Health in Glucocorticoid-Treated Men and Women. Edward Leib¹, Renaud Winzenrieth². ¹University of Vermont, USA, ²Med-Imaps, France

Edward S. Leib¹, Renaud Winzenrieth², (1) Dept. of Medicine, University of Vermont College of Medicine, Burlington, VT, USA (2) R&D Department; Med-Imaps, Berdeaux, France.

Introduction: Glucocorticoid (GC) treatment has been widely shown to have a negative impact on bone. The aim of this study is to investigate GC-induced effects on areal Bone Mineral Density (aBMD) and bone microarchitectural texture measured by Trabecular Bone Score (TBS).

Methods: 416 subjects aged 40 years and over who received GCs (=5 mg/day, for =3 months) were included in the study and matched with 1104 control subjects for sex, age and BMI. aBMD was measured at L1-L4 PA spine and at the femur (neck and total) by DXA, and TBS was evaluated at the spine. Clinical data, osteoporotic fractures (OPF) and dietary habits were documented in the medical report.

Results: Among the study population, 13.1% of the control subjects and 16.3% of the GC subjects sustained a prevalent osteoporotic fracture. GC-treated patients were characterized by a significant decrease of TBS (1.267 vs. 1.298, $p<0.001$) compared with control-matched subjects while no differences in BMD were observed at spine (1.060 vs. 1.056, $p=0.88$), femoral neck (0.858 vs. 0.848, $p=0.21$) or at total femur (0.903 vs. 0.899, $p=0.59$). These decreases were even more pronounced when fracture status was taken into account (1.222 vs. 1.298, $p<0.001$). The Odds Ratio (OR) for TBS was 1.44 [1.095–1.89] for OPF, whereas no significant ORs were found for BMD at spine ($p=0.36$), femoral neck ($p=0.61$) and total femur ($p=0.23$). The presence of a fracture was correlated with the same level of TBS as was GC treatment in subjects without fracture (?TBS=0.002, $p=0.66$). Those with fracture in the GC group had a greater decrease of TBS when compared to those without fracture (?TBS=-0.054, $p<0.01$) or to those with fracture in the control group (?TBS=-0.076, $p<0.001$). An influence on TBS by sex was also noted with a decrease in TBS of greater magnitude in GC men than in GC women (?TBS=-0.052 vs. ?TBS=-0.027) without differences in terms of age ($p=0.48$) and BMI ($p=0.08$).

Conclusion: GC-treated individuals have a significant deterioration of bone microarchitecture as assessed by TBS which is more marked in those with OP fracture and in men. TBS seems to be more sensitive than aBMD for GC-related fracture detection and should be a good surrogate indicator of bone health in such secondary osteoporosis.

FR0325

Does a specific bone pattern exist in patient suffering from Cushing's disease?. Amandine Boisson¹, Renaud Winzenrieth², Antoine Tabarin³, Thierry Schaeverbeke¹, Nadia Mehzen-Cetre¹. ¹Rheumatology department, CHU Pellegrin, France, ²R&D department, Med-Imaps, France, ³Endocrinology Department, France

Rational: Rare studies conducted in patients with Cushing's disease (CD), a model of endogenous hypercortisolism, have pinpointed dissociation between the increased risk of fracture and apparently normal areal Bone Mineral Density (aBMD). The aim of this study was to evaluate the bone impact of CD assessed by TBS and aBMD, at various status.

Patients and methods: 50 subjects with CD status confirmed by biochemical evaluations (ACTH, UFC), presence of a pituitary adenoma or dynamic hormonal

levels were recruited. CD status defined as active disease (AD), eucorticism treated patients (EU) or corticotrope insufficiency with hydrocortisone supplementation (CIH). aBMD at spine and at the hip has been evaluated using a iDXA densitometer (GE-Lunar, Madison, USA) as well as TBS at spine using TBS iN Sight® v2.1 (Med-Imaps, France).

Results: Compared with the normal values for age, CD subjects have lower TBS value (TBS=1.26±0.13, Z-score TBS = -0.8 SD; $p<0.01$) whereas no differences have been obtained for aBMD at spine (Z-score=0.3 SD, $p=0.49$) or at total femur (Z-score=0.0 SD, $p=0.95$). Significant differences were obtained over CD subjects depending on the CD status without difference in terms of age (all $p>0.25$). Those with AD have a significant TBS alteration when compared with reference values (Mean Z-score TBS=-1.3 SD, $p<0.001$) despite a normal aBMD at spine (Z-score = 0.4 SD) or at total femur (Z-score = 0.2 SD). Subjects with EU have both normal aBMD and TBS values for age (Mean Z-scores of 0.5 and 0.0 SD respectively). In addition, CD subjects with CIH have both decrease of aBMD and TBS (Mean Z-scores of -0.6 and -0.7 SD respectively) without significances. AD subjects have significant lower TBS values than those with EU (Δ TBS=-0.104, $p<0.05$) or with CIH (Δ TBS=-0.048, $p<0.05$) without differences in terms of aBMD at any sites (all $p>0.05$). Men with AD had lower TBS values than women with AD (TBS = 1.105 vs. 1.244; $p<0.01$). In addition, CIH had lower TBS values than EU subjects (Δ TBS=-0.056, $p<0.05$). **Conclusion:** A specific bone pattern exists in CD subjects consisting in a marked alteration of the trabecular texture assessed by TBS despite a normal aBMD. This alteration seems to be gender related with a higher impairment in men. One striking findings of this study is that a specific bone pattern exists for each CD status and activity, and that CIH subjects, usually considered in remission, have also a bone pattern alteration.

Endogenous Cortisol Levels Are Positively Correlated to Adrenal Androgens But Negatively to Total Testosterone and Estradiol Whereas Exogenous Glucocorticoids Suppress Both Adrenal and Gonadal Steroid Hormones in Elderly Men. Anna Nilsson¹, Claes Ohlsson², Mattias Lorentzon², Liesbeth Vandenput², Magnus Karlsson³, Ulf Lerner², Östen Ljunggren⁴, Dan Mellström². ¹Sahlgrenska University Hospital, Sweden, ²Center for Bone & Arthritis Research, Department of Internal Medicine & Clinical Nutrition, at the Institute of Medicine, Sahlgrenska Academy, Gothenburg University, Sweden, ³Clinical & Molecular Osteoporosis Research Unit Department of Clinical Sciences & Orthopaedic Surgery Lund University, Skåne University Hospital, Sweden, ⁴Department of Medical Sciences, University of Uppsala, Uppsala, Sweden, Sweden

Treatment with glucocorticoids is a strong risk factor for fragility fractures, due to several effects including suppression of gonadal hormones. We have studied the role of glucocorticoid treatment for bone density and fracture risk in the Swedish MrOS study (n=3014), and assessed the co-variation of endogenous cortisol levels to bone metabolism, bone density, and adrenal and gonadal steroid hormones in MrOS Sweden. Briefly, a population-based sample of 3014 men between 70 and 80 years of age was studied. Fractures were obtained from the radiology departments. Bone mineral density (BMD) was measured by dual energy x-ray absorptiometry, and hormone analyses were done by mass spectrometry.

The risk of fracture in men treated with glucocorticoids (n=59) tended to be higher 5 years after assessment (hazard ratio (HR) 1.82, $p=0.06$) but not after 10 years (HR 1.36, $p=0.23$). These men also had lower BMD at the total hip (0.87 ± 0.14 vs 0.93 ± 0.14 g/cm²) and clearly reduced serum levels of dehydroepiandrosterone (DHEA) (0.5 vs 1.8 ng/mL), DHEA-sulfate (0.2 vs 0.7 µg/mL), androstenedione (0.4 vs 0.8 ng/mL), total testosterone (12 vs 15 nmol/L) and estradiol (59 vs 77 pmol/L; $p<0.001$ for all comparisons in unpaired t-tests).

Fasting morning serum cortisol levels in men in MrOS Gothenburg excluding diabetics and glucocorticoid users (n=812), were strongly and positively correlated to DHEA ($r=0.31$) and androstenedione ($r=0.34$), but negatively to total testosterone ($r=-0.11$) and estradiol ($r=-0.10$) both in age-adjusted analyses and in models adjusted for age, body mass index (BMI), smoking, and renal function ($p<0.01-0.001$). There was a negative correlation between age-adjusted serum cortisol levels and BMD at the hip ($r=-0.08$, $p=0.02$) but not after adjustment for BMI, smoking, and renal function ($r=-0.04$, $p=0.29$). High serum cortisol was also associated with higher plasma glucose ($r=0.18$), serum insulin ($r=0.11$), systolic blood pressure ($r=0.11$), and C-reactive protein ($r=0.15$; $p<0.01-0.001$).

In conclusion, adrenal androgens were positively correlated to endogenous serum cortisol and suppressed by the use of exogenous glucocorticoids, as expected. Total testosterone and estradiol were low in subjects with high endogenous cortisol as well as in those using glucocorticoids. Low levels of DHEA have been suggested to increase fracture risk, and the role of DHEA in the development of glucocorticoid-induced osteoporosis needs to be further explored.

Effects of Denosmab on vertebral fractures in patients with Glucocorticoid-Induced Osteoporosis. Ikuko Tanaka¹, Mari Ushikubo², Takashi Kato³, Keisuke Izumi², Kumiko Akiya², Hisaji Oshima². ¹NAGOYA Rheumatology Clinic, Japan, ²Tokyo Medical Center, Department of connective Tissue Disease, Japan, ³National Center for Geriatrics & Gerontology, Japan

Background) Bisphosphonates have been widely used for prevention and treatment of glucocorticoid-induced osteoporosis. In recent years, denosmab, a monoclonal antibody against RANKL, has been proven for effective treatment of primary osteoporosis. However, effects of denosmab for glucocorticoid-induced osteoporosis (GIO) was not clearly resolved.

Purpose) This study was conducted to clarify effects of denosmab on vertebral fractures in GIO.

Subjects and Methods) Patients with connective tissue diseases at Tokyo Medical Center was subjected for one-year longitudinal cohort study. The number of subjects was 200 (female; 175, age; 65+/-14 (mean +/- SD), prednisolone dosage at base line; 7.7+/-11 mg/day, prednisolone dosage during 1yr; 6.0+/-11mg/day, duration of prednisolone treatment; 11.7+/-11.3yr, prevalent vertebral fracture (Genant, H. 1996); 46.0%). Lumbar bone mineral densities (IBMD) were measured as %YAM with Lunar 3030 (GE). Incident vertebral fractures were analyzed with XP at thoracic and lumbar spines. Patients were treated with bisphosphonates (74%) or denosmab (26%).

Results) The value of IBMD (%YAM) at the base line was 82.1+/-14.7%. The rate of incident fractures during the follow-up period was 13.0%. 2) Clinical data at the base line were not statistically different between two treatment groups (sex, age, prevalent fracture, prednisolone dosage, and IBMD). However, increases in IBMD after 1 yr were larger in patients with denosmab than in those with bisphosphonates (3.22+/-0.45% vs 2.97+/-0.25%, respectively; p<0.02). A logistic regression analysis showed that statistically significant contributors for incident fractures were IBMD (5% decrease, OR; 1.30; 95%CI; 1.10-1.54, p<0.01), prednisolone dosages (5mg/day increase, 2.09, 1.30-3.34, p<0.01), prevalent fractures (3.87, 1.40-10.7, p<0.01), and denosmab treatment (vs bisphosphonates, 0.12, 0.02-0.56, p<0.01).

Conclusions) It is suggested that denosmab may be more effective than bisphosphonates for prevention of osteoporotic fractures in patients treated with glucocorticoids.

Effects of Romosozumab in Japanese Women With Postmenopausal Osteoporosis: Phase 2 Trial Results. H Ishibashi¹*, DB Crittenden², A Miyauchi³, C Libanati⁴, J Maddox², L Chen², A Grauer². ¹Ina Hospital, Japan, ²Amgen Inc., USA, ³Miyauchi Medical Center, Japan, ⁴UCB Pharma, Belgium

Purpose: Romosozumab is a sclerostin inhibitor that rapidly increases BMD through a dual-effect on bone, causing increased bone formation and decreased bone resorption, as shown in a global phase 2 study in postmenopausal (PM) women with low bone mass (McClung *NEJM* 2014). Here we report the key results of a phase 2 dose-ranging study to assess the efficacy and safety of romosozumab in a Japanese population (NCT01992159).

Methods: This randomized, double-blind, placebo (Pbo)-controlled study enrolled PM Japanese women aged 55-85 years with a lumbar spine (LS), total hip (TH), or femoral neck (FN) DXA T-score ≤ -2.5 . Women were randomized to receive Pbo or 1 of 3 doses of subcutaneous romosozumab (70 mg, 140 mg, or 210 mg) monthly (QM) for 12 months. The primary endpoint was percentage change from baseline in LS BMD at month 12. Secondary endpoints included percentage change from baseline in LS BMD at month 6, TH and FN BMD at months 6 and 12, and percentage change from baseline in serum bone turnover markers.

Results: Women enrolled in the study (N=252) had a mean (SD) age of 68 (6.4) years and mean LS, TH, and FN T-scores of -2.7, -1.9, and -2.3, respectively. All romosozumab doses significantly increased BMD compared with Pbo at each of the 3 skeletal sites at month 12 (p<0.01). The largest improvements were observed with romosozumab 210 mg QM, which resulted in BMD gains from baseline of 16.9% and 4.7% at the LS and TH, respectively (Fig), and 3.8% at the FN, at month 12. All doses of romosozumab increased P1NP and reduced CTX vs Pbo by week 1 (p<0.0001). In the 210 mg QM group, P1NP levels peaked at month 1 (median increase 101.1%) and fell below Pbo levels by month 12; CTX levels were lowest at week 1 (median decline 45.6%) and were still below Pbo at month 12. Subject incidences of adverse events (AEs) and serious AEs were generally comparable between treatment groups. Numerical differences were observed between the total romosozumab vs Pbo groups for subject incidence of mild to moderate osteoarthritis AEs (6.9% vs 0%) and mild injection site reactions (3.7% vs 1.6%).

Conclusions: In this study of Japanese women with PM osteoporosis, romosozumab treatment resulted in rapid, large, and significant gains in BMD compared with Pbo and baseline, and the 210 mg QM dose showed the greatest efficacy. Romosozumab was generally well tolerated in this population. Global phase 3 studies evaluating the 210 mg QM dose for the treatment of osteoporosis are underway.

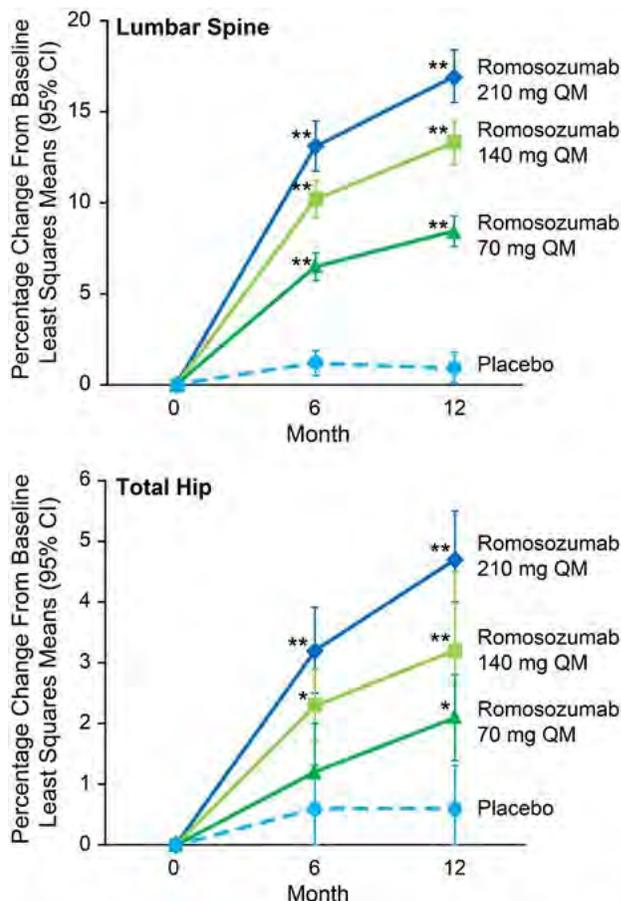

Fig. Percentage change in bone mineral density from baseline in women receiving placebo or romosozumab (70 mg, 140 mg, or 210 mg) every month for 12 months. Estimated least square means for the changes by linear models are presented. QM, every month. *p<0.01 vs placebo; **p<0.0001 vs placebo.

FR0333

Response Rates for Hip, Femoral Neck and Lumbar Spine BMD are Higher for Patients Treated with Abaloparatide when Compared to Placebo or Teriparatide – Results of the ACTIVE Trial. Gary Hattersley¹*, Alan Harris¹, Greg Williams¹, D. Black², Ming-Yi (Tristan) Hu¹. ¹Radius Health, USA, ²UC San Francisco, USA

Abaloparatide (ABL) is an osteoanabolic analog of PTHrP being developed for the treatment of postmenopausal osteoporosis (PMO). It has recently been reported from the ACTIVE trial that ABL reduces the incidence and risk of new vertebral, non-vertebral and clinical fractures relative to placebo (PBO) and teriparatide (TPTD) (Miller et al, ENDO 2015). ACTIVE was a randomized, double-blind, placebo-controlled Phase 3 fracture prevention trial in which PMO women received 18-months of daily SC PBO, ABL 80 µg, or TPTD 20 µg. 2,463 patients were randomized (ITT population) and 1,901 (77.9%) completed treatment. All patients were also treated with calcium and vitamin D supplementation as per local practice. To determine if women treated with 18-months of ABL were more likely to have increases in BMD than those treated with either PBO or TPTD, a pre-specified responder analysis was performed comparing the percentage of subjects experiencing BMD gains of >3% at three anatomic sites (total hip (TH), femoral neck (FN), lumbar spine (LS)) at 6, 12, and 18 months. For the purposes of this analysis, a responder was defined as a patient with a gain at all three sites (TH, FN and LS). A Chi-square test or Fisher's Exact test was used to determine the difference in the number of responders between the two treatment groups (e.g., ABL vs. TPTD), as appropriate. At Month 6, 54% of patients treated with ABL exhibited a statistically significant % change BMD of >3% compared to 3.4% for PBO (p<0.0001) and 39.7% for TPTD (p<0.0001), the comparison between PBO and TPTD was also significant at this 6 months (p<0.0001). At Month 12, 33.1% of ABL treated patients had BMD increases of >3% compared to PBO (1.5%) or TPTD (19.7%), and at Month 18, 44.4% of ABL

treated patients had BMD increases of >3% compared to PBO (1.8%) or TPTD (31.9%). All of the differences were statistically significant, $p < 0.0001$. In conclusion, in women with PMO, more subjects treated with ABL experienced greater clinically relevant BMD increases at all 3 anatomical sites compared to those treated with TPTD or PBO.

Inhibition of Osteoclastogenesis and Inflammatory Bone Resorption by Targeting BET Proteins and Epigenetic Regulation. Kyung-Hyun Park-Min^{*1}, Elisha Lim¹, Min Joon Lee¹, Sung ho Park¹, Eugenia Giannopoulos¹, Anna Yarillina¹, Marjolein van der Meulen², Baohong Zhao¹, Nicholas Smithers³, Rab Prinjha⁴, Lionel Ivashkiv⁵. ¹Hospital for Special Surgery, USA, ²Cornell University, USA, ³GSK, United Kingdom, ⁴Epinova DPU, United Kingdom, ⁵Hospital for Special Surgery, USA

Epigenetics is becoming increasingly appreciated as a new area of research that may provide insights into the pathogenesis of inflammatory autoimmune diseases such as rheumatoid arthritis. Epigenetics refers to the control of gene expression by chromatin regulators that bind to DNA and by modifications of chromatin components such as histones and DNA (hydroxyl)methylation. Recent drugs targeting epigenetic processes have shown great promise for the treatment of cancers and inflammatory conditions. Receptor activator of nuclear kappa B ligand (RANKL) is a key inducer of osteoclastogenesis and emerging evidence suggests that RANKL-induced changes in chromatin state are important for osteoclastogenesis. However, these epigenetic mechanisms in osteoclasts are not well understood and have not been therapeutically targeted. Thus, we have investigated the epigenetic regulation of osteoclast differentiation and we find that the small molecule inhibitor, I-BET151, that targets bromo and extra-terminal (BET) proteins that 'read' chromatin states by binding to acetylated histones strongly suppresses osteoclastogenesis. I-BET151 treatment suppresses *in vivo* pathologic bone loss in TNF-induced inflammatory osteolysis, inflammatory arthritis and postovariectomy models. Transcriptome analysis identifies a MYC-NFAT axis important for osteoclastogenesis. I-BET151 inhibits expression of the master osteoclast regulator, NFATC1 by suppressing expression and recruitment of its newly identified upstream regulator MYC. Importantly, MYC is elevated in rheumatoid arthritis macrophages and its induction by RANKL is important for osteoclastogenesis and TNF-induced bone resorption. These findings implicate the importance of MYC and BET proteins in osteoclast differentiation and demonstrate that targeting an epigenetic molecule in osteoclasts can be effective in suppressing the pathological bone resorption. Taken together, our study opens up a new line of investigation in the understanding and therapeutic targeting of inflammatory and oestrogen deficiency-mediated pathological bone resorption.

TBS and HbA1c but not BMD are Predictors of Incident Fractures in Type 1 Diabetes. Thomas Neumann^{*1}, Martin Keil², Gabriele Lehmann², Sabine Lodes², Bettina Kästner², Thomas Lehmann³, Michael Kiehnopf⁴, Didier Hans⁵, Olivier Lamy⁵, Ulrich-Alfons Müller², Gunter Wolf², Alexander Sämann². ¹Jena University Hospital, Germany, ²Jena University Hospital, Department of Internal Medicine III, Germany, ³Jena University Hospital, Institute of Medical Statistics, Computer Sciences & Documentation, Germany, ⁴Jena University Hospital, Institute of Clinical Chemistry & Laboratory Diagnostics, Germany, ⁵Lausanne University Hospital, Bone Disease Unit, Switzerland

Background

Fracture risk in type 1 diabetes (T1D) is reported to be greater compared with non-diabetic controls. Bone mineral density (BMD) underestimates the observed fracture rate in individuals with T1D. This study aimed to investigate potential risk predictors for incident fractures in middle-aged men and women with long-standing T1D.

Patients and Methods

105 individuals (52 males, 53 females, age 43.6 ± 8.7 years, diabetes duration 21.8 ± 10.4 years) were followed for 6.9 ± 0.3 years. Associations of traditional risk factors for fractures (e.g. age, gender, family history of osteoporosis and nicotine), BMD at lumbar spine (LS), femoral neck (FN) and total hip (TH), trabecular bone score (TBS) and HbA1c with incident fractures were analysed. Receiver operating characteristic (ROC) analysis of TBS and HbA1c were performed to identify potential threshold effects on incident fractures.

Results

BMD decreased at LS, FN and TH in females but only at FN in males. Only female gender was associated with greater decrease in BMD at lumbar spine and total hip in univariate regression analysis. At least one new fracture occurred in 18 individuals (17.1%), peripheral fractures in 17 and vertebral fractures in 3 individuals, with the first fracture event in all but 6 individuals. No differences appeared between

individuals with fracture and without for age (44.5 ± 8.2 vs. 43.4 ± 8.9 years, $p=0.510$) and BMD (LS: 1.099 ± 0.151 vs. 1.124 ± 0.108 g/cm², $p=0.405$; FN: 0.939 ± 0.129 vs. 0.941 ± 0.128 g/cm², $p=0.983$; TH: 1.011 ± 0.132 vs. 1.020 ± 0.143 g/cm², $p=0.976$). The 10-year risk for major osteoporotic fractures and hip fractures evaluated by FRAX[®] did not identify individuals with subsequent fractures. Individuals with fractures had higher HbA1c values (65.1 ± 12.6 vs. 57.9 ± 11.2 , $p=0.043$) and lower mean TBS scores (1.281 ± 0.125 vs. 1.369 ± 0.121 , $p=0.013$) at baseline. This association was confirmed by logistic regression analysis. The ROC curves showed that mean TBS score and HbA1c level can discriminate patients with incident fractures from those without fractures (AUC 0.72 [95% CI = 0.58 – 0.86; $P=0.003$] for combined mean TBS scores and HbA1c levels).

Conclusion

The occurrence of fractures in middle-aged men and women with T1D is high and not predictable with traditional parameters including BMD. Only HbA1c and mean TBS score are independently associated with incident fractures. Further studies in larger cohorts are needed to test a risk prediction model in T1D.

Bisphosphonate Therapy, and the Bone Protection Treatment Care Gap, in Men on Androgen Deprivation Therapy for Non-Metastatic Prostate Cancer. Lisa-Ann Fraser^{*}. Western University, Canada

Androgen deprivation therapy (ADT) is a mainstay of prostate cancer (PC) treatment, but is known to increase the risk of fracture. Although data from clinical trials support a bone density benefit to bisphosphonates (BP) used in men on ADT, no trials have shown a fracture benefit. We used population level data from Ontario, Canada to study whether treatment with a BP prevents fractures in men on ADT for non-metastatic PC. We conducted a nested-case control study among men ≥ 66 years diagnosed with PC and started on ADT between April 1, 2000 and March 31, 2010. ADT usage was defined as ≥ 6 months of continuous use of pharmacological ADT or bilateral orchiectomy. Men with a history of metastasis, or prior BP use were excluded. Cases were identified based on a new non-vertebral major osteoporotic fracture (MOF) occurring within 3 years of ADT initiation. Event-free controls were matched to cases (at a ratio of 5:1) on age, history of previous MOF, year of ADT initiation, and long-term care (LTC) vs community residence. Conditional logistic regression was used to estimate the odds ratio of MOF associated with BP use, controlling for possible confounding factors including comorbidities, medications, and health care utilization. A cohort of 18,726 men was identified. Only 10.4% were treated with a BP within 3 years of ADT initiation. Mean time between ADT initiation and the start of a BP was 402.3 days (SD: 334.5), median 350 days (IQR: 76-676). A total of 1,298 men experienced a MOF and were matched to 6,490 controls. In these 7,788 men, mean age was 78.5 (± 6) years, 8.8% had a prior osteoporotic fracture, and 1.1% resided in LTC. Bisphosphonates were used in 101 (7.8%) of cases and in 363 (5.6%) of controls. Bisphosphonates were not significantly associated with lower MOF incidence (adjusted OR=1.29, 95%CI 0.99-1.69). In this large study over 10 years we did not observe any reduction in MOFs with BP use in men with non-metastatic PC on ADT therapy. We suspect this negative result is due to the striking care gap in bone protection in these men. Current guidelines recommend bone assessment, and appropriate treatment, at the time of ADT initiation. However, in our cohort, only 10% of men were started on a BP within 3 years of ADT initiation. A bone treatment care gap exists in these men, which needs to be addressed before it is possible to study the real-world outcomes of BP intervention in this population.

Fracture Risk Following Bariatric Surgery: A Study Using Healthcare Administrative Databases. Catherine Rousseau^{*1}, Sonia Jean², Philippe Gamache³, Stefane Lebel⁴, Fabrice Mac-Way⁵, Laëtitia Michou⁵, Claudia Gagnon⁶. ¹Department of Medicine, Laval University; Endocrinology & Nephrology Unit, CHU de Quebec Research Centre, Canada, ²Institut national de santé publique du Québec; Department of Medicine, Laval University; University of Sherbrooke, Canada, ³Institut national de santé publique du Québec, Canada, ⁴Quebec Heart & Lung Institute, Canada, ⁵Endocrinology & Nephrology Unit, CHU de Quebec Research Centre; Department of Medicine, Laval University, Canada, ⁶Endocrinology & Nephrology Unit, CHU de Quebec Research Centre; Department of Medicine, Laval University; Institute of Nutrition & Functional Foods, Canada

Purpose: To investigate whether bariatric surgery increases fracture risk.

Methods: This retrospective, population-based cohort study used healthcare administrative databases. Fracture incidence for patients who had undergone bariatric surgery between 2001 and 2012 in the province of Quebec, Canada, was compared with the one of age- and sex-matched non-bariatric obese and non-obese controls. Moreover, for each group, fracture incidence before vs. after surgery (or index date)

was compared. Fractures were identified using a validated algorithm (sensitivity >80% for most fracture sites). Multivariate conditional Poisson regression models were adjusted for past fracture history, comorbidities (cardiovascular disease, hypertension, diabetes, renal failure, chronic obstructive pulmonary disease, depression, osteoporosis, hypothyroidism), material and social deprivation and area of residence.

Results: 10 662 individuals who underwent bariatric surgery (72.6% women; mean age (SD), 42 (11) years) were matched with 31 986 obese and 31 986 non-obese individuals who did not undergo surgery. At index date, patients in the bariatric group were less likely to come from metropolitan areas, were more materially and socially disadvantaged, had more comorbidities and a higher prevalence of fractures. Mean follow-up was 4.2 years (min-max: <1-12 years). 415 bariatric patients (3.9%) suffered at least one fracture after surgery compared with 826 obese (2.6%) and 750 non-obese (2.3%) controls (p<0.0001). For the bariatric group, first fracture occurred after a mean of 3.6 years (Q1-Q3: 1.6-5.1 years) (Figure 1). Adjusted fracture risk was significantly higher in the bariatric group compared with the non-obese (R.R. [95% CI]=1.45 [1.27-1.66]) and the obese (R.R. [95% CI]=1.36 [1.19-1.55]) control groups. While fracture risk did not change significantly before and after the index date in the obese and non-obese controls, it was significantly higher pre- vs. post-surgery in the bariatric group (R.R. [95% CI]=1.19 [1.06-1.34]) (Table 1).

Conclusions: After a mean follow-up of 4.2 years, patients who undergo bariatric surgery are more likely to sustain a fracture than non-obese or obese controls. Moreover, fracture risk is higher by about 20% after surgery in the bariatric group. These results suggest that bariatric patients are a high-risk group for fractures and that fracture risk assessment and management should be part of postoperative clinical care.

| Group | Period | Crude RR (95% CI) ¹ | Adjusted RR (95% CI) ² |
|---|--------------------------------|--------------------------------|-----------------------------------|
| Bariatric group (n=10 662) | Before surgery (or index date) | REF | REF |
| | After surgery (or index date) | 1.16 (1.04-1.31) | 1.19 (1.06-1.34) |
| Control group of obese individuals (n=31 986) | Before surgery (or index date) | REF | REF |
| | After surgery (or index date) | 0.93 (0.86-1.01) | 0.95 (0.87-1.03) |
| Control group of non-obese individuals (n=31 986) | Before surgery (or index date) | REF | REF |
| | After surgery (or index date) | 1.01 (0.92-1.09) | 1.01 (0.93-1.10) |

RR = relative risk.

¹ Unadjusted RR using conditional Poisson regression model.

FR0366

Sclerostin levels and changes in bone metabolism after bariatric surgery.

Christian Muschitz*¹, Roland Kocijan², Christina Marterer², Arastoo Rahbar Nia², Gabriela Katharina Muschitz³, Heinrich Resch², Peter Pietschmann⁴. ¹St. Vincent's Hospital, Austria, ²St. Vincent Hospital Vienna - Medical Department II, Austria, ³Division of Plastic & Reconstructive Surgery, Department of Surgery, Medical University of Vienna, Austria, ⁴Department of Pathophysiology & Allergy Research, Center for Pathophysiology, Infectiology & Immunology, Medical University of Vienna, Austria

Purpose: The role of sclerostin as a key regulator of bone formation remains unknown after Roux-en-Y gastric bypass (RYGB) or laparoscopic sleeve gastrectomy (SG). The objective was the evaluation of sclerostin and Dickkopf-1 (DKK-1) serum levels after surgery and correlations with bone turnover markers (PINP, CTX), parathyroid hormone (iPTH) and areal bone mineral density (BMD) changes at total body, lumbar spine and total hip. Methods: This was a prospective observational single-center two-arm study in premenopausal women with severe adipositas over 24 months. Prior to surgery and after 1, 3, 6, 9, 12, 18, and 24 months sclerostin, DKK-1, CTX, PINP and BMD were measured. Results: 52 premenopausal women (40.8 years, BMI 43.4) after RYGB and 38 premenopausal women (41.7 years, BMI 45.7) after SG were included. Sclerostin, CTX and to lesser extend PINP immediately increased after surgery and remained elevated during the entire study period (p<0.001). DKK-1 declined during months 3 - 9 (p<0.005) and then remained unchanged, serum phosphate continuously increased (p<0.001), iPTH remained in the upper normal limit. Sclerostin increases were significantly positively correlated with CTX and PINP increases and significantly negatively correlated with BMD loss. BMD independently declined regardless of RYGB and SG. Elevations of sclerostin, CTX, PINP, and phosphate but not DKK-1 and iPTH, were significant discriminating factors for BMD loss (AUC 0.920). Conclusions: Rapid and sustained increases of sclerostin, CTX and to lesser extend PINP causes an increase in bone metabolism and results in BMD loss at all skeletal sites.

Disclosures: Christian Muschitz, None.

FR0367

Strategies for the reduction of loss of bone and body lean mass after bariatric surgery.

Christian Muschitz*¹, Roland Kocijan², Judith Haschka², Christina Marterer², Arastoo Rahbar Nia², Gabriela Katharina Muschitz³, Heinrich Resch², Peter Pietschmann⁴. ¹St. Vincent's Hospital, Austria, ²St. Vincent Hospital - Medical Department II - Academic Teaching Hospital of Medical University of Vienna, Austria, ³Division of Plastic & Reconstructive Surgery, Department of Surgery, Medical University of Vienna, Austria, ⁴Department of Pathophysiology & Allergy Research, Center for Pathophysiology, Infectiology & Immunology, Austria

Purpose: Bariatric surgery causes ongoing weight loss, an increased bone turnover and loss of areal bone mineral density (aBMD) at different skeletal sites. The hypothesis of this study was to test if a specific postoperative intervention exerts different effects on bone metabolism, aBMD, body lean mass, and Trabecular Bone Score (TBS) compared to no intervention. In this prospective observational single-center two-arm study patients eligible for either laparoscopic Roux-en-Y gastric bypass (RYGB) or sleeve gastrectomy (SG) were randomly assigned into the two groups: The intervention group received preoperative vitamin D loading (28.000 IU/week for 8 weeks) and postoperative supplementation of vitamin D (16.000 IU/week), calcium citrate (500 mg/d), weight adjusted protein diet (range 50 - 110 g/day including protein supplementation), and physical exercise (Nordic walking 3x45 min/week). The non-interventional group received regular consultation for food intake behavior. The objectives were the evaluation of changes between the two groups of sclerostin (Scl) and Dickkopf-1 (DKK-1) serum levels, bone turnover markers (PINP, CTX), intact parathyroid hormone (iPTH), 25-OH vitamin D, areal bone mineral density (BMD) changes at total body, lumbar spine and total hip as well as body lean body mass, and changes of TBS. Measurements were performed prior to surgery and after 1, 3, 6, 9, 12, 18, and 24 months. Results: In each group 110 female and male patients with a median age of 41 years [IQR 34; 45] and a BMI of 44 kg/m² [IQR 41; 47] participated. Baseline characteristics of both groups did not differ with regard to type of surgery, serum values, and aBMD or body lean mass values. All investigated median values significantly changed within the groups regardless of RYGB or SG. At study endpoint in the intervention group median levels were lower for iPTH (51.8 vs 77.6 pg/mL), Scl (40.2 vs 53.0 pmol/L), CTX (0.524 vs 0.640 ng/mL; p<0.0001 for all) and PINP (41.5 vs 51.3 µg/L, p=0.004). Median levels were higher for 25-OH vitamin (32.5 vs 22.0 ng/mL), body lean mass (46.5 vs 42.6 kg), aBMD total body (1.178 vs 1.091 g/cm²), aBMD lumbar spine (1.272 vs 1.130 g/cm²), aBMD total hip (1.179 vs 1.064 g/cm², p<0.0001 for all), DKK-1 (25.9 vs 22.3 pmol/L, p=0.038), and TBS (1.226 vs 1.172, p=0.0067). Conclusions: Specific interventions for patients with RYGB and SG reduce high bone turnover, the loss of aBMD and body lean mass, as well as changes in TBS.

Disclosures: Christian Muschitz, None.

FR0369

Osteocyte production of PTHrP is necessary for normal osteocyte differentiation and bone remodeling. Niloufar Ansari¹, Patricia Ho¹, Jonathan Gooi², T John Martin¹, Natalie A Sims¹. ¹St. Vincent's Institute of Medical Research, Australia, ²Melbourne Medical School, University of Melbourne, Australia

Parathyroid hormone-related protein (PTHrP) is an autocrine/paracrine regulator in many tissues, including bone. Although *Pthrp* gene ablation is neonatal lethal in mice, heterozygotes were normal at birth but osteopenic by 12 weeks of age. That phenotype was recapitulated in mice with PTHrP knocked out in the osteoblast lineage. Since PTHrP is also expressed in osteocytes, we sought to determine the role of osteocytic PTHrP in bone.

We crossed mice carrying the DMP1.Cre transgene (10-kb promoter) with PTHrP-loxP mice to target PTHrP deletion to osteocytes (DMP1.Cre.PTHrP^{fl/fl}). DMP1.Cre⁺ PTHrP^{w/w} littermates were used as controls. Mice were born at the expected Mendelian ratios and grew normally. In 6 week-old DMP1.Cre.PTHrP^{fl/fl} mice and Cre⁺ PTHrP^{w/w} littermate controls, no significant differences were detected in periosteal or endocortical perimeter, cortical thickness, or in trabecular bone volume (BV/TV), trabecular number or separation (n=6-8/group). At 12 weeks of age however, BV/TV was 27% lower in male and 50% lower in female DMP1.Cre.PTHrP^{fl/fl} mice than in littermate controls (n=6-7/group, p<.05). Trabecular number was reduced to a similar extent in both males and females (both p=0.03), but trabecular thickness remained unchanged. The findings indicate a key role for osteocyte-derived PTHrP in bone remodeling in the adult skeleton, and in maintaining trabecular bone mass.

As a surrogate osteocyte system we used the OCY454 cell line; when these cells were differentiated for 14 days on plastic surfaces or on Alvetex scaffolds for 3D growth their mRNA levels for *Sost*, *Dmp1* and *Mepe* increased more than 50-100-fold. PTHrP treatment at this time point reduced *Sost* and *Mepe* mRNA levels by 70% and 80% respectively (p<0.01). Using shRNA, *Pthrp* mRNA levels were knocked down by 80% (compared to luciferase) but *Pthr1* mRNA levels were unaffected. PTHrP knockdown altered OCY454 cell differentiation such that *Sost* mRNA levels were >2-fold greater than luciferase control at day 7 of differentiation, and at day 14 *Mepe* and *Dmp1* were 3-4-fold higher. In addition, osteoblast markers *Alpl* and *Bglap* were reduced by PTHrP knockdown. This suggests that PTHrP deficiency pushes OCY454 cells towards an osteocytic phenotype. The results suggest osteocyte-derived PTHrP acting in an autocrine/paracrine manner is required for the normal differentiation of late-stage osteoblasts and osteocytes and maintenance of trabecular bone mass during adult bone remodeling.

A Complex Set of Distal Enhancers Linked to the Mouse *Tnfrsf11* Gene Direct Tissue-Specific and Hormone-regulated Expression of RANKL. Melda Onal^{*}, Hillary StJohn, Allison Danielson, Jon Markert, Wesley Pike. University of Wisconsin, USA

RANKL expression from the *Tnfrsf11* gene is regulated by numerous local and systemic factors whose activities are mediated via 10 enhancers (D1-D7, T1-T3) located 16kb to 155kb upstream of the *Tnfrsf11* transcriptional start site. Studies in osteoblastic cells have revealed inducible VDR and pCREB binding at D2 and Stat 3/5 binding at D6, suggesting that like D5, D2 mediates the induction of RANKL by PTH and 1,25(OH)₂D₃ whereas D6 mediates upregulation by IL-6 type cytokines. Similar studies in lymphocytes have revealed that T1 modulates RANKL expression in activated T cells. The importance of RANKL regulation by D5 *in vivo* has been previously described. Our recent studies indicated that the entire *Tnfrsf11* regulatory locus is required for tissue-specific expression of RANKL that is fully capable of rescuing the RANKL-null mouse phenotype. We therefore prepared 3 additional mouse strains containing genomic deletions of D2, D6 or T1 and examined the resulting phenotypes. Deletion of D2 or D6 did not alter lymphocyte expression of RANKL, whereas loss of D5 or T1 resulted in 15% and 80% decreases, respectively. Deletion of D5 or T1, but not D2 or D6, blunted the activation-induced increase in RANKL expression in T cells *ex vivo*. Loss of D5 and T1 enhancers also resulted in significantly lower RANKL expression in spleen and thymus. We also measured RANKL expression in the bones and in *ex vivo* stromal cultures of these enhancer null (KO) mice. Lack of D2 and D6, but not T1, blunted PTH- and LPS-induced increases in RANKL expression, respectively, both *ex vivo* and *in vivo*. Similar to D5KO mice, D2KO mice, but not D6KO or T1KO mice, exhibited an up to 50% reduction in RANKL expression in spine, tibia and femur shafts compared to wildtype controls. Decreased skeletal RANKL expression in D2KO mice led to decreased bone resorption and a progressive increase in cancellous bone mass, while lack of D6 or T1 had no effect on bone mass up to 12 months of age. These results suggest that D5, a multifunctional RANKL enhancer, operates in concert with both lineage- and factor-specific enhancers (D2, D6 and T1) to mediate RANKL expression in lymphoid and skeletal tissues. The organization of the *Tnfrsf11* gene highlights the increased regulatory complexity that has emerged experimentally from unbiased ChIP-seq analyses which describes most genes that encode factors involved in the regulation of key biological processes such as osteoclastogenesis.

FR0371

Deletion of a Distal Enhancer of the *RANKL* Gene Delays the Progression of Atherosclerotic Plaque Calcification in Hypercholesterolemic Mice. Soheil Shamsuzzaman^{*}, Melda Onal, Hillary St. John, J. Wesley Pike. University of Wisconsin-Madison, USA

Receptor activator of NF-κB ligand (RANKL) is a TNF-like factor which mediates osteoclast formation. Recent studies demonstrated the presence of RANKL in atherosclerotic lesions; however, its role in atherosclerotic plaque formation remains controversial. We and others have previously shown that an enhancer located 75kb upstream of the mouse *RANKL* gene's transcriptional start site designated as D5 is important for 1,25(OH)₂D₃ and PTH-induced expression of RANKL. Most importantly, deletion of the D5 enhancer results in reduced basal expression of RANKL in bone and lymphoid organs. Herein, we explore RANKL's role in atherosclerotic plaque formation *in vivo* in D5 enhancer-null mice. The D5^{-/-} mice were crossed with ApoE^{-/-} mice to obtain the ApoE^{-/-};D5^{-/-} mice; wild-type (WT) (ApoE^{+/+};D5^{+/+}) and D5^{-/-} (ApoE^{+/+};D5^{-/-}) littermates were used as controls. The animals were fed a high fat Western diet (HFD) to promote atherosclerosis. We analyzed the gene expression and atherosclerotic plaque formation after 12 and 18 weeks of HFD feeding. Bone density was higher in D5^{-/-} and ApoE^{-/-};D5^{-/-} mice due to reduced bone remodeling. RANKL was significantly elevated in aortic arches and thoracic aortas of ApoE^{-/-};D5^{+/+} and ApoE^{-/-};D5^{-/-} mice compared to controls; however, ApoE^{-/-};D5^{-/-} mice had lower RANKL compared to ApoE^{-/-};D5^{+/+} mice. Similarly, higher RANKL was identified in splenic T lymphocytes isolated from the ApoE^{-/-};D5^{+/+} mice and its level was reduced in ApoE^{-/-};D5^{-/-} mice. Osteogenic regulators *Runx2*, *Osx* (*Sp7*), *Opn* (*Spp1*), *Alpl* and *Mmp13* were elevated in aortic arches and thoracic aortas in the ApoE^{-/-};D5^{+/+} and ApoE^{-/-};D5^{-/-} animals as well; however, the smooth muscle cell markers Sm-α-actin (*Acta2*), Sm22α (*Tagln*) and Sm-MHC (*Myl11*) were reduced in ApoE^{-/-};D5^{+/+} and ApoE^{-/-};D5^{-/-} aortas. Atherosclerotic fatty streaks were identified in ApoE^{-/-};D5^{+/+} as well as ApoE^{-/-};D5^{-/-} mice after 12 weeks of HFD feeding. When analyzed by μCT, plaque calcifications were identified in 6 out of 8 ApoE^{-/-};D5^{+/+} mice whereas only 1 out of 8 ApoE^{-/-};D5^{-/-} mice developed plaque calcification when fed the HFD for 12 weeks. However, after 18 weeks of HFD challenge 100% of both ApoE^{-/-};D5^{+/+} and ApoE^{-/-};D5^{-/-} animals developed fatty streaks as well as plaque calcification. Our data suggest that RANKL D5 enhancer deletion delays the progression of atherosclerotic plaque calcification in mice. This work provides important insights into RANKL's regulatory role in atherosclerosis.

Decreasing Bone Mass in Mice Containing the High-Bone-Mass Mutation LRP5-G171V through the inhibition of Porcupine by LGK974. Cassandra R. Zylstra-Diegel, Mitchell McDonald^{*}, Bart Williams. Van Andel Research Institute, USA

Wnt/B-catenin signaling is important in bone proliferation, differentiation, and remodeling. Missense mutations in LRP5, the co-receptor for the Wnt/B-catenin pathway, cause high bone mass (HBM) in humans. Studies looking at the mechanism of LRP5-HBM mutations have shown these patients have no change in serum levels of Wnt signaling antagonists such as DKK1, SOST, and sFRP4; and treating animals carrying these mutations with these antagonists has relatively minor effects on modulating bone density (and no effects on mice carrying transgenes specifically directing expression of the LRP5-G171V allele). Considering that the LRP5-HBM mutation may still require a Wnt ligand for signaling we speculated that treating LRP5-G171V knock-in mice with an inhibitor of Wnt secretion would decrease their bone mass.

We treated Lrp5-G171V^{K1/+} and wildtype littermates with LGK974, a small molecule Porcupine inhibitor that blocks Wnt secretion. The animals were treated daily for 35 days and DEXA was performed every 7 days to assess changes in bone mineral density (BMD). We found LGK974 significantly reduced BMD in both Lrp5-G171V^{K1/+} and wildtype animals. We are currently assessing cortical and trabecular morphology by μCT and assessing histological phenotypes by histomorphometry.

This study will help us better understand the mechanism of the LRP5-HBM G171V mutation and also confirms this mutation is Wnt ligand dependent. Treating LRP5-HBM mutation patients with LGK974 may offer a therapeutic treatment to alleviate the symptoms of high bone mass.

LGK974 decreases BMD in LRP5-G171V animals as determined by DEXA.

Role of FKBP12 in Signal Transduction by Mutant ALK2 Responsible for Fibrodysplasia Ossificans Progressiva. Aiko Machiya^{*1}, Mai Fujimoto¹, Sho Tsukamoto², Mai Kuratani², Satoshi Ohte², Naoto Suda³, Takenobu Katagiri². ¹Division of Pathophysiology, Research Center for Genomic Medicine, Saitama Medical University, Division of Orthodontics, Department of Human Development & Fostering, Meikai University School of Dentistry, Japan, ²Division of Pathophysiology, Research Center for Genomic Medicine, Saitama Medical University, Japan, ³Division of Orthodontics, Department of Human Development & Fostering, Meikai University School of Dentistry, Japan

Fibrodysplasia ossificans progressiva (FOP) is a rare hereditary disorder characterized by postnatal progressive heterotopic ossification in skeletal muscle. Twelve independent mutations in ALK2, a type I BMP receptor, have been identified from patients with FOP. The mutant forms of ALK2 were active in vitro without adding exogenous BMPs, indicating that they were gain-of-function mutations. It has been suggested that a decrease in binding affinity of ALK2 to FKBP12, which is a repressor of type I receptor kinases, is involved in the activation of the mutant ALK2. Recently, F198 and L199 residues in ALK2 have been shown to act as the binding site to FKBP12. In the present study, we examined the role of FKBP12 in the activation of ALK2 by analyzing biochemical characteristics of ALK2 carrying the mutations, including at the FKBP12-binding site (P197_F198del-insL mutant). Over-expression of those mutant ALK2, but not WT, induced ALP activity in the cooperation with Smad1 in C2C12 cells. The co-expression of FKBP12 markedly reduced the ALP activity and phosphorylated levels of Smad1/5. However, in the cultures of P197_F198del-insL mutant, neither ALP activity nor phosphorylated Smad1/5 levels were changed in the presence of FKBP12. FKBP12 did not change the binding ability of ALK2 to Smad1. Co-IP experiments revealed that the mutant ALK2, except the P197_F198del-insL mutant, showed weaker binding ability to FKBP12 than that of WT. In contrast, however, the P197_F198del-insL mutant did not bind to FKBP12, confirming that this mutant ALK2 has been changed structure in the FKBP12-binding site. These findings suggest that FKBP12 can repress the ALK2 activity in vitro through a direct interaction with ALK2 via the binding site. However, heterotopic ossification in the patient carrying the P197_F198del-insL mutation started at 11-year-old similar to other patients carrying typical mutation in ALK2, suggesting that heterotopic ossification in FOP is induced additional molecular mechanisms. Recently, we found that the mutant ALK2, including the P197_F198del-insL mutant, were hypersensitive to BMP type II receptors and were activated by them. FKBP12 failed to repress the ALP activity induced by the co-expression of BMP type II receptors and mutant ALK2, not only P197_F198del-insL but also other mutants. Taken together, our findings indicate that mutant ALK2 were activated by BMP type II receptors even in the presence of FKBP12. Phosphorylation of mutant ALK2 by the type II receptors may cancel the inhibitory activity of FKBP12 in FOP.

The Clinical and Genetic Spectrum of Low Alkaline Phosphatase in Adults. Leyre Riancho-Zarrabeitia^{*1}, María T. García-Unzueta², Jair A. Tenorio³, Juan A. Gómez-Gerique², Pablo Lapunzina³, Jose Riancho⁴. ¹Service of Rheumatology, Hospital UM Valdecilla, Spain, ²Service of Clinical Analysis, Hospital UM Valdecilla, Spain, ³Inst. Medical Molecular Genetics, Hospital La Paz., Spain, ⁴University of Cantabria, Spain

Purpose.-Different from infantile forms, adult forms of hypophosphatasia have less severe manifestations and may go unrecognized. Low serum levels of alkaline phosphatase (ALP), the enzyme encoded by the ALPL gene, are a hallmark of hypophosphatasia. However, the clinical significance and the underlying genetics of low ALP in unselected populations are unclear. **Methods.**-In order to clarify this issue,

we performed a clinical and biochemical study of subjects with reduced serum ALP activity and sequenced the exons of the ALPL gene. **Results.**-Forty two adults with unexplained persistently low serum ALP were studied. There was a 3:1 female:male ratio. Age range was 20-77 yr. Although many subjects experienced minor complaints, such as mild musculoskeletal pain (60%), none had major health problems. ALPL mutations were found in 21 out of 42 subjects (50%). Twenty patients carried heterozygous mutations; whereas 1 had a homozygous mutation. Eight mutations were novel and had not been previously described. Eighteen of the 21 patients with mutations (86%) had a missense mutation; in 1 case the mutation caused a splice change and there were 2 frameshift mutations. Most mutations were located in exons 5 and 6 (12 aminoacid were mutated in 17 patients) and were predicted to have a damaging effect on the protein activity, both according to the structure-based Polyphen webtool and the evolutionary criteria proposed by Silvent. The presence of a mutated allele was associated with premature tooth loss (48% versus 12%; $p=0.04$), slightly lower levels of serum AP (30'6 vs 25'6 u/l; $p=0.002$) and higher levels of enzyme substrates, such as serum pyridoxal phosphate ($p<0.0001$) and urine phosphoethanolamine ($p<0.0001$), as well as mildly increased serum phosphate ($p=0.03$). Ten patients had pyridoxal phosphate levels above the normal range, a test frequently used when hypophosphatasia is suspected. All carried a gene mutation; predicted to be deleterious in 9 cases and of doubtful significance in one. **Conclusion.**-One half of adults with persistently low levels of total alkaline phosphatase had a mutated allele of the ALPL gene. Although clinical manifestations are usually mild, in about 50% of them enzyme activity is low enough to cause substrate accumulation and may predispose to disorders of the teeth and other calcified tissues.

Comparative effectiveness of FGF23 blocking antibodies versus daily or intermittent 1,25 dihydroxyvitamin D as therapies for X-linked hypophosphatemia in mice. Eva Liu^{*1}, Adalbert Raimann², Daniel Brooks³, Mary Bouxsein⁴, Marie Demay⁴. ¹Brigham & Women's Hospital & Massachusetts General Hospital, USA, ²Medical University Vienna, Massachusetts General Hospital, Austria, ³Massachusetts General Hospital, USA, ⁴Massachusetts General Hospital, Harvard Medical School, USA

X-linked hypophosphatemia (XLH) is characterized by elevated serum FGF23, leading to hypophosphatemic rickets. Current therapies, 1,25 dihydroxyvitamin D (1,25D) and phosphate supplementation, do not normalize skeletal growth or mineralization. Recent studies have shown that FGF23 blocking antibodies increase serum phosphate in adults with XLH. Therefore, Hyp mice (murine model for XLH) were treated from day 2 to 75 with a blocking FGF23 antibody (FGF23Ab, Amgen), daily 1,25D or intermittent high dose 1,25D. Litter-matched wild type (WT) and Hyp mice were treated with vehicle. Relative to Hyp controls, all treatments significantly increased serum phosphate and suppressed serum PTH, while maintaining normocalcemia. Daily 1,25D and FGF23Ab significantly suppressed urinary phosphate excretion. All treatments increased FGF23 mRNA in long bones. The FGF23Ab significantly increased serum 1,25D at day 35 relative to Hyp controls, but not at day 75.

Daily 1,25D normalized body weight, whereas FGF23Ab significantly increased but did not normalize body weight; intermittent 1,25D had no effect. All treatments significantly increased lumbar vertebral height and tail length, compared to Hyp controls. Hypophosphatemia leads to decreased p-Erk1/2 in the growth plate, decreased hypertrophic chondrocyte apoptosis and expansion of the hypertrophic chondrocyte layer. All treatments attenuated the rachitic phenotype of the Hyp growth plate, assessed by collagen type X *in situ* hybridization and increased p-Erk1/2 and hypertrophic chondrocyte apoptosis relative to Hyp controls.

MicroCT analyses (Table 1) showed that relative to WT mice, Hyp controls had shorter femurs and reduced cortical thickness (Ct.Th), cortical area (Ct.Ar), polar moment of inertia (pMOI), and trabecular bone volume (Tb.BV/TV). FGF23Ab increased femur length relative to Hyp controls, but not to the same extent as daily or intermittent 1,25D. Compared with Hyp controls, mice treated with daily 1,25D and FGF23Ab had significantly higher Ct.Th and Ct.Ar. Although FGF23Ab improved pMOI, unlike daily 1,25D it did not normalize this parameter. Intermittent 1,25D did not improve these parameters. No treatment improved Tb.BV/TV.

While all treatments improved growth plate maturation, these studies demonstrate the importance of 1,25D for long bone and vertebral growth and bone micro-architecture in XLH. The inability of FGF23Ab to sustain increased serum 1,25D levels suggests combined therapy may be beneficial.

Table 1: Bone microarchitecture of Hyp mice treated with daily 1,25D, FGF23 Ab, or intermittent 1,25D

| Femur microCT | Wild Type | Hyp Control | Daily 1,25D | FGF23 Ab | Intermittent 1,25D |

Bone impairment in primary hyperoxaluria (PH): an ultrastructural analysis.

Delphine Farlay^{*1}, Justine Bacchetta², Pierre Cochat³, Georges Boivin⁴.

¹INSERM, UMR1033; Université De Lyon, France, ²Service de Néphrologie, Rhumatologie et Dermatologie Pédiatrique, centre de Référence des Maladies Rénales Rares, Hôpital Femme Mère enfant, Bron; INSERM UMR1033, Université de Lyon, France, ³service de Néphrologie, Rhumatologie et Dermatologie Pédiatriques, Centre de Référence des Maladies Rénales Rares, Hôpital Femme Mère enfant, Bron; Université de Lyon, France, ⁴INSERM UMR 1033, Université de Lyon, France

Deposition of calcium oxalate crystals in the kidney and bone is a hallmark of systemic oxalosis. Patients with PH1 (less frequently PH2) present severe impaired renal function, and thus systemic oxalosis. Since the bone compartment stores massive amounts of oxalate, patients present with recurrent low-trauma fractures, bone deformations, severe bone pains and specific oxalate osteopathy on plain X-ray. The threshold of glomerular filtration rate at which this occurs is debatable and might be as high as 30 to 45 mL/min per 1.73m². The objective of the study is to present a single-centre experience of bone biopsies and bone ultrastructural analysis in cases with oxalosis. Data were obtained in 10 samples from 8 patients with oxalosis (16-68 years) who underwent iliac crest bone biopsy and bone quality analysis using modern methods (Microradiography, microindentation, Fourier Transform InfraRed Microspectroscopy, transmission electron microscopy) in addition to histomorphometry. Disseminated calcium oxalate deposits (whewellite) were found in the bone marrow space (with a granulomatous reaction) but not in the bone matrix. Calcium oxalate deposits were totally surrounded by macrophages and multinucleated giant cells, and a phagocytosis activity was sometimes observed. Very few calcium oxalate crystals were directly in close contact with the mineral substance of bone. Pathological deposits are composed of more or less numerous elongated, birefringent crystals identified as calciumoxalate monohydrate. Bone tissue close to oxalosis deposits was composed of apatite, the usual mineral component of bone tissue. Bone mineralization was not modified by the presence of calcium oxalate even in close vicinity. Mineral maturity and crystallinity index were also unchanged, indicating that age of bone mineral and crystal size/perfection were not significantly modified. However, a decrease in the CO3/PO4 ratio was found in the PH group compared to controls. Bone quality analysis also revealed a harder bone than normal, perhaps in relationship with decreased carbonate content in the mineral. This study reports in patients with oxalosis, the specific location of calcium oxalate deposits (whewellite) in the bone marrow space (with a granulomatous reaction) and not in the bone matrix. Bone hardness is increased, that could explain a more "brittle" bone. The formation and growth of calcium oxalate crystals in bone is independent of apatite. Despite these novel observations, the exact mechanisms leading to nucleation and growth of oxalate deposits are still unclear and deserve further studies.

GORAB missense mutations disrupt RAB6 and ARF5 binding and Golgi targeting. Uwe Kornak^{*1}, Johannes Egerer², Denise Emmerich², Wing Lee Chan², Björn Fischer-Zirnsak², David Meierhofer³, Francis A. Bari⁴.
¹Charité-Universitätsmedizin Berlin, Germany, ²Institut fuer Medizinische Genetik und Humangenetik, Charité-Universitätsmedizin Berlin, Germany, ³Max Planck Institute for Molecular Genetics, Germany, ⁴Department of Biochemistry, University of Oxford, United Kingdom

Geroderma osteodysplastica is a hereditary segmental progeroid disorder leading to infantile osteoporosis and fractures caused by loss-of-function mutations in *GORAB*. The GORAB protein is prominently expressed in osteoblasts, where it localizes to the Golgi apparatus and interacts with the small GTPase RAB6. In this study we used different approaches to shed more light on the recruitment of GORAB to this compartment. We show that GORAB best co-localizes with trans-Golgi markers and is rapidly displaced upon Brefeldin A exposition indicating a loose association to Golgi membranes. A yeast two-hybrid screening revealed a specific interaction with the small GTPase ARF5 in its active, GTP-bound form. ARF5 and RAB6 bind to GORAB via the same internal Golgi-targeting RAB6 and ARF5 binding (IGRAB) domain. Two GORAB missense mutations identified in geroderma osteodysplastica patients fall within this IGRAB domain. GORAB carrying the mutation p.Ala220Pro had a cytoplasmic distribution and failed to interact with both, RAB6 and ARF5. In contrast, the p.Ser175Phe mutation displaced GORAB from the Golgi compartment to vesicular structures and selectively impaired ARF5 binding. Our findings indicate that the IGRAB domain is crucial for the Golgi localization of GORAB and that loss of this localization impairs its physiological function in osteoblasts and other matrix producing cells.

Neonatal High Bone Mass With First Mutation Of the NF-κB Complex:

Heterozygous De Novo Missense (p.Asp512Ser) *RELA* (Rela/p65). Anja L

Frederiksen¹, Martin Larsen¹, Klaus Brusgaard¹, Deborah V Novack², Peter Juel Thiis Knudsen³, Henrik Daa Schroeder¹, Christina Eckhardt¹, William H McAlister², Steven Mumm², Morten Frost¹, Michael Whyte^{*4}.

¹Odense University Hospital, Denmark, ²Washington University School of Medicine, USA, ³University of Southern Denmark, Denmark, ⁴Shriners Hospital for Children, USA

Heritable disorders that feature high bone mass (HBM) are rare. The etiology is typically a mutation(s) within a gene that importantly regulates the differentiation and function of osteoblasts (OBs) positively, or osteoclasts (OCs) negatively. However, the molecular basis is unknown for approximately one-fifth of such entities. NF-κB signaling is a key regulator of bone remodeling and acts by enhancing OC survival while impairing OB maturation and function. The NF-κB transcription complex comprises five subunits. Deletion of the p50 and p52 subunits together causes osteopetrosis (OPT) in mice. However, mutations within the genes that encode the NF-κB complex, including the Rela/p65 subunit, have not been reported in humans. We describe a neonate who died suddenly and unexpectedly and was found at post-mortem to have HBM documented radiographically and by skeletal histopathology. Serum was not available for study. Radiographic changes resembled malignant OPT (see figure), but histopathological investigation showed morphologically normal OCs and evidence of intact bone resorption excluding OPT. Furthermore, mutation analysis was negative for eight genes associated with OPT. Instead, accelerated bone formation appeared to account for the HBM. Subsequently, trio-based whole exome sequencing revealed a heterozygous, de novo, missense mutation (p.Asp512Ser) in exon 11 of *RELA* encoding Rela/p65 that was then validated by bi-directional Sanger sequencing. Five unrelated patients with unexplained HBM did not show a *RELA* defect. Ours is the first report of a mutation within the NF-κB complex in humans. The missense change is associated with neonatal osteosclerosis apparently from *in utero* increased OB function rather than decreased OC action. This finding clarifies the importance for human skeletal homeostasis of the Rela/p65 subunit within the NF-κB pathway, and represents a new genetic cause of HBM.

FR0392

Appendicular lean mass index is associated with estimated bone strength at the distal radius and distal tibia in middle-aged and older adults. Jenna Gibbs¹, Lora Giangregorio¹, Andy Wong², Robert Josse³, Angela Cheung⁴.
¹University of Waterloo, Canada, ²University Health Network Osteoporosis Program, Canada, ³St. Michael's Hospital-University of Toronto, Canada, ⁴University Health Network-University of Toronto, Canada

Appendicular lean mass index (appendicular lean mass (kg) corrected by height squared (m²), ALMI) is widely used as the defining parameter of low muscle mass indicative of sarcopenia and is positively correlated with areal bone mineral density measured by dual energy X-ray absorptiometry (DXA). However, the association between ALMI and estimated bone strength measured by high-resolution peripheral quantitative computed tomography (HRpQCT) requires further investigation. Purpose: To determine whether there is an association between ALMI and estimated bone strength outcomes at the distal radius and distal tibia in middle-aged and older adults. Methods: Secondary data analysis of 197 adults (70 men and 127 women; age range 40-91 years) from the Canadian Multicentre Osteoporosis Study Toronto cohort was conducted. Sociodemographic, medical history, and medication characteristics were obtained by an in-person interviewer-administered questionnaire. Height and weight were measured. Total body DXA scans were performed to determine appendicular lean mass. HRpQCT scans were performed to assess bone microarchitecture at the distal radius and distal tibia. Finite element analysis was used to estimate failure load and ultimate stress from HRpQCT scans. Bivariate and multivariable linear regression analyses were used to examine the association between ALMI and bone strength outcomes. Results: Participants were a mean \pm SD age of 69.5 \pm 10.3 yr and had a mean \pm SD body mass index of 27.95 \pm 4.95 kg/m² and ALMI of 7.31 \pm 1.31 kg/m². ALMI was positively associated with failure load ($b=337.83$, SE=28.25, $p<0.001$ and $b=764.58$, SE=58.06, $p<0.001$) and ultimate stress ($b=2.17$, SE=0.47, $p<0.001$ and $b=2.00$, SE=0.42, $p<0.001$) at the distal radius and distal tibia, respectively. After adjusting for age, sex, prior fracture, calcium supplementation, estrogen replacement, osteoporosis medication use, and glucocorticoid use, ALMI explained 63.2% (F=41.6, $p<0.001$) and 57.7% (F=32.9, $p<0.001$) of the variance in failure load and 16.0% (F=5.5, $p<0.001$) and 15.8% (F=5.4, $p<0.001$) of the variance in ultimate stress at the distal radius and distal tibia, respectively. Conclusions: Our findings demonstrate that ALMI is a moderately strong positive correlate of failure load and may contribute to the preservation of bone strength. Future prospective studies are necessary to confirm the associations among ALMI, estimated bone strength, and incident fragility fractures.

Aging and caloric restriction significantly alter the microRNA cargo of exosomes and microvesicles in the bone marrow microenvironment. Colleen Davis¹, Amy Dukes¹, Sadanand Fulzele¹, Xingming Shi¹, William Hill¹, Carlos Isaacs¹, Yutao Liu¹, Mark Hamrick². ¹Georgia Regents University, USA, ²Georgia Health Sciences University, USA

Exosomes are small (40-100 nm) and microvesicles are larger (>100 nm) membrane-derived extracellular vesicles (EVs) that are released into the extracellular space by a variety of cell types. EVs derived from human bone marrow stromal cells (BMSCs) have been found to be enriched in microRNAs (miRNAs), and microvesicle- and exosome-derived transport of miRNAs is thought to represent a novel cellular and molecular pathway for epigenetic reprogramming of target cells. We tested the hypothesis that aging may contribute to bone loss by altering the microRNA profile of bone-derived EVs, and that caloric restriction might have a protective effect on the skeleton by suppressing these age-induced changes. We isolated EVs from bone marrow of young mice (3-4 mos) and aged mice (22-28 mo) fed ad-libitum and on caloric restriction using ExoQuick precipitation and centrifugation. Relative size and concentration of these extracellular vesicles was analyzed using nanoparticle tracking analysis (ZetaView), and the microRNA profile of the EVs assessed using microarray. These data indicate that the concentration and size distribution of EVs is similar between the young and aged mice; however, the miRNA profile differs significantly between the two age groups. Specifically, the microRNAs miR-141, miR-19b, and miR-183 are increased significantly in the aged mice, as assessed using either microarray or realtime PCR. Importantly, these miRNAs have been demonstrated previously to play key roles in suppressing osteogenesis and inducing cellular senescence. Caloric restriction (CR) is known to extend lifespan in vertebrates, and while CR inhibits bone mineral accrual during growth it can actually attenuate bone loss with aging. Our PCR data showed that CR can reverse the increased expression of miR-141, -19b, and -183 more than two-fold compared to aged mice fed libitum. Confocal imaging of BMSCs treated with labeled EVs demonstrate that BMSCs show uptake of EVs, indicating that exosomes and microvesicles are likely to play an important role in cell-cell communication within the bone marrow microenvironment. Moreover, changes in the microRNA cargo of these EVs with age may contribute to decreased bone formation and bone loss.

Advancing Muscle Measurement for Sarcopenia Assessment. Bjoern Buehring¹, Ellen Fidler², Yosuke Yamada³, Jessie Libber², Diane Krueger², Shubha Shankaran⁴, Gregg Czerwiec⁴, Chancy Fessler⁴, William Evans⁴, Scott Turner⁴, Marc Hellerstein⁴, Dale Schoeller⁵, Neil Binkley². ¹University of Wisconsin, Madison, USA, ²Osteoporosis Clinical Research Program, University of Wisconsin - Madison, Madison, USA, ³National Institute of Health & Nutrition, Japan, ⁴KineMed, Inc., USA, ⁵Department of Nutritional Sciences, University of Wisconsin-Madison, USA

Sarcopenia (SP), the age related decline in muscle mass and function, is common and associated with falls and fractures. Muscle function predicts adverse outcomes better than does muscle mass, possibly due to limitations of current clinically available mass assessment methods. Specifically, DXA measured lean mass is largely water, both intra- and extracellular. Extracellular water does not decline with advancing age thereby blunting the ability to detect age-related muscle loss. It is likely that newer mass methodologies, e.g., bioelectric impedance spectroscopy (BIS) and creatine (*methyl-d*₃) dilution (D₃-C) provide more accurate mass assessment. Here, we hypothesized that BIS and D₃-C measured muscle mass will better correlate with muscle function than does DXA measured lean mass.

In this ongoing study, muscle function and mass assessments were performed in 20 community dwelling individuals age 70+. Grip strength, gait speed, timed up and go (TUG), and chair rise time were assessed in standard manner. Jumping mechanography (JM) was used to measure weight-corrected jump power. DXA body composition was obtained using a GE Lunar iDXA, BIS with an Impedimed SFB7 device and D₃-C was administered orally. Descriptive statistics and linear correlations between total lean/muscle mass and functional tests were performed.

This preliminary analysis included 17 women and 3 men, mean age 81.8 \pm 6.3. Total body lean mass [mean (SD)] by DXA was 38.9 (7.0) kg, BIS total body intracellular water (ICW) was 16.6 (3.2) kg and D₃-C total muscle mass 20.6 (5.5) kg. Correlations between DXA lean mass, BIS and D₃-creatine measured muscle mass were good (R²-values ~0.82). Grip strength was highly correlated with D₃-C measured mass (R² = 0.60) and also with BIS and DXA (R² = 0.49 and 0.39 respectively). The other functional tests were not significantly related to mass. A marker of muscle composition/quality, the BIS leg ICW/total leg water ratio correlated with gait speed, jump power and TUG (R² = 0.29 – 0.68).

In conclusion, these preliminary data suggest that advances in measurement of muscle mass and quality, i.e., D₃-C and BIS, will likely improve the correlation with functional status in older adults. Including BIS and D₃-C in larger studies of adverse health outcomes e.g., falls and fractures, are needed for validation. These methods have potential to improve clinical assessment of muscle mass/quality and thus become an integral part of sarcopenia diagnosis and treatment.

Identification of Senescent Cells in the Bone Microenvironment: A Key Role for Osteocytes in Skeletal Aging. Joshua Farr*, David Monroe, Matthew Drake, Daniel Fraser, Tamara Tchkonja, Nathan LeBrasseur, James Kirkland, Sundeep Khosla, Mayo Clinic, USA

Cellular senescence is a fundamental mechanism by which cells cease dividing and undergo distinct phenotypic alterations, characterized by upregulation of *p16^{Ink4a}* (a robust biomarker and principle mediator of senescence) and secretome changes. Senescent cells accumulate in multiple tissues with aging where they secrete pro-inflammatory factors and matrix remodeling proteins. Accordingly, they have been hypothesized to promote degenerative pathologies, including osteoporosis. Thus, senescent cells and their senescence-associated secretory phenotype (SASP) are increasingly recognized as promising therapeutic targets. However, it is unclear which cell type(s) in the bone microenvironment is most prone to senescence with aging.

Thus, from young (6-month) and old (24-month) mice, we measured expression of senescence, SASP and pro-inflammatory markers *in vivo* via qPCR in highly enriched preparations of B cells, T cells, myeloid cells, osteoprogenitors, osteoblasts and osteocytes, all rapidly isolated using novel approaches without *in vitro* culture.

In both young and old mice, *p16^{Ink4a}* was not expressed in B cells, T cells, osteoblasts or osteoprogenitors. With aging, however, *p16^{Ink4a}* expression increased markedly (+6.5-fold, $p < 0.00001$; Fig. A) in the osteocyte-enriched fraction, as did other senescence mediators (*p19*, *p21*, *p53*, all $p < 0.05$; Fig. A). These increases correlated with higher abundance of an *in vivo* senescence biomarker (senescence-associated β -galactosidase). Corresponding with this age-associated accumulation of senescent osteocytes, were significant increases in the expression of multiple SASP (Fig. B) and pro-inflammatory (Fig. C) markers in the old vs young osteocyte fractions. Finally, several of these same SASP and pro-inflammatory markers were dramatically upregulated (>30-fold) in myeloid cells with aging.

When interpreted in the context of accumulating evidence demonstrating osteocyte control of myeloid lineage cells (e.g., osteocyte RANKL production leading to osteoclast development from myeloid progenitors), our data point to the provocative hypothesis whereby with aging, a subset of osteocytes become senescent and produce a SASP signal that is communicated to neighboring myeloid lineage cells. These myeloid lineage cells may in turn amplify this signal, resulting in excessive production and secretion of pro-inflammatory cytokines and chemokines, thereby creating a toxic local microenvironment that may contribute to age-related bone loss.

Requirement of nitric oxide in bone development and homeostasis informed by genetic deficiency of argininosuccinate lyase. Zixue Jin*, Jordan Kho, Monica Grover, Brian Dawson, Ming-Ming Jiang, Yuqing Chen, Terry Bertin, Brendan Lee, Baylor College of Medicine, USA

Although nitric oxide (NO) donors have been shown to have the potential to increase bone density, the effect is dependent on many factors and recent studies suggest NO may exhibit biphasic function on bone formation. The precise mechanism of NO regulation of bone development and homeostasis is unclear due to complexity of animal models. NO is enzymatically produced by three nitric oxide synthases (NOS1,2, however, analyses have been limited by the potential redundancy of the three NOS isoforms. Argininosuccinate lyase (ASL) is the only mammalian enzyme capable of generating arginine, the sole precursor for NOS-dependent NO synthesis. Moreover, we recently showed that it is also required for channeling extracellular L-arginine to NOS for NO production. Hence, deletion of ASL leads to a cell autonomous deficiency of NOS-dependent NO production due to combined loss of

endogenous arginine production and extracellular arginine channeling. As such, it serves as a powerful model for NOS-dependent NO production in biological processes. To study NO function in bone development and remodeling, we generated novel mouse models with conditional deficiency of ASL in osteoblastic lineage cells. Interestingly, we found that early deletion of ASL in osteoblasts using *ostx1-Cre* mice (*Asl^{flox/flox} osx-Asl cKO*) led to high bone mass. In contrast deletion of ASL in more mature osteoblasts using mouse type I collagen *Cre* mice (*Asl^{flox/flox} colla1-Asl cKO*) led to low bone mass. Mechanistically, we found that *Osx-Asl cKO* mice had dramatically decreased expression of RANKL, thereby reducing bone resorption. In contrast, *colla1-Asl cKO* mice showed suppressed bone formation with down-regulation of bone formation markers such as *Runx2*, *Osterix* and *Colla1*. Furthermore, *ex vivo* osteoblast differentiation was also decreased in *colla1-Asl cKO* mice compared with WT mice. In the context of postmenopausal osteoporosis, we found *colla1-Asl cKO* were resistant to ovariectomy (OVX) induced bone loss. This suggests that NO down-regulation may be a mechanism for estrogen deficiency induced bone loss. In conclusion, we established new mouse models to study NO function in bone by conditional deletion of ASL in osteoblastic cells. Our findings reveal that osteoblast autonomous NO depletion has biphasic and stage-dependent effects on bone formation and bone resorption, respectively.

A transcription factor *Zfhx4* functions as a transcriptional platform for Osterix during endochondral ossification. Eriko Nakamura*, Kenji Hata², Michiko Yoshida², Tomohiko Murakami², Yoshifumi Takahata², Makoto Abe³, Satoshi Wakisaka³, Toshiyuki Yoneda⁴, Riko Nishimura⁵. ¹Osaka University, Japan, ²Osaka University Graduate School of Dentistry, Dep Mol Cell Biochemistry, Japan, ³Osaka University Graduate School of Dentistry, Dep Oral Anat Dev Biol, Japan, ⁴Indiana University School of Medicine, USA, ⁵Osaka University Graduate School of Dentistry, Japan

Several transcription factors, including *Sox9*, *Runx2*, and *Osterix* play critical role in endochondral ossification. Considering the complex but harmonious regulation in endochondral ossification, it is possible that unknown transcription factors are involved in this biological event. To address this, we performed microarray analyses using mouse limb bud cells and isolated a novel transcription factor *Zfhx4* containing 4 homeobox and 22 zinc finger domains. *Zfhx4* is putatively proposed to be responsible for the 8q21.11 Microdeletion Syndrome, characterized by micrognathia, camptodactyly, and syndactyly. We first generated the *Zfhx4* knockout (KO) mice and examined the phenotype. *Zfhx4* KO mice died of respiratory failure within a day after birth. *Zfhx4* KO mice exhibited trivertebra thoracic cavity, malformation of skull and proximal skeletal elements and cleft palate. Histological analyses and *in situ* hybridization analyses indicated that endochondral ossification was arrested at hypertrophic stage in the *Zfhx4* KO mice. Although differentiation of chondrocytes into resting, proliferating and hypertrophic chondrocytes seemed normal, calcification and degradation of cartilage matrices was markedly suppressed in the *Zfhx4* KO mice. In addition, *MMP13* expression was dramatically down-regulated in the femur of *Zfhx4* KO mice at E15.5. Because these findings are similar to phenotype observed in the cartilage-specific conditional *Osterix* KO mice, we next examined interaction between *Zfhx4* and *Osterix*. Fluorescent imaging analyses showed co-localization of *Zfhx4* with *Osterix*, but not with *Runx2*. Co-immunoprecipitation experiments also indicated the physical association of *Zfhx4* with *Osterix*. Moreover, overexpression of *Zfhx4* up-regulated the *MMP13* gene promoter, which is one of the direct targets of *Osterix*. These results suggest that *Zfhx4* is a critical transcriptional factor that interacts with *Osterix* and regulates the late stage of endochondral ossification. Thus, *Zfhx4* seems to function as a transcriptional platform for *Osterix*.

AP-1 factor interacts with *Sox9* during mammalian chondrocyte hypertrophy. Xinjun He¹, Shinsuke Ohba², Hironori Hojo¹, Andrew McMahon¹. ¹University of Southern California, USA, ²University of Tokyo, Japan

Sox9 is essential for chondrocyte specification and differentiation. Despite extensive genetic and biochemical studies, the interplay and interactions of *Sox9* in the progression of chondrocyte development is not well understood. Our previous study on chromatin immunoprecipitation and sequencing (ChIP-seq) of *Sox9* in neonatal mouse rib chondrocyte revealed a *Sox9* regulated network of chondrocyte enhancers (see presentation by Ohba et al.). Interestingly, in addition to the expected *de novo* recovery of a *Sox9* binding sequence through motif analysis, analysis of the ChIP-seq data also demonstrated a highly significant enrichment of an AP-1 factor-binding motif in the *Sox9* ChIP-seq dataset. The AP-1 factor comprises Fos and Jun-related family members. Expression studies revealed localized expression of *Jun* and *Fos2* (a Fos-relative) overlapping *Sox9* cells in the proximal prehypertrophic/early hypertrophic subset of the *Coll10a1*+ hypertrophic chondrocytes, suggesting that AP-1 factor and *Sox9* may co-regulate chondrocyte gene activity in this segment of the growth plate. Though the action of *Sox9* in hypertrophy is controversial, *Sox9* levels are highest in prehypertrophic chondrocytes and *Sox9* removal specifically within this population blocked hypertrophic chondrocyte development. Clearly, *Sox9* is essential for continued progression of chondrocytes to maturing hypertrophic chondrocytes.

To directly determine AP-1 complex engagement in the hypertrophic process, we performed ChIP-seq for Jun (c-Jun). Intersection of Sox9 with Jun binding data showed that Jun is co-bound at most Sox9 interacting cis-regulatory modules. Further, the strength of interaction as determined by recovery of sequence reads was highly correlated and co-bound regions were strongly associated with skeletal development-related genes. These data suggest AP-1 factors act in conjunction with Sox9 to regulate chondrocyte hypertrophy. Consistent with this view, knockdown or inhibition of AP-1 factors in chondrocytes attenuated Sox9 controlled endochondral hypertrophy, supporting the argument that AP-1 complexes modulate Sox9 function during this process. Functional analysis identified Sox9 and AP-1 binding motifs in a *Coll10a1* distal enhancer responsible for Sox9 and AP-1 regulation of *Coll10a1* expression in hypertrophic chondrocytes. These data, together with biochemical studies of Sox9 and AP-1 factor interactions with their targets and each other, lead to complex model of target output to be presented at the meeting.

Bardet-Biedl Syndrome 3 Is Involved in the Development of Cranial Base. Makiri Kawasaki^{*1}, Tadayoshi Hayata², Yayo Izu¹, Yoichi Ezura¹, Masaki Noda¹. ¹Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical & Dental University, Japan, ²Department of Biological Signaling & Regulation, Faculty of Medicine, Project Office of Ph.D program in Life Science Innovation, Japan

Craniofacial dysmorphology presented in various genetic disorders could be a key for diagnosing the disease, and may also become a key for understanding its etiology. The patients of a typical ciliopathy, Bardet-Biedl syndrome (BBS) manifest characterized craniofacial abnormalities such as high-arched palate, mid-facial hypoplasia and hypo-odontia. However, the mechanisms involved in such phenotype have not been investigated enough. Here, we aimed to reveal morphological phenotype of the BBS mouse model by focusing on developmental craniofacial abnormalities. BBS3 is one of the causative genes for human BBS. Thus, we analyzed skeletal phenotype of the BBS3 knockout (KO) mice at E18.5. 3D micro-CT analysis revealed hypoplasia of basi-sphenoid in the midline, a loss of pre-sphenoid, and dysplasia of distal maxillae with 100% penetrance in Bbs3-KO embryos. Skeletal preparation revealed cleaved intrasphenoidal / sphenoid-occipital synchondrosis. Furthermore, intrasphenoidal synchondrosis was shortened longitudinally. Tooth germs of incisors were lost in Bbs3-KO embryos with nearly 100% penetrance. Histological analysis demonstrated that while the binate prechordal cartilages were formed almost normally, they were not fused in the midline and space between the cartilages was filled with fibroblastic cells in the cranial base of Bbs3-KO embryos. Mandibles, calvarias and occipital bones were morphologically normal. Our results demonstrate that Bbs3-KO embryos present severe defects in cranial base midline constructs. Impaired fusion of prechordal cartilages antecedent to the mineralization may be the cause. In addition, since skeletal elements constructing the craniofacial region are mostly derived from cranial neural crest cells (CNCCs), and their migration, proliferation and differentiation are tightly regulated by sonic hedgehog (Shh) signaling that takes place in primary cilia, our results may suggest that impaired Shh signaling due to dysfunction of the cilium in CNCCs may be the cause of midface dysplasia.

Bone-anabolic effects of histone methyltransferase EZH2 inhibition. Amel Dudakovic^{*1}, Emily Camilleri¹, Fuhua Xu¹, Scott Riester¹, Meghan McGee-Lawrence², Elizabeth Bradley¹, Christopher Paradise¹, Roman Thaler¹, Eric Lewallen¹, John Hawse¹, Malavannan Subramaniam¹, David Deyle¹, Noelle Larson¹, David Lewallen¹, Gary Stein³, Martin Montecino⁴, Jennifer Westendorp¹, Andre van Wijnen¹. ¹Mayo Clinic, USA, ²Georgia Regents University, USA, ³University of Vermont Medical School, USA, ⁴Universidad Andres Bello, Chile

Perturbations in skeletal development and bone degeneration can result in reduced bone mass and quality leading to greater fracture risk. Bone loss is mitigated by bone protective therapies, but there is a clinical need for new bone-anabolic agents. Here, we investigated if epigenetic enzymes regulating osteoblast differentiation can be leveraged for bone stimulatory applications. Expression screening for epigenetic regulators during osteoblast differentiation identified the histone methyltransferase Enhancer-of-Zeste homolog 2 (EZH2) as a potential target. Using loss-of-function models and pharmacologic inhibitors, we show that EZH2 not only controls early stages of mesenchymal cell commitment as reported but also maturation of pre-committed osteoblasts. Next-generation sequencing of mRNA (mRNASeq) and real-time quantitative PCR profiling establish that EZH2 inactivation promotes expression of bone-related gene regulators and extracellular matrix proteins. Mechanistically, enhanced gene expression is linked to decreased Histone 3 lysine 27 tri-methylation (H3K27me3) near transcriptional start sites in genome-wide chromatin immunoprecipitation analyses (ChIPSeq). Conditional genetic loss of Ezh2 in uncommitted mesenchymal cells (Prrx1-Cre) results in multiple skeletal patterning and bone defects, including shortened forelimbs, craniosynostosis and clinodactyly. Histological

analysis and mRNASeq profiling suggests that these effects are attributable to growth plate abnormalities and premature cranial suture closure due to precocious maturation of osteoblasts. Deletion of functional Ezh2 in the osteoblast lineage (Ox-Cre) generates normal appearing mice with a low bone mass phenotype at weaning (3 weeks), while the bone parameters become less prominent in early adulthood (8 weeks). Daily administration (five weeks) of an EZH2 inhibitor increases cortical bone density of female adult wild type mice. Strikingly, daily injection (six weeks) prevents cortical bone loss in an estrogen-deficient mammalian model (ovariectomy) for osteoporosis. Thus, although EZH2 is required for early skeletal patterning and development, inhibition of this enzyme has bone-anabolic and osteoprotective potential in adults.

FR0408

Deletion of the Prolyl Hydroxylase Domain-containing Protein 2 (PHD2) Gene in Chondrocytes Promotes Endochondral Bone formation by Elevating HIF-1 α Signaling. Shaohong Cheng^{*1}, Weirong Xing², Sheila Pourteymoor², Catrina Alarcon², Subburaman Mohan². ¹VA Loma Linda Health Care Systems, USA, ²Jerry L Pettis VA Medical Center, USA

Endochondral bone formation (EBF) initiates from differentiation and ossification of chondrocytes at the avascular growth plates of long bones. The hypoxic growth plate cartilage requires hypoxia-inducible transcription factors (HIFs)- mediated pathways to maintain chondrocyte survival and differentiation. HIF protein is closely regulated by prolyl hydroxylase domain-containing protein 2 (Phd2) mediated proteasomal degradation. To determine the role of Phd2 in chondrocytes in regulating EBF, we conditionally disrupted the Phd2 gene in chondrocytes by crossing Phd2 floxed and Col2a1-Cre mice, and found massive increases in the trabecular bone mass of the long bones (145%) and lumbar vertebra (53%) of 12 week old Phd2 conditional knockout (cKO) mice. Trichrome staining of bone sections revealed increased bone in the primary and secondary spongiosa of cKO mice. Dynamic histomorphometry revealed that while the mineral apposition rate was unchanged, the bone formation rate was increased by 77% (p<0.01) due to a 62% increase (p<0.05) in osteoblast (OB) number in the trabeculae of cKO mice, measured as Osterix-positive cells. Bone resorption was decreased by 16% (p<0.05) in the cKO mice measured by Oc.S/B.S. (osteoclast surface per bone surface). To determine the mechanism for increased EBF, we measured expression levels of genes involved in the EBF process in the growth plates by quantitative RT-PCR. Expression levels of chondrocyte (Sox9, Col2 and aggrecan) as well as OB markers (ALP and BSP) were increased significantly in the cKO growth plate. Since the HIF pathway are the major target of Phds, we next examined HIF-1 α and HIF-2 α expression by immunohistochemistry, and detected a marked increase of HIF-1 α protein in the hypertrophic chondrocytes, while the HIF-2 α protein level was not changed in the cKO growth plate. Accordingly, expression levels of HIF-1 α targets, VEGF, Epo, and glycolytic enzymes (Glut1, Ldha1, Pdk1, Pkg1) were significantly upregulated in the growth plates of cKO mice compared to WT mice. This expression profile was recapitulated in vitro upon adenoviral Cre-mediated knockdown of Phd2 expression in chondrocytes-derived from Phd2 floxed mice. Based on our findings, we conclude that Phd2 deficiency leads to upregulation of HIF-1 α signaling and elevation of VEGF, Epo expression and glycolysis to promote chondrocyte survival and differentiation into osteoblasts and, thereby, EBF.

Disclosures: Shaohong Cheng, None.

FR0410

ER Stress Signaling Transducer IRE1 α Links ER Stress to Canonical Wnt Signaling in Regulating Postnatal Bone Development and Homeostasis. Shankar Revu^{*1}, Kai Liu¹, Konstantinos Verdelis¹, Alejandro Jose Almarza¹, Donna Stolz², Hong-Jiao Ouyang³. ¹School of Dental Medicine, University of Pittsburgh, USA, ²School of Medicine, University of Pittsburgh, USA, ³University of Pittsburgh, USA

The inositol-requiring enzyme 1 α (IRE1 α)/ X-box binding protein 1s (XBP1s) pathway is an evolutionarily conserved endoplasmic reticulum (ER) stress signal transduction pathway required for the development of secretory cells and organs, such as pancreatic β cells and salivary glands. However, it remains unknown whether IRE1 α is required for bone development and homeostasis. Recently, our laboratory found that the activation of IRE1 α /XBP1s signaling is a physiological event intrinsic to osteoblast differentiation and bone development. This prompted us to generate mice lacking osteoblast-specific IRE1 α (CKO), and their wild type littermates (WT), by breeding *Irel1^{Flox/Flox}* mice with *Osterix-Cre* mice. It was observed that IRE1 α -deficient osteoblasts exhibited exacerbated ER stress and consequently experienced activation of the PRKR-like endoplasmic reticulum kinase (PERK)/eukaryotic translation-initiation factor 2 α subunit (EIF2 α) signal transduction pathway, both in vivo and in vitro, compared with WT counterparts, as shown by immunohistochemical (IHC) staining and Western blot analysis for phosphorylated PERK (p-PERK) and EIF2 α (p-EIF2 α). Furthermore, IRE1 α CKO mice displayed osteoporosis/osteopenia with increased bone marrow fat, recapitulating the bone phenotypes resulting from loss-of-function of canonical Wnt signaling in mice. Consistent with this notion, IRE1 α -deficient osteoblasts had a reduced steady-state protein level of β -Catenin, a transcription factor central for canonical Wnt signaling, both in vivo and in

vitro, compared with WT counterparts, as shown by IHC staining and Western blot analysis, respectively. It was observed that IRE1 α deficiency did not affect the gene expression of β -Catenin in osteoblasts, both in vivo and in vitro, as shown by quantitative real-time PCR (qRT-PCR) analysis. Instead, IRE1 α deficiency resulted in compromised protein synthesis of β -Catenin in osteoblasts via its induction of p-EIF2 α , an inhibitor for global protein synthesis, as shown by ³⁵S pulse labeling assays. Taken together, our studies identified the ER stress signaling transducer IRE1 α as a novel regulator for postnatal bone development and homeostasis. In addition, we discovered that the p-EIF2 α -mediated regulation of β -Catenin protein synthesis is a novel molecular mechanism, by which ER stress affects canonical Wnt signaling in regulating postnatal bone development and homeostasis.

FR0411

Matrix vesicle-mediated initiation of skeletal mineralization depends on PHOSPHO1 and PIT-1 function. Manisha Yadav*¹, Massimo Bottini², Pia Kuss², Esther Cory³, Robert Sah³, Laurent Beck⁴, Colin Farquharson⁵, Jose Luis Millan². ¹Sanford-Burnham Medical Research Institute, USA, ²Sanford Children's Health Research Center, Sanford-Burnham Medical Research Institute, USA, ³Department of Bioengineering, University of California San Diego, USA, ⁴Centre for Osteoarticular & Dental Tissue Engineering (LIOAD), Nantes, Cedex, France, France, ⁵The Roslin Institute, The University of Edinburgh, Easter Bush, Roslin, Midlothian, EH25 9RG, United Kingdom

We have previously shown that ablation of either the Phospho1 or Alpl gene, encoding PHOSPHO1 and tissue-nonspecific alkaline phosphatase (TNAP) respectively, lead to hyperostoidosis but that their chondrocyte- and osteoblast-derived matrix vesicles (MVs) are able to initiate mineralization. In contrast, the double ablation of Phospho1 and Alpl completely abolishes initiation and progression of skeletal mineralization. We argued that MVs initiate mineralization by a dual mechanism: PHOSPHO1-mediated intravesicular generation of Pi and phosphate transporter-mediated influx of Pi generated perivesicularly. To test this hypothesis, we generated mice with col2a1-driven cre-mediated ablation of Pit1 alone or in combination with a Phospho1 gene deletion. Pit1col2/col2 mice did not show any major phenotypic abnormalities, while severe skeletal deformities were observed in the [Phospho1^{-/-}; Pit1col2/col2] double knockout mice that were more pronounced than those observed in the Phospho1^{-/-} mice. Histological analysis of 15-day-old [Phospho1^{-/-}; Pit1col2/col2] bones showed growth plate abnormalities with a shorter hypertrophic chondrocyte zone and extensive hyperostoidosis. The [Phospho1^{-/-}; Pit1col2/col2] skeleton displayed significantly decreases in BV/TV%, trabecular number and bone mineral density with increased trabecular separation for both tibia and femur compared to Phospho1^{-/-} mice. Three-point bending analysis also showed that [Phospho1^{-/-}; Pit1col2/col2] bones exhibit decreased stiffness, decreased strength, and increased post-yield deflection. By atomic force microscopy we found that approximately 70% of [Phospho1^{-/-}; Pit1col2/col2] MVs were empty in comparison to about 20-30 % empty MVs for the WT, Phospho1^{-/-} and Pit1col2/col2 MVs. We also found a significant decrease in the number of MVs produced by both Phospho1^{-/-} and [Phospho1^{-/-}; Pit1col2/col2] chondrocytes. These data prove the involvement of Pit-1 function in the initiation of skeletal mineralization and it provides compelling evidence that PHOSPHO1 mediates MV biogenesis.

Disclosures: Manisha Yadav, None.

FR0412

Newly Identified FGFR2 Isoform Modulates FGF10-FGFR Signaling During Osteochondrogenesis. Kazuko Kagawa*¹, Hirotaka Yoshioka², Saki Okita³, Koh-ichi Kuremoto¹, Yuichiro Takei², Tomoko Minamizaki², Kotaro Tanimoto³, Kazuhiro Tsuga¹, Yuji Yoshiko². ¹Department of Advanced Prosthodontics, Hiroshima University Institute of Biomedical & Health Sciences, Japan, ²Department of Calcified Tissue Biology, Hiroshima University Institute of Biomedical & Health Sciences, Japan, ³Department of Orthodontics & Craniofacial Developmental Biology, Hiroshima University Institute of Biomedical & Health Sciences, Japan

Fibroblast growth factor (FGF) family consists of 22 members and plays diverse roles in angiogenesis, wound healing, embryonic development, and endocrine signaling. FGF activities are mediated by receptor tyrosine kinases and implicated in skeletal growth and its related disorders. Gain-of-function mutations in a common extracellular domain of FGF receptor (FGFR) 2 isoforms (type b and c) cause craniosynostosis and chondrodysplasia syndromes. FGF10, a major ligand for FGFR2b, is secreted from mesenchymal cells and regulates epithelial-mesenchymal interactions. Meanwhile, FGF10 regulates early chondrogenesis, and abrogation of FGF10 in an Apert syndrome mouse model rescues skeletal defects. Thus, FGF10-FGFR signaling during osteochondral development remains unclear. We generated transgenic mice expressing mouse FGF10 under the control of doxycycline. Fetuses were exposed to doxycycline from embryonic day 12.5, and FGF10 transgenic (TG) pups were compared with control littermates. Similar to FGF10- and FGFR2b-deficient mice, TG mice died shortly after birth. TG pups were smaller in size, while

limb and vertebral deformities were worthy of little attention. These mice showed craniomaxillofacial dysmorphology including rostrocaudal hypoplasia, developmental retardation in mandibular condylar cartilage, cleft palate and so on. Expression profiling of *Fgfr* genes in multiple tissues and cells suggested the presence of the additional alternative RNA splicing isoform of *Fgfr2* (*Fgfr2bc*). Among tissues and cells tested, this isoform was expressed in particular tissues/cells including mandibular condylar cartilage and ATDC5 cells. The predicted translation product of *Fgfr2bc* appears to include both exon 8- and 9-encoded residues (type b and c, respectively) and lack membrane-spanning and tyrosine kinase domains, suggesting a soluble form of FGFR2b (sFGFR2). sFGFR2 was identified in the conditioned media in ATDC5 cells and overexpressing sFGFR2 increased cell proliferation, suggesting that sFGFR2 may act as a decoy receptor for FGFs. Thus, a large amount of FGF10 may trap sFGFR2 and allow for enhancing other FGF-FGFR signaling pathways, with resultant skeletal anomalies in TG mice.

Sex-related Differences in the Axial Skeletal Development of Newborns and Infants. Skorn Ponrartana¹, Patricia Aggabao¹, Naga Dharmavaram², Carissa Fisher¹, Tishya Wren¹, Vicente Gilsanz*³. ¹Children's Hospital Los Angeles, Keck School of Medicine, University of Southern California, USA, ²Children's Hospital Los Angeles, Keck School of Medicine, University of Southern California, USA, ³Children's Hospital Los Angeles, USA

Compared with boys of the same body mass, healthy prepubertal girls have less musculature and smaller vertebrae – phenotypic differences that account, at least in part, for the variance in vertebral fracture risk among sexes. The purpose of this study was to examine for pre- and early post-natal sex differences in the morphogenesis of the axial skeleton. Using magnetic resonance imaging techniques that allow for fast and reliable determinations of newborn and infant development without the need for sedation, we longitudinally characterized musculoskeletal development in 25 boys and 25 girls at birth, three months, and six months of age.

We found a striking sexual dimorphism in vertebral size at birth; on average, the lumbar vertebral cross-sectional area (CSA) was 9.6% smaller in newborn girls than boys (p=0.0004) – a difference that persisted even after accounting for gestational age, weight, body length, or paraspinal musculature. In contrast, the sexes were monomorphic with regard to paraspinal musculature at birth (p=0.95). As expected, the cross-sectional dimensions of the vertebrae increased during infancy in both sexes. The gains were, however, greater in boys than in girls, which further enhanced the sexual dimorphism in vertebral size. Whereas mean values for vertebral CSA increased from birth to 6 months of age by 54% (SD=10%) in boys, those in girls only increased by 35% (SD=13%); p < 0.0001. Among both sexes, the rate of growth was threefold higher during early infancy than from three to six months of age (32 ± 12% vs 10 ± 9%; p < 0.0001) and closely related to muscle development, consistent with knowledge that neonates experience a "mini-puberty" during the first three months of life. Regression analysis indicated that vertebral growth during early infancy was strongly related to differences in gains in paraspinal musculature (0.22 ± 0.63; p=0.001).

In conclusion, sex has a differential effect on the intrauterine programming of the axial skeleton, while differences in muscle development are key determinants of the sexual dimorphism in skeletal growth during infancy. The strong relations found between bone accrual and increases in muscle mass even in early postnatal life, stress the need for preventive strategies to start in childhood and be geared toward those infants with the smallest vertebrae and highest risk for developing vertebral fractures later in life.

Suppression of Autophagy by Postnatal FIP200 Deletion Compromises Cortical Bone Development with Minimal Effect on Trabecular Bone Development. Li Wang*¹, Fei Liu². ¹University of Michigan, USA, ²University of Michigan School of Dentistry, USA

Autophagy is a conserved lysosomal-catabolic process, by which superfluous or damaged cellular material is delivered, degraded and then recycled to maintain cellular homeostasis and normal physiology. In previous study, we found that suppression of autophagy by ablation of focal adhesion kinase family interacting protein of 200 kD (FIP200), an essential component of mammalian autophagy, led to severe osteopenia in mice. In that study, FIP200 was deleted in osteoblast from embryonic stage with Osterix-Cre. Autophagy deficient mice had significant early postnatal skeleton growth retardation, which prevented us from concluding to what extent the osteopenic phenotype observed at later stages can be ascribed to the role of FIP200/autophagy at adult stage. To address this, we suppressed osteoblast autophagy in mice from 2 month old to 6 month old (4-month suppression group, male) and from 4 month old to 6 month old (2-month suppression group, female) by inducibly deleting FIP200 using doxycycline-controlled Tet-off Osx-Cre expression system (removed doxycycline food at 2 months of age and 4 months of age respectively). Bone morphology was evaluated in femur and vertebrae by microCT analysis. In contrast to the result from our previous mouse model, postnatal osteoblast autophagy suppression did not result

in notable trabecular BV/TV change in both femur (4 months and 2 months suppression groups) and vertebrae (2 months suppression group). However, we found that the tissue mineral density of trabecular bone had a small (3-5%) but statistically significant decrease ($p < 0.05$ for 4 months suppressing group femurs and 2 months suppression group vertebrae, $p = 0.08$ for 2 months suppression group femurs) in autophagy deficient mice, indicating the compromised bone quality. In both 4 months and 2 months suppression group, the femoral cortical area was significantly decreased (-6.3% and -6.8% respectively). To further determine the effect of autophagy deficiency on cortical bone, we measured the calvarial thickness and found that the calvaria thickness dramatically decreased (-29%, $p < 0.01$) in 4 months but not in 2 months suppression group. In summary, our preliminary data suggest that FIP200/autophagy has overlapping but different roles in bone development during later postnatal stage compared to early postnatal stage. FIP200/autophagy may play more important roles in regulating cortical bone development and remodeling compared to trabecular bone at later postnatal stage.

The role of Wnt signal modulator, sFRP4, in bone formation and metabolism.

Ryuma Haraguchi^{*1}, Riko Kitazawa², Yuuki Imai², Sohei Kitazawa².

¹Ehime University Graduate School of Medicine, Japan, ²Ehime university, Japan

Background: Activation of the Wnt signaling pathway leads to the buildup of bone strength and bone mass. Its excessive hyperactivity, however, leads to musculoskeletal tumors and the progression of articular disorders. Secreted Frizzled-related protein 4 (sFRP4) is a member of the secreted Wnt antagonist gene family that adequately fine-tunes its signal activity by direct binding to Wnt-ligands. We have previously reported that bone loss under the oxidative stress of diabetes and aging is related to the suppression of canonical Wnt pathways through the reactivation of sFRP4 gene expression by a unique epigenetic mechanism. To explore the functions of sFRP4 as a balancer molecule for Wnt signal activity in bone development, we engineered an sFRP4 knock-in mouse strain in which the sFRP4 gene locus was replaced by the LacZ reporter gene. In addition to genetic gene inactivation, the generation of the sFRP4-LacZ knock-in mouse provides the additional advantage of the highly sensitive and easy *in situ* detection of LacZ gene expression, for *in vivo* analysis of the gene expression of sFRP4. In this study, we investigated the details of sFRP4 expression patterns during long bone formation and the characteristic features of the bone phenotype in sFRP4-LacZ knock-in mice.

Finding: X-gal staining in sFRP4-LacZ knock-in mice revealed spatial-temporal Sfrp4 expression patterns in the developing limb. Until stage E16.5, LacZ expression was undetectable in limb bud tissues; it then became evident only in a restricted area of the diaphysis at E17.5. At the postnatal and puberty stages, strong LacZ expression was observed on the trabecular bone surface and the periosteum in the long bone shaft. Immunohistochemistry on the X-gal stained tissue sections showed that most of LacZ positive cells were Osterix-positive osteoprogenitor cells and Cathepsin K-positive osteoclasts. μ CT analysis of long bones revealed an increased trabecular BV/TV and bone mineral density, and reduced cortical bone thickness in sFRP4-LacZ $-/-$ mice compared with that in control mice. Histological analysis of sFRP4-LacZ $-/-$ mice trabecular bones confirmed the increased number of osteoprogenitor cells and the reduced number of normal osteoclasts. **Conclusion:** sFRP4 is expressed in dual osteogenic lineages, osteoblastic cells and osteoclasts, in the neonatal and postnatal skeleton. Inactivation of the sFRP4 gene in these cell lineages shows dramatic increase in trabecular bone volume with alteration in skeletal metabolism. These findings raise the possibility that sFRP4 is one of the key molecules that regulate the balance between cortical and trabecular bone volume by efficiently influencing both bone formation and bone absorption directly during long bone development and maintenance.

TrkA Signaling by Sensory Nerves is Required for Skeletal Development and Repair.

Ryan Tomlinson^{*1}, Zhi Li¹, Qian Zhang¹, Labchan Rajbhandari¹, Arun Venkatesan¹, David Ginty², Thomas Clemens¹. ¹Johns Hopkins University, USA, ²Harvard University, USA

The development and repair of the skeleton requires inductive signals from multiple cell types, which act in a sequential and hierarchical fashion to program lineage allocation of osteochondral progenitors. Critical to the early stages of this program is the invasion of blood vessels and sensory nerves, which appear simultaneously at sites of incipient bone formation. In contrast to the well-established role of angiogenesis in bone development and repair, relatively little is known about the function of sensory nerves in bone. Since nearly all sensory nerves in bone express TrkA, we first characterized the role of TrkA signaling during endochondral bone development. Using established reporter mice, we show that TrkA expressing sensory neurons of the dorsal root ganglion (DRG) project axons that reach perichondrial bone surfaces adjacent to primary ossification centers by E14, coincident with the appearance of NGF expressing perichondrial cells. To selectively disrupt TrkA signaling, we used mice harboring TrkA-F592A knockin alleles that render the endogenous TrkA kinase sensitive to inhibition by the membrane-permeable molecule 1NMPP1 (Chen X et al. 2005). The efficacy of this approach was confirmed *in vitro* by

demonstrating impaired axonal growth of TrkA-F592A DRG neurons exposed to 1NMPP1 and *in vivo* by reduced TrkA phosphorylation in DRGs from TrkA-F592A mice treated with 1NMPP1. To determine the requirement of TrkA signaling during endochondral bone formation, we analyzed femurs from newborn offspring of heterozygous TrkA-F592A mothers that received 1NMPP1 in their drinking water throughout pregnancy. The inhibition of TrkA signaling during embryogenesis significantly diminished bone volume, reduced innervation density, and decreased vascularity at birth. We also assessed the requirement of TrkA signaling during bone repair by subjecting adult TrkA-F592A mice to an ulnar stress fracture, a regenerative process that incorporates mechanosensation, angiogenesis, and osteogenesis. In this model, inhibition of TrkA signaling severely diminished woven bone formation during healing. Taken together, these studies demonstrate that TrkA signaling is required for normal endochondral bone development and stress fracture repair. We hypothesize that TrkA sensory nerves deliver key signaling molecules that initiate osteoblast lineage commitment and progression while also providing a template for vascular invasion of newly formed bone.

FGF23 metabolism, a new paradigm for chronic kidney disease. Isabelle Picc*¹, Christopher Washbourne², Holly Nicholls², Jonathan Tang², William D. Fraser². ¹BioAnalytical Facility, University of East Anglia, United Kingdom, ²University of East Anglia- bioanalytical facility, United Kingdom

Introduction: Fibroblast growth factor-23 (FGF23) is a major regulator of phosphate metabolism often elevated in genetic hypophosphataemic disorders (XLH, ADHR) and in chronic kidney disease (CKD). Recent studies have identified relationships between FGF23 and various markers of iron status including ferritin. New assays measuring the intact form of FGF23 have been released.

Objective: To determine the relationship between ferritin and C-terminal and intact FGF23 concentrations in blood.

Method: FGF23 concentrations were measured using the second generation, two-site enzyme-linked immunosorbent assay for either C-terminal or intact FGF23 (immotopics Inc, CA, USA). Ferritin was measured on a COBAS 6000 (Roche Diagnostics, UK). Assay accuracy and precision were monitored using kit controls supplied by the manufacturers.

Results: We observed a weak correlation between measurements of C-terminal and intact FGF23 (Pearson's rho = 0.85 p<0.0001) suggesting that the turnover of FGF23 is not 100% and cleaved fractions can accumulate. We observed no statistically significant correlation of ferritin concentrations with either FGF23 C-terminal or intact. However high concentrations of ferritin were observed in samples showing low concentrations of C-terminal FGF23 (<140RU/mL) and intact FGF23 (<122pg/mL).

Conclusion: Although not statistically significant, we observed a negative relationship between concentrations of ferritin and FGF23 (Pearson's rho =-0.3 and rho = -0.2 for C-terminal and intact FGF23, respectively). A high concentration of C-terminal FGF23 is found in patients with CKD, especially in patients with end-stage renal disease usually regarded as a compensatory response to hyperphosphatemia. We observed a number of patients (16%) with retention of both C-terminal and intact FGF23 associated with low levels of ferritin suggesting that metabolism and/or excretion of FGF23 in CKD patients might be an iron-dependent enzyme mediated mechanism.

Sclerostin and FGF-23 Protein Expression in Bone of Patients With Various Stages of Decline in Kidney Function. Florence Lima*, Marie-Claude Monier-Faugere, Hanna W. Mawad, Harmut H. Malluche. University of Kentucky, USA

Renal osteodystrophy occurs in the early stages of chronic kidney disease (CKD) and progresses during loss of kidney function. Sclerostin and FGF-23, both produced by osteocytes, are increased in blood of patients with reduced kidney function. The aim of this study was to analyze the impact of decline in kidney function on sclerostin and FGF-23 protein expression in bone and to study their relationship with bone histomorphometry.

Thirty-six patients underwent anterior iliac crest biopsies after double-tetracycline labeling. Eleven patients were CKD-2, 16 were CKD-3 and 9 were CKD-4 to 5. Fourteen aged-matched patients without CKD were included as controls. Immunostaining was performed on undecalcified bone sections to quantify sclerostin and FGF-23 expression. Bone sections were also evaluated by histomorphometry for bone turnover, mineralization and volume.

Sclerostin expression in bone correlated positively with CKD stages (rho=0.50, P<0.001) with an increase from 3.8- to 5.1-fold starting at CKD-2 compared to those with non-CKD. This increase was progressive and significantly greater in cortical than cancellous bone (Figure 1A).

FGF-23 expression in bone correlated positively with CKD stages (rho=0.55, P<0.001) with an increase from 5.3- to 7.1-fold in patients starting at CKD-2 compared to those with non-CKD. No difference in FGF-23 expression was seen between trabecular and cortical bone (Figure 1B).

Sclerostin expression in bone correlated negatively with parameters of trabecular thickness, osteoid surface (rho=-0.50 and -0.51, respectively; P<0.05), osteoblast and osteoclast numbers and erosion depth (rho=-0.61, -0.60 and -0.60, respectively; P<0.01). FGF-23 bone expression correlated positively with cortical porosity (rho=0.75, P<0.001).

These data show a progressive increase in sclerostin and FGF-23 bone expression associated with decrease in kidney function. This is associated with changes in bone structure (decrease in trabecular thickness, increase in cortical porosity) and bone turnover (osteoblast and osteoclast numbers and erosion depth). These findings suggest that targeting the suppression of sclerostin and/or FGF-23 expression early in the course of loss of kidney function may be of interest to protect bone against renal osteodystrophy.

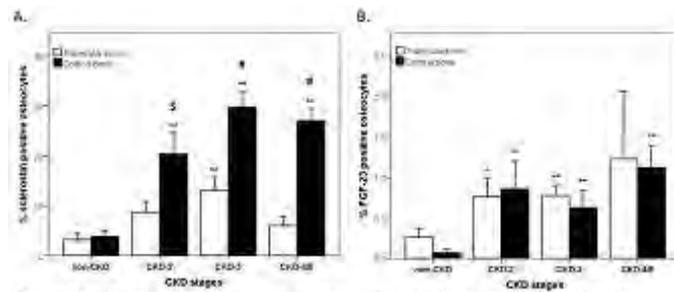

Figure 1-Quantification of positive osteocytes per total osteocyte number for (A) sclerostin and (B) FGF-23. Values are represented by mean and standard errors. * P<0.05 or ** P<0.01 for CKD stages 2 to 5 versus non-CKD. † P<0.05 or ‡ P<0.001 for trabecular versus cortical bone.

Altered RNA Stability And A Gfi1-Induced Epigenetic Switch Regulate Runx2 Repression In Multiple Myeloma-Exposed Pre-Osteoblasts. Juraj Adamik*¹, Wei Zhao², Peng Zhang¹, Quanhong Sun¹, G. David Rodman³, Deborah L. Galson¹. ¹University of Pittsburgh, USA, ²Indiana University, USA, ³Indiana University & Veterans Administration Medical Center, USA

Multiple myeloma (MM) causes osteolytic bone lesions that rarely heal even after therapeutic remission. We reported that the MM-induced pro-inflammatory bone marrow microenvironment causes upregulation of the transcriptional repressor Gfi1 in bone marrow stromal cells (BMSC) via TNF α . Gfi1 represses the key osteoblast (OB) differentiation factor Runx2, resulting in impaired BMSC differentiation into OB. Proliferating pre-OB treated with TNF α or cocultured with 5TGM1 MM cells exhibited a rapid (1.5-3h) decrease in Runx2 mRNA and later (48h) the Runx2 gene became refractory to OB differentiation stimuli even after removal of the TNF α or MM cells. We showed that Gfi1 knockdown in pre-OB did not block the MM-induced rapid decrease of Runx2 mRNA, but it prevented the sustained repression of Runx2 following induction of OB differentiation for 2-4d. We found that the initial Runx2 decline is due to decreased mRNA stability. The Runx2 promoter in MC4 pre-OB cocultured with 5TGM1 MM cells (48h) had reduced activating acetylation (H3K9ac) levels and enhanced heterochromatic methylation (H3K27me3), consistent with decreased expression that stayed refractory to OB differentiation. BMSC from MM patients (3) compared to normals (2) also had decreased levels of H3K9Ac at the Runx2 gene promoter. Further, MM coculture induced binding of Gfi1 to the Runx2 promoter in pre-OB with increased occupancy at 36 and 48h, concomitantly with increased histone deacetylase HDAC1 (erases H3K9ac) and the PRC2 complex methyltransferase subunit EZH2 (adds H3K27me3). Ectopic Gfi1 also bound Runx2 and recruited these histone modifiers. The HDAC1 inhibitor MC1293 prevented Runx2 mRNA suppression in MM treated pre-OB. Interestingly, TNF α inhibited expression of H3K27me3 demethylases JmjC-domain-containing proteins UTX and JMJD3, and increased global H3K27me3 levels in pre-OB, further arguing for the role of PRC2 complex in Runx2 suppression. We found that Gfi1 knockdown pre-OB lacked MM-dependent HDAC1 recruitment, resulting in prevention of Runx2 deacetylation and rescue of differentiation-induced Runx2 mRNA expression. These data show that Gfi1 is required for the MM-induced epigenetic repression of Runx2. We report that MM cells utilize dual modes of suppressive effects on OB differentiation by reducing Runx2 mRNA stability in proliferating pre-OB and employing Gfi1 to recruit HDAC1 and EZH2 to establish long-term epigenetic suppression of Runx2 transcription.

The Relationship between Vitamin D Status and Clinical Outcomes of Patients with Hepatic Cirrhosis. Edward Marchese*¹, Francine Almeda², Isabel Camara², Thomas Layden², Stephanie Kliethermes², William Adams², Pauline Camacho². ¹Loyola University Stritch School of Medicine, USA, ²Loyola University Medical Center, USA

Purpose: Vitamin D insufficiency is prevalent amongst patients with hepatic cirrhosis due to a multitude of factors, including decreased dietary intake, limited sunlight exposure, and impaired hepatocyte function. In a previous report, we found an inverse correlation between vitamin D levels and frequencies of lung transplant rejection and infection. (Lowery et al 2012). Given the recognized immunoregulatory effect of vitamin D, we aimed to determine its impact on clinical outcomes in hepatic

cirrhosis patients. We utilized the frequency of hepatic decompensation, Child-Pugh (CP), and model for end-stage-liver disease (MELD) scores to quantify endpoints, as previously described by Bankuti et al. (2012). Additionally, bone density status of patients was assessed using dual energy x-ray absorptiometry (DXA) data.

Methods: A retrospective electronic medical chart review was conducted on consecutive patients seen at Loyola University Medical Center between 2009-2014, who had 25(OH) vitamin D levels measured after diagnosis of hepatic cirrhosis. Vitamin D sufficiency was defined as a 25(OH)D level of ≥ 30 ng/ml. Within a one-year timeframe, we tracked liver biochemistries, abdominal ascites, hepatic encephalopathy, and calculated CP and MELD scores for each patient. Chi-square and two-sample t-tests were used to compare demographic, laboratory, clinical, and DXA results between the groups.

Results: The cohort included 60 subjects (51.7% female) with a mean age of 58.2 ± 10.5 years. The mean 25(OH)D for sufficient patients ($n=24$) was 38.1 ng/ml versus 18.8 ng/ml ($p=.003$) in the insufficient group ($n=36$). Nine (38%) sufficient patients suffered from hepatic decompensation as compared to 27 (75%) in the insufficient cohort ($p=0.004$). The mean CP scores in the sufficient versus insufficient groups were 6.11 ± 1.05 and 7.65 ± 1.78 ($p<.001$). MELD scores were 8.47 ± 7.51 vs. 12.65 ± 5.13 for these groups, respectively ($p<.001$). There were no significant differences in femoral neck T-scores; however, there was a trend toward lower lumbar T-scores in the insufficient group as compared to the sufficient group (-1.14 ± 0.44 vs. 0.25 ± 0.46 , $p=0.06$).

Conclusions: Vitamin D status showed a strong inverse correlation between CP and MELD scores; however, its role in liver pathogenesis is not clearly defined. Additionally, the trend towards lower lumbar T-scores may indicate preferential decreases in bone mineral density of trabecular bone as compared to cortical bone.

Tumour-Induced Osteomalacia due to a Gluteal Phosphaturic Mesenchymal Tumour: A Case Report. Rachel Johnston¹, Brendan C. Dickson², Peter C. Ferguson², Ina Radziunas³, Sandra A. Kim⁴. ¹University of Toronto, Canada, ²Mount Sinai Hospital, University of Toronto, Canada, ³Women's College Hospital, Canada, ⁴Women's College Hospital, University of Toronto, Canada

Case:

A 47-year-old male sustained multiple rib fractures and a non-displaced fracture of the left hip, requiring a total hip replacement, after slipping on ice. Post-operatively, his hip pain worsened and he developed diffuse bony pain and proximal muscle weakness. Multiple occult pelvic fractures and a right hip stress fracture were identified on repeat imaging.

The patient was previously healthy, with no personal or family history of bone disease or cancer. There was no history of prior fragility fractures or glucocorticoid use. Physical examination was remarkable only for proximal myopathy.

Baseline bone density revealed a Z-score of -2.5 at the lumbar spine. His bone scan was consistent with osteomalacia. Biochemical work-up revealed hypophosphatemia, hyperphosphaturia, elevated alkaline phosphatase and undetectable calcitriol.

The diagnosis of tumour-induced osteomalacia (TIO) was confirmed based on elevated fibroblast growth factor-23 (FGF-23) level of >800 pg/mL (reference range 8-54 pg/mL). He was commenced on phosphate and calcitriol supplementation. An octreotide scan revealed a focal ovoid area of increased octreotide avidity deep to the left gluteal minimus muscle. CT-guided biopsy confirmed a phosphaturic mesenchymal tumour, mixed connective tissue variant (PMT). He underwent an uncomplicated surgical resection of the tumour, and had complete clinical and biochemical recovery at 3-month follow-up.

Discussion:

Phosphate plays a critical role in bone mineralization and cellular metabolism. Its homeostasis is regulated by FGF-23, parathyroid hormone and calcitriol through renal tubular reabsorption, bone mineralization, and intestinal absorption. Eighty to 95% of filtered phosphate is reabsorbed at the proximal convoluted tubule via the type IIa sodium-phosphate NaPi co-transporter. FGF-23 increases renal phosphate excretion by down-regulating the NaPi co-transporter and calcitriol conversion. Persistent hypophosphatemia may manifest as proximal myopathy and debilitating fragility fractures due to osteomalacia.

Conclusion:

TIO is a rare paraneoplastic process; inappropriately elevated levels of FGF-23 secreted from an occult PMT lead to renal phosphate wasting, hypophosphatemia, decreased calcitriol levels and subsequent fractures. PMT are notoriously difficult to localize. With tumour excision, prognosis is excellent, with complete symptomatic and biochemical resolution.

Genetic Variants Associated with Bisphosphonate-Associated Osteonecrosis of the Jaw: A Whole-Exome Sequencing Analysis. Yan Gong^{*1}, Joseph Katz², Alberto Riva¹, Noa Davis³, Issam Hamadeh¹, Bernadett Bella⁴, Janos Kosa⁴, Mihaly Vaszilko⁵, GIAN ANDREA PELLICIONI⁶, Peter Lakatos⁴, Jan Moreb¹, Taimour Langae¹. ¹University of Florida, USA, ²Department of Oral Medicine, College of Dentistry, USA, ³Micromedic Technologies Ltd, Israel, ⁴Semmelweis University Medical School, Hungary, ⁵Semmelweis University Dental School, Hungary, ⁶University of Bologna, Italy

Purpose: Osteonecrosis of the jaw (ONJ) is a rare and serious adverse drug event that was reported initially with bisphosphonates use and more recently with other drug classes such as RANKL inhibitors and anti-angiogenic agents. The purpose of this study is to identify functional genetic variants associated with ONJ in patients treated with intravenous (IV) bisphosphonates using a whole-exome sequencing approach.

Methods: Whole-exome sequencing analysis was performed on 46 multiple myeloma patients treated with IV bisphosphonates (zoledronate or pamidronate), including 23 individuals with ONJ and 23 age, gender and race-matched controls who did not develop ONJ after at least 24 months of IV bisphosphonate treatment. Standard bioinformatics analysis was applied and the reads were aligned to the human genome (version GRCh37/hg19) using bowtie (version 2.2.3). Variant calling was performed using GATK pipeline (version 3.2-2). The association of the variants with ONJ was performed in PLINK with Fisher's exact test and logistic regression controlling for age, gender and race. Variants with $p < 1.2 \times 10^{-7}$ were considered statistically significant and those with $p < 10^{-4}$ were considered suggestive.

Results: The patients had mean age of 63 years, 54% male and 96% were self-identified as Whites. An average of 3,667,001 SNPs per sample (min=3,441,884, max=4,048,829) were identified. After quality control steps, 427,367 variants were analyzed. In the Fisher's exact analysis, 5 SNPs had $p < 10^{-4}$. Four SNPs were associated with lower odds of ONJ including an intronic SNP rs795489 on *PRDX4* gene encoding peroxiredoxin 4 with odds ratio (OR) of 0.14 ($p = 2.16 \times 10^{-5}$), rs6504184 in the promoter region of gene *CCDC47* with OR of 0.13 ($p = 3.2 \times 10^{-5}$) and rs11074355 in *TMC7* gene with OR of 0.15 ($p = 4.4 \times 10^{-5}$). One SNP was associated with higher odds of ONJ: intronic SNP rs11938792 on chromosome 4 had OR of 22.93 ($p = 6.98 \times 10^{-5}$). The *TMC7* and *CCDC47* SNPs remained significant in the multiple logistic regression analysis.

Conclusions: We identified 5 novel variants that might be associated with ONJ in multiple myeloma patients treated with IV bisphosphonates. Functional analysis is warranted to understand the underlying mechanisms of these associations. If validated, these genetic variants could be used to guide personalized therapy for bisphosphonates for multiple myeloma patients.

KLF10 is a Critical Mediator of Wnt Signaling in Calcific Aortic Valve Disease. Nalini M. Rajamannan¹, John Hawse², Malayannan Subramaniam². ¹Mayo Clinic, Rochester MN, USA, ²Mayo Clinic, USA

We have previously demonstrated that β -catenin plays important roles in valve calcification with a specific osteogenic phenotype defined by increased bone mineral content and overall valve thickening. Recent studies indicate that KLF10, a transcription factor known to play critical roles in osteoblast differentiation and bone mineralization, may also be involved in mediating the Wnt signaling pathway in the skeleton. Therefore, we sought to determine if KLF10 participates in regulating Wnt signaling, as well as differentiation and mineralization in valve interstitial cells (VICs). As a first step, we analyzed the expression patterns of Wnt pathway genes in VICs prior to and following differentiation. Following exposure of VICs to osteogenic differentiation media, increased expression of Runx2, Sox9, and osteocalcin were observed compared to non-differentiated cells. Differentiated cells also stained positive with Von Kossa while undifferentiated cells stained negative confirming the induction of an osteogenic phenotype. As expected, transfection of VICs with Lef1, β -catenin or both resulted in activation of the canonical Wnt signaling top-flash reporter construct. Interestingly, expression of KLF10 also significantly up-regulated the top-flash reporter construct alone and further enhanced the activity of both Lef1 and β -catenin. These data suggested that KLF10, Lef1 and β -catenin interact with each other to form a transcriptionally active protein complex leading to enhanced Wnt signaling in VICs. This possibility was confirmed by the observation that KLF10 and β -catenin co-localize with one another in the nucleus of VICs following stimulation with Lf1 or treatment with TGF- β , a cytokine known to induce KLF10 expression and enhance osteogenic phenotypes. In an experimental model of hypercholesterolemia using LRP5 null mice, the expression levels of LRP6, KLF10 and Runx2 were significantly increased following cholesterol treatment of mice as compared to controls suggesting that hyperlipidemia may also enhance Wnt signaling via LRP6 and downstream KLF10. Taken together, these data implicate important roles for KLF10 in mediating Wnt signaling and LEF1 transcriptional activity in VICs, and imply a potential role for the canonical Wnt signaling pathway in the observed osteogenic bone phenotype in aortic valves.

The association between vitamin D receptor gene polymorphisms (TaqI and FokI) and micro/macrovacular complications in postmenopausal women with type 2 diabetes. Juliana Maia de Almeida¹, Andreia Soares Silva², Rodrigo Feliciano do Carmo², Taciana Belmonte², Luiz Griz¹, Patricia Muniz Moura², Francisco Bandeira¹, Mirna De Sa³. ¹Division of Endocrinology & Diabetes, Agamenon Magalhães Hospital, University of Pernambuco Medical School, Recife, Brazil, ²Institute of Biological Sciences, University of Pernambuco Medical School, Recife, Brazil, ³University of Pernambuco Medical School, Brazil

Some studies have shown that vitamin D deficiency is associated with increased risk of developing type 2 diabetes (T2DM) and atherosclerotic cardiovascular disease but few studies have examined the association of vitamin D receptor (VDR) polymorphisms with these two common conditions as well as with the chronic complications of T2DM. Aims: To examine the associations between VDR polymorphisms (FokI and TaqI), T2DM and its chronic complications in postmenopausal women. Methods: This cross-sectional study analyzed 100 postmenopausal women with T2DM (mean age 65.7 \pm 7.18 years) and 100 postmenopausal women without diabetes in the control group (mean age 65.1 \pm 9.18 years; $p=0.1608$). We evaluated clinical and metabolic parameters and analyzed TaqI and FokI polymorphisms. Results: There were no significant differences in genotype and allele frequencies between patients and controls in either of the polymorphisms studied. In the group of patients with diabetes, there were no significant differences in either polymorphism in relation to stroke, retinopathy, nephropathy or neuropathy. However, in patients with T2DM and coronary artery disease (CAD) Ff genotype ($p=0.0361$) and the combination of Ff+ff genotypes were observed less frequently ($p=0.0462$) [Table 1]. Conclusions: Our data demonstrated a protective effect of FokI polymorphism for CAD in postmenopausal women with T2DM in the recessive model.

Key words: 1) Type 2 diabetes; 2) VDR; 3) Polymorphism; 4) Vitamin D

The MicroRNA Signatures in the Patients with Lumbar Disc Herniation. Lili Chen¹, Xiaoya Zhou², Songlin Peng^{3,4}, Shishu Huang⁴, Sibylle Grad⁵, Mauro Ajimi⁵. ¹Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Peoples republic of china, ²Center for Human Tissues & Organs Degeneration, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, China, ³Shenzhen People's Hospital, Jinan University School of Medicine, China, ⁴State Key Laboratory of Oral Diseases, Sichuan University, China, ⁵AO Research Institute Davos Clavadelstrasse, Switzerland

Introduction: Lumbar disc herniation (LDH) is one of the major causes for back and sciatic pain that costs large medical expense. Accumulating evidence has indicated that microRNAs (miRNAs), a small non-coding RNA molecule, are associated with disc degeneration, the profile of miRNAs in the LDH patients with indication for laminectomy remains unclear.

Material methods: MicroRNA profiling was performed on plasma samples of 4 groups: LDH-young group (n=8, average age is 31), LDH-old group (n=8, average age is 56), healthy control-young group (n=4, average age is 20), healthy control-old group (n=6, average age is 58). The miRNAs expression were further validated by qRT-PCR.

Results: The miRNAs with p -values < 0.05 and fold change values ≥ 2 or ≤ 0.5 compared to healthy control were regarded as dysregulated miRNAs. 61 miRNAs were upregulated and 302 were downregulated in LDH-young group compared to healthy control-young group. In addition, there are 46 upregulated miRNAs and 115 downregulated in LDH-old group compared to healthy control-old group. In particular, 12 upregulated and 71 downregulated miRNAs expressed significant differences both in the LDH-young group vs healthy control-young group and the LDH-old group vs healthy control-old group. Among them, miR-224 was upregulated 4.04-, 16.99-fold in LDH-young and LDH-old groups compared to healthy control-young and healthy control-old groups, respectively ($p < 0.01$ for both). Besides, relative to old groups, miR-130b and miR-147b were downregulated significantly in young groups, both of which were reported to be associated with disc degeneration.

Conclusion: The selected miRNAs might play a vital role in the molecular pathogenesis of LDH and further research for the understanding of the functionality and pathological mechanism of the miRNAs in LDH is important and would shed new light on LDH.

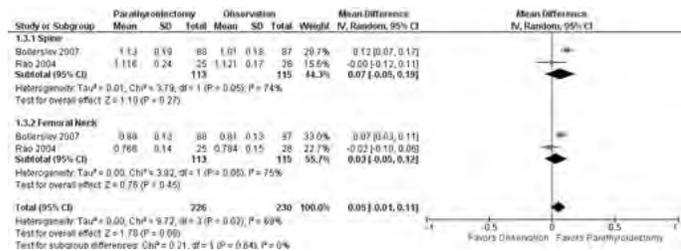

Key words: LDH, microRNAs, disc degeneration

Bone Mineral Density Changes and Fracture Risk in Patients with Asymptomatic Primary Hyperparathyroidism. Systematic Review and Meta-analysis. Spyridoula Maraka¹, Naykky Singh Ospina¹, Ana Espinosa De Ycaza², Rene Rodriguez Gutierrez³, Sina Jasmin⁴, Michael Gionfriddo⁵, Ana Castaneda-Guarderas⁵, Alaa Al Nofal⁶, Victor Montori¹, Robert Wermers². ¹Mayo Clinic, Division of Endocrinology, Knowledge & Evaluation Research Unit, USA, ²Mayo Clinic, Division of Endocrinology, USA, ³Mayo Clinic, Knowledge & Evaluation Research Unit, USA, ⁴Endocrinology, Mayo Clinic, ⁵Mayo Clinic, Knowledge & Evaluation Research Unit, USA, ⁶Mayo Clinic, Division of Pediatric Endocrinology, USA

Many patients with asymptomatic primary hyperparathyroidism (PHPT) have mild uncomplicated disease without indications for surgical intervention. A better understanding of the potential benefits of surgical intervention would help clinicians counsel these patients. The purpose of this study is to summarize the available evidence regarding changes in bone mineral density (BMD) and fracture risk in PHPT when comparing parathyroidectomy with active surveillance. We performed a computerized bibliographic search of published articles and citation review by an experienced medical reference librarian. We included randomized (RCT) and observational studies that evaluated the changes in BMD and fracture risk in patients with asymptomatic PHPT and no strong indications for surgery undergoing parathyroidectomy or active surveillance as treatment options. Trained reviewers independently screened for eligible studies, assessed risk of bias and extracted data in duplicate. Statistical analysis was performed following a random effect model. The search yielded 3141 articles for abstract screening of which 4 studies were included; 2 RCTs with 113 patients undergoing surgery and 115 surveillance and 2 single arm cohort studies of 124 patients followed with active surveillance. The BMD change (g/cm²) was 0.07 (95% CI: -0.05, 0.19) at the lumbar spine and 0.03 (95% CI: -0.05, 0.12) at the femoral neck when comparing these 2 treatment modalities at 2 years of follow up. When evaluating the patients followed by active surveillance the overall lumbar spine BMD change from baseline was -0.03 (95% CI: -0.08, 0.02) at 2 years of follow up. There were no reported fractures in any patients included in the RCT (53 patients) or in the 136 patients followed with active surveillance (follow up 12-123 months). Overall, studies had moderate to high risk of bias mainly driven by unclear allocation and attrition for RCTs and/or inappropriate patient selection and follow up for observational studies. The available evidence regarding the effects of surgical intervention versus active surveillance on bone health in patients with asymptomatic PHPT without strong clinical indications for parathyroidectomy is scarce. Available data suggest a minimal BMD gain at the spine and femoral neck in favor of parathyroidectomy and minimal BMD loss in patients with active surveillance. The confidence in these estimates is weakened by moderate to high risk of bias and imprecision.

Bone Effect

Bone Observation

Table1. Summary of Included Studies of patients with mild PHPT and without strong indications for surgical intervention

| Author | Year | Type of study | Inclusion Criteria | Patients with Surgery | Patients with Observation | Mean follow up time |
|------------|------|--|--|--|---------------------------|------------------------------|
| Bollerslev | 2007 | RCT | Untreated, asymptomatic PHPT; serum calcium 2.6-2.85 mmol/L Age 50-80 years No medications interfering with calcium metabolism | 88 | 87 | Final follow up at 24 months |
| Rao | 2004 | RCT | Age 50-75 years, mean albumin adjusted serum calcium between 10.1-11.5 mg/dL; intact PTH > 20 ng/L, normal renal function, serum creatinine less than 1.5 mg/dL, forearm bone mineral density within 2 SD adjusted for age, sex, race, absence of symptoms and complications from hypercalcemia or excess PTH, living 150 miles from the institution | 25 | 28 | At least 24 months |
| Rao | 2003 | Single arm | Patients discovered fortuitously with biochemical screening and without symptoms of hypercalcemia, nephrolithiasis, serum calcium > 12 mg/dL, serum creatinine > 1.5 mg/dL or forearm bone density > 2.5 SD below the mean for age, race and sex | NA | 108 | 12-120 months |
| Grey | 1996 | RCT (only arm with active surveillance used) | Postmenopausal women with mild PHPT and hypercalcemia detected incidentally. No concurrent systemic illness, untreated thyroid disease, hepatic or renal dysfunction, genital bleeding, estrogen therapy in the last 6 months, history of bisphosphonate use or fluoride therapy, steroids, anticonvulsant or thiazide | Hormone replacement therapy (not used) | 16 | 24 months |

Familial hypocalciuric hypercalcemia and primary hyperparathyroidism: different clinical manifestations in one family with a previously undescribed calcium-sensing receptor gene mutation. Melissa Sum¹, Robert Udelsman², Tobias Carling², Shonni Silverberg¹. ¹Columbia University Medical Center, Division of Endocrinology, USA, ²Yale University School of Medicine, Section of Endocrine Surgery, USA

Familial hypocalciuric hypercalcemia (FHH) is characterized by hypercalcemia without suppressed parathyroid hormone (PTH) levels and hypocalciuria. It has a benign course with an autosomal dominant inheritance pattern of a mutation in the calcium-sensing receptor (CaSR) gene. In primary hyperparathyroidism (PHPT), hypercalcemia is due to inappropriate PTH secretion and may be associated with skeletal and renal target organ effects. Families with mixed clinical pictures of FHH and PHPT have been described. We report the clinical characteristics of three family members with a previously undescribed mutation of the CaSR who present with three phenotypes. The mother, a 63-yr-old Caucasian woman, was referred for low bone density and a 30-year history of hypercalcemia. Evaluation (Table) revealed mild PHPT with hypercalcemia, hypercalciuria and a normal PO4. BMD was typical for PHPT: preserved at the lumbar spine, close to osteoporotic at the femoral neck, with severe osteoporosis at the 1/3 radius. She was diagnosed with PHPT and underwent subtotal parathyroidectomy. Intraoperative PTH predicted cure [baseline 89 to 14 pg/ml 15 min post-PTX]. Calcium fell to 8.5 mg/dl. Hypercalcemia was incidentally noted in her 35 yo son (Table), with low PO4, 25OHD and hypocalciuria. BMD was normal. FHH or familial hyperparathyroidism was suspected. Genetic testing identified a point mutation in the 7th exon of the CaSR gene leading to change (P798L) in the transmembrane domain and no MEN1 mutation. He was diagnosed with FHH. Screening of his 31 yo sister (Table) revealed hypercalcemia, urinary calcium at the upper normal range and normal BMD, consistent with asymptomatic PHPT. Genetic testing of the mother and daughter identified identical point mutations. In summary, three family members with identical CaSR mutations exhibited disparate clinical phenotypes: the mother had features of PHPT with both hypercalciuria and forearm osteoporosis; the son had FHH; the daughter had PHPT with increased urinary calcium excretion but no bone loss, and BMD was not lower at the cortical site. This

kindred, with autosomal dominant hypercalcemia caused by a previously undescribed point mutation of the transmembrane domain of the CaSR, includes members displaying clinical phenotypes of FHH and PHPT with and without skeletal sequelae. This kindred underscores the possibility of diverse phenotypic expression of unique mutations and highlights the expanding clinical spectrum of CaSR mutations.

INTRAOPERATIVE PARATHYROID HORMONE MEASUREMENT AND OUTCOME FOLLOWING PARATHYROIDECTOMY IN PRIMARY HYPERPARATHYROIDISM. Patamaporn Lekprasert*, Catherine Anastasopoulou, Goral Panchal. Einstein Medical Center of Philadelphia, USA

BACKGROUND:

Primary hyperparathyroidism (PHPT) is the most common cause of hypercalcemia in an ambulatory setting. Surgery is the mainstay of the treatment. Focused parathyroidectomy and minimally invasive parathyroidectomy (MIP) are preferred operations in non-complicated patients given an advancement of pre-operative localizing, and rapid intraoperative parathyroid measurements (IOPTH).

STUDY DESIGN:

This is a retrospective study aimed to compare recurrent rate, persistent hypercalcemia rate, complications (infection, bleeding, and hypocalcemia), operative time, and length of hospital stay between MIP with IOPTH and conventional parathyroidectomy. We included all PHPT patients who underwent parathyroidectomy at our tertiary care hospital during January 2006 to January 2014. For MIP with IOPTH, intact parathyroid hormone (iPTH) was measured preoperatively, baseline before the excision of the gland, and at 5-, 10- and 20-minute intervals after the excision. MIP was considered complete after appropriate glands were excised and iPTH fell to less than 50% of baseline levels. Tertiary hyperparathyroidism patients were excluded.

RESULTS:

We included 220 patients who underwent surgery during the 8-year period; 131 patients underwent MIP with IOPTH, and 89 patients had conventional surgery. Patients were 29% men and 71% women. There was no difference in demographics, pre-operative serum calcium, and iPTH level between the 2 groups. Operation demonstrated 90% of patients had single adenoma, 7% had four-gland hyperplasia, and 3% had double adenomas. Recurrent rate was 6.7% in conventional group, and 6.1% in MIP group (p=0.266). Persistent hypercalcemia rate was 0% in conventional group, and 6.1% in MIP group (p=0.021). In the group of patients with persistent hypercalcemia, the IOPTH did not drop by 50% at 20 minutes after resection. The operative time and length of hospital stay were shorter in MIP group (81.03 vs 110.49 minutes, p = 0.032, and 1.94 vs 3.1 days, p = 0.034 respectively). There was no difference in post-operative complications between two groups. Ten out of 21 patients with persistent and recurrent HPTH underwent a second operation.

CONCLUSIONS:

MIP with IOPTH monitoring is safe, effective and helps to shorten the operative time and length of hospital stay compared to conventional parathyroidectomy.

Parathyroid Hormone (PTH) 1-34 Therapy Decreases Urinary Citrate in Hypoparathyroidism. Rachel Gafni*¹, Craig Langman², Lori Guthrie³, Beth Brillante¹, Robert James⁴, Nancy Yovetich⁴, Alison Boyce¹, Michael Collins¹. ¹National Institutes of Health, USA, ²Northwestern University & the Ann & Robert H Lurie Children's Hospital of Chicago, USA, ³NIDCR, National Institutes of Health, USA, ⁴Rho, Inc, USA

Many studies have shown that PTH therapy can effectively manage the hypocalcemia in patients with hypoparathyroidism (HPTH), with varying effects on

hypercalcemia. However, little is known about PTH's ability to decrease the renal comorbidities of HPTH: nephrocalcinosis (NC), nephrolithiasis (NL), and chronic kidney disease. Urinary citrate promotes the solubility of urinary calcium; hypocitraturia is a risk factor for NC/NL. The prevalence of hypocitraturia in PTH-treated HPTH patients is unknown. Urinary calcium (Ca), citrate (cit), and Ca/cit ratios were measured in 30 patients with HPTH receiving PTH 1-34 replacement therapy for up to 5 years in an ongoing study. Renal ultrasounds and CT scans were performed annually. Before PTH, mean \pm SD Ca excretion was elevated at 383 ± 203 mg/d (nl <250) and cit excretion was 703 ± 394 mg/day (nl 250-1190), with a geometric mean Ca/cit ratio of 0.61 mg/mg, 95% CL 0.46, 0.8 (target <0.7) (N=23). After 6 mos of PTH, urine Ca had not significantly changed (308 ± 242 mg/d, p=NS) while urine cit had decreased significantly (338 ± 203 mg/d, p<0.01), resulting in an increased Ca/cit (0.87 mg/mg, CL 0.52, 1.48; p=NS) (N=19) that became statistically significant with time (p=0.0078, repeated measures ANOVA, Fig). In 12 subjects, K-citrate (30-60 meq/d) was added with varying response. Overall, however, urinary cit levels remained low and Ca/cit remained elevated while on PTH. After stopping PTH, compared to the last measures on PTH, cit had risen to 572 ± 473 mg/d (p=0.0072), reducing the Ca/cit to 0.55 mg/mg, CL 0.37, 0.82 (p<0.0001) (N=10) without change in Ca (353 ± 427 mg/d). Urine pH, serum bicarbonate, and eGFR were unchanged throughout. On imaging, 12 subjects did not have NC/NL, 8 had NC/NL prior to PTH, and 8 developed NC/NL after starting PTH (with resolution in 2). Impaired urinary acidification leading to proximal renal tubular acidosis is a known effect of excess PTH, both experimentally and in primary hyperparathyroidism. Metabolic acidosis reduces tubular secretion of citrate, which may lead to hypocitraturia and increased NC/NL. Our data demonstrate that, while PTH therapy might be promising for hypocalcemia management in HPTH, hypocitraturia appears to be an untoward effect that may result in an increased risk of renal morbidity. Thus, with increasing use of PTH therapy in patients with HPTH, close monitoring and treatment for hypocitraturia may be indicated to prevent acceleration of NC/NL and compromised renal function.

Urinary calcium, citrate and calcium/citrate ratio before, during, and after PTH 1-34

Skeletal Microstructure and Estimated Bone Strength in Hypoparathyroidism. Natalie Cusano*¹, Kyle Nishiyama¹, Chengchen Zhang¹, Mishaela Rubin¹, Donald McMahon¹, X. Edward Guo², John Bilezikian¹. ¹Columbia University College of Physicians & Surgeons, USA, ²Columbia University Bone Bioengineering Laboratory, Department of Biomedical Engineering, USA

Hypoparathyroidism (HypoPT) is characterized by low bone turnover, above average areal bone mineral density (BMD), and abnormal structural indices by bone biopsy. Little is known about microstructure or bone strength in this PTH-deficiency disease. We studied 61 HypoPT subjects by high resolution peripheral quantitative computed tomography (HRpQCT, Scanco Medical) of the distal radius and tibia and estimated bone strength by finite element analysis (FEA). Demographics: 49 women/12 men; age 46 ± 12 (SD) years; etiology: 35 postsurgical, 25 idiopathic, 1 DiGeorge; duration 11 ± 11 years; serum calcium 8.6 ± 0.8 mg/dL; PTH 1.3 ± 3 pg/mL. We compared HypoPT subjects to published normative data from the 20-29 year-old female and male cohorts of the Canadian Multicentre Osteoporosis Study. We present here results for the premenopausal women <40 (n=18) and men <50 years (n=7). In both the women and men, areal BMD was above average at the lumbar spine (T-score +1.37, +1.88) and total hip (+1.26, +1.27); the 1/3 radius site was also above average for women (+0.55). HRpQCT results are summarized in the figure. At both the radius and tibia, cortical (Ct) volumetric BMD was increased in the HypoPT women and men compared to controls. Ct porosity was reduced at both the radius and tibia in women and at the tibia in men. At the tibia alone, Ct thickness was lower in women and men. Tb thickness was lower in women and Tb number was lower in women and men. Ultimate stress and failure load at both sites were similar for the HypoPT subjects vs. controls. We used a linear regression model that included age, sex and disease duration to further evaluate their relationships to bone strength in all subjects. At both radius and tibia, each 1-year increment in age decreased ultimate stress (-0.27, -0.21 MPa) and failure load (-15, -32 N) while each increment in disease duration improved these same indices (ultimate stress: +0.29, +0.34 MPa, failure load: +14, +37 N). Using non-invasive high resolution imaging, these data show abnormal micro-architecture in HypoPT subjects, giving additional evidence for the critical role of

PTH in establishing and maintaining bone quality. Despite above average areal BMD, estimated bone strength was not different from controls, consistent with registry data showing similar fracture incidence in HypoPT subjects vs. controls. Increasing disease duration appears to negate the adverse effects of increasing age on estimated bone strength in HypoPT.

HRpQCT results at the distal radius and tibia in HypoPT subjects

Age-related changes in 3D bone microstructure are more pronounced in the sub-endplate region than in the central region of human vertebral bodies.

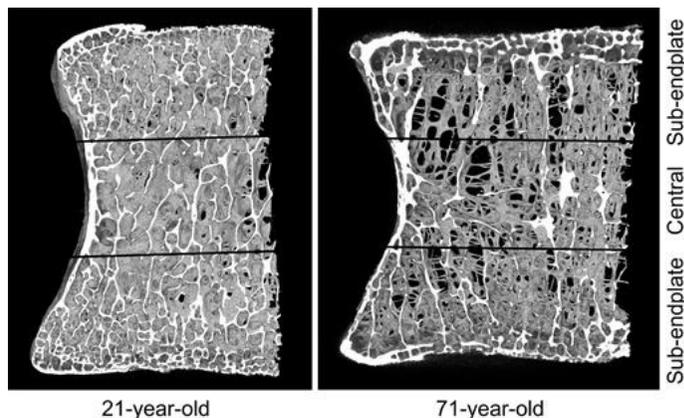

Jesper Thomsen¹, Ebbe Ebbesen², Annemarie Br uel³. ¹Aarhus University, Denmark, ²Department of Biomedicine, University of Aarhus, Denmark, ³Department of Biomedicine, Aarhus University, Denmark

Purpose: The 3D bone microstructure of the vertebral body of young individuals appears to be divided into three equally high horizontal regions: two adjacent to the endplates and one in the centre of the vertebral body. With increasing age this regional subdivision of the 3D microstructure of the vertebral bodies appears to vanish. Therefore, the aim of the study was to investigate the differences in the age-related changes in 3D microstructure of the sub-endplate region and the central region in human vertebral bodies.

Materials and Methods: The material comprised 80 9-mm-thick frontal slices of L2 from 41 women and 39 men aged 18 to 96 years with an even age-distribution. The bone samples were μ CT scanned at an isotropic voxel size of 18.5 μ m. By use of custom made software the vertebral bone specimens were divided into two regions: one spanning the central third and another spanning the two remaining thirds adjacent to the endplates. Standard 3D microstructural parameters were determined in each of the two regions.

Results: In both regions, BV/TV, Tb.N, and vBMD decreased significantly with age, structure model index (SMI), Tb.Sp, and bone material density increased significantly with age, while Tb.Th was independent of age. In the central region connectivity density (CD) and the degree of anisotropy (DA) were independent of age, while in the sub-endplate region these two parameters decreased and increased significantly with age, respectively. The slope of the fit lines was significantly larger for CD, Tb.N, and DA in the sub-endplate region than in the central region. Furthermore, the age-related changes in the 3D microstructural parameters CD, Tb.N, and DA were significantly different in the two regions.

Conclusion: The bone in the sub-endplate region is denser, more well-connected, and less mineralised, than the bone in the central region, and the trabeculae in the sub-endplate region is more closely spaced, more rod-like, and of similar thickness as in the central region. Finally, 3D bone microstructural parameters change significantly differently with age in the two regions. Therefore, caution should be exercised when examining the age-related changes of the 3D bone microstructure of human vertebral bone.

Application of novel broadband ultrasound transducer in quantifying trabecular bone properties. Jian Jiao^{*1}, Xiaofei Li¹, Liangjun Lin¹, Yi-Xian Qin¹, Raffi Sahul², Ed Nesvjski². ¹Stony Brook University, USA, ²TRS Technologies Inc., USA

Ultrasound, as an oscillating mechanical wave, can be used to scan bones and its behavior in bone can reflect the structural and mechanical properties of that bone, such as density and Young's modulus. The technology of quantitative ultrasound (QUS) has been developed to measure bone properties and predicting fractures. Broadband ultrasound attenuation (BUA) has demonstrated high correlation to density in trabecular bones and it has been used as a good indicator for the femoral fracture risk. Ultrasound attenuation in bone is frequency dependant and it becomes strongly correlated in the frequency ranges from 0.3 to 0.7 MHz. In our study, a pair of conventional panametric confocal transducers which are manufactured by OLYMPUS, Inc. and a pair of novel broadband ultrasound transducers which are developed by Technologies, Inc. are respectively used to scan the same bone samples. The broadband transducers are fabricated from spiral-wrapping multiple piezoelectric PMN-PT single crystal of various center frequencies onto a flexible sheet and have a resonant frequency from 0.5MHz to 8MHz. To evaluate their application in bone scanning, three groups of trabecular bovine bone cubes were prepared, each group has five different degrees of decalcified samples. The confocal transducers scanning results indicate that with bone density loss by 23.94%, ultrasound velocity decreased from 1951.04 ± 77.49 m/s to 1591.24 ± 30.31 m/s, attenuation decreased from 18.75 ± 0.60 dB to 11.12 ± 0.95 dB, nBUA decreased from 22.77 ± 2.33 dB/MHz/cm to 10.14 ± 0.93 dB/MHz/cm. Comparing to the broadband transducers scanning results, the ultrasound velocity decreased from 1871.33 ± 148.14 m/s to 1532.90 ± 25.23 m/s, attenuation decreased from 21.07 ± 1.25 dB to 14.12 ± 2.35 dB, nBUA decreased from 33.27 ± 3.45 dB/MHz/cm to 22.49 ± 6.30 dB/MHz/cm. Due to multiple piezoelectric crystal structure, the broadband transducer has more harmonic waves and noise, but the broadband transducer is still good enough to use to quantify bone quality. Moreover, the wider frequency band can reveal more information than conventional single frequency transducer.

Bending Stiffness Predicts Bending Strength More Accurately than Cortical Diameter or Porosity in Cadaveric Human Ulnas. Gabrielle C. Hausfeld¹, Emily R. Ellerbrock², Jennifer M. Neumeyer², Tyler C. Beck², Maureen A. Dean², John R. Cotton³, Lyn Bowman^{*2}, Anne Loucks². ¹Honors Tutorial College, Ohio University, USA, ²Department of Biological Sciences, Ohio University, USA, ³Department of Mechanical Engineering, Ohio University, USA

Purpose: Cortical Porosity (CP) is measured to help identify individuals at high risk of fracture, but the *in vivo* method suffers from low image resolution and limitations in image processing and analysis. Increased bone fragility in post-menopausal women has been attributed to inadequate periosteal bone formation in compensation for endosteal bone resorption. Bone strength and stiffness are strongly

associated, and Mechanical Response Tissue Analysis (MRTA) measures ulna bending stiffness (k_B) noninvasively. The purpose of this study was to compare the accuracies with which ulna bending strength (F_{peak}) is predicted by CP, diameter, and k_B .

Methods: Fresh-frozen cadaveric human arms of 35 donors ($17 \leq \text{age} \leq 99$ yrs; $13 \leq \text{BMI} < 40$ kg/m²) were imaged with 250-820µm pixels by computed tomography (CT). In one day (1) an arm was thawed, (2) ulna k_B was measured by MRTA, (3) the arm was defleshed, and (4) ulna k_B and F_{peak} were measured by gold standard Quasistatic Mechanical Testing (QMT). Fractured ulnas were imaged with 10-15µm pixels by gold standard micro-computed tomography (µCT) in three 2mm cross-sections (33% and 55% of length from the distal end and adjacent to the fracture). The endosteum was located in 3D computer models made from 200 consecutive µCT slices at each site and CP was measured in CT and µCT images with *ImageJ*. Confounding of k_B by differences in ulna length (L) was corrected by computing ulna flexural rigidity ($EI = k_B L^3/48$). F_{peak} was related to CP, ID, EI and clinical predictors by simple and forward stepwise multiple regression.

Results: Standard errors of the estimate (SEE) for predictions of F_{peak} ($191 \leq F_{peak} \leq 1287$ N) appear in Table 1. ID at 55%L ($13 \leq ID \leq 23$ mm) predicted F_{peak} more accurately ($p=0.02$) than CP ($4 \leq CP \leq 64\%$) at any site. Predictions by ID in CT and µCT images were similar ($p=0.35$). As second predictors, body mass ($32 \leq BM \leq 129$ kg), height ($1.47 \leq Ht \leq 1.88$ m) and CP improved ($p \leq 0.02$) ID predictions similarly ($p \geq 0.24$). Predictions by EI_QMT ($10 \leq EI \leq 69$ Nm²) and EI_MRTA ($10 \leq EI \leq 74$ Nm²) were similar ($p=0.12$) and more accurate ($p \leq 0.02$) than CP, ID or both together. Only age explained any variance ($p \leq 0.03$) not explained by EI. No model with >2 predictors was significant.

Conclusions: Until MRTA is clinically available, the bending strength of ulnar cortical bone can be estimated more accurately by ID from CT images and other clinical data than by CP.

Contra-Lateral Bone Loss in Post-Menopausal Women After a Distal Radius Fracture: A Two-Year Follow-Up HR-pQCT Study. Joost De Jong*¹, Frans Hever², Paul Willems³, Jacobus Arts³, Martijn Poeze⁴, Piet Geusens⁵, Bert van Rietbergen⁶, Joop van den Bergh⁷. ¹Maastricht University Medical Center, The Netherlands, ² Department of Surgery & NUTRIM, Maastricht University Medical Center, Maastricht, The Netherlands, Netherlands, ³Department of Orthopaedics & CAPRHI, Maastricht University Medical Center, Maastricht, The Netherlands, Netherlands, ⁴Department of Surgery, Maastricht University Medical Center, Maastricht, The Netherlands, Netherlands, ⁵Department of Rheumatology & CAPRHI, Maastricht University Medical Center, Maastricht, The Netherlands, Netherlands, ⁶Faculty of Biomedical Engineering, Eindhoven University of Technology, Eindhoven, The Netherlands, Netherlands, ⁷Department of Internal Medicine, Viecuri Medical Center Venlo & Maastricht University Medical Center, The Netherlands, Netherlands

After fracture of the lower limbs, e.g. a hip fracture, bone loss not only occurs at the fractured side but also at the contra-lateral side due to a period of immobilization. Whether bone loss also occurs at the contra-lateral side of the upper, non-weight bearing limbs, such as the distal radius, is unknown.

The contra-lateral distal radius of 14 post-menopausal women (aged 63.7±7.9 years) with a stable distal radius fracture was scanned by high resolution peripheral quantitative computed tomography (HR-pQCT) at baseline (1-2 weeks post-fracture), 12 weeks and 2 years post-fracture. Standard bone density and micro-structural parameters were assessed, and compression stiffness was calculated using finite element analysis (FEA). Furthermore, markers of bone formation (procollagen type-I N-terminal propeptide; PINP) and resorption (carboxy-terminal telopeptide of type I collagen; ICTP), and inflammation (C-reactive protein; CRP) were measured in venous blood samples. A mixed-effect model with random intercept and visit as fixed effect was used to compare the bone parameters between the three visits. Linear regression was used to assess the correlation between early changes (from baseline to 12 weeks post-fracture) in CRP, PINP and ICTP, and the changes in bone parameters from 12 weeks to 2 years post-fracture.

Ten patients (71%) used bisphosphonates (BP). During 2 years post-fracture, no significant changes occurred in total or trabecular bone density, nor in the trabecular micro-structure and neither in cortical perimeter or thickness at the contra-lateral side. For cortical density (Dcort) and compression stiffness (Scomp) an initial 12 week period without change was followed by a significant decrease of 4.0% (p<0.001) and 4.8% (p=0.005), respectively, at 2 years post-fracture. This change in Scomp correlated positively to the early change in PINP (ρ=0.676, p=0.011). The change in Dcort did not correlate to any of the early changes in PINP, ICTP or CRP. BP use did not affect the results.

Similar to weight-bearing limbs, contra-lateral bone loss was observed 2 years after a fracture at the forearm. Changes in Dcort and Scomp appear to be higher than reported during normal aging, in BP users and non-users. We conclude that a stable fracture at the distal radius is associated with bone and strength loss at the contra-lateral distal radius. Interestingly, a lesser decrease of PINP in the first 12 weeks correlated to less loss of bone strength after 2 years.

Determination of Elastic Modulus of Mouse Bones Using Data from BioDent Reference Point Indentation (RPI). Ganesh Thiagarajan*¹, Sruvan Kola², Mark Begonia², Mark Dallas², Vladimir Dusevich², Nuria Lara², Mark Johnson². ¹University of Missouri - Kansas City, USA, ²University of Missouri Kansas City, USA

Young's Modulus is a standard measurement of bone stiffness, and 3-point bending is a destructive test used to obtain this value. Reference Point Indentation (RPI) offers a nondestructive alternative to assess bone mechanical properties. However, little is known regarding RPI measurements and their association with widely accepted bone mechanical properties. This study aims to determine the Young's (indentation) Modulus of mouse bones using RPI measurements with the eventual goal of conducting longitudinal in vivo studies in mice. We developed a numerical analysis procedure using the Oliver-Pharr (O/P) method to estimate the indentation elastic modulus using the 1st cycle indentation depth hf and 1st cycle unloading slope at the peak load. Two methods were used to determine the area function: (1) Oliver-Pharr (O/P) and (2) Geometric. Indentations using BioDent were performed on PMMA and on mouse bones.

Femurs from 4-5 mo. and 1.5 yr. TOPGAL old mice were tested under 3-point bending to obtain the elastic modulus for comparisons with the indentation elastic modulus from RPI. Ulnae from mice were also indented and imaged via SEM to assess the damage at each site. The indentation modulus of PMMA calculated by the O/P (3.49-3.68 GPa) and Geometric (3.33-3.49 GPa) methods was similar to values in

literature (~3.5-4 GPa). When comparing the indentation elastic moduli from RPI vs. 3-point bending in 4-5 mo. old femurs, we found that the moduli from both the Geometric and O/P methods were similar to the 3-point bending modulus. In males, the indentation modulus from the Geometric (5.61±1.25 GPa) and O/P (5.53±1.27 GPa) methods was higher than the 3-point bending modulus (5.28±0.34 GPa). In females, the indentation modulus from the Geometric (7.45±0.86 GPa) and O/P (7.46±0.92 GPa) methods was also higher than the 3-point bending modulus (7.33±1.13 GPa). Further elastic modulus comparisons for each age group for mutant and control mice will be presented in detail along with SEM micrographs on mouse ulnae. Based on initial tests conducted on PMMA and mouse bones, RPI indentation modulus values compare well with the Young's modulus values obtained from 3-point bending. The findings of this study indicate that this method could be applied to mice in longitudinal in vivo studies to analyze the effects of anabolic agents on bone material properties.

SA0026

Early changes in estimated bone stiffness and serum bone markers predict clinical outcome 2 years after stable distal radius fractures: An HR-pQCT exploratory study. Frans Hever*¹, Joost de Jong², Paul Willems³, Chris Arts³, Martijn Poeze¹, Piet Geusens⁴, Bert van Rietbergen⁵, Joop van den Bergh⁶. ¹Department of General Surgery & NUTRIM, Maastricht University Medical Center, Netherlands, ²Department of Rheumatology & NUTRIM, Maastricht University Medical Center, Netherlands, ³Department of Orthopaedic Surgery & CAPRHI, Maastricht University Medical Center, Netherlands, ⁴Department of Rheumatology & CAPRHI, Maastricht University Medical Center, Netherlands, ⁵Faculty of Biomedical Engineering, Eindhoven University of Technology, Netherlands, ⁶Department of Internal Medicine, Viecuri Medical Center Venlo & NUTRIM, Maastricht University Medical Center, Netherlands

Stable distal radius fractures are usually treated by cast immobilization. Functional outcome in this group is highly variable and cannot be predicted by fracture classification. Therefore, we aim to develop methods based on changes in bone micro-architectural parameters during the early stages of fracture healing to predict long-term functional outcome, which will aid in clinical decision making and can also serve as an early outcome measurement in clinical trials.

The development of high-resolution peripheral quantitative computed tomography (HR-pQCT) enables the in vivo assessment of bone microarchitecture and strength estimation with micro-finite elements analysis (μFEA). We hypothesized that HR-pQCT measurements at the fracture location reflect the healing response and are predictive of long-term functional outcome.

In this exploratory study we evaluated 15 patients up to 2 years after a stable distal radius fracture treated by cast immobilization. HR-pQCT scans were performed at 1-2 (baseline), 3-4, 6-8 and 12 weeks and 2 years postfracture. During study visits, pain and disabilities were assessed using the patient rated wrist evaluation (PRWE) questionnaire. Bone stiffness was estimated from the HR-pQCT scans at each time point using μFEA. In addition, markers of bone formation (procollagen type-I N-terminal propeptide; PINP), bone resorption (carboxy-terminal telopeptide of type I collagen; ICTP) and inflammation (CRP) were measured in venous blood samples. Area under the curve (AUC) in the first 3 months was used as a summary statistic to reflect the longitudinal changes between 1-2 and 12 weeks postfracture. Linear regression models were used to predict 2 year functional outcome by PRWE from early AUCs.

The changes from baseline to 12 weeks postfracture in torsional (ρ=-0.54; p=0.037) and bending stiffness (ρ=0.84; p<0.001), and PINP (ρ=0.62; P=0.014) were correlated with PRWE outcome after 2 years (table 1 and 2). Using regression analysis, these parameters predicted up to 50% of the variation in long-term functional outcome after stable distal radius fractures.

Although limitations of this study are the low number of patients and lack of validation of μFEA in metaphyseal fractures, our results indicate that early changes in torsional and bending stiffness as measured with HR-pQCT, and serum markers of bone formation are useful for the prediction of long term clinical outcome (pain and disability) after distal radius fractures.

Effect of Intermittent Radiation Exposure in vivo On Tibia Micro-Architecture in OVX Sprague-Dawley Rats Over 3 Months. Amanda Longo*, Sandra Sacco, Wendy Ward. Brock University, Canada

Recent advances in in vivo micro-computed tomography (μ CT) allow researchers to measure changes in tibia micro-architecture at multiple times throughout the lifespan and/or in response to an intervention. This is highly advantageous as it substantively reduces the number of animals required for long-term testing of an outcome. However, continued radiation exposure may have a negative impact on the skeletal region under investigation. The purpose of this study was to elucidate an effect of intermittent radiation exposure over a three-month period to micro-architecture of the tibia in the ovariectomized (OVX) rat and to determine if estrogen modulates this response. The right proximal tibia of three-month OVX or sham-operated Sprague-Dawley rats (n=12/group) was scanned one-week following OVX or sham-surgery and at 1, 2 and 3 months post-surgery. The contralateral proximal tibia was scanned at study endpoint only, 3 months post-surgery, to allow direct comparison with the right proximal tibia. All scans were performed using high-resolution parameters (18 μ m resolution, 60kV, 200 μ A, 1mm Al filter, 0.5° rotation step, SkyScan 1176) at a radiation dose of approximately 600mGy (TN-502RD-H, Best Medical Canada). A repeated measures ANOVA was performed to assess an effect of age and estrogen status. A two-way ANOVA was used to quantify an effect of the frequency of radiation exposure and estrogen status between left and right legs at study endpoint. As expected, there was an interaction of age and estrogen status for trabecular morphometry of the right proximal tibia: percent bone volume (p=0.002), trabecular number (p<0.001), trabecular separation (p<0.001), and structural model index (p<0.001). These findings support the role of estrogen in the maintenance of bone architecture with aging. Trabecular thickness increased with age in both OVX and sham-operated rats (p=0.007). There were no differences in bone micro-architecture between the left and right proximal tibia when exposed to a single or repeated scans, respectively. Moreover, having observed no interaction between estrogen status and frequency of radiation exposure, suggests that endogenous estrogen production does not alter the susceptibility of trabecular bone of the proximal tibia to the effects of either single or repeated scans. These findings provide support for the use of repeated in vivo scans by high-resolution μ CT in the well-characterized OVX rat model.

Effect of Varying Levels of Compositional Heterogeneity on Fracture Resistance in Cortical Bone. Ani Ural*. Villanova University, USA

The recent reports of atypical femoral fracture and its possible association with prolonged bisphosphonate use highlighted the importance of a thorough understanding of mechanical modifications in bone due to bisphosphonate treatment. The reduced compositional heterogeneity of bone is one of the modifications in bone due to extensive suppression of bone turnover. The goal of the current study is to evaluate the influence of varying levels of compositional heterogeneity on fracture resistance in human cortical bone using finite element modeling.

A transverse microscopy image of cortical bone from the mid-diaphysis of a 70-year-old male donor tibia was converted to a 3D finite element model which was inserted in a compact tension test specimen to evaluate the fracture resistance of the bone (Fig. 1). Crack formation and propagation was modeled by cohesive extended finite element method in the osteons and interstitial bone and by cohesive interface elements at the cement lines. Five models were generated including a model with homogeneous material properties (HM) and four heterogeneous models with 5 (HT1), 10 (HT2), 15 (HT3), and 20 (HT4) different material property groups in the microstructural region. Heterogeneous material properties were randomly assigned to each element in the microstructural region using a MATLAB script based on values reported in the literature. The average material properties were used for the

homogeneous model. The fracture response was assessed through crack growth path and the volume of cracked elements.

There was only 1% difference in the crack volume between HM and HT1 (Fig. 2a). On the other hand, the crack volume in HT2 and HT3 was reduced to 62% and 75% of HM, respectively. The crack volume increased for HT4 which had 92% of crack volume of HM. The crack growth paths exhibited mostly smooth crack growth for HM and HT1. HT2 and HT3 demonstrated extended uncracked sections of bone with low damage whereas this behavior was limited for HT4 (Fig. 2b-2f).

In summary, the results showed that although increasing heterogeneity enhanced the fracture resistance of bone, there is a threshold after which its beneficial effects were not as significant. These results provide new information on the relationship between varying levels of tissue heterogeneity and fracture resistance and may improve the understanding of the influence of material level changes due to prolonged bisphosphonate use on the fracture resistance of bone.

FES-Rowing Training Improves Bone Strength of the Paralyzed Legs in a Dose-Dependent Fashion. Leslie Morse*¹, Can Tan¹, Ricardo Battaglini², Rajiv Gupta¹, J.A. Taylor¹. ¹Harvard Medical School, USA, ²The Forsyth Institute, USA

Objective: To determine if the combination therapy of FES-rowing plus zoledronic acid (ZA) improves bone strength in participants with lower extremity paralysis.

Methods: This was a longitudinal comparative clinical trial, where 29 non-ambulatory volunteers with SCI were randomized into treatment (ZA, n = 13) or no treatment (n = 16), and all were enrolled in a 12-month FES-rowing exercise program.

Lower extremity computed tomography (CT) scans were obtained at baseline (all volunteers) and after 6 (n = 18) or 12 months (n = 27) of exercise (n=17 at all three time points). Axial stiffness of the proximal fibula (non-weight-bearing bone, reflecting the effect of ZA treatment alone), and proximal tibia and distal femur (reflective of weight-bearing and ZA treatment) were quantified via finite element analysis using reconstructed 3D models of volumetric CT scans. Effects of ZA treatment, exercise, and time were assessed via a linear mixed-effect model, repeated on each side (dominant vs non-dominant) nested within each subject with a random intercept, taking into account correlations between each bone within each side and subject.

Results: Volunteers were 37 + 2 (SE) years old with a BMI 26.0 + 1.0. All but five had adult-onset spinal cord injury (average age at injury 26 + 11) at C4 – T12 level, ASIA A – C. At the time of enrollment, volunteers were 2 months – 38 years post-injury (average 11 + 2 years). On average, volunteers exercised 1.6 + 0.1 times a week and the intensity of exercise varied substantially among volunteers. There was a time-dependent decline in fibula stiffness, which was prevented by ZA treatment (treatment x time effect $p < 0.01$). In contrast to the fibula, there was no decline in tibia stiffness for either rowing-only or rowing plus ZA treatment ($p > 0.2$ for time, treatment, or interaction effects), suggesting that both ZA treatment and exercise were effective at preventing bone loss. Furthermore, a subgroup analysis showed that gains in axial stiffness varied in a dose-dependent fashion based on the total amount of exercise performed in the rowing-only arm (1.3 + 4.3% at the tibia and 7.9 + 4.4% at the femur in the lowest rowing tertile versus 5.3 + 9.4% at the tibia and 15.7 + 16.8% at the femur, respectively).

Conclusions: Our results from the fibula confirm that ZA treatment prevents SCI-related osteoporotic bone loss. We also show that FES-row exercise alone improves bone strength in a dose-dependent fashion at mechanically stimulated sites, suggesting that FES-row training is an important therapeutic exercise that may reduce fracture risk after SCI.

In vivo precision of three HR-pQCT-derived finite element models of the distal radius and tibia in postmenopausal women. Chantal Kawalilak*, Saija Kontulainen, Morteza Amini, Joel Lanovaz, James D Johnston. University of Saskatchewan, Canada

Objective. The objective of our study was to define and compare in vivo precision errors for 3 high-resolution peripheral quantitative computed tomography (HR-pQCT) based finite element (FE) models of distal radii and tibiae in postmenopausal women. Models include: a single-tissue model (STM), a cortical-trabecular double-tissue model (DTM) and one model scaled according to imaged density. Methods. Using HR-pQCT, we scanned the distal radius and tibia of 34 postmenopausal women (74.7 years), at two time points. Primary outcomes for each model included: bone stiffness (N/mm), apparent modulus (MPa), average von Mises stress (MPa), and failure load (kN). Precision errors (root-mean-square coefficient of variation, CV%; and 95% limits of agreement, LOA) were calculated. Multivariate ANOVA was used to compare mean CV% for all outcomes among the 3 FE models. Significance was accepted at $P < 0.05$. Results. At the distal radius, CV% precision for STM and DTM were $< 5.5\%$ (range: 2.8-5.4%) and $< 9.0\%$ for the scaled model (range: 2.6-8.7%). Compared to STM and DTM, the scaled FE model had significantly higher precision error for apparent modulus (mean CV% difference: 3.3-3.4%, $P < 0.020$) and von Mises stress (3.3%, $P = 0.001$). At the distal tibia, precision was $< 5.0\%$ for STM and DTM (range: 0.9-4.8%) and $< 2.5\%$ for the scaled model (range: 1.2-2.1%). The scaled FE model had statistically lower precision error for stiffness compared to the STM (-1.6%; $P = 0.034$). Conclusion. Overall, the scaled FE model appeared more precise for modeling the distal tibia whereas STM and DTM appeared more precise for modeling the distal radius. Qualitative analyses suggest that precision error differences between the FE models are due to different periosteal boundary definitions.

Intravertebral Heterogeneity of Lumbar Vertebral Trabecular Bone Density Assessed from in vivo QCT is Weakly Associated with Lumbar Spine TBS Measured by DXA. Fjola Johannesdottir*¹, Arunima Awale², Paul Fein³, Brett Allaire⁴, Robert R. McLean⁵, Kerry E. Broe², Elizabeth J. Samelson⁵, Douglas P. Kiel⁵, Elise Morgan³, Mary L. Bouxsein⁶.

¹University of Cambridge, United Kingdom, ²Institute for Aging Research, Hebrew SeniorLife, USA, ³Boston University, USA, ⁴Beth Israel Deaconess Medical Center, USA, ⁵Hebrew SeniorLife Institute for Aging Research & Harvard Medical School, USA, ⁶Beth Israel Deaconess Medical Center, Harvard Medical School, USA

In vitro studies show that accounting for the spatial variation, or heterogeneity, of bone density within the vertebral body improves the prediction of vertebral strength compared to bone mass alone [1-3]. Trabecular Bone Score (TBS) is an index that

reflects very local variations in pixel gray-scale values from 2D lumbar spine DXA images. Low TBS values are associated with increased fracture risk, in some cases independently of aBMD [4]. Yet, the skeletal traits that influence TBS are not well understood. In particular, the relationships among TBS and measures of spatial variation in bone density are not known. Thus, we aimed to determine the association between DXA-derived TBS and the intravertebral heterogeneity in trabecular bone density measured by 3D QCT of lumbar vertebrae. Methods: We studied 230 individuals (124 women and 106 men, 44-81 years old) from the Framingham Heart Study cohort who had both 3D QCT and DXA scans of the spine within 6 months of each other. L3 vertebrae were analyzed for aBMD by DXA (Lunar Prodigy) and L3 TBS was computed from the DXA image using TBS iNsight software (V.2.1). QCT scans were analyzed to quantify average trabecular bone density (Tb.BMD) and the intravertebral heterogeneity in density in L3. For heterogeneity measures, we first subdivided the trabecular centrum into 5mm contiguous cubic regions and then measured the vBMD for each cube. Two global measures of heterogeneity were calculated from the cube vBMD values for a given vertebra: 1) the interquartile range (IQR); and 2) the quartile coefficient of variation (QCV) in cube vBMD values [3]. Correlation analyses were used to determine associations between variables. Results: TBS and QCT-derived average trabecular vBMD were moderately, positively correlated ($r = 0.29$, Table 1), whereas TBS and L3 aBMD were unrelated. TBS was weakly associated with the indices of intravertebral heterogeneity in trabecular bone density: IQR ($r = 0.13$, $p = 0.04$) and QCV ($r = -0.18$, $p = 0.005$). In conclusion, TBS by DXA was only weakly associated with global measures of the spatial variation in trabecular bone density assessed by QCT and was moderately correlated with average trabecular vBMD. These findings imply that DXA-based TBS does not reflect global heterogeneity of trabecular bone density throughout the vertebral centrum. Thus, the TBS index may reflect more localized density variations within the trabecular centrum and/or may be influenced by the cortical shell or posterior processes.

Rate of Change of Cortical Mass with Age over the Femoral Surface.

Graham Treece*¹, Andrew Gee¹, Carol Tonkin², Kenneth Poole¹.

¹University of Cambridge, United Kingdom, ²Nova Scotia, Canada, Canada

Purpose: Cortical bone mapping (CBM, Treece MedIA 2015) allows structural properties of the proximal femur, including cortical thickness and density, to be measured from QCT data and displayed as a colour map on the femoral surface. Here we apply CBM to a large cohort of women spanning a wide age range, to investigate in detail how the cortex changes with age at different parts of the femur.

Methods: Mindways Software Inc (Austin, TX, USA) recruited 630 Caucasian women aged 19-97 years (mean 47 ± 17 SD) from 1998 to 2002 at 11 centres in the USA. The cohort comprised women having BMD assessments as part of their clinical evaluation and volunteers who desired an assessment. QCT data, using the Mindways liquid K₂HPO₄ phantom, was obtained from below the lesser trochanter to above the femoral head. The data was collected for the purposes of FDA (510k) approval (K030330) and was subject to Investigational Review Board oversight. Of the 630, 11 were excluded due to incomplete scans and metalwork. For the remaining 619, CBM was used to measure cortical mass surface density (CMSD mg/cm², the product of cortical BMD and cortical thickness) across each proximal femur. All measurements were mapped onto a canonical surface and a model was fitted to the mapped data, explaining CMSD in terms of (1 + age + age²) and other confounding variables. Quadratic modelling allows for different rates of change at different ages and the possibility of detecting peaks.

Results: Figure 1 shows the mean CMSD, its rate of change at ages 30 and 80, and (where detectable) the age at which CMSD peaks. Of particular interest are the regions (a) and (b), where CMSD increases until late middle age before starting to plateau (a) or decline (b), and the region (c) where there is steady, significant loss of CMSD across the entire age range. In terms of hip fragility, region (c) is associated with cervical fracture and (b) with trochanteric fracture: our findings are consistent with cervical fractures being more strongly associated with age than are trochanteric fractures [Lofman OI 2002]. Cortical thickening with age in region (a) has been noted previously [Mayhew Lancet 2005]. Conclusion: CBM has produced a more detailed map of ageing across the proximal femur than has previously been available. This "healthy ageing" baseline might find application in finite element models, fracture studies and intervention planning (pharmaceutical and exercise).

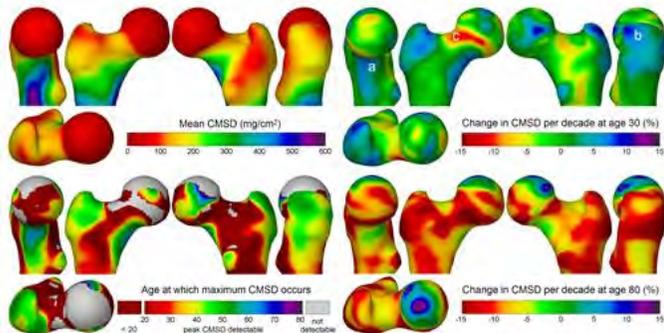

Figure 1. The distribution of cortical mass surface density (CMSD) in the proximal femur. Left top shows the average for women of age 20 to 90. Right column shows the rate of change per decade for young (age 30) and old (age 80) women. Bottom left is the age at which CMSD starts to decline.

Sensitivity of Imaging Biomarkers for Detecting Postmenopausal Bone Loss. Wenli Sun^{*1}, Chamith Rajapakse¹, Mahdieh Bashoor-Zadeh¹, Jeremy Magland¹, Mona Al Mukaddam², Rhiannon Miller², Elizabeth A. Kobe², MICHELLE SLINGER², Peter J. Snyder¹, Felix W. Wehrli¹.
¹University of Pennsylvania, USA, ²UPenn, USA

Background: Declined estrogen levels following menopause lead to rapid loss of bone mass, increasing the risk of osteoporosis. The rate of postmenopausal bone loss is a key determinant of bone fracture risk later in life. Early detection of greater than normal bone loss in this population could guide pharmacological interventions, which are known to be effective in reducing fractures. Besides DXA BMD, various imaging modalities and biomarkers are currently available for in-vivo assessment of bone quality, including densitometric, structural, and strength measures. The purpose of this study was to determine which image-based bone outcomes are most affected following menopause.

Methods: This prospective study involved 90 postmenopausal women, aged 55-79 years (mean age = 65.1 ± 5.7 years). Microstructural MRI of the distal tibia and radius was performed on a 3T scanner using 4-channel surface coil at 0.137 mm x 0.137 mm x 0.410 mm voxel size. Structural parameters (bone volume fraction, surface curve ratio, erosion index, trabecular number, separation and thickness) were computed on the basis of these images using digital topological analysis and volumetric topological analysis. Trabecular and whole-section axial stiffness were measured from elastic modulus by finite element analysis. Cortical and trabecular BMD were assessed at the diaphysis and metaphysis, respectively, both in the tibia and radius by means of pQCT. Total hip and lumbar spine areal BMD were determined with DXA. 90 subjects were categorized into three age groups: 50-59 (n = 22), 60-69 (n = 46), and 70-79 (n = 22).

Results: Out of all the parameters measured, only whole-section stiffness and cortical BMD significantly declined with age ($p < 0.05$) in this cohort representing a narrow age range (Figure 1), suggesting that the decline is most likely due to the thinning of cortex rather than trabeculae. Loss of cortex with age in the distal tibia and radius is visually evident from the MR images (Figure 2). All tibial parameters were positively correlated with the corresponding ones at the radius ($R = 0.25 - 0.65$, $p < 0.05$), indicating the systemic nature of bone loss.

Conclusions: Measures involving only trabecular bone or 2D measures were not significantly different among the three groups in this cohort (age 55-79 years). Cortical bone parameters or those being a function of both cortical and trabecular bone (e.g., MRI stiffness and pQCT cortical BMD) were significantly decremented with age.

Variation in Cortical Bone Tissue Composition and Mechanical Properties show Significant Genetic Effects. Daniel Nicoletta^{*1}, Ellen Quillen², Arthur Nicholls¹, Don Moravits¹, Jennifer Harris², Shayna Levine², Travis Eliason¹, Matt Allen³, Jeff Nyman⁴, Todd Bredbenner¹, Lorena Havill².
¹Southwest Research Institute, USA, ²Texas Biomedical Research Institute, USA, ³Indiana University, USA, ⁴Vanderbilt University, USA

At the tissue level, cortical bone mechanical integrity is a complex, multivariate function of bone tissue composition and microstructural organization. Co-adaptation of these traits results in trait combinations that provide redundant strategies to provide nominally equivalent functionality. Combinations of traits that are sufficient for everyday loading may be suboptimal for atypical, traumatic loads. The aim of this study was to determine the degree to which normal population level variation in both individual and composite cortical bone mechanical and compositional traits is due to genetic variation. Cortical bone tensile test specimens were obtained from the femur mid diaphysis from 102 baboons (46 males, 56 females). (All animals died naturally or were sacrificed for reasons unrelated to this study). Specimens were monotonically loaded to failure under displacement control at a strain rate of 0.01%/sec. Elastic modulus (E, GPa), yield stress (0.2% offset method) (MPa), ultimate stress (MPa), strain at failure (%), toughness (MPa), and post-yield energy (MPa) were investigated. We also measured cortical porosity, apparent density, ash and water content, collagen crosslinks (pyridinoline (PY), deoxypyridinoline (DPD), pentosidine (PE)), and total collagen content for the same specimens. We identified independent, composite traits (combinations of the tissue composition and biomechanical traits) that describe variability within the group using principal components analysis (PCA). Using a variance decomposition approach, we quantified the contribution of additive genetic effects (heritability [h^2]) to variation in the individual as well as composite cortical bone traits. PCA resulted in a set of 11 composite traits that explains 100% of the variation in individual composition traits and 7 composite traits that explain 100% of the variation in the individual mechanical property traits. After accounting for age and sex effects, significant genetic effects were determined for ash content ($h^2=0.63$, $p=0.003$), DPD xlinks ($h^2=0.52$, $p=0.02$), PE xlinks ($h^2=0.39$, $p=0.03$), post yield energy ($h^2=0.53$, $p=0.007$), toughness ($h^2=0.48$, $p=0.01$), peak strain ($h^2=0.47$,

p=0.012), and three composite traits from the PCA: PC1 ($h^2=0.52$, $p=0.009$), PC3 ($h^2=0.38$, $p=0.04$), and PC5 ($h^2=0.40$, $p=0.04$). These results indicate that normal population level variation in individual bone composition, mechanical property, and complex composite traits are significantly influenced by genes.

ESR1 and ESR2 Exert Opposing Influence on Bone's Susceptibility to Unloading. Jevantt Srinivas Sankaran^{*1}, Manasvi Varshney¹, Leah-Rae Donahue², Stefan Judex¹. ¹Stony Brook University, USA, ²The Jackson Laboratory, USA

Genetics is a strong determinant of bone's response to mechanical stimuli or absence thereof. Disparity in the amount of bone loss in astronauts/cosmonauts highlights the genetic control of bone loss. To identify genes that regulate this adaptation we performed a mouse linkage study to isolate genomic regions (Quantitative Trait Loci or QTL) that modulate this trait. These QTLs were processed to select bone related genes, yielding estrogen receptor 1 (ESR1) as a genetic target. ESR1 and ESR2 regulate estrogen signaling, critical for the maintenance of bone. Here, we determined whether ESR1 and ESR2 modulate bone loss induced by unloading. 9wk old, female ESR1 KO mice (ESR1^{-/-}, n=38), ESR2 KO (ESR2^{-/-}, n=20) were assigned to baseline control, age matched control, and hindlimb unloaded (HLU) groups. C57BL/6J (B6J, n=34) mice, the background strain of the KOs, were used as wild type (WT) controls. Following 2wk of hindlimb unloading, femurs were harvested and scanned via μ CT. In normal controls, ESR1^{-/-} mice had greater trabecular quantity than their WT counterparts without differences in the thickness of trabeculae. The differences between WT and ESR1^{-/-} mice ranged from 38% greater trabecular number (Tb.N) to 105% greater bone volume (BV) (all $P<0.05$). Between ESR2^{-/-} and WT mice, the differences ranged between 4% lower trabecular thickness (Tb.Th) to 17% greater BV (all $P<0.05$). BV/TV was unaffected by knocking out ESR2. In ESR1^{-/-} mice, unloading did not cause loss of trabecular bone while in WT-B6J mice, HLU significantly degenerated all trabecular indices. When the HLU responses were directly compared between the two strains, the degree of trabecular thinning was lower in HLU ESR1^{-/-} mice when compared to WT-B6J mice (Tb.Th: 7% vs. 19%, Gene*HLU, $P<0.05$). In contrast, ESR2^{-/-} mice exhibited a greater susceptibility to loss of weightbearing. When compared to WT mice, the trabecular compartment of ESR2^{-/-} mice exhibited greater losses in BV (56% ESR2^{-/-} vs. 32% WT), BV/TV (55% vs. 31%), Tb.N (14% vs. 5%) and Tb.Th (27% vs. 19%) (Gene*HLU, all $P\leq 0.05$). Both ESR1^{-/-} and ESR2^{-/-} mice had enhanced cortical architectural indices at baseline but their response to hindlimb unloading was similar to WT-B6J mice. Validation of ESR1 and ESR2 as contrasting modulators of trabecular adaptation during unloading may aid in development of specific drug targets to treat disuse bone loss.

Does premenarcheal gymnastics training benefit bone structural strength at the proximal femur after long-term retirement?. Marta Erlandson^{*1}, Stefan Jackowski², Adam Baxter-Jones¹. ¹University of Saskatchewan, Canada, ²University of Saskatchewan & Pivotal Therapeutics Inc, Canada

We have previously found that when adjusted for body size, a group of premenarcheal gymnasts had significantly greater indices of both axial strength and bending strength at the narrow neck (NN) and femoral shaft regions of the proximal femur (PF), as well as a greater bone strength index at the femoral shaft (S). It is thought that the mechanical loading experienced during growth increased their adolescent bone mass and positively influenced their adolescent bone geometry and architecture. If these bone adaptations were to be maintained when the gymnastics stimulus was withdrawn it could result in a decreased risk of developing osteoporosis and related fractures later in life. Therefore, the purpose of this investigation was to determine if the former gymnasts maintained the bone strength advantages after a long term retirement from gymnastics. A dual x-ray absorptiometry (DXA) scan of

the non-dominant hip was obtained in 23 retired female gymnasts and 22 controls, age range 22 to 30 years. Cross-sectional area (CSA), section modulus (Z), cortical thickness (CT) and buckling ratio (BR) at the NN, intertrochanter (IT), and S were estimated using hip structural analysis (HSA). Multivariate analysis of covariance (covariates: age, height, weight, age at menarche, and physical activity) was used to compare properties between retired gymnasts and controls. Adjusted means showed that gymnasts had 13% greater NN CSA (0.42 ± 0.15 cm², $p<0.05$), 13% greater NN Z (0.21 ± 0.10 cm³, $p<0.05$), 21% greater NN CT (0.05 ± 0.008 cm², $p<0.05$), 33% lower NN buckling ratio (-2.4 ± 0.63 , $p<0.05$), 11% greater IT CSA (0.61 ± 0.29 cm², $p<0.05$), 13% lower IT buckling ratio (-1.1 ± 0.39 , $p<0.05$), and 9% greater S CSA (0.42 ± 0.18 cm², $p<0.05$) compared to controls. These results suggest that former gymnasts maintain significantly better geometric and bone architectural properties at the hip 10 years after retirement from gymnastics training.

Effect of Exercise Modality during Weight Loss on Bone Mineral Density in Overweight and Obese, Older Adults. Kristen Beavers^{*1}, Daniel Beavers², Sarah Martin¹, Anthony Marsh¹, Mary Lyles², Leon Lenchik², Barbara Nicklas². ¹Wake Forest University, USA, ²Wake Forest School of Medicine, USA

Purpose: Identification of weight loss therapies that minimize bone loss in older adults is critical. The purpose of this study was to determine whether resistance training (RT) attenuates loss of hip and spine BMD compared to aerobic training (AT) during caloric restriction (CR) in overweight and obese, older adults. Methods: We combined data from 2 5-month, randomized controlled trials of CR with either RT or AT in overweight and obese (BMI=27-45 kg/m²), older (65-79 years) adults, free from clinically diagnosed osteoporosis at baseline. The first study randomized participants to a structured RT program (3 days/week; 8 upper/lower body exercises, 3 sets, 10 repetitions at 70% 1 repetition maximum) with and without CR. The second study randomized participants to a structured AT program (4 days/week; 30 minutes at 65-70% heart rate reserve) with and without CR. We compared the effect of RT+CR versus AT+CR, only. All participants received a daily calcium (1200 mg) and vitamin D (1600 IU) supplement. BMD at the total hip, femoral neck, and lumbar spine (L1-L4) regions was assessed via DXA at baseline and 5-months. Results: Sixty-three and 60 participants completed the RT+CR and AT+CR interventions, respectively. Average age was 69.4 ± 3.5 years. 67% of the study sample was female, and 81% was Caucasian. Baseline BMI was lower in RT+CR (30.4 ± 2.2 kg/m²) than AT+CR (34.7 ± 3.7 kg/m²). Overall exercise compliance was excellent (>80% sessions attended for both RT and AT) and average weight loss was 5.7% (95% CI: 4.6-6.7%) and 8.2% (95% CI: 7.2-9.3%) in the RT+CR and AT+CR groups, respectively. After adjustment for age, gender, baseline BMI, baseline regional BMD, and weight change, differential treatment effects were observed for the total hip and femoral neck regions (both $p<0.05$), but not lumbar spine. Specifically, total hip (0.001 [95% CI: -0.003, 0.006] g/cm²) and femoral neck (0.008 [95% CI: -0.000, 0.016] g/cm²) BMD was unchanged in RT+CR participants, and modestly decreased in AT+CR participants (total hip: -0.008 [95% CI: -0.012, -0.003] g/cm²; femoral neck: -0.007 [95% CI: -0.014, 0.001] g/cm²). Conclusion: Exercise modality differentially effects change in BMD in older adults undergoing CR. Data suggest that AT+CR results in greater loss of hip and femoral neck BMD than RT+CR. Findings warrant replication from a long-term, randomized controlled trial.

Table 1. Baseline descriptive characteristics according to treatment group.

| Baseline Characteristics | RT+CR | AT+CR |
|---|--------------|--------------|
| | n=63 | n=60 |
| Age (years) | 70.0 ± 3.8 | 68.7 ± 3.1 |
| Female, n (%) | 37 (58.7) | 45 (75.0) |
| White, n (%) | 55 (87.3) | 45 (75.0) |
| Weight (kg) | 85.4 ± 11.7 | 92.4 ± 12.2 |
| BMI (kg/m ²) | 30.4 ± 2.2 | 34.7 ± 3.7 |
| Bone Medication Use*, n (%) | 4 (6.3) | 3 (5.0) |
| Year of Menopause** (years) | 46.0 ± 6.5 | 46.4 ± 8.4 |

Higher Levels of Habitual Physical Activity Results in Region-specific Gains in Cortical Mass Distribution in Pre-pubertal Boys, but not Girls. [Rachel L Duckham](#)¹, [Timo Rantalainen](#)¹, [Gaele Ducher](#)¹, [Briony Hill](#)², [Richard M Telford](#)³, [Rohan D Telford](#)⁴, [Robin M Daly](#)². ¹Centre for Physical Activity & Nutrition Research, Deakin University, Australia, ²Centre for Physical Activity & Nutrition Research, Deakin University, Australia, ³Centre for Research & Action in Public Health, University of Canberra, Australia, ⁴Medical School, College of Medicine, Biology & Environment, Australian National University, Canberra, Australia

Cortical bone is a non-uniform tissue, with its apparent mass and density varying around the bone cross-section. Targeted weight-bearing exercise during the pre-

pubertal years can improve bone mass, structure and cortical distribution at loaded sites, but less is known about the influence of habitual physical activity (PA). This study examined the effects of habitual PA on cortical bone density, geometry and its mass distribution in pre-pubertal children. A total of 245 girls and 241 boys aged 7-9 years had a pQCT scan to measure tibial mid-shaft (66%) total and cortical area, volumetric bone density, polar strength strain index (SSI_{polar}) and the mass/density distribution through the bone cortex (radial distribution divided into endo-, mid- and peri-cortical regions) and around the centre of mass (polar distribution). PA quartiles were generated based on daily step counts (pedometer, 7-days) for boys and girls separately. Boys were 1.4 cm taller (p<0.05) and had 16.6% less tibial fat CSA than girls (p<0.01). On average, 25% of boys and 15% of girls were classified as inactive based on the recommended cut-points of 12,000 and 10,000 steps per day, respectively. There were no gender differences in total and cortical bone area or density, but cortical mass in the lateral region was 6.7% (p<0.001) greater in boys versus girls. In contrast, peri-cortical density (outer third of cortical bone) was greater (0.7%, P<0.05) in girls. There were no differences in any of the bone parameters across the PA quartiles for either sex, with the exception that boys in the highest versus lowest quartile had 8.5% (p<0.05) greater cortical mass at the lateral region. When PA was categorized into high and low levels based on the recommended cut-points, boys in the high PA group had 4-6% greater cortical bone mass compared to the less active group across nearly all sectors of the tibia cortex. In girls, contrasting levels of PA had no effect on polar cortical bone mass distribution. In conclusion, higher levels of habitual PA resulted in small regional specific gains in mid-tibial cortical bone mass distribution, with no significant effect on whole cortical bone parameters, in pre-pubertal boys but not girls. While these findings suggest that higher levels of habitual PA may produce small structural changes in cortical bone in healthy pre-pubertal boys, the clinical relevance of these changes remains to be determined given there was no apparent effect on whole bone strength

Serum Sclerostin Decreases Following 12 Months of Resistance- or Jump-training in Men with Low Bone Mass. [Pam Hinton](#)^{*}, [Peggy Nigh](#), [John Thyfault](#). University of Missouri, USA

Purpose: We previously reported that 12 months of resistance training (RT, 2x/wk, N= 19) or jump training (JUMP, 3x/wk, N= 19) increased whole body and lumbar spine BMD and increased serum bone formation markers relative to resorption in physically active (≥4 hr/wk) men (mean age: 44 ± 2 y; median: 44 y) with osteopenia of the total hip or lumbar spine. The purpose of this secondary analysis was to examine the effects of the RT or JUMP intervention on potential mediators of the exercise effects on bone, specifically IGF-I, PTH and sclerostin. **Methods:** Fasting blood samples were collected after a 24-h period of no exercise at baseline and after 12 months of RT or JUMP. IGF-I, PTH and sclerostin were measured in serum by ELISA. The effects of RT or JUMP on IGF-I, PTH and sclerostin were evaluated using 2x2 repeated measures ANOVA (time, group). This study was conducted in accordance with the Declaration of Helsinki and was approved by the University of Missouri IRB. **Results:** There was a significant time main effect for serum sclerostin (p=0.012), such that sclerostin decreased ~7% from 39.2 ± 11.6 ng/mL at baseline to 36.8 ± 13.3 ng/mL after 12 months of RT or JUMP. IGF-I increased ~26% from 203 ± 71 ng/mL to 239 ± 109 ng/mL after 12 months of RT or JUMP (time main effect, p=0.036). PTH remained unchanged from baseline to 12 months. **Conclusion:** The beneficial effects of RT or JUMP on BMD and bone turnover in moderately active, osteopenic men are associated with decreased sclerostin and increased IGF-I.

SA0049

Spinal Bone Texture Assessed by Trabecular Bone Score (TBS) in Adolescent Girls with Anorexia Nervosa. Catherine Gordon^{*1}, Abigail Donaldson², Henry Feldman³, Jennifer O'Donnell⁴, Geetha Gopalakrishnan⁵. ¹Hasbro Children's Hospital & Brown University, USA, ²Division of Adolescent Medicine, Hasbro Children's Hospital & Alpert Medical School of Brown University, USA, ³Clinical Research Center, Boston Children's Hospital, USA, ⁴Division of Adolescent Medicine, Hasbro Children's Hospital, USA, ⁵Division of Endocrinology, Women & Infant's Hospital, USA

Purpose: Trabecular bone score (TBS) is a novel bone assessment tool that offers information beyond that afforded by standard dual-energy X-ray absorptiometry (DXA) bone mineral density (BMD) measurements. Adolescents with anorexia nervosa (AN) are known to exhibit deficits in both bone density and skeletal strength. Lumbar spine TBS was derived from spinal DXA measures to determine whether this assessment provided evidence of degraded bone microarchitecture in this patient group. This study also aimed to examine the relation of TBS to measures of axial and peripheral BMD and bone strength, anthropometrics, body composition, disease duration, and fracture among a sample of adolescent girls with AN. **Methods:** Fifty-seven females with AN, age 11-18 years, were enrolled from an urban eating disorders program. DXA BMD spinal measures were retrospectively analyzed for TBS. Findings were compared to clinical variables (height, weight, BMI, 25-hydroxyvitamin D); spine and whole body DXA measures of areal BMD and body composition; tibial peripheral quantitative computed tomography (pQCT) volumetric BMD measures and strength-strain index (SSI); and self-reported data (illness duration, amenorrhea, exercise, fracture, family history of osteoporosis, and antidepressant use). **Results:** TBS scores were abnormal in 44% of participants: 6 (11%) showed degraded and 19 (33%), partially degraded, microarchitecture. Spinal TBS correlated significantly ($p < 0.05$) with age, height, weight, BMI, absolute BMD and BMD Z-score at all skeletal sites. TBS was also correlated significantly ($p < 0.001$) with total volumetric BMD at the 3% tibial site, and SSI at both the 38% and 66% sites by pQCT; and lean body mass by DXA. Clinical variables that were not correlated with TBS included duration of amenorrhea or AN, fracture, body fat percentage, exercise, antidepressant use, family history of osteoporosis, vitamin D status, race or ethnicity. **Conclusions:** To our knowledge, this is the first study to test use of TBS as part of a skeletal evaluation in a pediatric population. TBS was abnormal in over 40% of adolescents with AN, and was strongly correlated with measures of areal and volumetric BMD, skeletal strength, body composition, and anthropometric measures. TBS is a novel, additional bone assessment method that indicates compromised bone health in adolescents with AN.

SA0050

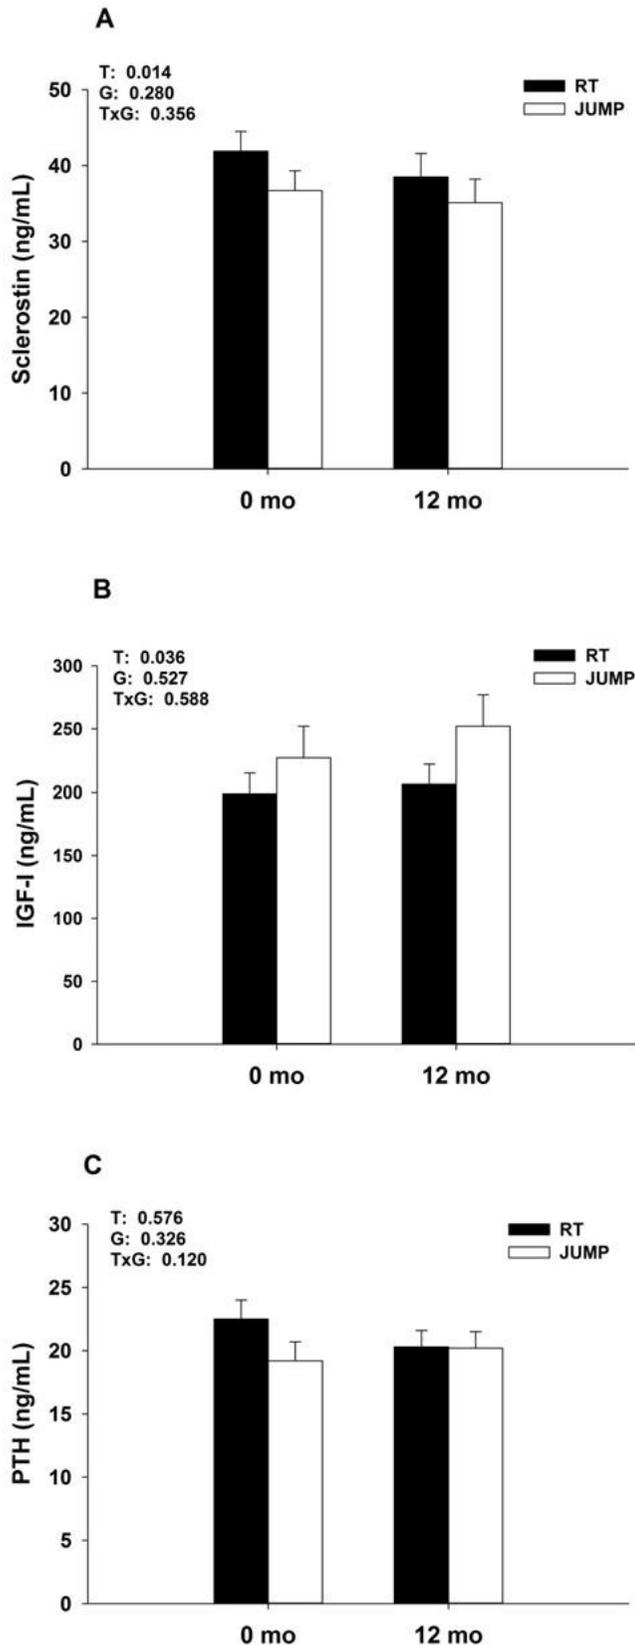

Weight Percentile is an Effective Predictor of Osteoporosis in Patients with Cerebral Palsy. A Cross Sectional Study Analyzed by Simulation and Data-mining Approaches. Abdulhafez Selim¹, Abeer Hegazy^{*2}. ¹Center for Chronic Disorders of Aging, PCOM, USA, ²Dammam Medical Complex Rehab Center, Saudi Arabia

Cerebral palsy (CP) is the most common physical disability in children and affects 3.6/1,000 children. Babies with CP may not gain weight at the same rate as other babies their age. In addition to poor linear growth, children with moderate to severe CP often sustain painful pathological fractures due to poor mineralization of bone. The risk of osteoporotic fracture is further complicated by the difficulty associated with BMD assessment due to limitations induced by difficult positioning and other artifacts in these children. Clinicians, therefore, need methods that can easily predict low BMD scores early on in order to prevent osteoporosis-related complications. We therefore conducted a cross-sectional study in order to satisfy this clinical need by identifying an effective prediction method.

The study included thirty CP patients of both genders, between 5 and 8 years of age. Case record forms were used to record full medical history including weight; height; BMI; mid-arm circumference; head circumference; triceps skin fold thickness; prenatal, perinatal and postnatal history; nutritional history; type of rehabilitation program and physiotherapy; and medications used. Weight, height, and BMI percentiles were classified into three categories: above 50th percentile (rank 3), at 50th percentile (rank 2), and below 50th percentile (rank 1). Ranked data were used for further analyses. Subjects underwent dual energy x-ray absorptiometry (DXA) scan and results were compared to reference values in children relative to age, gender and body size. The collected data was analyzed using correlation, step-wise regression, Bayesian simulation analysis, and data-mining approaches.

A significant correlation was observed between the weight percentile rank and BMD scores (0.8, P -value = 0.001). Stepwise regression analysis demonstrated that weight rank can effectively predict the BMD score (BMD score = $-3.7 + 0.8 * (\text{weight rank})$, $R^2 = 0.6$ and P -value < 0.00). The positive predictive value of this equation was found to be 100%. Simulation outcomes further demonstrated that subjects with weight below 50th percentile are at high risk of having low BMD scores (-2.9 ± 0.17). Additionally, data-mining analysis suggested that those patients with weight rank less than 50th percentile are likely to have a BMD score of -3 . Collectively, these data suggest that managing physicians can use patient's weight rank in order to effectively predict the BMD status. To our knowledge this is the first study that proposes a simplified yet effective approach for BMD prediction in CP patients.

Maintenance on a Low Calcium Diet Results in an Osteocyte-Mediated Reduction of Long-Term Hematopoietic Stem Cell Engraftment. Benjamin Frisch^{*1}, Alexandra Goodman¹, Olga Bromberg¹, Xiaolin Tu², Teresita Bellido², Laura Calvi¹. ¹University of Rochester School of Medicine & Dentistry, USA, ²Indiana University Department of Anatomy & Cell Biology, USA

The bone marrow microenvironment, including osteolineage cells, is known to play a critical role in the regulation of hematopoietic stem cells (HSCs). Intermittent pharmacologic treatment with parathyroid hormone, PTH (1-34), is anabolic to bone, and increases HSCs in mice through microenvironmental signals, as HSCs do not express the PTH receptor (PTH1R). However, continuous PTH treatment is catabolic to bone, while its effects on HSCs are not known. We used a model of secondary hyperparathyroidism in which we maintained mice on a low calcium (LCa) diet in order to investigate the role of continuous PTH exposure on HSCs. In juvenile mice placed on the low calcium diet immediately upon weaning, PTH levels were significantly elevated as early as 7 days. Fourteen days on the LCa diet caused a significant reduction in long-term engraftment potential as measured by secondary competitive transplants over 22 weeks (Normal vs LCa diet donors, 2-way ANOVA $p \leq 0.001$, $N \geq 20$ mice/group), while there was no decrease in HSCs when adult mice were placed on the LCa diet. These data suggest that sustained PTH signaling decreases microenvironmental support for HSCs in juvenile mice. Osteocytes are the most abundant osteolineage cells in the bone and activation of PTH signaling specifically in osteocytes is anabolic. Osteocytes are also known to regulate multiple cellular components of the HSC niche. Therefore, we studied the role of osteocytic PTH signaling in our model using cre recombinase driven by the 8kb-DMP1 promoter to conditionally delete PTH1R in osteocytes (OCyPTHRko mice). In juvenile mice the lack of PTH signaling in osteocytes rescued the long-term engraftment defects, suggesting that PTH signaling in osteocytes mediates the loss of long-term HSC support caused by the LCa diet. In further support of a deleterious effect mediated by the PTH1R in osteocytes in the setting of continuous PTH, adult OCyPTHRko mice placed on LCa diet had superior long term HSC function. Our findings demonstrate that continuous exposure to elevated levels of PTH in a model of secondary hyperparathyroidism leads to osteocyte-mediated loss of long-term engraftment potential of HSCs in juvenile mice. These data also suggest that additional effects of continuous PTH, likely mediated by other HSC niche cellular populations, are instead supportive of LT-HSC function and that the relative contributions of niche populations to HSC regulation are modulated by age.

Radiation Injury Links Mineral Homeostasis to Hematopoietic Stem Cell Niche Activation. Corey Hoffman^{*}, Mark LaMere, Alexandra Goodman, Brandon Zaffuto, Benjamin Frisch, Laura Calvi, University of Rochester, USA

Hematopoietic Stem Cells (HSCs) reside at the apex of hematopoiesis, and are regulated by their bone marrow microenvironment or niche, including osteolineage cells. While hematopoietic injury is a major cause of morbidity and mortality following radiation, the role of the HSC niche in hematopoietic and HSC recovery after radiation is poorly understood. Recently an increase in endosteal osteoblasts was reported after radiation in mice, however the mechanism for this increase is not well-understood. We sought to investigate niche engagement at acute time points (24 and 48 hours) after sub-lethal (6.5Gy) total body irradiation (TBI). Using this in vivo model, we confirmed HSC loss and quantified osteoblastic (OBCs), mesenchymal (MSCs) and osteoprogenitor (OPs) populations after TBI. Phenotypic OBCs (CD45⁻, Lineage⁻, CD31⁺, CD51⁺, Sca1⁺) were expanded 1.73 Fold (31.78 ± 3.07 vs 55.13 ± 3.40 % of % non-hematopoietic cells $P=0.0005$, $N=6$ mice/group) and 1.83 Fold (29.63 ± 2.73 vs 54.12 ± 3.40 % non-hematopoietic cells $P=0.0002$, $N=6$ mice/group) 24 and 48 hours after 6.5Gy TBI. TBI caused a decrease in functional OPs from bone associated cells (36.11 ± 3.066 vs 3.444 ± 0.729 Colonies/ 10^4 Cells, $P=0.0005$, $N=3$ mice/group) and bone marrow (19.17 ± 2.798 vs 5.667 ± 1.5 Colonies/ 10^6 Cells, $P=0.01$, $N=3$ mice/group) as measured by CFU-AlkPhos 48 hours post TBI. Functional MSCs, measured by CFU-F, were also severely decreased 48 hours after TBI (44.11 ± 2.336 vs 26.00 ± 1.633 Colonies/ 10^4 Cells, $P<0.0001$, $N=3$ mice/group). We next determined if mineral homeostasis is affected by TBI. Hyperphosphatemia was seen at 18 and 24 hours after TBI, while mice had no concurrent measurable changes in ionized Ca⁺⁺. Concurrently there was a 10 fold increase in circulating Parathyroid Hormone (PTH) (0Gy vs 24 vs 48 hours: 31.91 ± 11.53 vs 305.5 ± 68.55 vs 331.5 ± 119.1 pg/mL, $P<0.005$, $N=7-17$ mice/group). Notably, PTH is known to improve hematopoietic recovery after radiation. Since PTH also known to activate OBCs to increase their ability to support HSCs, our data suggest that TBI increases circulating PTH in response to elevated PO₄³⁻, preventing hypocalcemia but also engaging the niche through OBC expansion, thus increasing HSC support. While further studies are needed to determine if the PTH increase is required for HSC recovery after TBI injury, our data demonstrate acute changes in mineral metabolism that may impact the hematopoietic response to TBI.

Phosphate Restriction Leads to Low Bone Mass and Impaired Marrow Vasculature. Frank Ko^{*1}, Beth Bragdon², Amira Hussein², Louis Gerstenfeld², Marie Demay¹. ¹Massachusetts General Hospital, USA, ²Boston University School of Medicine, USA

Phosphate restriction in growing mice leads to rachitic expansion of the growth plate due to impaired hypertrophic chondrocyte apoptosis. Histological analyses of the long bones of phosphate restricted mice were performed to identify effects of phosphate restriction on osteogenesis. Dietary phosphate restriction was shown to be associated with a reduction in both trabecular and cortical bone. Recent investigations demonstrate that marrow angiogenesis and osteogenesis are coupled, with increased bone formation being associated with an increase in mature vessels expressing high levels of endothelial CD31 and endomucin. Thus, we investigated the relationship between bone and marrow vasculature in growing mice subjected to dietary phosphate restriction.

Mice were phosphate-restricted d28-50. Immunohistochemical staining for osteocalcin and Runx2 in the metaphysis revealed a significant decrease in the number of osteocalcin (Chow, 7.1 ± 1.7 /mm; Phosphate-restricted 0.4 ± 0.2 /mm) and Runx2 (Chow, 11.6 ± 5.8 /mm; Phosphate-restricted, 0.80 ± 0.6 /mm) expressing osteoblasts per mm metaphyseal trabecular bone surface in the phosphate-restricted mice relative to chow fed controls. This decrease in osteoblasts and osteoprogenitors was associated with decreased pSmad1/5/9 immunoreactivity in osteolineage cells. A significant decrease in TRAP positive osteoclasts was also observed in the metaphysis of phosphate-restricted mice (Chow 1.5 ± 0.7 /mm; Phosphate-restricted, 0.3 ± 0.5 /mm).

Metaphyseal blood vessel density, evaluated by microCT of Microfil perfused tibiae, demonstrated a significant reduction in vascular volume per total volume in the phosphate-restricted mice (Chow, 0.12 ± 0.05 mm³/mm³; Phosphate-restricted, 0.09 ± 0.02 mm³/mm³). Neither vessel diameter nor vessel separation was affected by phosphate restriction. In addition to decreasing the overall vasculature, phosphate deficiency markedly decreased mature vasculature evidenced by a dramatic reduction of vessels with endothelial expression of CD31 and endomucin.

In conclusion, phosphate restriction in mice resulted in decreased bone associated with a reduction in osteoprogenitors, osteoblasts and mature marrow vasculature. Decreased expression of pSmad1/5/9 suggests that phosphate restriction impairs osteogenesis and angiogenesis by attenuation of the BMP signaling pathway.

Aromatase Inhibitor-Induced Bone Loss Causes Muscle Weakness and Increased Progression of ER-Negative Breast Cancer in Bone in a Murine Model. Laura Wright^{*}, David Waning¹, Ahmed Harhash¹, Khalid Mohammad¹, Andrew Marks², Theresa Guise¹. ¹Indiana University, USA, ²Columbia University, USA

Adjuvant endocrine therapy using an aromatase inhibitor (AI) is a standard treatment for postmenopausal women with ER-positive breast cancer. Unfortunately, up to 50% of women treated with an AI develop muscle weakness, bone loss and joint pain that result in treatment discontinuation. Previous studies in our laboratory have demonstrated bone loss and muscle weakness in ovariectomized (OVX) mice. We therefore hypothesized that the combination of AI-OVX would cause more profound estrogen deprivation and bone loss than OVX alone, and that this high bone turnover state could alter the bone microenvironment in ways that accelerate the progression of breast cancer growth in bone and exacerbate muscle weakness systemically. Four-week female athymic nude mice underwent OVX or sham surgery and were treated daily with vehicle or AI (10µg/day; n=20/group). Three weeks after surgery and onset of treatment, serum levels of 17β-estradiol in OVX-AI mice were reduced by 56% (p<0.01; Calbiotech ELISA) and trabecular bone volume fraction at the proximal tibia was reduced by 67% (p<0.001; SCANCO viva40CT) relative to vehicle-sham. After confirming estrogen deficiency and bone loss, the same animals were inoculated with ER-negative MDA-MB-231 human breast cancer cells into the left cardiac ventricle and followed for cancer progression in bone. Since MDA-MB-231 cells are ER-negative, effects of estrogen deprivation on the tumor should be indirect and attributed to the microenvironment. Five weeks after inoculation, osteolytic lesion area increased by 110% (p<0.01, X-Ray) and tumor burden in bone assessed by histology was increased by 87% (p<0.01) in OVX-AI mice relative to sham-vehicle. Furthermore, ex vivo maximal contractile force of the extensor digitorum longus muscle was significantly reduced in OVX-AI mice (-12%, p<0.001) relative to sham-vehicle. Our murine studies confirm that AI treatment induces bone loss and skeletal muscle weakness, recapitulating effects in cancer patients. As hypothesized, the severe bone loss resulting from AI-induced estrogen depletion may prime the bone microenvironment for the development of breast cancer metastases to bone and potentiate muscle weakness. This model serves as an excellent tool to study the mechanisms of underlying musculoskeletal defects in cancer patients and to assess potential therapeutics. Ongoing studies will evaluate whether protection of bone with bisphosphonates can prevent AI-induced musculoskeletal complications in our model of breast cancer bone metastases.

Ectopic Production of FGF23 in Tumor-Induced Osteomalacia is Mediated by HIF-1α. Qian Zhang^{*}, Michele Doucet², Ryan Tomlinson², Xiaobin Han³, Darryl Quarles³, Michael Collins⁴, Thomas Clemens². ¹Johns Hopkins University, USA, ²Department of orthopaedic surgery, Johns Hopkins University, USA, ³University of Tennessee Health Science Center, USA, ⁴NATIONAL INSTITUTES OF HEALTH, USA

Tumor-induced osteomalacia (TIO) is a rare phosphate-wasting syndrome in which patients harboring non-malignant hemangioma/pericytomas overproduce fibroblast growth factor-23 (FGF23). In this study, we investigated the mechanisms responsible for increased FGF23 production in primary tumors recovered from patients with proven TIO. Our approach was informed by recent studies showing that deficiency in iron, a known regulator of HIF-1α, predisposes patients with Autosomal Dominant Hypophosphatemia to phosphate wasting. Freshly isolated tumor tissue was finely minced and cultured for 24 hours in DMEM medium containing 5% of fetal bovine serum. FGF23 levels measured by ELISA were increased within 1 hour and remained elevated throughout the culture period. Western blot analysis showed that expression of HIF-1α in the tumor tissue was also markedly elevated. Treatment of organ cultures with digoxin, which inhibits HIF-1α translation, profoundly suppressed HIF-1α protein levels with parallel reductions in FGF23 levels, suggesting that HIF-1α directly activates FGF23 expression. In accordance with this idea, overexpression of HIF-1α in SaOS2 osteoblasts increased FGF23 promoter activity while chromatin immunoprecipitation (ChIP) assays demonstrate HIF-1α occupancy at HRE elements within the FGF23 promoter. Finally, immunohistochemical analysis in fixed tumor tissue reveals that spindle-shaped tumor cells, immediately adjacent to blood vessels, coexpressed FGF23 and HIF-1α, and some of which were also positive for bone markers including osteocalcin. Based on these observations, we conclude that aberrant upregulation of HIF-1α secondary to a yet to be identified mutation, elevates FGF23 by transcriptionally activating its promoter. Based on previous reports of pediatric hemangiomas that spontaneously regress to adipose tissue through a HIF-1α dependent endothelial mesenchymal transition (EMT), we speculate that a similar phenomenon occurs in TIO whereby HIF-1α drives EMT to convert endothelial cells to bone-like cells that produce FGF23.

Sympathetic Activation Alters the Bone Vasculature: Implication for Osteotropic Breast Cancer Metastasis. Patrick Mulcrone^{*}, J. Preston Campbell¹, Ana Lia Anbinder², Florent Elefteriou¹. ¹Vanderbilt University, USA, ²Universidade Estadual Paulista Campus de Sao Jose dos Campos, Brazil

Most cancer-related deaths are due to metastasis of the primary tumor. Breast cancer commonly metastasizes to the skeleton, an organ innervated by the sympathetic nervous system (SNS). Emotional stresses chronically activate the SNS, and such conditions have been associated with the progression of breast cancer, reduced survival, and increased recurrence. Preclinical evidence suggests that SNS activation promotes the establishment of breast cancer cells in bone, by increasing bone-derived RANKL expression and the migration of these cells toward RANKL-expressing osteoblasts. However, the receptor for RANKL is detected in only 30% of breast cancers; hence other mechanisms may contribute to the establishment of metastatic breast cancer cells in bone following SNS activation. We observed that isoproterenol (ISO), a beta1/2 adrenergic receptor (βAR) agonist used in mice to mimic sympathetic activation, induced the expression of *Vegfa* in bone in vivo and in osteoblast cultures in vitro. Because VEGF is pro-angiogenic and tumor cells depend on blood vessels to form distant metastases, we hypothesized that SNS activation may increase bone marrow vascular density, via effect on osteoblasts and *Vegf* expression, thus promoting the chance of metastatic breast cancer extravasation into the skeleton. To address this question, we measured the formation of CD31⁺ vessels in adult femurs in vivo by histomorphometric analyses and ex vivo, following osteoblastic βAR stimulation. Daily ISO treatment for 6 wks increased vessel area and number in WT mouse femurs, and this effect was blunted in mice lacking the β2AR (n>6/group, P=.0003). The conditioned media (CM) from MC3T3 osteoblasts treated with ISO for 24 hrs augmented blood vessel formation in an *ex vivo* metatarsal assay as compared to the CM of PBS-treated osteoblasts (n>3, P<.0001). VEGF treatment promoted HUVEC endothelial cell tube formation, whereas direct ISO treatment did not (n=3, P=.0076). Ongoing assays aim at determining the effect of VEGF blockade on bone vessel formation and on GFP-tagged MDA-231 breast cancer cell bone metastasis upon ISO treatment. These results suggest that the effect of stress/SNS activation on metastatic breast cancer cell establishment in the skeleton is mediated via the β2AR in osteoblasts, and an increase in bone VEGF and RANKL expression that promotes bone vascular density and homing in the bone marrow environment, respectively, contributing to higher chance of cancer cells engraftment.

Up-regulation of the pH sensor TRPV1 in myeloma cells and their adaption to an acidic microenvironment. Ryota Amachi^{*}, Masahiro Hiasa², Jumpei Teramachi³, Asuka Oda⁴, Hirofumi Tenshin², Keiichiro Watanabe³, Shing Nakamura⁴, Hirokazu Miki⁴, Kumiko Kagawa⁴, Shiro Fujii⁴, Endo Itsuro⁴, Eiji Tanaka⁵, Toshio Matsumoto⁶, Masahiro Abe⁴. ¹University of Tokushima, Japan, ²Department of Biomaterials & Bioengineering, Institute of Biomedical Sciences, Tokushima University Graduate School, Japan, ³Department of Histology & Oral Histology, Institute of Biomedical Sciences, Tokushima University Graduate School, Japan, ⁴Department of hematology, endocrinology & metabolism, Institute of Biomedical Sciences, Tokushima University Graduate School, Japan, ⁵Department of Orthodontics & Dentofacial Orthopedics, Institute of Biomedical Sciences, Tokushima University Graduate School, Japan, ⁶Fujii Memorial Institute of Medical Sciences, Tokushima University, Japan

Myeloma (MM) cells preferentially grow and expand in acidic bone lesions in MM. We have demonstrated that MM cells in acidic bone lesions up-regulate their acid sensing to enhance the PI3K-Akt survival signaling to adapt to harsh acidic microenvironment in MM bone lesions. Transient receptor potential cation channel subfamily V member 1 (TRPV1), an acid-sensitive ion channel, is among major pH sensors expressed in cancer cells, including MM cells. In the present study, we therefore explored the regulatory mechanism of TRPV1 expression and its role in MM cell growth and survival in acidic conditions. The expression of *TRPV1* mRNA was up-regulated in all MM cell lines tested at pH6.8 compared to at pH7.4, which was abolished by addition of the PI3K inhibitor LY294002. Activation of the PI3K-Akt

pathway by rh IGF1 or cocultured with acid-producing OCs was able to enhance *TRPV1* mRNA expression in MM cells even at pH7.4, suggesting a critical role of the PI3K-Akt pathway in *TRPV1* expression in MM cells. Although MM cell viability was marginally affected at pH6.8, MM cells underwent cell death preferentially at pH6.8 than at pH7.4 by LY294002, and to a lesser extent by the *TRPV1* antagonist SB366791. Treatment with the *TRPV1* agonist resiniferatoxin induced the phosphorylation of Akt in MM cells even at pH7.4, indicating *TRPV1*-mediated activation of the PI3K-Akt survival signaling. To further clarify the mechanisms for acid-induced up-regulation of *TRPV1* in MM cells, we looked at nuclear localization of Sp1, a transcription factor responsible for *TRPV1* gene expression. Nuclear localization of Sp1 was enhanced in MM cells cultured at pH6.8 compared to those at pH7.4 in a manner inhibitable by LY294002; the up-regulation of *TRPV1* mRNA expression in acidic conditions was suppressed by the PI3K inhibition as well as treatment with terameprocol, a competitive inhibitor of Sp1 binding to promoter regions. Sp1 is also known as a transcription factor of *HDAC* genes. Together with our previous observation of the role of Sp1 in acid-induced gene repression by HDAC, these results collectively suggest that an acidic condition activates the PI3K-Akt pathway in MM cells, which induces Sp-1 nuclear localization and thereby *TRPV1* expression to form a progressive vicious cycle between acid sensing and survival signaling while altering gene expression in MM cells in acidic bone lesions in MM.

ELISA measurement of circulating periostin in animal models of bone loss or bone formation, and identification of circulating and tissue-specific associated forms of periostin. Evelyne Gineys¹, Nicolas Bonnet², Cindy Bertholon¹, Aurélien Pagnon-Minot³, Olivier Borel¹, Daniel Hartmann³, Roland Chapurlat⁴, Serge Ferrari², Patrick Garnero¹, Philippe Clezardin¹, Jean-Charles Rousseau^{*1}. ¹INSERM UMR 1033, Lyon, France, ²University Geneva Hospital (HUG), Faculty of Medicine (UNIGE), Department of Internal Medicine Specialties, Service of Bone Diseases, Geneva, Switzerland, ³Novotec, France, ⁴INSERM UMR 1033 & Hospices Civils de Lyon, Lyon, France

Purpose: Matricellular protein periostin (PN) mediates the bone anabolic effect of parathyroid hormone (PTH) and is associated with metastasis from solid tumors. The aim of this study was to develop an enzyme-linked immunosorbent assay (ELISA) to measure PN levels in the serum of animals treated with intermittent PTH or inoculated with 4T1 breast cancer cells. Circulating- and tissue-associated forms of PN recognized by the antibodies used for the ELISA were also characterized.

Methods: We developed a sandwich ELISA using polyclonal antibodies raised against the recombinant mouse PN (Ab1) or the last C-Ter 22 amino acids (Ab2). In the "PTH model", mice (12 weeks old) were treated with intermittent PTH (40mg/kg/day) or vehicle for 5 weeks. In the "metastasis model", mice (5 weeks old) were inoculated iv with 4T1 cells and sacrificed at day 14 after tumor cell inoculation. Mice developed bone and lung metastases. Osteolytic lesions were monitored at day 13 by radiography. Lung metastases were assessed by histology and immunohistochemistry. At sacrifice, serum and tissues were collected and stored at -80°C. Using 2-D gel electrophoresis and western blotting, PN forms in the serum and bone and soft tissues of wild type mice were characterized and PN spot specificity was controlled using a model of Postn deficient mice. The ability of recombinant human cathepsin K to cleave the recombinant mouse PN (R&D) was also tested.

Results: In the "PTH model", serum PN levels were significantly increased compared to untreated animals, (+44%, mean ± SD: 2178 ± 198 vs 3139 ± 213 ng/ml, p=0.02). In contrast, in the "metastasis model", a significant decrease of serum PN levels was observed, compared to age-matched control mice (-26%, mean ± SD: 560 ± 100 vs 756 ± 64 ng/ml, p<0.002). In serum and tissues, the two antibodies recognized several PN spots differing according to their isoelectric points and molecular weights (MW). We found a "bone signature" corresponding to a 50 kDa PN fragment not recognized by Ab2. Additionally, PN was a substrate for cathepsin K, leading to the generation of fragments with a range of MWs similar to that found in the bone signature.

Conclusion: ELISA measurement of serum PN levels reflects variations of the bone metabolism that are associated with an anabolic treatment or cancer-induced bone disease. Additionally, we found that PN was cleaved by cathepsin K, enabling the identification of a "bone signature" in the animals.

Loss of the Vitamin D Receptor Promotes the Metastatic Potential of Human Breast Cancer Cells to Bone. Konstantin Horas^{*1}, Yu Zheng², Shu-Oi Chow², Colette Fong-Yee², Colin Dunstan², Hong Zhou², Markus Seibel². ¹ANZAC Research Institute, The University of Sydney, Australia, ²ANZAC Research Institute, Australia

Breast cancer is amongst the most prevalent malignancies globally with up to 40% of patients developing skeletal metastases. We have demonstrated that vitamin D deficiency, partly through an increase in bone turnover, accelerates the growth of human breast cancer cells in rodent models of bone metastasis. The purpose of the current study was to define the role of the vitamin D receptor (VDR) in systemic breast cancer spread to bone.

VDR expression was knocked down in the human breast cancer cell line, MDA-MB-231 (MDAVDR^{-/-}). Compared to non-target (NT) controls transfected with an empty vector, knockdown efficiency in MDAVDR^{-/-} cells was ~80%. MDAVDR^{-/-} and NT-cells were further transfected with a luciferase gene and injected into the left ventricle of female nude mice (n=11 for each, MDAVDR^{-/-} and NT). Systemic cancer cell spread and tumour growth were monitored by sequential *in vivo* bioluminescent imaging (BLI), high resolution X-ray and μ -CT imaging for a period of 30 days. Affected bones were analysed by histomorphometry and immunohistochemistry at endpoint (day 30).

Compared to NT controls, MDAVDR^{-/-} cells were characterised by a significant increase in cell migration and cell invasion *in vitro* (Fig.1A, B). Mice injected intracardially with MDAVDR^{-/-} cells developed more metastases at day 5 (p<0.01) and 10 (p=0.03), with light emission measurements generating significantly higher values at all time points in MDAVDR^{-/-} mice compared to animals injected with NT-cells (Fig.1C). After 20 days, multifocal metastases were detectable in all animals and tumours were visible on X-ray. Of note, mice injected with MDAVDR^{-/-} cells had significantly larger bone lesions compared to control mice (P<0.01).

We conclude that silencing the VDR in human breast cancer cells boosts their systemic metastatic potential, resulting in significantly greater tumour burden. Our results clearly indicate that the VDR itself has a critical function in controlling cancer cell behaviour and osteotropism.

Osteoclast TGF- β signaling-mediated basic-FGF promotes breast cancer bone metastasis. Xiangqi Meng¹, Alexandra Vander Ark¹, Priscilla Lee¹, Galen Hostetter¹, Neil A. Bhowmick², Lynn M. Matrisian³, Bart O. Williams¹, Cindy K. Miranti¹, xiaohong li¹. ¹Van Andel Institute, USA, ²Cedars Sinai Medical Center, USA, ³Pancreatic Cancer Action Network, USA

Breast cancer (BCa) bone metastases cause osteolytic bone lesions, which result from the interactions of metastatic BCa cells with osteoclasts and osteoblasts. Transforming growth factor beta (TGF- β) is a cytokine that functions as both tumor suppressor and oncogene, which plays important roles in advanced BCa bone metastasis. To understand the cell-specific role of TGF- β signaling in osteoclasts in BCa bone metastases, MDA-MB-231 BCa cells were intra-tibially or intra-cardially injected into *LysM^{Cre}/Tgfb2^{flloxE2/flloxE2}* knockout (*LysM^{Cre}/Tgfb2* KO) or *Tgfb2^{flloxE2/flloxE2}* mice. Metastatic bone lesion development was monitored by X-ray and compared by analysis of both lesion number and area. We found that *LysM^{Cre}/Tgfb2* knockout significantly decreased MDA-MB-231 induced bone lesion development in both the cardiac and tibial injection models. *LysM^{Cre}/Tgfb2* knockout inhibited the tumor cell proliferation, angiogenesis, and osteoclastogenesis in the metastatic bone microenvironment. Cytokine array analysis and ELISA results showed that basic fibroblast growth factor (bFGF) was down regulated in MDA-MB-231-injected tibiae from the *LysM^{Cre}/Tgfb2* KO group. Intravenous injection of the recombinant bFGF to *LysM^{Cre}/Tgfb2* KO mice rescued the inhibited metastatic bone lesion development. The mechanism by which bFGF rescued the bone lesion development was by promotion of tumor cell proliferation through the downstream MAPK-ERK-cFos pathway after binding to the FGF receptor 1 (FGFR1). Consistent with animal studies, we found that in human BCa bone metastatic tissues, TGF- β type II receptor (T β RII) and p-Smad2 were expressed in osteoclasts and tumor cells, and were correlated with the expression of FGFR1. Our studies suggest that osteoclast TGF- β signaling-mediated bFGF in the bone promotes BCa bone metastasis.

Organic Phosphate Regulates Chondrocyte Expression of Extracellular Matrix Genes and Osteocyte Associated Mediators (FGF23, Phex, MEPE) of Mineralization. Margaret Cooke^{*}, Louis Gerstenfeld. Boston University, USA

Introduction: A phosphate gradient in the cartilage growth plate increases from the proliferative to the hypertrophic region. Inorganic phosphate has been shown to regulate chondrocyte maturation and induce matrix mineralization and cell apoptosis. This study sought to determine the role of organic phosphate in chondroprogenitor development and mineralization. **Methods:** ATDC5 chondroprogenitor cells were cultured to confluence in growth media (50/50 DMEM/F12 with 10% FBS). At confluence, they were switched to a differentiating media (a-MEM, 5% FBS, 25ug/ml ascorbate-2-phosphate, 1X insulin-transferrin-selenium and with or without 54ug/ml β -glycerol phosphate (BGP). Cells were harvested at day 7, 14, 21, days and assayed for growth (MTT), differentiation (Alkaline phosphatase and gene expression [qRT-PCR]) and mineralization (Alizarin Red). **Results:** Across the 21 day time course of differentiation (SOX9) and overall growth was unaffected by BGP. While Collagen 2a1, Aggrecan, and Collagen 10a1 expression showed respective ~ 250, 5 and 200 fold increase with chondrocyte differentiation in the presence of BGP. The absence of BGP in the media led to a further ~2, 8 and 3 fold further increase in the expression of these genes respectively (Figure 1). Differentiation in the presence of BGP led to a 2.91 fold increase alkaline phosphatase activity and a 7.11 fold increase in mineralization with a 67% decrease in alkaline phosphatase activity and 31% decrease in mineralization seen in cultures in the absence of BGP (Figure 2). Strikingly, several genes associated with osteocytes were expressed by these cells including DMP1, FGF23, Phex and MEPE. Over the time course of differentiation BGP induced the expression of DMP1 ~12x and FGF23 ~400x while MEPE and Phex decreased over time by 50%. In the absence

of BGP both FGF23 and MEPE increased an additional ~3x and DMP1 and Phex decreased 25% to 50% respectively. **Conclusions:** This study demonstrates that organic phosphate directly controls chondrogenic differentiated functions. Moreover current studies suggest that chondrogenic cells express the same central molecular mediators that control mineralization and phosphate metabolism including FGF23, Phex as osteogenic cells. The regulation of these genes in the absence of BGP is comparable to that seen in a hypophosphatemia state in bone tissues. These studies suggest that organic phosphate as well as inorganic phosphate directly regulates in chondrocyte differentiation and function.

Estrogen deficiency exacerbates type 1 diabetes induced bone loss. Sandra Raetz*, Nara Parameswaran, Laura McCabe. Michigan State University, USA

Estrogen deficiency following menopause is associated with rapid bone loss, osteoporosis and increased fracture risk. Type 1 Diabetes (T1D), characterized by little or no insulin secretion and hyperglycemia, is also associated with bone loss and increased fracture risk. With better treatment options, T1D patients are living longer and therefore the number of patients having both T1D and estrogen deficiency is increasing. Little is known about the impact of type 1 diabetes and estrogen deficiency on bone health and density. To investigate this, 11 week old mice were ovariectomized (ovx) and T1D (blood glucose greater than 300 mg/dl) was induced by multiple low dose streptozotocin injection. As expected, ovx mice gained body and fat pad mass whereas T1D and T1D-ovx mice lost body and fat pad mass. MicroCT analysis of both distal femur and lumbar vertebrae trabecular bone indicated significant bone volume fraction (BVf) losses in all groups. However, while ovx and T1D mice lost roughly 50% BVf, the combination of T1D and ovx led to a BVf loss of 82% in the distal femur. A similar response was seen in the vertebrae. 2-way ANOVA analyses indicated a significant interaction between T1D and ovx resulting in greater bone loss. mRNA analysis of bone remodeling markers revealed no change in osteocalcin expression in ovx mice, but a significant decrease in both T1D and T1D-ovx mice. In addition, TRAP5b expression was only increased in the T1D-ovx mice. Taken together, our results show that T1D combined with estrogen deficiency can have a profound effect on bone health. Understanding the additive effects of estrogen deficiency and T1D on bone health is essential for fracture prevention in this patient population.

IGFBP2/FOXC2 interactions: effects on body composition and bone mass. Victoria Demambro*¹, David Clemmons², Beata Lecka-Czernik³, Clifford Rosen¹. ¹Maine Medical Center Research Institute, USA, ²University of North Carolina Chapel Hill, USA, ³University of Toledo, USA

We have previously reported that *Igfbp2* *-/-* ovariectomized (OVX) females have 'browning' of the inguinal fat depot coinciding with reduced weight gain and intra-abdominal fat mass, as well as increased bone loss, insulin sensitivity and energy expenditure relative to OVX *+/+* mice. In addition, inguinal fat depots from OVX *-/-* mice were found to have a 10-fold increase in *Foxc2* expression compared to OVX *+/+* depots. *Foxc2* transgenic mice, on the other hand, are lean, insulin-sensitive, and have high bone mass due to increased bone formation associated with high bone turnover. These mice also exhibit a 10-fold increase in *Igfbp2* expression, suggesting a possible regulatory mechanism between IGFBP2 and FOXC2. The IGFBP2 molecule contains two Heparin Binding Domains (HBD), the first of which is thought to be

anabolic for bone. To test the effect of HBD1 on bone loss in an OVX model we treated ovariectomized 8-week-old *+/+* mice with HBD or control peptide for 4 weeks. Surprisingly, HBD-treated OVX mice did not gain as much weight as control-treated OVX mice (HBD1: 23.25 ± 0.8318 vs. CON: 25.87 ± 0.1848, *p*=0.003), which was primarily due to a reduction in fat mass (HBD1: 4.233 ± 0.3887 vs. CON: 6.300 ± 0.4716, *p*=0.007) accrual. MicroCT of the distal trabecular bone of the femur revealed that HBD treatment was able to partially rescue OVX-induced bone loss with an increase in BV/TV compared to controls (HBD1: 0.0196 ± 0.0023 vs. CON: 0.0134 ± 0.0011 *p*=0.036), however HBD-treated mice were still well below sham mice (SHAM: 0.0343 ± 0.0031). This increase in BV/TV was accompanied by modest increases in trabecular number and thickness with subsequent decreases in spacing. No changes in cortical bone were noted with treatment. Analysis of gene expression in the inguinal fat depot revealed a 2-fold increase in *Foxc2* transcripts in OVX HBD-treated mice relative to controls. Interestingly, in the absence of IGFBP2, up-regulation of *Foxc2* was noted, suggesting a possible inhibitory role of IGFBP2 on FOXC2. However, the increase in *Foxc2* expression with HBD treatment suggests a possible feedback loop between the two molecules. Further experiments will be required to determine the exact interaction between the two. Previous findings in humans have shown correlations between low levels of IGFBP2 and browning of white adipose tissue, with our findings suggesting that this browning could be directly mediated through FOXC2-dependent mechanisms.

Inability to Generate Bone Marrow Adipocytes Does Not Protect the Skeleton from Disuse-Induced Cancellous Bone Loss in Adult Male Mice. Jessica Keune*, Adam Branscum, Urszula Iwaniec, Russell Turner. Oregon State University, USA

Skeletal adaptation to disuse and spaceflight typically includes rapid site-specific bone loss due to unbalanced bone turnover. Bone marrow adiposity is also increased during disuse and spaceflight. Since osteoblasts and adipocytes are derived from the same precursors, it has been hypothesized that increased bone marrow adipogenesis during disuse occurs at the expense of osteoblast differentiation. We have recently demonstrated that bone marrow adipocytes are absent in *c-kit*-deficient *Kit^{w^{fl/y}}* mice. The goal of this study was to determine if a lack of marrow adipocytes confers resistance to disuse-induced bone loss. Male *Kit^{w^{fl/y}}* mice and their wild-type (WT) littermates were obtained at 4 weeks of age and housed singly at 32°C for the duration of study. At 16 weeks of age, animals within each genotype were randomly assigned to one of two groups, control or hindlimb-unloaded (HLU) with 10 mice/group, and unloaded for two-weeks. Control mice were single-housed in the same caging units as HLU mice and pair-fed to their respective genotype HLU counterparts. Cancellous bone in distal femur metaphysis was evaluated using micro-computed tomography and analyzed using two-way ANOVA. Effects of genotype, treatment and their interaction on cancellous bone volume and architecture in the distal femur metaphysis are shown in the table below. *Kit^{w^{fl/y}}* mice exhibited a high cancellous bone phenotype associated with higher connectivity density, trabecular number and thickness, and lower trabecular spacing. HLU resulted in lower cancellous bone volume fraction, connectivity density, trabecular number and trabecular thickness, and higher trabecular spacing. However, the magnitude of bone loss was greater in the marrow adipocyte-deficient *Kit^{w^{fl/y}}* mice. In summary, the absence of bone marrow adiposity was not protective against disuse-induced cancellous bone loss in mice. Indeed, the greater bone loss in marrow adipocyte-deficient *Kit^{w^{fl/y}}* mice suggest that marrow adiposity may have a protective role in limiting disuse-induced osteopenia.

Sirt1 Stimulates Browning of Marrow Fat: From Mice To (Wo)men. Hanna Artsi*¹, Irina Gurt¹, Madi El-Haj¹, Ralph Müller², Gisela Kuhn², Gal Ben Shalom¹, Rotem Paz³, Einav Cohen-Kfir¹, Rivka Dresner-Pollak¹.
¹Hadassah-Hebrew University Medical Center, Israel, ²ETH Zurich, Institute for Biomechanics, Swaziland, ³TAU, Dept. of Zoology, Faculty of Life Science., Israel

Adipose tissue consists of 3 depots: visceral, subcutaneous and marrow. These depots are comprised of predominantly lipid storing white adipocytes (WAT), mitochondria-rich brown adipocytes (BAT), and presumably beige adipocytes bearing characteristics of both. The role of marrow adipose tissue (MAT) in metabolism and skeletal health remains elusive. Conditions associated with increased bone fragility including aging, osteoporosis, glucocorticoid excess, estrogen deficiency, anorexia nervosa and type 1 diabetes mellitus are associated with increased MAT. Moreover, the lineage origin of marrow adipocytes arising from marrow mesenchymal stem cell (BM-MSC) is unclear. Induction of BAT is a much desired goal for combating obesity and appears to be beneficial to bone health. The role of Sirtuin1, a key player in aging, metabolism and bone biology in MAT physiology is unknown and is the focus of this study. Studies were performed in 5-7-month-old Sirt1 haplo-insufficient 129/Sv (Sirt1^{+/-}) and WT female mice (Endocrinology;2011;152:4514-24), C3H10T1/2 over-expressing Sirt1, and human femoral BM-MSCs obtained from women who sustained an osteoporotic hip fracture. Whole body fat content and tibia MAT volume were assessed by DXA and osmium staining followed by ζ CT, respectively. WAT and BAT characteristic genes and proteins were determined by real time RT-PCR and western blotting in abdominal WAT, sub-scapular BAT, whole tibia extracts including MAT, primary murine tibial and human BM-BMCs cultures treated with the Sirt1 activator SRT3025. No difference in food intake, body weight, blood glucose, plasma FFA, whole body and tibial fat content were observed in Sirt1^{+/-} compared to WT mice. A marked 50% reduction in mRNA expression of the BAT characteristic genes: $\text{O}3\text{AR}$, Foxc2 , PRDM16 and $\text{PGC1}\alpha$ was found in BAT and whole tibiae derived from Sirt1^{+/-} compared to WT mice. A Sirt1 cell autonomous effect was confirmed by similar results in Sirt1^{+/-} vs WT-derived BM-MSCs cultures. Consistently, a reciprocal 2-fold increase in gene expression of BAT marker genes and in PRDM16 and $\text{PGC1}\alpha$ protein was observed in Sirt1 over-expressing C3H10T1/2 cells and in human BM-BMCs treated with SRT3025. These results indicate that Sirt1 is a regulator of the bone marrow adipocyte fate and stimulates browning of MAT in both murine and human cells. Whether Sirt1 activation in MAT enhances bone strength and favorably affects whole organism energy metabolism remains to be investigated.

Thyroid Hormone Induces Browning of Bone Marrow Adipose Tissue via Activation of TR β Signaling. Richard Lindsey*, Sheila Pourteymoor, Catrina Alarcon, Subburaman Mohan. VA Loma Linda Healthcare System, USA

Mutant mouse models deficient in thyroid hormone (TH) action have recently shown that there is an important prepubertal period in which TH is critical for the regulation of skeletal growth and development. Furthermore, TH negatively regulates total body fat during the prepubertal growth period, an observation consistent with the well-established effects of TH to accelerate resting energy expenditure. Since bone marrow mesenchymal stromal (BMMS) cells differentiate into both adipocytes and osteoblasts, and since a relationship between bone marrow adipogenesis and osteogenesis has been predicted, we examined the effect of TH deficiency during the postnatal growth period on bone marrow adiposity in mice. We found that bone marrow adiposity, measured by DEXA, was increased by >20% ($P < 0.01$) in TH deficient (Tshr^{hyt/hyt}) mice at 3 weeks of age at multiple skeletal sites, and 10 day treatment with T3/T4 at a time when serum levels of T3/T4 normally increase (day 5-14) rescued this phenotype. Furthermore, treatment of TH deficient mice with a TH receptor (TR) β -specific agonist, GC-1, rescued the adipogenesis phenotype equally well, thus suggesting TH effects on adipose tissue are primarily mediated via TR β signaling. To further examine the mechanism for TH regulation of bone marrow adiposity, we tested the effects of TH on mRNA expression levels of markers of adipocyte differentiation using primary cultures of mouse BMMS cells and the ST2 mouse stromal cell line *in vitro*. We found that 1- or 6-day treatment with 10 ng/mL T3 significantly increased expression levels of several markers of brown/beige fat, including UCP-1, PGC-1 α , P2RX5, PAT2, PRDM16, and Zfp516. In BMMS cells, real-time RT-PCR measurements revealed a 3.5-fold increase in UCP-1, a 2.5-fold increase in PGC-1 α , 1.4-fold increase in P2RX5, and a 1.9-fold increase in PAT2 (all $P < 0.05$). In ST2 cells, T3 treatment caused a 2.6-fold increase in PGC-1 α , a 1.8-fold increase in P2RX5, a 14.4-fold increase in PAT2, and a 1.5-fold increase in Zfp516 (all $P < 0.05$). Moreover, 6-day treatment of ST2 cells with GC-1 produced a 1.6-fold increase in PRDM16. Based on our data, we conclude that 1) TH regulation of bone marrow adiposity is mediated primarily via activation of TR β signaling, and 2) the TH effect on energy metabolism may in part be due to increased production of brown/beige adipose tissue in bone marrow.

“Skeletal Alterations in Hyp (C57BL/6J-PhexHyp/J) Mouse Model of X-linked Hypophosphatemia (XLH) in humans”. Ed Berryman*¹, David Zakur², Cedo Bagi². ¹Pfizer Global Research & Development, USA, ²Pfizer Research & Development, Groton CT, USA

PURPOSE: Hypophosphatemia can impact various tissues and cause osteomalacia, rickets, rhabdomyolysis, cardiomyopathy, metabolic acidosis, and disruption of red blood cell function. Increased urinary excretion of phosphate due to impaired reabsorption is the key mechanism underlying X-linked hypophosphatemic rickets (XLH), a rare disease associated with skeletal abnormalities and growth retardation. This study was conducted to investigate the progression of skeletal alterations in the Hyp (C57BL/6J-PhexHyp/J) mouse that is frequently used as a model of XLH disease in humans. **METHODS:** Male and female wild type (WT) and Hyp mice were obtained at the age of 2, 4, and 6 months to evaluate differences in skeletal development over time. A Dynamic Weight Bearing (DWB) system was utilized to measure functional capacity of the musculoskeletal system, and evaluation via 3-point bending was used to assess femoral strength. X-ray and Micro-CT (mCT) were used to evaluate bone size, geometry and bone structure. Fluorescent labels were used to assess bone remodeling and paraffin histology was used for cellular analysis of bone and cartilage. **RESULTS:** Hyp mouse featured numerous changes in bone morphology and structure at all skeletal sites assessed including hock joint, femur, lumbar vertebrae, and mandible. Hyp mice exhibited shorter but wider bones, lower BMD, impaired structure and reduced strength relative to WT controls. **CONCLUSIONS:** Results from this study clearly showed genotype-related skeletal differences between the C57BL/6J mice and the C57BL/6J-PhexHyp/J mice. Similar to patients with XLH, the negative impact of lower hypomineralization and structural alteration were partially compensated in Hyp mice by an increase in bone diameter, however the bone strength was diminished.

Monitoring of Collagen Replacement in a Transplant Model for Treatment of Osteogenesis Imperfecta Using GFP-Collagen Donor Mice. Molly Hulbert*¹, Hong Zhao¹, Richard Campos¹, Yixia Xie¹, Michael Grillo¹, Donna Pacicca², Charlotte Phillips³, Sarah Dallas¹. ¹University of Missouri - Kansas City, USA, ²Children's Mercy Hospital, Kansas City, USA, ³University of Missouri, USA

Osteogenesis Imperfecta (OI) is an inherited disorder of bone fragility which is mainly caused by mutations in COL1A1 and COL1A2 genes that encode type I collagen. The spectrum of disease ranges from perinatal lethal/severe forms with intrauterine fractures to milder forms with fewer fractures. There is no cure and treatment is limited to management of symptoms. Bisphosphonate treatment is the current standard of care but there is a need to develop new treatments due to concerns over the potential of long term bisphosphonates to impair bone remodeling.

Marrow and mesenchymal stem cell (MSC) transplantation is a potential treatment that could be of benefit in severe OI cases. As a novel model to optimize transplantation approaches for OI, we have generated transgenic mice expressing a GFP-tagged collagen construct driven by the 3.6kb-COL1A1 promoter. GFP-collagen expression is seen in bone, teeth, tendon, skin and other connective tissues. Collagen-GFP transgenic mice were used as donors for transplantation of marrow and MSC into the *oimloim* mouse model of OI. Male and female *oimloim* mice (6-12 wks) were injected with busulfan to ablate their marrow and were reconstituted with donor marrow from GFP-collagen mice. To provide osteoprogenitors, the mice also received intramedullary or intratibial MSC injections from GFP-collagen donors. One month after transplantation, OI mice with $\geq 80\%$ donor marrow reconstitution were evaluated to determine collagen replacement. 12 of 13 injected femurs and 5 of 5 injected tibias showed robust incorporation of GFP-collagen into bone, confirming both engraftment of osteoprogenitors and their contribution of donor collagen to host bone matrix. The donor-derived GFP-collagen was frequently seen as a thick, well defined seam on the endocortical bone surface. Quantitation of GFP+ve (donor-

derived) bone area compared to host bone area showed a mean replacement of $8.7\% \pm 2.1$ by 1 month. Deposition of GFP-collagen in adjacent bones that were not injected with MSC was only seen in 1 of 6 bones examined, suggesting the osteoprogenitors came from the injected MSC rather than donor marrow. This further suggests that the osteoprogenitors do not circulate. Together, these data show that the GFP-collagen mouse is a powerful model for evaluating replacement of OI-collagen with donor collagen and will be useful for developing strategies to enhance collagen replacement, such as treatment with bone anabolic or anti-resorptive agents.

The Skeletal Phenotype of *Serpinf1*- Null Mice. Hadil Al-Jallad*¹, Pierre Moffatt¹, Hazem Eimar², Faleh Tamimi², Marc McKee², Frank Rauch¹.
¹Shriners Hospital for Children, Canada, ²McGill University, Canada

Osteogenesis imperfecta (OI) type VI is caused by recessive loss-of-function mutations in *SERPINF1*, the gene coding for pigment epithelium derived factor (PEDF). Patients with OI type VI have undetectable circulating levels of PEDF, but the mechanism whereby lack of PEDF leads to bone disease is not clear. In the present study we assessed a *Serpinf1*-null mouse model. Primary osteoblast cultures from neonatal *Serpinf1*- mice did not produce PEDF and had decreased expression of osteoblast differentiation markers, alkaline phosphatase, Sp7, *Ank*, *Phospho 1* and *Enpp1*, whereas adiponectin expression was increased. Von Kossa staining showed fewer mineralization nodules in *Serpinf1*- cultures as compared to osteoblasts from wild type littermates. These data suggest that *Serpinf1* is important for osteoblast differentiation and that PEDF is required for mineralization. The skeletal phenotype of *Serpinf1*- mice was investigated at 20 weeks of age (*Serpinf1*^{+/+}, N=10; *Serpinf1*^{-/-}, N= 8). Serum PEDF was absent in *Serpinf1*- mice, but serum levels of C-terminal telopeptide of collagen type I and procollagen type I N-propeptide were similar to wild type mice. Micro-computed tomography (μ CT) of femurs, in addition to quantitative bone histomorphometry of femurs and vertebrae, showed no significant differences between *Serpinf1*- mice and their wild type littermates. Even though human OI type VI bone is characterized by a mineralization defect with increased unmineralized osteoid, *Serpinf1*- mice had an osteoid thickness, osteoid volume, mineral apposition rate, and bone formation rate similar to wild type mice. However, μ CT analyses of craniofacial bones showed a significant decrease in cranial length, maxillary length, palatine length, inter-molar distance and inter-zygomatic distance. Our results demonstrate that *Serpinf1*- mice have apparently normal axial and appendicular bone mineralization and bone mass, but have abnormalities in the craniofacial skeleton.

Targeted sequencing for monogenic causes of High Bone Mass: Predictions in LRP5 protein structure explain variation in the clinical severity of LRP5 High Bone Mass. Celia Gregson*¹, Lawrie Wheeler², Sarah Hardcastle³, Kathryn A Addison², Marieke Brugmans², Kate Ward⁴, Margaret Paggiosi⁵, Louise Appleton⁶, Jane Turton⁷, Michael Stone⁷, Joegi Thomas⁸, Rohan Agarwal⁹, Kenneth Poole⁹, Eugene McCloskey⁵, Eleanor Williams¹⁰, Alex Bullock¹⁰, George Davey Smith¹¹, Matthew A Brown², Jon H Tobias³, Emma L Duncan². ¹University of Bristol, United Kingdom, ²Human Genetics Group, University of Queensland Diamantina Institute, Australia, ³Musculoskeletal Research Unit, School of Clinical Sciences, University of Bristol, United Kingdom, ⁴MRC Human Nutrition Research Unit, Elsie Widdowson Laboratory, United Kingdom, ⁵Mellanby Centre for Bone Research, Academic Unit of Bone Metabolism, University of Sheffield, United Kingdom, ⁶NIHR Oxford Musculoskeletal Biomedical Research Unit, Nuffield Orthopaedic Centre, United Kingdom, ⁷Bone Research Unit, University Hospital Llandough, United Kingdom, ⁸James Paget University Hospital Foundation NHS Trust, United Kingdom, ⁹Department of Medicine, University of Cambridge, United Kingdom, ¹⁰Structural Genomics Consortium, University of Oxford, United Kingdom, ¹¹MRC Integrative Epidemiology Unit at the University of Bristol, United Kingdom

Rare monogenic high bone mass (HBM) disorders (e.g. due to *LRP5* or *SOST* mutations) augment understanding of bone regulatory pathways and can inform development of novel anabolic therapies for osteoporosis. We aimed to identify the genetic cause of presumed monogenic HBM and determine associated clinical characteristics in a large HBM population.

258 unrelated HBM cases identified from review of 335,115 DXA scans from 13 UK centers were assessed clinically and underwent targeted sequencing of known anabolic HBM loci: *LRP5* (exons 2, 3 & 4), *LRP4* (exons 25 & 26), *SOST* (exons 1 & 2) and the van Buchem's disease 52kb intronic deletion 3' of *SOST*. Family members were assessed for HBM segregation with identified variants. 3-D protein models were constructed for identified variants.

Two novel missense *LRP5* HBM mutations (c.C518T; p.T173M, c.C796T; p.R266C) were identified, plus 3 previously reported missense *LRP5* mutations (c.A593G; p.N198S, c.G724A; p.A242T, c.A266G; p.Q89R), associated with HBM in 11 adults from 7 families. Those with *LRP5* HBM (~population prevalence 5/100,000) displayed a variable phenotype of skeletal dysplasia with increased trabecular BMD and cortical thickness on HRpQCT, and fat mass accumulation in a gynoid distribution on DXA, compared with both non-*LRP5* HBM and controls. One woman carried a novel heterozygous nonsense *SOST* mutation (c.C530A; g.C3335A) predicted to prematurely truncate sclerostin; apart from mandible enlargement (ME) and BMD Z-scores L1 +3.5, Hip +1.7 she was asymptomatic.

Protein modelling suggests the severity of the LRP5-HBM phenotype corresponds to the degree of protein disruption and the consequent effect on SOST-LRP5 binding. We predict N198S directly disrupts SOST binding and the larger threonine side chain in A242T leads to steric clashes destabilising the SOST binding site, both correspond to severe HBM phenotypes (Z-scores +3.1 to +12.2, inability to float, ME, no fractures, 2 of 8 have nerve compression). Less disruptive structural alterations predicted from R266C, Q89R, T173M associate with less severe phenotypes (Z-scores +2.4 to +6.2, able to float, of 3 only 1 has ME, 1 high trauma fracture, 1 nerve compression).

Heterogeneity in LRP5-SOST interactions may have implications for the therapeutic effects of Wnt antagonists. Variants in known HBM loci account for a very small proportion of people with HBM, suggesting that either monogenic HBM mutations yet to be identified or polygenic inheritance is responsible.

Tiptoe Walking (*ttw*) Mice, Rodent Spinal Ligamentous Ossification Models, Exhibiting High Serum FGF23 Level. Ryuichi Watanabe*, Takeshi Miyamoto, Morio Matsumoto, Masaya Nakamura. Department of Orthopaedic Surgery, Keio University School of Medicine, Japan

Background:

Mouse models of ectopic ossification, tiptoe walking (*ttw*) mice, exhibit ectopic ossification of the posterior longitudinal ligament of the spine (OPLL) with extensive mineralization in Achilles tendon. The *ttw* mice demonstrate the accelerated bone formation in the cortical vertebrae, while showing the osteopenic changes in the cancellous vertebrae. Although aggravated ectopic mineralization has been reported in the *ttw* mice fed with high phosphate diet, the precise mechanism underlying ectopic ossification due to the disturbance in phosphate metabolism remains unknown. Thus, the objective of this study is to clarify the role of phosphate metabolism of the ectopic ossification in the *ttw* mice.

Methods and Results:

Serum levels of phosphate and FGF23 in *ttw* mice and control littermates fed with either normal or high phosphate diet that is 1.5 times higher phosphate concentration than normal diet were analyzed. Furthermore, ectopic ossification of spinal ligament was examined with micro CT scan. The level of serum phosphate in *ttw* mice placed on high phosphate diet was significantly lower than WT mice placed on high phosphate diet. Micro CT findings indicated that the ectopic calcification of spinal ligament in the *ttw* mice was strikingly worsened by high phosphate diet. Moreover, the *ttw* mice fed with high phosphate diet exhibited the accelerated osteopenic changes in the cancellous vertebrae. We found that the serum FGF23 level in the *ttw* mice placed on high phosphate diet was significantly higher than either the *ttw* mice placed on normal diet or WT mice placed on high phosphate diet. Therefore, we investigated whether the aggravation of spinal ligamentous calcification was due to the elevated serum FGF23 level with phosphate overload. Exhibiting high serum FGF23 level, *Phex* mice fed with high phosphate diet were analyzed ectopic ossification using CT scan. Micro CT analysis showed that ectopic calcification in the spinal ligament was not detected in *Phex* mice fed with high phosphate diet.

Summary:

We found that high phosphate diet exacerbated the spinal ligamentous ossification and osteopenic phenotypes in *ttw* mice. The serum FGF23 level was significantly elevated in *ttw* mice via high phosphate diet, however, the elevated serum FGF23 level with phosphate overload did not induce the development of ectopic spinal ligamentous ossification in *Phex* mice.

Continuous Parathyroid Hormone Injection in Mouse Has Differential Effects on Osteoclast Activation in Primary and Secondary Spongiosa. Nobuhito Nango*¹, Shogo Kubota¹, Wataru Yashiro², Atsushi Momose², Shizuko Ichinose³, Koichi Matsuo⁴. ¹Ratoc System Engineering Co., Ltd., Japan, ²Institute of Multidisciplinary Research for Advanced Materials, Tohoku Univ., Japan, ³Research Center for Industry Alliances, Tokyo Medical & Dental University, Japan, ⁴Laboratory of Cell & Tissue Biology, Keio University School of Medicine, Japan

Parathyroid hormone (PTH) is used clinically to accelerate bone formation, but how it functions remains unclear. In this study, we determined the effect of continuous PTH injection especially on mouse primary trabecular bone. Seven-week-old mice implanted with osmotic pumps were continuously dosed with PTH. Tibiae were isolated after 144 h and proximal tibial growth plates were scanned using a Talbot phase method with synchrotron radiation (Fig. 1). We then compared sections of non-injected versus injected groups using backscattered scanning electron microscopy (SEM, Fig. 2). After continuous PTH injection, the longitudinal length of the calcified matrix of hypertrophic chondrocytes increased approximately 2-fold compared with that of the non-injected group (Fig. 2). In controls, vascular channels were invaded, transverse septa were resorbed, and bone formation occurred normally along remaining longitudinal septa (Fig. 1A). By contrast, in the injection group, we observed a hypertrophic chondrocyte zone expanded over a few hundred micrometers, mineralized cartilaginous matrix in the absence of resorption of transverse septa (Fig. 1B), deposition of bone matrix with low mineralization on the inner wall of chondrocytic lacunae (Fig. 1B), which retained their original ellipsoid form (Fig. 1B), and emergence of primary bone with two highly mineralized layers (Fig. 2B). Furthermore, injected animals exhibited calcified matrix with extremely greater bone volume and trabecular star volume in primary spongiosa but lower values of these parameters in secondary spongiosa relative to non-injected controls. These results indicate that continuous parathyroid hormone injection inhibits

osteoclast activation in the primary spongiosa and stimulates it in the secondary spongiosa. The Talbot phase method can measure slight differences in bone mineralization (Fig. 1). In the figure, bone with low mineralization is formed on septa (Fig. 1B). Thus, bone with low mineralization formed inside the lacuna without absorption of septa in the injected group (Fig. 1B), indicating that bone-forming osteoblasts appear before blood vessel penetration and osteoclast formation. The presence of double-layered primary bone with high mineralization suggests that blood vessel penetration stops in the middle of the two layers. We conclude that resorption of calcified cartilage by osteoclasts decreases in continuously PTH-injected mice.

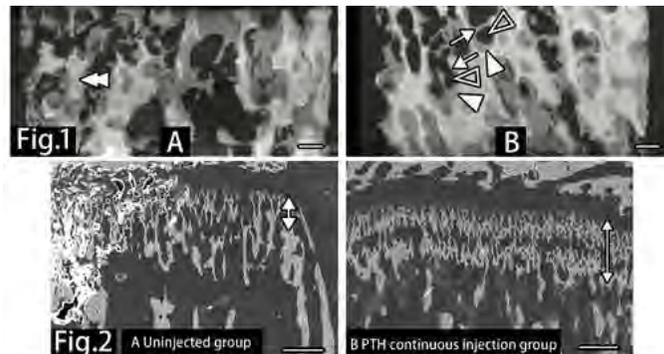

Fig.1 Talbot differential phase image generated by synchrotron radiation. (scale bar: 20 μ m) Gray image shows degree of mineralization. In the continuously PTH injected group, hypertrophic chondrocyte lacunae (\blacktriangleleft) remain, and bone with low mineralization (\blacktriangleleft) forms in lacunae. The mineralized septa (\blackleftarrow) also remains. In the uninjected group, the septa and mineralized matrix of hypertrophic chondrocytes are absorbed, and the new bone forms on the remaining matrix wall (\blackleftarrow).

Fig.2 Backscattered SEM image (scale bar: 200 μ m) In B the PTH injection group, primary bone layers (\blackleftrightarrow) extended approximately 300 μ m with double-layered, and the vascular path from the bone marrow to calcified cartilage lacunae was apparently blocked by the septa. In A the uninjected group, the thickness of the primary bone layer was approximately 100 μ m (\blackleftrightarrow). The lacuna septa were partly absorbed, and a path to the bone marrow was formed.

Evaluation of Different Schedules of Teriparatide Injection on Sinus Bone Graft in Rabbit. Jisun Huh*¹, Ui-Won Jung², Kyeong-Mee Park¹, Jin-Sun Jeong¹, Kee-Deog Kim¹, Wonse Park³. ¹Department of Advanced General Dentistry, College of Dentistry, Yonsei University, South Korea, ²Department of periodontology, Research Institute for Periodontal Regeneration, College of Dentistry, Yonsei University, South Korea, ³Dental College, Yonsei University, USA

Purpose

This study evaluated two different teriparatide injection schedules-intermittent (5 times/week) and episodic (2 times/week) on sinus bone graft in rabbit.

Material and Method

25 New Zealand white rabbits were used. Bio-Oss was grafted on maxillary sinus. Rabbits were divided into 3 groups; 1) Saline (N=10), 2) PTH (N=10), 3) PTHalt (alternative injection group, N=5). Saline and PTH groups were injected intermittently 5 times a week for 2 weeks and PTHalt group was injected episodically 2 times a week for 4 weeks. Halves of Saline and PTH groups were sacrificed 2 weeks post op and the last halves of these 2 groups and PTHalt group were 4 weeks post op. Radiographic and histomorphometric analysis were performed.

Result

At 2 weeks new bone area (NB, %) of Saline and PTH groups were 5.72% and 7.19%. At 4 weeks NB of Saline, PTH and PTHalt groups were 15.18%, 14.50% and 10.00%. In the small region near the Schneiderian membrane, NB of PTH group was 14.24% and higher than Saline (8.56%) and PTHalt (6.61%) groups at 4 weeks. In total augmented area and all specific small regions near window, center and membrane, PTHalt group represented smaller NB than Saline and PTH groups.

Conclusion

The intermittent teriparatide injection improves new bone formation specifically near the Schneiderian membrane at 4 weeks healing period in sinus bone graft of rabbit. The episodic injection of teriparatide is not effective as intermittent injection.

Sorting Nexin 27 Promotes Rapid Activity-dependent Recycling of the Parathyroid Hormone Receptor. Jennifer McGarvey^{*1}, Tatyana Mamonova¹, Shanna Bowman², W. Bruce Sneddon¹, Manojkumar Puthenveedu², Peter Friedman¹. ¹University of Pittsburgh, USA, ²Carnegie Mellon University, USA

The parathyroid hormone receptor (PTHr) is a GPCR that regulates mineral ion homeostasis and bone remodeling. Its C-terminal tail contains a Type I PDZ ligand that binds PDZ-domain containing proteins. Upon agonist stimulation, the PTHR is internalized into early endosomes and subsequently traffics to the retromer complex. Sorting nexin 27 (SNX27) is a cargo selector for the retromer complex that promotes recycling of surface receptors. We analyzed the role of SNX27 on PTHR trafficking in early endosomes. Co-immunoprecipitation, fluorescence polarization, and molecular modeling experiments show that SNX27 is a novel PTHR binding partner in the endomembrane system and establish the molecular determinants of the interaction. Endogenous SNX27 both colocalizes and co-immunoprecipitates with PTHR after treatment with PTH (1-34). Mutation of the C-terminal PDZ ligand of PTHR or deletion of the PDZ domain of SNX27 abolishes this interaction in co-immunoprecipitation assays. Molecular modeling suggests that the C-terminal motif of PTHR recognizes SNX27 PDZ domain through canonical PDZ-ligand interactions, supporting the biochemical data. Primary interactions occur through the GYGF core-binding motif of PDZ domain and the carboxy-terminal methionine at ligand position 0. We examined the binding affinity between PDZ domain of SNX27 and the PTHR ligand using fluorescent polarization binding assay. The measured dissociation constant $K_D = 1.7 \mu\text{M}$ is consistent with the molecular dynamics modeling prediction of PDZ-ligand binding of PTHR. We generated a PTHR construct tagged with the pH sensitive GFP variant super-ecliptic pHluorin (SEP) at the N-terminus to investigate recycling of the PTHR. TIRF-based, live cell imaging was used to measure the rate of receptor recycling by visualizing exocytic events at the cell surface. RNAi depletion of either SNX27 or Vps35, a component of the retromer complex, resulted in a 50% decrease in the rate of recycling of SEP-PTHr following agonist stimulation, and a similar effect was observed when actin was inhibited with Latrunculin A. Consistent with the role of SNX27 in retromer trafficking, RNAi depletion of SNX27 abolished PTHR interacting with retromer. We conclude that a portion of internalized PTH receptors are returned to the cell surface through a rapid recycling pathway that involves SNX27 and the retromer complex.

β 2-adrenergic Receptor Control of PTH Receptor Signaling. Jean-Pierre Vilaradaga¹, Frederic Jean-Alphonse^{*2}. ¹University of Pittsburgh, School of Medicine, USA, ²University of Pittsburgh, USA

Osteoblasts express several cell surface G protein-coupled receptors (GPCRs) that respond to multiple extracellular signals and regulate bone growth and turnover. A rational therapeutic approach targeting bone and mineral diseases thus requires a comprehensive understanding of osteoblast activity resulting from the integration of multiple GPCR signaling pathways. This is of particular relevance to parathyroid hormone (PTH) osteoanabolism mediated by the PTH receptor (PTHr) because β 2-adrenergic receptor (β 2AR)-deficient mice show no osteoanabolic activity after intermittent injection of PTH(1-34). Thus, β 2AR signaling is required for the osteoanabolic activity of PTHR. These findings raise the hypothesis that PTH anabolism is regulated by β 2AR signaling in osteoblasts, and that this regulation has therapeutic relevance for the treatment osteoporosis. Here we tested this hypothesis by determining the molecular and cellular mechanisms by which the β 2AR regulates PTHR signaling in cells, and develop in a systems biology approach a quantitative modeling of β 2AR-mediated the regulation of PTHR signaling in osteoblasts.

Pregnancy and Post-Lactation Recovery Rescue Low Bone Mass and Hypocalcemia in *Cyp27b1* Null Mice That Cannot Make Calcitriol. Brittany Gillies^{*1}, Brett A. Tonkin², Yue Ma¹, Beth J. Kirby¹, René St-Arnaud³, Natalie A. Sims², Christopher Kovacs¹. ¹Memorial University of Newfoundland, Canada, ²St. Vincent's Hospital & University of Melbourne, Australia, ³Shriner's Hospital & McGill University, Canada

Vdr null mice lack calcitriol's receptor and have hypocalcemia, hypophosphatemia, and rickets, but during pregnancy, *Vdr* nulls upregulate intestinal calcium absorption, mineralize osteoid, and increase BMC by 58%. They also lose a normal amount of BMC during lactation and restore it fully within 14 days after weaning. These data suggest that factors other than calcitriol upregulate intestinal calcium absorption and bone formation post-weaning. An alternative explanation is that the high calcitriol levels observed in *Vdr* null mice may act through non-genomic receptors to have these effects. If true, then loss of calcitriol itself should lead to effects that loss of VDR does not.

We tested this hypothesis by examining the calcitriol-deficient *Cyp27b1* null mouse line. Adult *Cyp27b1* null mice have hypocalcemia, hypophosphatemia, and rickets on a normal diet, but reportedly normal mineral metabolism when maintained on a "rescue" diet (high calcium, phosphorus and lactose). We studied sister *Cyp27b1* null and WT pairs raised on the rescue diet from weaning and mated at 10 weeks. Bones (DXA and μCT), blood, and urine were obtained at pre-pregnancy baseline, end pregnancy, end lactation, and days 7, 14, 21, and 28 of post-weaning recovery.

Litter sizes were equal between *Cyp27b1* null and WT. Compared to WT, and despite the rescue diet, at baseline *Cyp27b1* nulls were hypocalcemic (1.69 ± 0.14 vs. 1.98 ± 0.03 mM) with markedly increased PTH ($2,815 \pm 1,292$ vs. 8.4 ± 3.9 ng/l) and 30% lower BMC (0.42 ± 0.03 vs. 0.56 ± 0.02 g); μCT confirmed a rickets-like phenotype. During pregnancy serum calcium increased, PTH reduced, and BMD increased 45%, so that all values became equivalent to WT. During lactation, serum calcium of *Cyp27b1* nulls dropped to 1.11 ± 0.13 mM, PTH increased to $5,500 \pm 680$ ng/ml, and BMC declined to baseline. During post-weaning, serum calcium of *Cyp27b1* null normalized (1.89 ± 0.08 mM), PTH remained high, and BMC increased 40% to 0.54 ± 0.04 g.

In summary, pregnancy rescued hypocalcemia, secondary hyperparathyroidism, and low bone mass of *Cyp27b1* nulls. This implies increased intestinal calcium absorption and mineralization of rachitic bone via calcitriol-independent mechanisms. During lactation normal loss of BMC occurred. The increased BMC during post-weaning recovery suggests calcitriol-independent stimulation of new bone formation.

In conclusion, calcitriol-independent mechanisms regulate mineral and bone metabolism during pregnancy, lactation, and post-weaning.

A bone-seeking anabolic agent, LLP2A-Ale, prevented and restored glucocorticoid-induced bone loss. Nancy Lane¹, Yu-An Lay¹, Haley Berka¹, Lorna Ringwood¹, Alexander Kot¹, Haiyan Chen¹, Wei Yao².

¹University of California at Davis Medical Center, USA, ²University of California, Davis Medical Center, USA

Introduction. Glucocorticoid induced osteoporosis (GIOP) is the most common cause of secondary osteoporosis. Glucocorticoid (GC) treatment has prolonged effects on osteoblast maturation and activity. Currently, rhPTH (1-34) is on the only approved anabolic treatment that can restore bone mass and bone strength in GIOP. A bone-seeking compound, LLP2A-Ale that selectively targets the integrin $\alpha 4\beta 1$ on

the mesenchymal stem cell surface, can increase endogenous (MSC) recruitment to the bone surface, stimulate bone formation and increase bone mass. The purpose of this study was to determine if treatment with the LLP2A-Ale, or PTH or the combination treatment (LLP2A-Ale + PTH) could prevent GIOP or treat GIOP in a mouse model of GC excess. **Methods.** Four month old male mice of Swiss-Webster background were randomized to a prevention study with Placebo (PL), GC (2.8 mg/kg/d), GC + LLP2A-Ale (200 μ g/kg, IV at day 1) or a treatment study with PL, GC (2.8mg/kg/d) from day 1-60, LLP2A-Ale (300 μ g/kg at day 28), PTH (10 μ g/kg/d, 5x/wk) or GC +LLP2A-Ale + PTH from days 28 to 60. Mice were sacrificed at day 28 (prevention arm) or at day 60 (treatment arm). The study endpoints included a biochemical marker of bone turnover (PINP), surface-based bone turnover, bone mass and bone strength. **Results.** For the prevention study, GC alone reduced serum PINP levels by 45%, and trabecular bone mass and strength, while GC +LLP2A-Ale increased levels of PINP to 180% over PL (p<0.05), and prevented loss of bone mass and strength (Figure 1). For the treatment study, compared to GC alone, GC+LLP2A-Ale, PTH or LLP2A-Ale+PTH all significantly increased PINP, trabecular surface based bone formation, bone mass, and strength (p<0.05). Also, compared to GC alone, GC +LLP2A-Ale, PTH or and LLP2A-Ale + PTH all significantly increased both trabecular bone mass and strength at day 60 (p<0.05), and trabecular (treatment study) and cortical (prevention study) bone strength were not different from PL treated mice at day 60. (Figure). **Conclusion.** GC treatment significantly reduced both trabecular and cortical bone mass and strength. Treatment with GC+ LLP2A-Ale prevented these changes and GC+LLP2A-Ale, PTH or LLP2A-Ale+PTH completely restored both the bone mass and strength that was lost from the GC treatment. Additional studies with LLP2A-Ale are warranted to further evaluate the potential of this agent that can direct MSCs to bone surface for the treatment of GC induced osteoporosis and possibly osteonecrosis. **Methods.** Four month old male mice of Swiss-Webster background were randomized to a prevention study with Placebo (PL), GC (2.8 mg/kg/d), GC + LLP2A-Ale (300 μ g/kg, IV at day 1) or a treatment study with PL, GC (2.8mg/kg/d) from day 1-60, LLP2A-Ale (300 μ g/kg at day 28), PTH (10 μ g/kg/d, 5x/week, day 28-60) or GC +LLP2A-Ale + PTH from day 28 to 60. Mice were sacrificed at day 28 (prevention arm) or at day 60 (treatment arm). The study endpoints included a biochemical marker (PINP) and surface-based bone turnover, bone strength and assessments of angiogenesis including serum VEGF- and vascular density of the left femur (n=3/group) measured with microCT. **Results.** For the prevention study, GC alone reduced serum PINP levels by 45%, and trabecular bone mass and strength, while GC +LLP2A-Ale increased levels of PINP to 180% over PL (p<0.05), and prevented loss of bone mass and strength (Figure 1). For the treatment study, compared to GC alone, GC+LLP2A-Ale, PTH or LLP2A-Ale+PTH all significantly increased PINP, trabecular surface based bone formation, bone mass, and strength (p<0.05). Also, compared to GC alone, GC +LLP2A-Ale, PTH or and LLP2A-Ale + PTH all significantly increased both trabecular and cortical bone mass and strength at day 60 (p<0.05), and both trabecular and cortical bone strength were not different from PL treated mice at day 60. (Figure). Preliminary data on angiogenic effect of endogenous MSCs found that GC reduced serum levels of VEGF-A by 58% and blood vessel density by 88% compared to PL, and this decrease was reduced to 50% when the mice were treated with GC + LLP2A-Ale. **Conclusion.** GC treatment significantly reduced both trabecular and cortical bone mass and strength. Treatment with GC+ LLP2A-Ale prevented these changes and GC+LLP2A-Ale, PTH or LLP2A-Ale+PTH completely restored both the bone mass and strength that was lost from the GC treatment. Also, LLP2A-Ale treatment appeared to prevent GC induced reduction in serum VEGF-A levels and blood vessel density. Additional studies with LLP2A-Ale are warranted to further evaluate the potential of this agent that can direct MSCs to bone surface for the treatment of GC induced osteoporosis and possibly osteonecrosis.

Cbl-PI3 Kinase Interaction Controls Osterix Expression And Regulates Periosteal Proliferation Upon Injury. Vanessa Scanlon, Bhavita Walia, Jungeun Yu, Peter Mave, Hicham Drissi, Archana Sanjay*. UConn Health Center, USA

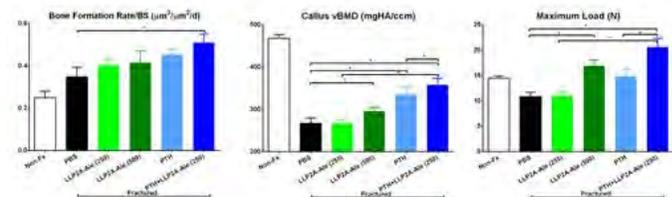

Tight regulation of Phosphatidylinositol kinase (PI3K) enzymatic activity is required for cell proliferation, differentiation and apoptosis. One major function of the adaptor and E3 ligase protein, Cbl, is to regulate PI3K activity by binding to the p85 regulatory subunit. We have reported that in mice where Cbl-p85 interaction is abrogated (YF mice) are osteopetrotic and have increased cortical thickness. Periosteum, a connective tissue covering the outer surface of long bones, is required for cortical bone modeling. To determine if the YF mutation alters the osteogenic potential of periosteal progenitors, we isolated periosteum from WT and YF long bones and cultured these cells in conditions that promote osteogenesis. We found that the osteogenic differentiation of YF periosteal cells was enhanced as evidenced by increased ALP activity and calcium content. RT-PCR analysis showed that although in YF cultures, expression levels of Runx2 were not altered, there was a significant upregulation in Osterix (Osx) expression. Immunofluorescence staining using anti-Osterix antibodies showed that under basal conditions compared to WT cells, YF cultures had increased numbers of cells with Osterix expression in the nucleus (WT 5.44%; YF 14% $p < 0.05$). While chemical inhibition of PI3K reduced the presence of Osx in WT cells, significantly higher numbers of cells with nuclear localization of Osx persisted in YF cultures (WT 1.74%; YF 10.4%, $p < 0.05$). To visualize Osx expression, we also bred both WT and YF mice with Osterix RFP reporter mice to generate WT-Osx-RFP and YF-Osx-RFP mice. To gain further insight into the process of initiation of periosteal bone formation and the role of Cbl-PI3K interaction in this process, we used a well-defined model of closed femoral fracture healing. Histological analysis of frozen sections showed that 3-days post fracture, compared to WT-Osx-RFP fractured femurs, YF-Osx-RFP showed a 2-fold increase in the periosteum thickness (WT 90.11um, YF188.8um, $p < 0.043$) and was largely comprised of Osterix-RFP+ cells. Additionally, in vivo EdU labeling showed that while there were very few EdU+ cells in intact WT or YF femurs, upon femoral fracture, proliferation of periosteal cells is enhanced in YF periosteum (WT 4.1%, YF 21.9%, $p < 0.052$). Cumulatively, these studies suggest that the Cbl-PI3K interaction controls cellular localization of Osterix regulating osteogenesis under basal and dynamic conditions of cortical bone modeling.

Effect of LLP2A-Ale on fracture healing in growing mice. Wei Yao*¹, Yu-An Lav², Haiyan Chen², Alexander Kot², Nancy Lane². ¹University of California, Davis Medical Center, USA, ²University of California at Davis Medical Center, USA

Introduction. Bone fractures can result in surgery, increased physician visits, lost work time, and ongoing pain/disability. No FDA-approved medical treatment that augments fracture healing exists. A bone-seeking compound, LLP2A-Alendronate (LLP2A-Ale) that selectively binds integrin $\alpha 4\beta 1$ on endogenous mesenchymal stem cell (MSC) surfaces and increases MSC recruitment to bone surfaces, may stimulate callus formation and increase periosteal bone apposition. Our purpose is to find whether LLP2A-Ale alone, PTH alone or LLP2A-Ale+PTH accelerates healing in a murine fracture model. **Methods.** A closed fracture (fx) of the right mid-femur of two-month-old C57BL/6 male mice was created. A medullary pin was then placed to stabilize the fx and the wound was closed. The fx mice were divided into five groups (N=16/grp) and treated immediately with vehicle (VEH), LLP2A-Ale [250cg/kg (low dose-LD) or 500 μ g/kg (high dose-HD), IV at days 1 and 22], PTH (1-34) (20 μ g/kg/d, 5X/wk), or combined (LLP2A-Ale [LD]+PTH, COMBO). Unfractured, untreated mice (Non-Fx) (N=16) of equal age were included. Necropsy (N=8/grp) was conducted at Days 21 and 42 post-fx. Fx healing was assessed by measuring surface-based bone formation (BFR/BS) in the callus, callus volume/total volume (CV/TV), callus volumetric bone mineral density (vBMD), and right central femur maximum load (CFML). **Results.** At Day 21, PTH and COMBO groups had higher CV/TV than VEH ($P < 0.05$). At Day 42, callus BFR/BS was 40% higher in COMBO than VEH ($P < 0.05$). At Day 42, vBMD was 20%, 40%, and 50% greater in LLP2A-Ale (HD), PTH, and COMBO than VEH, respectively, and COMBO was better than either LLP2A-Ale (HD) or PTH (all $P < 0.05$). At Day 42, CFML was higher in LLP2A-Ale (HD), PTH, and COMBO than VEH, and COMBO was higher than PTH (all $P < 0.05$) (Figures 1-3). **Conclusion.** At Day 42 after fracture, LLP2A-Ale (HD) mice had higher callus vBMD and bone strength than VEH mice. COMBO mice had even higher callus vBMD and strength than any monotherapy. These results indicate a need for additional pre-clinical studies that use LLP2A-Ale alone or with PTH, to accelerate fracture healing.

Effects of Endoxifen, a Selective Estrogen Receptor Modulator, on Bone in Ovary-intact and Ovariectomized Rats. Anne Gingery*¹, Malavannan Subramaniam², Kevin Pitel², James N Ingle², Matthew P Goetz², Russell T Turner³, Urszula T Iwaniec³, Thomas C Spelsberg², John Hawse². ¹Mayo Clinic School of Medicine, USA, ²Mayo Clinic, USA, ³Oregon State University, USA

Endoxifen (END) has been identified as the predominant active metabolite of tamoxifen and is currently being developed as a novel hormonal therapy for the treatment of estrogen receptor positive breast cancer. We have previously shown that treatment with END increases cortical and cancellous bone in an ovariectomized (OVX) mouse model. We have extended these studies to a pre-clinical rat model to examine the effects of END in both intact and OVX animals. Four month old Sprague-Dawley rats (n=40) underwent either sham or OVX surgeries and were randomized to placebo or END (10mg/kg/day, for 35 days) treatment via oral gavage. Micro-CT analysis of the proximal tibial metaphysis revealed significantly greater bone volume per tissue volume (BV/TV), connectivity density, and trabecular number (Tb.N.) in END-treated OVX animals compared to vehicle-treated OVX, while trabecular spacing (Tb.Sp.) was significantly lower. Interestingly, BV/TV and Tb.Th. were also significantly greater in ovary-intact animals treated with END compared to vehicle. Cortical measurements (cross sectional volume, cortical volume and cortical thickness) at the tibial diaphysis were lower in END-treated animals compared to controls. Analysis of the vertebrae (LV5) revealed significant increases in BV/TV, Tb.N., Tb.Th., and reductions in Tb.Sp. in END-treated animals compared to vehicle controls, irrespective of gonadal status. END treatment resulted in no differences in serum levels of the bone resorption marker CTX1 in ovary-intact animals. However, CTX1 levels were significantly decreased in OVX END treated animals. The bone formation marker PINP was significantly reduced in both intact and OVX END-treated rats. Interestingly, END treatment also reduced serum sclerostin levels in both the intact and OVX setting. In summary, END enhanced many bone parameters in both ovary-intact and OVX rats. Importantly END improved many skeletal parameters in the ovary-intact pre-clinical rat model, making it an attractive therapeutic for pre-menopausal breast cancer patients where both estrogen deprivation and tamoxifen treatment result in bone loss.

Measles Virus Nucleocapsid Protein Expression in Osteoclasts Increases SPHK1/S1P/S1PR3 to Enhance Osteoblast Differentiation in Paget's Disease. Yuki Nagata*¹, Khalid Mohammad², Theresa Guise², Laëtitia Michou³, Jacques P. Brown³, Jolene J. Windle⁴, Noriyoshi Kurihara⁵, G. David Roodman⁶. ¹Indiana University-Purdue University Indianapolis, USA, ²Indiana University, Medicine/Endocrinology, USA, ³Department of Medicine, Laval University, CHU de Quebec Research Center, Canada, ⁴Human & Molecular Genetics, Virginia Commonwealth University, USA, ⁵Indiana University, Medicine/Hematology-Oncology, USA, ⁶Indiana University, Medicine/Hematology-Oncology, Roudebush VA Medical Center, USA

We reported that osteoclasts (OCLs) from 70% of Paget's disease (PD) patients express measles virus nucleocapsid protein (MVNP) and high levels of IL-6. Similarly, transgenic mice with MVNP targeted to OCLs (MVNP mice) express high levels of IL-6 and develop pagetic bone lesions that display highly localized increased bone resorption and formation. We recently found that OCLs expressing MVNP (MVNP-

OCLs) from PD patients and MVNP mice express increased IGF1 and ephrinB2 that was induced by IL-6. Further, IL-6 increased EphB4 on osteoblasts (OBs) and IGF1 further enhanced OB differentiation in MVNP mice. However, other factors also appear to be involved. Recently, sphingosine-1-phosphate (S1P) was identified as a coupling factor in bone remodeling. OCLs produce S1P which enhances bone formation through specific interactions with S1P-receptors on OBs. Therefore, we determined if S1P and its receptors also act as coupling factors in PD. We tested MVNP-OCLs from PD patients and healthy donors. MVNP-OCLs from PD patients and MVNP transduced human OCL highly expressed sphingosine kinase-1 (SPHK1), which phosphorylates sphingosine to form S1P, compared to normal or EV transduced human OCLs. We then examined if IL-6 contributed to the enhanced SPHK1 signaling in MVNP-OCLs. Treatment of OCL precursors from MVNP, MVNP/IL-6^{-/-}, IL-6^{-/-} and WT mice with RANKL for 5 minutes significantly increased p-SPHK1 in MVNP-OCL precursors compared to WT and MVNP/IL-6^{-/-} mice. IL-6^{-/-} OCL precursors had very low p-SPHK1 levels. Basal SPHK1 levels were increased in MVNP-OCL precursors. Western blot analysis of OBs from bone explants of WT and MVNP mice showed that S1P-receptor 3 (S1PR3) expression was higher in OBs from MVNP mice and was further increased by IL-6 and IGF1 (10ng/ml), which are secreted by MVNP-OCLs. Immunohistochemistry of bones from MVNP and WT mice confirmed increased SPHK1 in OCLs and S1PR3 expression in OB of MVNP mice compared to WT mice. To determine if S1P stimulates OB differentiation, OB derived from MVNP or WT mice were treated with S1P (50 ng/ml) for 3 days, and Runx2 assayed by Western blot. Runx2 levels were higher in OBs from MVNP mice compared to WT. Further, S1P increased the activation of Akt and Erk signaling in OBs from MVNP mice to a greater extent compared to WT OBs. These results suggest that IL-6 and IGF1 produced by MVNP expressing OCLs can enhance SPHK1/S1P/S1PR3 interactions to increase bone formation in PD.

Treatment with Sclerostin Antibody Converts Trabecular Rods into Trabecular Plates in Male Cynomolgus Monkeys. Jonathan Matheny*, Ashley Torres, Christopher Hernandez, Sibley School of Mechanical & Aerospace Engineering, Cornell University, USA

Trabecular microstructure with a more plate-like morphology has been associated with reduced risk of fragility fracture. Sclerostin antibody (Scl-Ab) treatment increases modeling-based bone formation and bone volume fraction while reducing bone resorption; however, the degree to which individual trabeculae are converted from rod-like to plate-like in response to treatment has not been examined. Here we used three-dimensional images of bone and bone formation markers to measure changes in rod-like and plate-like trabecular morphology associated with Scl-Ab

treatment. Specimens from a previously reported, IACUC approved study of adolescent (4-5-year-old) male cynomolgus monkeys were examined [1]. Animals had been treated bi-weekly with either Scl-Ab (romosozumab, 30 mg/kg, sc, n=6) or vehicle (Veh, n=6) for 10 weeks. Animals had received bone formation labels on days 14 and 24 (25 mg/kg tetracycline) and on days 56 and 66 (8 mg/kg calcein). Animals were euthanized at day 70. Cylindrical specimens of cancellous bone were obtained from the 5th lumbar vertebrae. Three-dimensional images of bone and formation markers were obtained using serial milling (0.7 X 0.7 X 5.0 um voxel size) and the volume of bone formed during the experiment was determined in three-dimensions (Shown in green, See Figure). Trabecular morphology was analyzed using Individual Trabecula Segmentation (ITS). Changes in trabecular microstructure (rod-like vs plate-like) over the 8 week period between the first and last bone formation label were determined by examining images of the specimens with and without the volume spanned by the formation labels. Over the 8 week period, 10% of rod-like trabeculae were converted to plate-like trabeculae in Scl-Ab treated animals compared to 4% in the Veh group (p=0.01). Plate bone volume fraction (pBV/TV) was higher in the Scl-Ab group relative to Veh (mean 43% v. 30%, p<0.05). Newly formed volume fraction (FV/TV) was also higher in Scl-Ab treated groups (9.0 v. 5.4%, p=0.02). Our results demonstrate that increased bone formation associated with Scl-Ab treatment not only increases bone volume fraction, but also provides additional improvements to trabecular bone microstructure by converting rod-like trabeculae to plate-like trabeculae. Fluoxetine Affects Bone Remodeling Via Peripheral, Serotonin-Independent, And Central, Serotonin-Dependent, Mechanisms. Maria J Ortuno Romero*¹, Riccardo Paone², J John Mann³, Patricia Ducy⁴. ¹Columbia University Medical Center, USA, ²Department of Biotechnological & Applied Clinical Sciences, University of L'Aquila, Italy, ³Division of Molecular Imaging & Neuropathology, Department of Psychiatry, College of Physicians & Surgeons, Columbia University, USA, ⁴Department of Pathology & Cell Biology, College of Physicians & Surgeons, Columbia University, USA

Clinical studies have reported a correlation between long-term use of Selective Serotonin Reuptake Inhibitors (SSRIs), are a class of drugs widely prescribed for anxiety disorders and decreased bone mass and/or the risk of fracture raising concerns about the broadening of SSRIs use in the general population. Using a combination of genetic, pharmacologic and in vitro approaches we have identified two distinct modes of action of SSRIs on bone remodeling explaining this observation.

First, SSRIs inhibit osteoclast differentiation and function through a direct, serotonin-independent, effect on osteoclasts. Indeed, treatment of primary osteoclasts with fluoxetine, one of the most frequently prescribed SSRIs, or with other SSRIs impairs several key aspects of osteoclast maturation. This inhibition is independent of fluoxetine's canonical mode of action on serotonin reuptake since it affects to same extent wild-type, *Tph1*-, *Tph2*- and *5Htt*-deficient osteoclasts. Instead, fluoxetine inhibits osteoclast biology by impairing Creb phosphorylation by the Ca²⁺-

calmodulin pathway, thereby limiting its activation of *Nfatc1* expression. This inhibitory effect on bone resorption could be observed in vivo in wild-type mice treated with fluoxetine for a short time (3 weeks). Gene expression analyses demonstrated a RANKL/OPG-independent inhibition of NFATc1 activity as the basis of this effect.

When the fluoxetine treatment was extended, however, a second mode of action overcame this direct inhibition of bone resorption. Mice treated for 6 weeks with fluoxetine showed a normalized bone resorption due to the combination of the direct inhibitory effect of fluoxetine on osteoclasts and of a RANKL/OPG-dependent increase in bone resorption. These mice also showed a decrease in bone formation, leading to bone loss. This second mode of action is dependent on brain serotonin signaling, as it could not be observed in *Tph2*^{-/-} mice, and is mediated by an increase of sympathetic output. Given this observation, we hypothesized that blocking sympathetic signaling could reverse the bone loss caused by a long-term fluoxetine treatment and co-treated wild-type mice with fluoxetine and a dose of the β -blocker that does not induce a bone phenotype by itself. This combined treatment indeed prevented fluoxetine-induced bone loss by normalizing bone formation and decreasing bone resorption, suggesting that long-term users of SSRIs could benefit from co-treatment with a low dose of β -blockers.

Histone 3 lysine 9 methyltransferase G9a is essential for the growth and differentiation of tenocytes. Satoshi Wada*¹, Hisashi Ideno², Akemi Shimada², Taichi Kamiunten¹, Yoshiki Nakamura¹, Kazuhisa Nakashima², Hiroshi Kimura³, Makoto Tachibana⁴, Akira Nifuji². ¹Department of Orthodontics, Tsurumi University School of Dental Medicine, Japan, ²Department of Pharmacology, Tsurumi University School of Dental Medicine, Japan, ³Graduate School of Bioscience & Biotechnology, Tokyo Institute of Technology, Japan, ⁴The Institute of Enzyme Research, The University of Tokushima, Japan

The growth and differentiation of tenocytes were regulated by genetic and epigenetic mechanisms. Posttranslational modifications of histone tails affect cell differentiation and gene expression by regulating chromatin. So far, however, the effects of epigenetic modifications on gene expression and differentiation in tenocytes remain unclear. In this study, we focus on expression and function of H3K9 methyltransferases (H3K9MTases), the enzymes mediating histone 3 lysine 9 (H3K9) methylation. Specifically, we investigated the functional roles of an H3K9MTase, G9a, in the growth and differentiation of tenocytes. First, we isolated tail tenocytes from neonatal mice by using collagen gel methods (Shimada et al. 2014) and examined the expression of H3K9MTases during tenocyte differentiation. Next, we investigated the localization of H3K9MTases in embryonic tendon tissues in mice by *in situ* hybridization (ISH). Finally, using tenocytes isolated from G9a-flox/flox mice, we deleted G9a by infecting the cells with Cre-expressing adenoviruses and investigated the effects of G9a deletion on the growth and differentiation of tenocytes. The mRNA expression levels of six H3K9MTases increased with the duration of tenocytes culture. Among them, G9a mRNA expression was relatively high in six H3K9MTases. By ISH, we observed that G9a mRNA was expressed in tenocytes, which were overlapped with or were adjacent to cells expressing tenomodulin. Using tenocytes isolated from G9a-flox/flox mice, we deleted G9a by Cre-expressing adenoviruses. We confirmed that G9a mRNA and protein expression levels decreased in the Cre-expressing adenovirus-infected tenocytes. Proliferation of G9a-null tenocytes decreased compared with that of control tenocytes. The mRNA expression levels of tendon-related genes were downregulated in G9a-null tenocytes. Similarly, tenomodulin protein expression was suppressed in G9a-null tenocytes compared with control cells. These results suggest that G9a expression is essential for the proliferation and differentiation of tenocytes, and that G9a play important roles in tendon development.

Therapeutic Potential of Myostatin (GDF8) in Protecting Immobilization-Induced Muscle Atrophy at an Adult Stage. Toshimi Tando*, Takeshi Miyamoto, Morio Matsumoto, Masaya Nakamura. Department of Orthopedic Surgery, Keio University School of Medicine, Japan

Femoral neck fracture is a big concern in the osteoporosis patients. Most cases of fractures are caused by falls, and at least some of the falls are due to sarcopenia, characterized by muscle weakness accompanied by muscle atrophy in elderly people. Myostatin (also named GDF8), a member of TGF β superfamily, was an inhibitor of muscle hypertrophy, and that was considered a therapeutic target to prevent muscle atrophy, however, the inhibitory effects of Myostatin in preventing muscle atrophy at an adult stage remain unclear. Therefore, the purpose of this study is to clarify the effects of Myostatin-inhibition in protecting muscle atrophy at an adult stage.

We utilized adult stage specific Myostatin conditional knockout (cKO, Mx Cre; *Myostatin*^{flox/flox}) or control (Ctl, *Myostatin*^{flox/flox}) mice, and performed two independent mouse immobilization induced muscle atrophy models, denervation of sciatic nerve or fixation of hind limb, in these mice. Gastrocnemius muscles were harvested from atrophic side (immobilized side) and non-atrophic side (sham operated side), and muscle weight and the expression of Atrogin-1 and MuRF1, both of which are ubiquitin ligases required for muscle atrophy, were analyzed.

Gastrocnemius muscle weight was equivalent between Ctl and cKO before the immobilization. Reduction of gastrocnemius muscle weight in immobilized compared with non-immobilized side was equally seen in Ctl and cKO mice. Elevation of both Atrogin-1 and MuRF1 expression in atrophic compared with non-atrophic muscles was also similarly seen in both Ctl and cKO mice. These results suggest that inhibition of Myostatin is not effective to prevent immobilization induced muscle atrophy.

Today, Myostatin is considered as a therapeutic target to prevent or treat sarcopenia. However, our results suggest that Myostatin is not a preferable target to protect the immobilization induced muscle atrophy at an adult stage.

Window of Opportunity: Circulating Osteoblast Precursors Were Decreased after Infiximab Therapy in Patients with Ankylosing Spondylitis. Seong-Ryul Kwon*¹, WON PARK¹, MIN-JUNG SON¹, MIE-JIN LIM², KYOUNG-HEE JUNG², SHIN-GOO PARK³. ¹INHA University Hospital, South Korea, ²Rheumatism Center, INHA University Hospital, South Korea, ³Department of Occupation & Environmental Medicine, INHA University Hospital, South Korea

Background

It was known TNF alpha blocker therapy had little or no effect on new bone formation or structural remodeling in patients with ankylosing spondylitis (AS).

Objective

We studied the differentiation and activity of osteoblast by novel cell culture technique of osteoblast in peripheral blood and other methods in candidates for infiximab therapy with AS and controls.

Methods

Male sixteen individuals with AS were enrolled. They met modified New York criteria and were candidates for infiximab therapy. Sex and age matched nineteen controls were also recruited. Peripheral blood mononuclear cells were collected and cultured in growth medium. Once cell multi-layering has been observed, cells were transferred to differentiation medium and cultured for 3 weeks. They were then fixed and stained with alizarin S stain to detect any calcified nodules. The optical density (OD) of alizarin S was measured for quantitative analysis.

We evaluated 1) the numbers of circulating osteoblast precursors in peripheral blood, 2) the OD of alizarin S red staining of circulating osteoblast precursors, 3) total procollagen type 1 N-terminal propeptide (PINP) as osteoprogenitor marker, osteocalcin as mature osteoblast marker in patients with AS and in healthy controls at baseline and 14 weeks after infiximab therapy in AS patients.

Results

The serum level of PINP (osteoprogenitor marker) was significantly higher in patients with AS than in the controls (p = 0.08), but that of osteocalcin (mature osteoblast marker) was not. The number of osteoblast precursor cells and optical density of alizarin S were decreased after infiximab therapy (p = 0.028 for optical density of alizarin S). The serum level of PINP was decreased after infiximab therapy (p = 0.002), but that of osteocalcin was increased (p = 0.007).

Conclusions

These results support the hypothesis, 'window of opportunity' that acute inflammation resolved completely but mature lesion could not alter the new bone formation.

Evaluation of Vitamin D Levels in Women with Carpal Tunnel Syndrome. Hyun Sik Gong*¹, Seung Hoo Lee². ¹Seoul National University Bundang Hospital, South Korea, ²Seoul National University, South Korea

Background: Carpal tunnel syndrome (CTS) is the most common compressive neuropathy in the upper extremity and commonly occurs in postmenopausal women. Recent studies suggest an association between vitamin D and peripheral nerve disorders. Vitamin D has been shown to improve myelination and recovery after nerve injuries, and low levels of vitamin D were associated with neuropathy in patients with diabetes or Sjögren's syndrome. Thus, we aimed to evaluate levels of vitamin D and their association with clinical features of CTS in women undergoing carpal tunnel release.

Methods: We measured vitamin D levels in 154 women (mean age, 57 ± 10 years) undergoing surgery for CTS and 388 control women (mean age, 56 ± 8 years) without neurologic symptoms. Patients with CTS were evaluated for electrophysiologic severity of the disease and perceived disability using the Disabilities of the Arm, Shoulder, and Hand (DASH) questionnaire. Vitamin D levels were compared between women with CTS and control women, and correlation analyses were performed between vitamin D levels and clinical features of CTS such as age, symptom duration, electrophysiologic severity, and perceived disability in CTS patients.

Results: Vitamin D levels were comparable between women with CTS and control women (mean ± standard deviation (SD), 20.6 ± 11.5 ng/ml and 20.8 ± 9.8 ng/ml, respectively; p = 0.801). However, CTS women less than 50 years of age (n = 40) had significantly lower levels of vitamin D (mean ± SD, 16.7 ± 8.1 ng/ml) than age-matched controls (n=107, mean ± SD, 20.7 ± 9.6 ng/ml, p = 0.021), while there were no such differences in other age groups. Lower vitamin D levels were associated with lower age of onset (r = 0.159, p = 0.048). Other clinical features did not correlate with vitamin D status.

Conclusions: In this study, CTS women less than 50 years of age had significantly lower levels of vitamin D than age-matched controls, and lower vitamin D levels were associated with lower age of onset. This study suggests a potential link between vitamin D status and the occurrence of CTS in women younger than 50 years of age. Further studies are necessary to explore the potential role of vitamin D in the pathogenesis of CTS.

Quantifying the Progression of Preclinical Osteoarthritis as an Organ Disease Using Co-Registered Analysis in Five Tissues (CRAFTs). Joseph Temple*¹, Tieshi Li², Alessandra Eposito², Anna Spagnoli². ¹University of North Carolina at Chapel Hill, USA, ²Department of Pediatrics, Rush University Medical Center, USA

It has become accepted that osteoarthritis (OA) is a complex organ disease involving inter-tissue regulation in the cartilage, subchondral bone, osteophyte border, synovium, and meniscus. As the established preclinical OA scoring technique (i.e. OARSI) centers on assigning cartilage grades to sampled histological slices, it provides semi-quantitative data about only one joint tissue and has histological limitations.

Here, we present Co-Registered Analysis in Five Tissues (CRAFTs), an imaging analysis platform designed to progressively quantify OA progression as an organ disease. To optimize precision, we developed a co-registration technique that uses validated anatomically invariant bone landmarks to uniformly align all scans. Briefly, murine post-traumatic OA was induced via surgical destabilization of the medial meniscus (DMM). Knees were harvested 2, 4, 8, 12, 16, and 20 weeks (W) post-operatively and scanned natively (no contrast) using Micro-Computed Tomography to evaluate OA-related bone changes (osteophytes, subchondral sclerosis, meniscal calcification). Knees were stained (1.0% phosphotungstic acid/70% EtOH, EPTA) and rescanned for cartilage damage and synovitis. DMM results were evaluated vs. controls (t test) and over time (ANOVA). Significance was set at p < 0.05 and there were n ≥ 10 samples per group.

On native DMM scans, we measured significant increases in the amount of mineralized tissue vs. controls in the subchondral bone (BV: 0.626 ± 0.018 vs. 0.558 ± 0.019), meniscus (TV: 0.118 ± 0.005 vs. 0.085 ± 0.004 mm³), and osteophyte border (TV: 0.037 ± 0.006 vs. 0.000 ± 0.000 mm³) at 2W. These changes progressively increased over time. On EPTA DMM scans, we quantified decreased matrix integrity vs. controls at 2W (Attenuation: 875.6 ± 14.0 vs. 938.2 ± 26.8 TU). Full thickness fissuring and significant volumetric cartilage loss were present at 8W (TV: 0.074 ± 0.004 vs. 0.087 ± 0.006 mm³). These results correlated with the OARSI scores, which were not significant at 2W (0.6 ± 0.4 vs. 0.3 ± 0.3, p = 0.109), but were significant at 8W (3.2 ± 1.1 vs. 0.4 ± 0.2). Significant synovitis was present at 12W (Thickness: 0.035 ± 0.008 vs. 0.020 ± 0.005 mm).

Our results suggest that CRAFTs is a high-precision technique capable of quantifying subtle OA changes and progression in multiple joint tissues. Excitingly, the simultaneous early pathology that we identified in multiple joint tissues further reinforces the concept of OA as a complex organ disease.

Favorable Effects of anti TNF Therapy on Bone Turnover in Peripheral Blood Despite Inadequate Response of Inflammatory Markers in Seropositive RA Patients. Mie Jin Lim*¹, Won Park², Seong Ryul Kwon², Kyung Hee Jung². ¹Inha University Hospital, South Korea, ²Inha University Hospital, South Korea

Objectives

We investigated the circulating osteoclasts and osteoblast activity in peripheral blood before and 6 months after anti TNF- α therapy in seropositive RA patients.

Materials and Methods

Thirteen seropositive RA patients were enrolled. They had been refractory to disease modifying antirheumatic drugs (DMARDs) and were preparing for anti TNF- α Therapy including infliximab, adalimumab and etanercept. Peripheral blood mononuclear cells (PBMCs) were collected before and 6 months after anti TNF- α Therapy. PBMCs (1 x 10⁶ cells/well) were placed in a 96-well tissue culture plate and cultured for 14 days. Histochemical staining for tartrate resistant acid phosphatase (TRAP) was carried out using an acid phosphatase kit (Sigma 386-A, St. Louis, MO). TRAP positive giant cells with more than 3 nuclei were regarded as osteoclasts. To assess resorption potential of osteoclasts, PBMCs were also cultured on bone slices for 3 weeks under the same condition as described above. Osteoclasts were then removed and the pits were visualized with 0.1% toluidine blue. The areas of pits were quantified using a computerized image analysis program. PBMCs were also cultured, fixed and stained with alizarin S stain to detect any calcified nodules. The optic density measurement of total alizarin S solute was performed for quantitative analysis.

Results

After 6 months of anti TNF- α therapy, number of ex vivo cultured osteoclasts was reduced and the area of resorption pit decreased as shown in Table 1. The optic density of calcified nodules increased significantly. On the other hand, systemic inflammatory markers including erythrocyte sedimentation rate (ESR) and c-reactive protein (CRP) failed to show significant response after anti TNF therapy. Anti-TNF therapy reduced swollen and tender joint counts, resulting in improvement of RA disease activity.

Conclusion

The number of peripheral osteoclasts and osteoblast activity decreased after 6 months of anti TNF- α treatment despite inadequate response of inflammatory mediators. The clinical signs of patients also improved after anti TNF therapy.

| | Before TNF- α Therapy | 6 months after TNF- α therapy | p |
|---|------------------------------|--------------------------------------|--------|
| Number of osteoclasts (per well) | 586.8 ± 284.8 | 321.5 ± 131.7 | 0.013 |
| Area of resorption pit (mm ²) | 0.18 ± 0.113 | 0.08 ± 0.076 | 0.007 |
| Optic density from osteoblastic nodules (μ mol/well) | 125.2 ± 157.62 | 1215.5 ± 676.65 | 0.013 |
| Swollen Joint counts | 18 ± 6.9 | 8 ± 4.9 | 0.002 |
| Tender Joint Counts | 18 ± 6.4 | 8 ± 4.9 | 0.001 |
| ESR (mm/hr) | 28 ± 17.7 | 22 ± 28.3 | 0.2 |
| CRP (mg/L) | 13.8 ± 13.32 | 6.9 ± 17.08 | 0.2 |

TGF- β 1 Induces TRAF3 Autophagic Degradation leading to GSK-3 β -induced β -catenin Inactivation and Inhibition of Osteoblast Differentiation. Jinbo Li*¹, Zhenqiang Yao², Lianping Xing², Brendan F. Boyce². ¹University of Rochester Medical Center, USA, ²U of Rochester Medical Center, USA

TNF receptor-associated factor 3 (TRAF3) is an adaptor protein that transduces signaling of cytokines, including TNF and RANKL. Conditional deletion of TRAF3 (TRAF3 cKO) in myeloid cells resulted in osteoporosis due to increased osteoclast (OC) activity, and TRAF3 cKO in mesenchymal progenitor cells (MPCs) also led to early onset osteoporosis in the cKO mice. Importantly, we have found that TRAF3 protein levels are significantly lower in the bones of 18- than 3-m-old mice. These findings suggest that increased bone resorption and decreased formation in age-related osteoporosis could be linked to the reduced TRAF3 levels in bone with aging, but the mechanisms involved are unclear. We treated mouse and human MPCs with factors that regulate osteoblast (OB) differentiation and found that TGF- β 1 clearly reduced TRAF3 protein levels. Consistent with this, TGF- β 1 significantly inhibited ALP and Runx2 gene expression, OB differentiation (ALP⁺ OB area 5.4 ± 2.4 vs. 42 ± 15 mm²/well in veh) and nodule formation (mineral area 0.2 ± 0.1 vs. 41 ± 16 mm²/well in veh) from WT MPCs. Similar changes were observed in MPCs from TRAF3 cKO mice. Ubiquitination (Ub) followed by either proteasomal or autophagic degradation is a common mechanism to degrade proteins. We found that TGF- β 1 significantly increased TRAF3 Ub, and TGF- β R2 directly associated with TRAF3 in WT MPCs. Of note, TGF- β 1 significantly increased co-localization of TRAF3 with the lysosome protein LAMP2; the autophagy inhibitor, chloroquine, partially blocked this effect. We used TRAF3 cKO and WT mouse MPCs to identify potential signaling pathways regulated by TRAF3. We found that active β -catenin levels were significantly lower in the cKO than in WT MPCs, with no difference in total β -catenin protein levels; in contrast, levels of active GSK-3 β , which degrades β -catenin, were increased in the cKO MPCs. Importantly, the GSK-3 β inhibitors, lithium chloride and SB-216763, significantly increased active β -catenin protein levels and partially reversed the inhibition of OB differentiation in TGF- β 1-treated WT MPCs and of TRAF3 cKO MPCs. In summary, 1) TRAF3 protein levels are reduced in bone with aging; 2) TGF- β 1/TGF- β R2 signaling induces TRAF3 autophagic degradation; 3) GSK-3 β is activated in TRAF3 cKO MPCs and degrades β -catenin to inhibit OB differentiation. We conclude that prevention of TRAF3 degradation could be a novel strategy to reduce bone resorption and increase bone formation to treat age-related osteoporosis.

Oxidativestress-induced apoptotic insults to rat osteoblasts is attenuated by nitric oxide pretreatment via GATA-5-involved regulation of *Bcl-X_L* gene expression and protein translocation. Ruei-Ming Chen*¹, Gong-Jhe Wu², Yi-Ling Lin¹. ¹Taipei Medical University, Taiwan, ²Taipei Medical University Hospital, Taiwan

Nitric oxide (NO) has biphasic effects on regulating osteoblast survival and death. This study was aimed to evaluate the effects of NO pretreatment on hydrogen peroxide (HP)-induced osteoblast insults and the possible mechanisms. Exposure of osteoblasts prepared from rat calvarias to HP significantly increased intracellular reactive oxygen species levels, decreased alkaline phosphatase activity and cell survival, and ultimately induced cell apoptosis. However, NO pretreatment lowered HP-induced oxidative stress and apoptotic insults. In parallel, HP increased Bax levels and its translocation from the cytoplasm to mitochondria. NO pretreatment caused significant attenuations in HP-induced modulations in Bax synthesis and translocation. In contrast, pretreatment with NO enhanced levels and translocation of anti-apoptotic Bcl-XL protein in osteoblasts. RNA analyses further revealed that HP inhibited Bcl-XL mRNA expression without affecting Bax mRNA levels. In comparison, NO induced Bcl-XL mRNA production and alleviated HP-caused inhibition of this mRNA expression. As to the mechanism, HP suppressed RNA and protein levels of transcription factor GATA-5 in osteoblasts. Pretreatment with NO induced GATA-5 mRNA and protein expressions and simultaneously attenuated HP-induced inhibition of this gene's expression. Consequently, GATA-5 knockdown using RNA interference inhibited Bcl-XL mRNA expression and concurrently lowered NO's protection against HP-induced apoptotic insults. Therefore, this study showed that NO can protect osteoblasts from HP-induced apoptotic insults. The protective mechanisms are mediated by GATA-5-mediated transcriptional induction of Bcl-XL gene, and translocational modulation of Bcl-XL and Bax proteins.

Regulation of Osteoclasts by Scavenger Receptor-A. Larry Suva¹, Nisreen Akel², Jessica Webber³, Sean Parham⁴, Diarra Williams⁴, Frances Swain⁴, Dana Gaddy⁴, Steven Post³. ¹University of Arkansas for Medical Sciences, USA, ²UAMS Orthopaedic Surgery, USA, ³UAMS Department of Pathology, USA, ⁴UAMS Department of Orthopaedic Surgery, USA

The class A scavenger receptor (SR-A) is a multifunctional receptor predominantly expressed by macrophages critical for mediating ligand uptake, cell attachment and signaling. SR-A binds a broad array of macromolecular ligands including modified proteins and lipoproteins, nucleic acids, as well as a variety of microbial proteins. Since osteoclasts are derived from the monocyte/macrophage lineage, SR-A has the potential to significantly impact osteoclast development and function. In this study the impact of SR-A deletion on bone, muscle and fat was investigated. SR-A null mice (males and females) deficient in SR-AI, AII, and AIII on a C57Bl6 background were examined at 3, 4, 5 and 6 months of age and compared with WT age-matched controls. Body composition analyses demonstrated greater total lean and fat body mass in SR-A^{-/-} animals, with no significant difference in percent fat and lean body mass by DEXA, and no differences in food intake. In addition, the evaluation of long bones and spine by microCT confirmed a previously identified high trabecular bone mass phenotype, significantly increased BV/TV and Tb.N. with decreased Tb.Sp. in SR-A^{-/-} mice, with the phenotype apparent at even the earliest (3 month) time point. The cortical bone was also affected, with cortical thickness and periosteal perimeter both significantly increased. Histologically, the bone phenotype is explained by significantly decreased osteoclasts in SR-A^{-/-} compared to wild type mice, with no measurable differences in osteoblast or adipocyte progenitors. Interestingly, there appears to be an increase in the number of nuclei/osteoclast in SR-A^{-/-} mice. *Ex vivo* bone marrow cultures from wild-type and SR-A^{-/-} mice revealed a dramatic decrease in osteoclastogenesis in SR-A^{-/-} bone marrow and isolated bone marrow macrophages, along with mild suppression of osteoblastogenesis. The increased osteoclast nuclei per cell was reproduced *in vitro*, implicating SR-A as a novel regulator of cell fusion. These data suggest that the deletion of SR-A *in vivo* induces changes in osteoclast development that involve osteoclast differentiation, fusion and function. Collectively, SR-A is necessary for normal osteoclast development and we hypothesize a novel role for SR-A in the scavenging and removal of bone resorption debris by osteoclasts.

The deletion of *Hdac4* in osteoblasts influences both catabolic and anabolic effects in bone. Teruyo Nakatani¹, Tiffany Chen², Eric Olson³, Nicola Partridge². ¹New York University College of Dentistry, USA, USA, ²New York University College of Dentistry, USA, ³University of Texas Southwestern Medical Center, USA

Histone deacetylase (Hdac4) is known to control chondrocyte hypertrophy and bone formation. Since the global knockout *Hdac4* mice do not survive to weaning, we cannot obtain samples for mature bone analysis nor treat the animals with PTH. To analyze the function of Hdac4 in bone, we generated osteoblast-specific knockout of *Hdac4* (*Hdac4*^{ob/-}). We crossed transgenic mice bearing col2.3 1a(1)-Cre recombinase with mice bearing loxP-*Hdac4*. To determine the effect of PTH on bone resorption in these mice, we conducted experiments infusing hPTH (1-34) with Alzet microosmotic pumps (8 mg/100g BW/day) or saline vehicle implanted subcutaneously on the back at a normal pumping rate of 0.25 ml/h for 14 days in 8 week old female *Hdac4*^{ob/-} and wild type (*Hdac4*^{fl/fl}) mice. The *Hdac4*^{ob/-} mice survive to adulthood but show a clear but mild bone phenotype. At 12 weeks of age, they have a shortened and irregular-shaped stiff tail due to shorter tail joints, with almost no growth plates. Similarly, the thickness of the tibial growth plate zone was shortened. MMP-13 and SOST mRNAs were increased in the distal femurs of *Hdac4*^{ob/-} mice. Immunohistochemistry showed that Mef2c and Runx2 were increased in cells of trabecular bone in *Hdac4*^{ob/-} mice, suggesting that Hdac4 inhibits their gene expression. It is likely that the increase in these transcription factors causes the increase in MMP-13 and SOST. Serum CTX, a marker of bone resorption was increased in *Hdac4*^{ob/-} mice with or without PTH treatment. Tibial cortical BV/TV, Cs/Th, and relative cortical area (RCA) were decreased in *Hdac4*^{ob/-} mice but PTH caused no further decrease in *Hdac4*^{ob/-} mice. Tibial trabecular thickness tended to decrease in *Hdac4*^{ob/-} mice and further decreased with PTH treatment. These results indicate that Hdac4 might inhibit bone resorption and also have an anabolic effect via inhibiting MMP-13 and SOST gene expression. Hdac4 influences cortical bone mass and thickness and knockout of *Hdac4* seems to prevent the catabolic effect of PTH in cortical bone.

The effects of GPR43 allosteric agonist on bone. Myeongmo Kang¹, Namhee Kim¹, HeeJin Nam¹, Seong Hwan Kim², Dongdong Zhang¹, Bo Mi Park³, YuMie Rhee¹, Sung-Kil Lim³, ChuHyun Bae³. ¹Yonsei Univ., Sinchon-dong, Seodaemun-gu, Seoul, Korea, South Korea, ²Korea Research Institute of Chemical Technology, South Korea, ³Brain Korea 21 PLUS Project for Medical Science, Yonsei University, Seoul, Republic of Korea, South Korea

Absence of gut microbiota leads to increased bone mass associated with reduced number of osteoclasts (OCLs) per bone surface, decreased frequency of CD4⁺T cells and OCL precursor cells in bone marrow. Sodium butyrate, short chain amino acid increased alkaline phosphatase (ALP) activity of cloned osteoblastic cell line MC3T3-E1 by the stimulation of *de novo* enzyme synthesis and it decreased tartrate resistant acid phosphatase (TRAP)-positive multinucleated cells (MNC) formation from bone marrow cells. Short chain amino acids metabolized from fiber in gut stimulate both GPR41 and GPR43. CMTB is the first synthetic allosteric agonist for GPR43. To test the effects of CMTB on bone, we established stable cell line for expressing GPR43 and NFATc luciferase reporter. CMTB efficiently activated the reporter activity dose dependently. GPR43 was expressed bone marrow cells, preosteoclast extensively, meanwhile expression was low in mature osteoclast and primary cultured osteoblast cells. It suppressed the expression of Runx2, Osterix and RANKL induced by osteogenic media. It also inhibits significantly the osteoclastogenesis induced by RANKL and M-CSF. Furthermore it suppressed Alp expression in MC3T3E1 cells at the high dose, however it stimulated BMP4 induced ALP expression in C2C12 cells. Taken together, activation of GPR43 suppresses osteoclastogenesis and differentiation of osteoblast at the stage of preosteoblasts after enhancing the commitment of precursor cells into osteoblast lineage cells. The *in vivo* effects of GPR43 allosteric agonist will be presented in the meeting

Estrogen regulates the activity of avian medullary bone osteoclasts through Eph/ephrin signaling. Shinji Hiyama*¹, Ki-ichi Nakamori², Mineo Watanabe¹, Takashi Uchida¹. ¹Hiroshima University Institute of Biomedical & Health Sciences, Japan, ²Hiroshima University, Japan

Estrogen induces mammalian osteoclast apoptosis, which may be related to postmenopausal osteoporosis, while this hormone does not promote apoptosis of avian medullary bone (MB) osteoclasts. MB is a unique tissue of female birds, which acts as a calcium reservoir of egg-shell formation and remodeled in the bone marrow cavity under the powerful control of circulating estrogen. In this process, increased circulating estrogen does not facilitate apoptosis of osteoclasts, and osteoclasts are present as a resting state on the surface of MB. Until now, we reported using the avian medullary bone osteoclastogenesis model that estrogen had not effect on apoptosis of MB osteoclasts, while their activity and morphology were affected. Clarifying the difference between avian and mammalian osteoclast responses to estrogen may be helpful to identify additional roles of estrogen in bone. Recently, there are reported that Ephrin (Eph) receptors and its ligands, ephrin, are related to osteoclast activity. Therefore, we focused on the effects of estrogen on the expression of Eph receptors and its ligands in MB osteoclasts. Male Japanese quails were given a single injection of 17beta-estradiol (E2). After a couple of days, bone marrow cells were collected and cultured in the presence of RANKL/M-CSF for a week. Continued treatment of E2 did not effect to the expression of Eph receptors and its ligands. On the other hand, EphA2, EphA4 and EphrinB1 expression levels were decreased by transient exposure of E2 at late stage of culture. In this culture stage, intracellular pH of these cells had no effect, while the immunoresponse of MMP-9 of these cells was decreased by E2 treatment. These results suggest that Ephrin receptors and its ligands may regulate to avian osteoclast activity and these signaling may be regulated by estrogen. Further studies will determine the relationship between estrogen and Eph/ephrin signaling.

Lnk Deficiency leads to TPO-Mediated Osteoclastogenesis and Increased Bone Mass Phenotype. David Olivos*¹, Ying-Hua Cheng², Marta Alvarez², Adam Hooker², Wendy Ciovacco³, Brahmananda Chitteti⁴, Pierre Eleniste⁵, Mark Horowitz⁶, Edward Srour⁴, Angela Bruzzaniti⁵, Robyn Fuchs⁷, Melissa Kacena⁸. ¹Department of Orthopaedic Surgery, Indiana University School of Medicine; Department of Microbiology & Immunology, Indiana University School of Medicine, USA, ²Department of Orthopaedic Surgery, Indiana University School of Medicine, USA, ³Department of Orthopaedic Surgery, Indiana University School of Medicine; Department of Orthopedics & Rehabilitation, Yale University School of Medicine, USA, ⁴Department of Medicine, Indiana University School of Medicine, USA, ⁵Department of Oral Biology, Indiana University School of Medicine, USA, ⁶Department of Orthopaedics & Rehabilitation, Yale University School of Medicine, USA, ⁷Department of Physical Therapy, Indiana University School of Health & Rehabilitation Sciences, USA, ⁸Department of Orthopaedic Surgery, Indiana University School of Medicine; Department of Orthopaedics & Rehabilitation, Yale University School of Medicine, USA

The Lnk adapter protein negatively regulates the signaling of thrombopoietin (TPO), the main megakaryocyte (MK) growth factor. As expected Lnk-deficient (-/-) mice have increased TPO signaling and therefore increased MK number. Interestingly, several mouse models exist in which increased MK number leads to a high bone mass phenotype. Here we demonstrate that Lnk-/- mice also exhibit a high bone mass phenotype. While MK-mediated osteoblast proliferation contributes to the high bone mass phenotype, we also show that Lnk is expressed by cells of the osteoclast (OC) lineage. Moreover, when Lnk-/- OC progenitors are cultured in the presence of TPO, significantly more TRAP+ OCs are observed than in wild-type (WT) control cultures. However, in vitro, Lnk-/- OC bone resorbing activity is impaired. MicroCT and static histomorphometric analyses at 20 weeks found the distal femur of Lnk-/- mice to have significantly higher bone volume per total volume (BV/TV), increased trabecular number (Tb.N), and decreased trabecular separation (Tb.Sp) compared to WT mice. Of note, despite a significant increase in the number of OC per tissue area (N.Oc/T.Ar), and decreased bone formation rate per total volume (BFR/TV) in Lnk-/- mice compared to WT mice, Lnk-/- mice demonstrated a 2.5-fold greater BV/TV suggesting impaired osteoclast function in vivo, consistent with the in vitro results. Additionally, Lnk-/- mouse femurs exhibited increases in mid-shaft cross-sectional area and periosteal BFR compared to that observed in WT femurs. In agreement with this, Lnk-/- femurs had an increased polar moment or inertia. Lnk-/- cortical bone area and thickness was markedly reduced and biomechanical testing showed femurs to be less stiff, have reduced strength, and a decreased modulus compared to WT femurs. Taken together, these data suggest that Lnk both directly regulates bone mass through its actions on OC (impaired resorptive activity) while also indirectly regulating bone mass through its actions on MK which in turn regulate osteoblasts. Thus, targeting Lnk may serve as a novel therapeutic approach for treating bone loss diseases such as osteoporosis.

A Transmembrane Osteoclastic Protein-Tyrosine Phosphatase (PTP-oc), a Positive Regulator of Osteoclast Activity, Is Regulated Post-transcriptionally in part by miR17 in Osteoclastic Cells. Matilda Sheng*¹, Virginia Stiffel², Mehran Amoui², Kin-Hing William Lau². ¹Jerry L. Pettis Memorial VA Medical Center & Loma Linda University, USA, ²Jerry L. Pettis Memorial VA Medical Center, USA

PTP-oc has been shown to be a positive regulator of functional activity of osteoclasts. This study sought to determine the mechanism by which PTP-oc is regulated. Accordingly, we found that PTP-oc is regulated post-transcriptionally as several resorption effectors increased PTP-oc mRNA levels without altering its promoter activity. To test if PTP-oc expression is regulated by miRNAs, we searched for potential miRNA target sites on PTP-oc mRNA and found three potential miRNA target sites; one of which is for *miR17*. We focused on *miR17*, because *miR17* has been shown to negatively regulate a structurally-related PTP (*PTPRO*). During the RANKL-induced osteoclast differentiation, there was a corresponding time-dependent reduction in *miR17* and a significant inverse relationship between the levels of *miR17* and *PTP-oc* mRNA. *miR17* in osteoclasts was suppressed by those resorption effectors that also upregulated PTP-oc. The pre-*miR17*-92-transfected osteoclasts showed ~2-fold increase in *miR17* and ~50% decrease in *PTP-oc* mRNA. The average size of osteoclasts derived from pre-*miR17*-92 transfected cells was 43 ± 8% smaller. To ascertain that the observed effects of *miR17* overexpression were not due to off-target effects, we transduced osteoclast precursors of *miR17*-92^{fllox/fllox} mice with a Cre-expressing adenoviral vector (Ad5-CMV-Cre) to delete *miR17*-92. The cellular *miR17* level in Ad5-Cre-transduced osteoclasts was <50% of that of Ad5-GFP-treated control cells. The average size of *miR17*-92 cKO osteoclasts was 35-40% larger than control osteoclasts. The average number of nuclei in *miR17*-92 cKO osteoclasts was also 75% more. The *miR17*-92 cKO cells showed an increase in *PTP-oc* mRNA level by 86 ± 32%, and the relative size of resorption pits formed by *miR17*-92 deficient osteoclasts was significantly larger (~2-fold). To confirm that these observed effects were caused by deficient *miR17*, we transfected osteoclast precursors with LNA-modified antisense inhibitor of mouse *miR17*-5p. Inhibition of *miR17* also yielded ~twice as large osteoclasts with more nuclei per cells as control-LNA oligo-treated cells. Importantly, transgenic mice with conditional disruption of *miR17*-92 in osteoclasts have very similar bone and osteoclast phenotypes to those of transgenic mice with conditional overexpression of PTP-oc in osteoclasts. In conclusion, PTP-oc is a target gene for *miR17* and that *miR17* regulates osteoclast activity in part through suppression of PTP-oc expression.

C/EBP α mediates osteoclast differentiation through SOX4 downregulation and promotes osteoclast activity by inducing cell survival. Joel Jules*¹, Wei Chen, Yi-Ping Li. University of Alabama at Birmingham, USA

The transcription factor CCAAT/enhancer binding protein α (C/EBP α) is essential for osteoclastogenesis by committing bone marrow macrophages (BMMs) into the osteoclast (OC) lineage. However, whether C/EBP α is also crucial for OC differentiation and function is unknown. It was reported that while treatment of BMMs with permissive levels of receptor activator of NF- κ B ligand (RANKL) was unable to stimulate OC differentiation, it was sufficient to prime BMMs into the OC lineage for tumor necrosis factor- α (TNF) and interleukin 1 (IL-1)-induced OC differentiation. Here, we utilized this strategy to investigate the role of C/EBP α in OC differentiation and thereby bypass its requirement for lineage commitment. C/EBP α overexpression in BMMs could induce OC differentiation and strongly up-regulate OC markers with RANKL-evoked OC lineage commitment. Accordingly, C/EBP α overexpression in different stages of osteoclastogenesis revealed that while C/EBP α played a stronger role in the early stages of osteoclastogenesis, it was also critical for the later stages and could also promote OC activity. Consistently, C/EBP α silencing in different stages of osteoclastogenesis drastically inhibited OC formation and significantly abrogated the expression of OC markers as well as OC activity. Notably, C/EBP α promoted OC activity by regulating cell survival. Importantly, ectopic expression of rat C/EBP α could rescue osteoclastogenesis in the C/EBP α depleted BMMs. TNF and IL-1 are known to stimulate bone loss in many inflammatory bone diseases, so we then investigated the role of C/EBP α in TNF- and IL-1-induced OC differentiation. C/EBP α overexpression in BMMs significantly enhanced RANKL-

mediated TNF- α /IL-1-induced OC differentiation and markedly induced bone loss in a mouse model of periodontitis. Given the established role of C/EBP α in regulating gene expression, we hypothesized that C/EBP α mediates OC differentiation by not inducing OC markers but also by repressing novel OC inhibitors. We found that C/EBP α negatively regulates the expression of SRY (sex determining region Y)-box 4 (SOX4) during osteoclastogenesis. Remarkably, SOX4 overexpression in BMMs drastically inhibited RANKL-induced osteoclastogenesis. Also, SOX4 overexpression inhibited OC differentiation by TNF or IL-1. Taken together, these results indicate that C/EBP α is critical for all stages of osteoclastogenesis. Significantly, our data support that C/EBP α may evolve as an important therapeutic target for bone loss.

MKP-1 Regulates LPS-Induced Osteoclastogenesis by Regulating TRAIL Function. Michael Valerio*, Keith Kirkwood. Medical University of South Carolina, USA

Osteoclasts (OC) are specialized bone resorptive cells required for a physiologic bone turnover. Under pathologic conditions, the inflammatory microenvironment produced both pathogens and cytokines drives inflammatory OC and subsequent bone loss. MAP kinase phosphatase-1 (MKP-1, gene Dusp1), regulates p38 and JNK MAPK and was shown to regulate inflammatory OC by reducing inflammatory cytokines and chemokines. MKP-1 was also shown to attenuate apoptosis in cells stimulated with endotoxin LPS. TNF-related apoptosis-inducing ligand (TRAIL), a member of the TNF ligand superfamily, has been shown to be involved in regulating cell death by apoptosis, but more interestingly was shown to induce OC formation. Based on these observations, we aim to investigate the role of MKP-1 regulating TRAIL in LPS-stimulated OC. OC progenitors (dOCP) derived from WT and Dusp1 $^{-/-}$ mouse bone marrow (BM) were immunophenotyped as CD3-CD45R-GR1-CD11b/CD115+ and sorted via magnetic bead separation. Cells were primed with MCSF (25ng/ml) and RANKL (50ng/ml) for 48 hours, washed out and stimulated with LPS (100ng/ml) for up to 10 days. In some experiments, cells were also treated in the presence of inhibitors p38 (SB203580), JNK (SP600125), Erk (U0126) and NF κ B (BAY) alone or in combination. Additionally, some cells were treated with rTRAIL (250-500ng/ml) or TRAIL-R2 blocking Antibody (2ug/ml) prior to stimulation with LPS (100ng/ml). Treated cells were TRAP stained to measure osteoclast formation. RNA was extracted using Trizol and mRNA expression for Traf6 (Traf6), NFATc1 (Nfatc1), DR5 (TNFRsf10b) and Trail (Tnfsf10). Trail-R2 protein expression was measured using flow cytometry. In the current study, we reveal that OC stimulated with LPS have prolonged survival in the absence of MKP-1, along with significantly more expression of intracellular traf6 and cytokines TNF and NOS2 ($P < 0.05$). dOCP stimulated with LPS had 50-fold increase in Trail mRNA expression ($P < 0.05$) and significantly more protein expression compared to WT counterparts. Trail receptor 2 (DR5) is increased up to 3-fold in LPS stimulated cells lacking MKP-1 ($P < 0.01$). Blocking Trail R2 blunted LPS-induced OC formation in WT and Dusp1 $^{-/-}$ cells. rTRAIL (up to 500ng/ml) induced significantly more OC in Dusp1 $^{-/-}$ cells. In all, these results reveal that TRAIL expression is activated in the absence of MKP-1 but does not induce cell death, rather promotes OC survival.

Nitric Oxide Pathway is Involved in the Intensity-Dependent Biphasic Effects of Static Magnetic Fields on Osteoclastogenesis. Ting Huyan*¹, Jian Zhang², Dandan Dong², Jingbao Li², Huiyun Xu², Zhouqi Yang², Peng Shang². ¹Key Laboratory for Space Bioscience & Biotechnology, School of Life Sciences, Peoples republic of china, ²Key Laboratory for Space Bioscience & Biotechnology, Institute of Special Environmental Biophysics, School of Life Sciences, Northwestern Polytechnical University, China

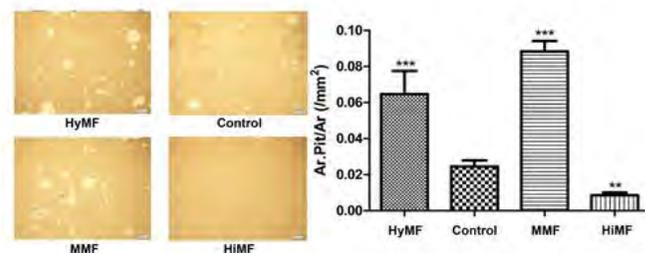

Numerous studies have demonstrated that certain magnetic fields have positive influence on human skeleton system. Static Magnetic Fields (SMF) is considered as a potential physical therapy to improve bone healing and keep bones healthy nowadays. In our previous study, it is showed that SMF which is increased progressively from hypo-magnetic field (HyMF, $< 5 \mu\text{T}$), weak magnetic field (WMF, $5 \mu\text{T} \sim 1 \text{mT}$), moderate SMF (MMF, $1 \text{mT} \sim 1 \text{T}$) to high SMF (HiMF, $> 1 \text{T}$), have intensity-

dependent biphasic effect on the osteoclasts differentiation. However, the mechanisms of SMF environment on osteoclastogenesis are inadequately understood till now and need to be further investigated. Nitric oxide is a short lived free radical involved in the regulation of bone turnover and bone cell function. The present study aims to investigate the co-relationship between nitric oxide pathway and SMF during osteoclast differentiation.

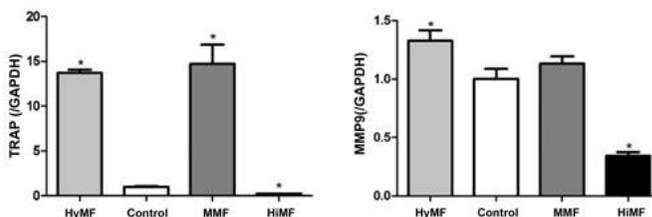

Our results showed that firstly HyMF and MMF had a positive effect on the osteoclasts formation and expression of marker gene Tartrate Resistant Acid Phosphatase (TRAP) and Matrix Metalloproteinase-9 in osteoclasts, but HiMF inhibited the formation and bone resorption activity of osteoclasts; secondly, the stronger SMF boosted the more nitric oxide production and endothelial nitric oxide synthase (NOS) activity. We hypothesized that nitric oxide pathway may play a vital role with SMF in the regulation of osteoclastogenesis. Further results demonstrated that sodium nitroprusside (SNP), a nitric oxide donor, had an inhibited effect on the elevated osteoclasts formation in HyMF and MMF, but N^G-Nitro-L-arginine methyl ester (L-NAME), a nitric oxide synthase inhibitor, rescued the inhibited osteoclast formation in HiMF. These findings indicate that nitric oxide pathway is involved in the intensity-dependent biphasic effect of SMF on osteoclastogenesis. Moreover, with regard to physical therapy in some bone disorders and maintenance of bone health, HiMF is preferable to HyMF and MMF which may cause negative effect to bone remodeling. In conclusion, these results will provide new horizons to our understanding of the SMF molecular mechanisms in osteoclastogenesis and HiMF may be a useful ancillary therapeutic modality in treating or preventing human osteoporosis.

Osteoclasts formation under SMF environments

Osteoclasts resorption activity under SMF environments

marker gene expression of osteoclast under SMF

old male ICR wild-type mice and Rankl^{-/-} mice were injected with human PTH (1-34; 80cg/kg) directly from the external jugular vein. After calcein injection, mice were sacrificed and the femora and tibiae were processed for paraffin- or epoxy resin-embedding or grind sections. These specimens were subjected to toluidine blue staining, von Kossa staining, observation under transmission electron microscopy (TEM) and fluorescence microscopy, and nanoindentation by atomic force microscopy (AFM). Furthermore, we fed Ca deficient diet to lactating mice, and fixed them after 12, 24, 36, 48 and 72 hours. Grind sections were used for nanoindentation by AFM and examined under confocal laser microscopy for detecting calcein labeling. Epoxy resin sections were used for von Kossa staining and TEM observation. Results and Discussion: Serum Ca concentration was increased at 1 hour after PTH administration with ligation of renal artery and vein in wild-type and Rankl^{-/-} mice. At six hours after PTH administration, enlarged osteocytic lacunae were observed mainly in the cortical bone, and von Kossa staining demonstrated broadly demineralized bone matrix surrounding the osteocytes. Under TEM, fragmented collagen fibrils and pieces of mineralized matrices were observed in the enlarged osteocytic lacunae with irregular shape of walls. In addition, calcein labeling was seen on the walls of some osteocytic lacunae. In lactating mice, the serum concentration of Ca was decreased at around 36-48 hours after feeding with Ca deficient diet. The osteocytic lacunae after 48 hours fed with Ca deficient diet, consistently, were enlarged, and sometimes labeled with calcein. It seems likely, therefore, that osteocytes erode the surrounding bone matrix, i.e., osteocytic osteolysis, and deposit minerals on their lacunae.

The treatment of human monocytes with the anti-microbial peptide LL-37 produces a novel bone forming cells with large inclusion bodies of LL-37. Zhifang Zhang*, Keith Le, Deirdre La Placa, John E. Shively. City of hope, USA

We previously showed that the antimicrobial peptide LL-37 induces human monocyte differentiation to a novel bone forming cell, termed monoosteophil, which exhibits the acceleration of bone repair in murine model. We here demonstrate that LL-37 is internalized by monocytes in the inclusion bodies. Over 1 hour to 16 hours, internalized LL-37 vesicles become larger vesicles in the cytosol. At the 4 hour time point, LL-37 positive vesicles are co-localized with Golgi but not ER, Mitochondria and lysosomes. At 16 hours, LL-37 positive vesicles even are co-localized with mitochondria and lysosomes. At day 6, LL-37 positive vesicles large as 10 micron long × 2 micron wide inclusion bodies and are not localized with mitochondria, ER, lysosome and Golgi. Interestingly, the concentration of LL-37 in the supernatant remains in the range of 3.8µM to 4.5µM from day 1 to day 6 with initial concentration of 5µM. Day 6 monoosteophil supernatant retains the ability to differentiate freshly isolated monocytes to monoosteophils according to morphology and unique monoosteophil surface markers integrin α3 and α6. Therefore, LL-37 remains intact during differentiation and form unique LL-37 inclusion bodies in the cytosol of monoosteophils.

Sclerostin enhances adipocyte differentiation in 3T3-L1 preadipocytes. Mayumi Ukita*¹, Taihiko Yamaguchi¹, Masato Tamura². ¹Crown & Bridge Prosthodontics, Graduate School of Dental Medicine, Hokkaido University, Japan, ²Biochemistry & Molecular Biology, Graduate School of Dental Medicine, Hokkaido University, Japan

Sclerostin, a secreted protein of the Sost gene product, is produced by osteocytes and is inhibited osteoblast differentiation and bone formation. Recently, a functional association between bone and fat tissue has been suggested, and a correlation between circulating sclerostin levels and the lipid metabolism in humans has been reported. However, the effects of sclerostin on adipogenesis remain unexplored. In the present study, we examined the role of sclerostin in regulating adipocyte differentiation using

nitric oxide production and NOS activity of osteoclasts under SMF

effect of nitric oxide donor and inhibitor in osteoclast formation under SMF

Histological examination on osteocytes and their lacunae after PTH administration or during lactation of mice fed with calcium deficient diet. Hiromi Hongo*¹, Muneteru Sasaki², Masami Saito³, Nobuyuki Udagawa⁴, Norio Amizuka⁵. ¹Hokkaido University, Japan, ²Division of Oral Implantology, Nagasaki University, Japan, ³Bruker AXS K. K., Japan, ⁴Department of Biochemistry, Matsumoto Dental University, Japan, ⁵Departments of Developmental Biology of Hard Tissue, Graduate School of Dental Medicine, Hokkaido University, Japan

Introduction: The idea of "osteocytic osteolysis" by injection of parathyroid hormone (PTH) or low calcium (Ca) diet has been proposed by Bélanger in 1960's. In addition, recent studies have suggested that the lactating mice might also show enlarged osteocytic lacunae. In order to clarify the occurrence of osteocytic osteolysis, we have examined osteocytes and their lacunae in mice after PTH administration and those in lactating mice fed with Ca deficient diet. **Materials and Methods:** Eleven-week

3T3-L1 preadipocytes. Oil red O stained-accumulated cytoplasmic lipid droplets and absorbance of oil red O staining were increased during adipogenic cultures in response to 5 ng/mL of sclerostin and further increased with increasing doses of sclerostin compared to sclerostin untreated cells. The mRNA expression level of adiponectin, lipoprotein lipase and fatty acid-binding protein 4 was also increased dose-dependently by sclerostin. Although sclerostin up-regulates CCAAT/enhancer binding protein (C/EBP) beta expression, cell proliferation and caspase3/7 activity did not alter by sclerostin in 3T3-L1 cells. TAZ is a transcriptional coactivator originally identified in a proteomic screen for 14-3-3 binding protein and is well-known for their regulation by Hippo signaling pathway. Recently, it is reported that TAZ is a downstream of the canonical Wnt signaling pathway independent Hippo pathway. Sclerostin reduced the TAZ responsive transcriptional activity using 8xGT10C-Lux, a synthetic luciferase reporter and TAZ-responsive ctgf gene expression which activated by Wnt3a. Although following transfection of 3T3-L1 cells with siRNA for the TAZ, the lipid deposits and adipogenic gene expression was increased, sclerostin could not alter adipocyte differentiation induced by siRNA for TAZ. These results show that sclerostin up-regulates adipocyte differentiation in 3T3-L1 cells, suggesting a possible role for the osteocyte derived sclerostin as a regulator of fat metabolism and of reciprocal regulation between bone and adipose tissue.

Biochemical markers of bone turnover and distal radial fracture in men: MR F study. Michael Prediger¹, Birgit Hanusch², Roger Francis³, Stephen Tuck², Harish Datta^{*4}. ¹Blood Sciences, The newcastle upon tyne hospitals nhs foundation trust, United Kingdom, ²Musculoskeletal Research Group, Institute of Cellular Medicine, Newcastle University, United Kingdom, ³Institute for Ageing & Health, Newcastle University, United Kingdom, ⁴Newcastle University, United Kingdom

It has been suggested that distal forearm fractures represent an early and sensitive marker of skeletal fragility in Caucasian men. We tested the hypothesis whether men with higher bone turnover, reflected by elevated levels of bone turnover markers (BTMs), would have an increased risk of distal radial fracture. We measured both the established as well as newer biochemical markers of bone turnover (BTMs). This investigation is an age- and gender-matched case-controlled study and subjects were recruited from one geographical location in the UK over a period of 24 months. Patients with distal forearm fracture were recruited within six months of the fracture; age-matched control subjects without fracture were recruited at any time throughout the investigation. All subjects were Caucasian males over 50 years. Fasting serum and plasma were collected from controls subjects (n=60) and men with distal radial fracture (n=60) after minimum of six months following fracture and stored at -80°C. The following serum BTMs were measured: type I collagen N-propeptide (PINP); β -terminal cross-linked telopeptide of type I collagen (CTX); sclerostin, fibroblast growth factor (FGF23); dickkopf-related protein 1 (DKK1). The fracture group had significantly lower BMD at the hip (mean (SD) femoral T-score of -0.953 (0.943) vs. -0.401 (0.975); $p < 0.001$) and at the lumbar spine BMD (-0.933 (1.392) vs 0.091 (1.750); $p < 0.01$). But there were no significant differences in age, weight, height or BMI. The concentration of the established BTMs PINP (38.94 (15.11) vs 33.5 (11.97), $p < 0.0005$) and CTX (0.45 (0.18) vs. 0.37 (0.18), $p < 0.05$) was significantly higher in the fracture group compared with the controls. In contrast, the serum concentration of sclerostin was lower in the fracture group (0.75(0.31) vs 0.89(0.51), $p < 0.05$). However, DKK1 and FGF23 showed no significant differences between the two cohorts. The correlation of BTMs with BMD revealed strong positive correlation between sclerostin and the lumbar spine (Pearson's $r = 0.400$, $p = 0.0001$) and total hip (Pearson $r = 0.266$, $p = 0.003$) Z-scores. Whereas PINP showed significant negative correlation with BMD with hip Z-score (Pearson's $r = -0.323$, $p = 0.0003$). The suppression of sclerostin concentration in fracture group is likely to reflect lower osteogenic activity and possible activation of bone formation following fracture. In conclusion, our findings show that men with distal radial fracture have increased bone turnover.

Bone and serum manganese content in osteoporotic and normal subjects with hip replacement. Werner Maurer-Ertl¹, Joerg Friesenbichler¹, Ulrike Pirker-Frühaut¹, Michael Maier¹, Doris Wagner¹, Thomas Pieber¹, Andreas Leithner¹, Astrid Fahrleitner-Pammer^{*1}, Karin Amrein². ¹Medical University of Graz, Austria, ²Medical University of Graz, Division for Endocrinology & Metabolism, Austria

Introduction

Manganese (Mn) is an essential trace element required as cofactor in many enzymes, particularly in metabolism and in the antioxidant system. Recently, a pivotal role of manganese nutrition content has been suggested for the biomechanical properties of deer antlers (increased work to peak force). The purpose of this study was therefore to test if the manganese content in bone is different in subjects with and without osteoporosis.

Methods

In a cross-sectional, observational study, we sampled bone biopsies from the femoral neck and the corresponding iliac crest in patients with elective hip replacement for coxarthrosis or avascular necrosis of the femoral head. Dry ashed bone samples were used to assess manganese content. Blood samples and DXA measurements at the lumbar spine, the hip and the radius (Lunar, GE) were performed in all patients. Osteoporosis was defined by a T-Score ≤ 2.5 SD in DXA.

Results

38 patients aged 67 ± 13 years were included (17 men, 21 women, BMI 28.6 ± 8.6). There was no significant difference between osteoporotic and normal subjects neither for manganese bone content at the femoral neck (0.07 vs. 0.06 $\mu\text{g/g}$, $p = 0.78$), iliac crest (0.10 vs. 0.19 $\mu\text{g/g}$, $p = 0.24$) nor Mn serum levels (9.36 vs. 8.91 $\mu\text{g/l}$, $p = 0.61$). Mn serum levels did also not correlate with bone content (Pearson's correlation for femoral neck 0.200, $p = 0.24$; iliac crest 0.082, $p = 0.71$). Interestingly, the Mn content of the weight-bearing site (femoral neck) was almost threefold and significantly lower than at the non-weight-bearing site iliac crest (0.06 vs. 0.15 $\mu\text{g/g}$, $p < 0.01$)

Discussion

In this first human study on bone mineral Mn content of bone biopsies from weight-bearing and non weight-bearing sites, we found no significant difference between osteoporotic and normal subjects. Although we have not assessed biomechanical properties of bone, our small pilot study does not support a pivotal role in human bone biology as previously suggested in deer.

Determinants of Serum FGF23 and Sclerostin in Elderly Hospitalized Individuals. Luigi Gennari^{*1}, Claudio Vitali², Stefano Rotatori³, Daniela Merlotti⁴, Gualberto Gussoni⁵, Daniele Diacinti⁶, Luigi Sinigaglia⁷, Antonella Valerio⁵, Aurora Patti⁸, Maria Stella Campagna⁸, Maria Beatrice Franci⁸, Barbara Lucani⁸, Stefano Gonnelli⁸, Ranuccio Nuti⁸. ¹University of Siena, Italy, ²Internal Medicine, Hospital of Piombino, Livorno, Italy, ³Department of Medicine Surgery & Neurosciences University of Siena, Italy, ⁴Division of Genetics & Cell Biology, San Raffaele Scientific Institute; Department of Medicine, Surgery & Neurosciences University of Siena, Italy, ⁵FADOI Foundation, Research Department, Italy, ⁶Section of Osteoporosis & Musculoskeletal Diseases, Department of Radiological, Oncological & Anatomical-Pathological Sciences, University "La Sapienza", Italy, ⁷Rheumatology, "G. Pini" Institute, Italy, ⁸Department of Medicine Surgery & Neurosciences University of Siena, Italy

Sclerostin (SCL) and FGF23 are osteocyte-secreted factors with a major role in bone turnover and mineral homeostasis. Despite their skeletal effects, variations in their circulating levels were also described in patients with diabetes, chronic renal failure (CRF) and/or cardiovascular disease. In order to better characterize the determinants of circulating SCL and FGF23 and their relationships with bone turnover or fractures we assessed their levels in peripheral blood samples from the POINT (Prevalence of Osteoporosis in Internal medicine) study cohort (n=1199 patients, mean age 75 ± 8 yrs), a cross-sectional multicenter sample that was specifically designed to assess the prevalence of morphometric vertebral fractures in patients hospitalized in Internal Medicine Units (*Bone 2015;74:114-20*). For each patient, the index of coexistent disease (ICED, which assesses the severity and the index of physical impairment for each disease category according to 5 levels of severity) was calculated. Serum SCL levels were positively correlated with CTX ($p < 0.05$), creatinine ($p < 0.0001$) and inversely with physical activity score ($p < 0.05$), while FGF23 levels were positively correlated with PTH ($p < 0.05$) and creatinine ($p < 0.05$). In the overall sample, serum SCL did not significantly differ between patients with or without prevalent fractures or morphometric vertebral fractures. A significant association was observed between FGF23 levels and prevalent nonvertebral fractures ($p < 0.005$) but not morphometric vertebral fractures. Either SCL or FGF23 levels progressively increased with the increase of comorbid conditions, particularly in subjects with the highest ICED levels of severity for cardiovascular disorders (mainly coronary heart disease), cerebrovascular diseases, diabetes and CRF. After exclusion of subjects with all those comorbid conditions, the association between FGF23 levels and fractures became nonsignificant, while serum SCL levels were significantly lower in patients with morphometric vertebral fractures than in patients without fractures (36.0 ± 14 vs. 41.5 ± 18 pmol/L, $p < 0.05$). The opposite association was observed when patients with cardiovascular disorders, diabetes and/or CRF were considered, with statistically significant higher levels of SCL in patients with morphometric fractures (58.3 ± 20 vs. 43.1 ± 19 pmol/L, $p < 0.01$). The mechanisms underlying the increase in either FGF23 or SCL levels in the presence of these extraskelatal disorders remain to be investigated.

Examining phospholipids interference in LC-ESI-MS/MS measurements of 25-hydroxyvitamin D in long term storage samples. Jonathan Tang*¹, Holly Nicholls², Milka Budnik-Zawilska², John Dutton², Isabelle Picc², Chris Washbourne², William Fraser². ¹University of East Anglia, Norwich, UK, United Kingdom, ²University of East Anglia, United Kingdom

Background: Endogenous phospholipids in biological fluids present a major problem in liquid chromatography tandem mass spectrometry (LC-MS/MS) analysis. Due to their strong retention characteristics in reversed phase chromatography phospholipids are often very difficult to separate from analytes of interest. This co-elution leads to areas of suppression or enhancement in the chromatogram which in turn can cause analytical errors. The use of matrix matched reference standard materials with isotopically labelled internal standard are likely to improve accuracy of 25 hydroxyvitamin D (25(OH)D) measurements. However, we observed greater level of phospholipids present in human serum samples after long periods of -20°C storage, and found significant variability on 25(OH)D measurements when assayed retrospectively by isotopic dilution protein precipitation method.

Objective: We developed an approach to monitor and assess the level of phospholipids in samples and investigate the effects of long term storage on 25(OH)D measurements. We have developed an effectiveness phospholipid elimination technique using Supported Liquid Extraction (SLE) and evaluated improvement to assay recovery.

Method: Serum samples from a human vitamin D clinical study stored in -20°C for up to 10 years were selected from various time points and analysed retrospectively for 25(OH)D using protein precipitation and lipid removing extraction techniques. Phospholipids were monitored using *m/z* 184 Da productions.

Results: A near tenfold increase in phospholipids was observed in serum samples undergone long term storage samples and found to be directly proportional to the length of storage. Retrospective measurements of total 25(OH)D using non phospholipid removing method showed a maximum of 40.5% variability when compared to original measurement.

Conclusion: Our study showed phospholipids present in samples increases over time and have profound effect 25(OH)D measurements. We have developed sample clean up protocols using SLE that substantially reduce the presence of phospholipids and significantly improve analyte recovery in older samples. From our findings we concluded that phospholipid interference is a major concern that could result in misinterpretation of vitamin D measurements. Removal of phospholipid is essential in clinical studies involved the use of 25(OH)D measurement particularly in retrospective studies where samples from long term storage are used.

Performance of a Novel Automated TRACP 5b Immunoassay in Renal Disease Patients. Jussi Hallee*¹, Jani Salmivaara², Henna Ek², Tiina Lehto³, Tommi Vaskivuo³. ¹Pharmatest Services Ltd, Finland, ²Valirx Finland Ltd, Finland, ³NordLab Oulu, Finland

Tartrate-resistant acid phosphatase isoform 5b (TRACP 5b) is released into the blood circulation from osteoclasts and is considered as a marker of osteoclast number. Human serum contains a closely related isoform TRACP 5a derived from inflammatory macrophages that has a different pH optimum and smaller active site space for substrates than TRACP 5b. A previously developed manual immunoassay for TRACP 5b (BoneTRAP®) uses a monoclonal antibody that binds both TRACP 5a and 5b, but no other interfering acid phosphatases in serum. The assay utilizes the difference in pH-optimum of TRACP 5a and 5b to minimize cross-reactivity to TRACP 5a. While the cross-reactivity of the assay to TRACP 5a is usually less than 10%, it can be a problem in cases with highly elevated TRACP 5a values. A recently developed automated TRACP 5b immunoassay uses the same monoclonal antibody than the manual assay, and a large substrate that does not fit into the active site of TRACP 5a, completely preventing cross-reactivity. Previous studies have shown that renal function has no effect on manually determined TRACP 5b values. In this study we have compared the manual and automated TRACP 5b assays for their performance in patients with impaired renal function. Serum samples were collected from 65 patients, including 38 patients with glomerular filtration rate (GFR) below 15 ml/min/1.73 m². C-terminal cross-linked telopeptides of type I collagen (CTX-I), intact procollagen I N-terminal propeptide (PINP), bone-specific alkaline phosphatase (BAP) and intact parathyroid hormone (PTH) were measured with automated assays. As expected, renal function had no effect on the manually determined TRACP 5b values, or the PINP and BAP values, while CTX-I and PTH values were substantially (3-5 -fold) elevated in patients with GFR under 15 ml/min/1.73 m². The correlation coefficient between the manual and automated TRACP 5b assays was 0.92, and renal function did not affect TRACP 5b values determined with the automated assay. We conclude that TRACP 5b measured with the automated assay can be used as a marker of bone resorption in patients with impaired renal function without the need to worry that renal function would affect the results. These results suggest that the method could be used to demonstrate elevated bone resorption due to renal osteodystrophy in end-stage renal disease patients.

Bisphosphonate Associated Femur Fractures Treated with Teriparatide. Michelle Lalinde*¹, Deborah Aggers¹, Tina Savage¹, Ed McCarthy², Paul Miller¹. ¹Colorado Center for Bone Research, USA, ²John Hopkins University, USA

We performed an uncontrolled longitudinal study examining the response of 24 months of teriparatide (20 mcg SQ daily) on bone remodeling in subjects with bisphosphonate-associated atypical sub-trochanteric femoral fractures. The primary endpoint of our study was to compare the mineralizing surface to bone surface (MS/BS) in the cancellous compartment of the iliac crest. This was assessed by bone biopsy using tetracycline labelling, pre- and post-12 months of teriparatide. The secondary endpoints of the study were to measure changes in bone turnover markers, fracture healing, and subjects' report of pain.

A total of 14 post-menopausal subjects (mean age 68.3 years) with a documented atraumatic diaphyseal femoral fracture within 12 months of screening were recruited. The mean duration of bisphosphonate exposure was 105 months (range: 36 -174 months). Bone turnover marker procollagen type 1 N-terminal propeptide (PINP) was obtained every six months during treatment. In addition, dual-energy x-ray absorptiometry (DXA) was performed at baseline, 12 and 24 months. CT scan was performed at baseline, month 12 and month 24, to assess for fracture healing.

Results revealed that there was heterogeneity in bone turnover at baseline when assessed by quantitative histomorphometry. The MS/BS (Figure 1), an indicator of osteoblast activity, increased in 12 out of the 14 subjects. The two subjects that did not have an increase in MS/BS also had a decrease in PINP at months 12 and 24. No subject sustained a new or worsening vertebral fracture while on treatment. However, two subjects sustained atypical femoral fractures on the contralateral femur side after 8 days and 254 days of teriparatide. One of these subjects also had no tetracycline labels. Eleven of the subjects had intramedullary rods in the femur prior to entry in the study. After 24-months of treatment, two of the three non-surgical subjects showed fracture site healing, assessed by CT scan. Using a visual analog pain scale (Figure 2), 13 of the subjects had improved pain scales at the fracture site from baseline to 24 months.

In this small sample size, the majority of subjects seemed to respond to teriparatide. However there appears to be a small portion of subjects who may be non-responders, as evidenced by inconsistency of fracture healing, bone markers and quantitative histomorphometry.

The role of high-resolution peripheral quantitative tomography (HR-pQCT) in musculoskeletal research is rapidly expanding through its inclusion into multicenter clinical trials and observational cohort studies, such as the Osteoporotic Fractures in Men Study (MrOS, an observational study being conducted at 6 clinical sites). Previously¹, we found that positioning variability is an important source of imprecision. In this study, we aimed to reduce inter-operator positioning precision errors through standardized training.

The training procedure included theoretical and practical demonstrations led by a vendor representative and MrOS investigator, followed by simulated scan positioning exercises using software developed at UCSF. The software reproduced the graphical user interface of the XtremeCT (Scanco Medical AG) and provided the user with a series of scout images of the radius and tibia to perform simulated scan positioning. In this study, we enrolled 6 new operators with various background and no previous HR-pQCT experience, who required certification to perform HR-pQCT exams for MrOS. After successful completion of the software training and evaluation, operators performed a blinded positioning exercise to test intra- and inter-operator reproducibility. In these exercises, we measured positioning precision and the corresponding precision error in cortical and trabecular bone measurements. Results from the MrOS

trainees were compared to previously acquired data from experienced operators with a heterogeneous training history¹.

Intra-operator precision errors of the trainees were not significantly different compared to the experienced operators (e.g. Ct.Th: 3.2% vs. 3.5%), indicating that new operators achieved equivalent reliability to experienced operators (Table 1). Inter-operator precision errors of trainees in this study were half than errors of the experienced operators (e.g. Ct.Th: 4.9% vs. 8.4%, p<0.001) and approached the level of intra-operator precision. Thus the training regimen led to the new operators achieving a superior level of multicenter reproducibility.

In conclusion, we found that inter-operator variability in scan positioning can be significantly reduced with standardized training procedures in a controlled environment. With the purpose of making our training platform available to the community, we are developing a version of the training and evaluation tool that will be openly disseminated as a web application.

Vertebral strength index calculated by finite element method using bone material properties of non-diabetes subjects does not reflect the bone fragility of the patients with type 2 diabetes mellitus. Masahiro Yamamoto*, Nobuaki Kiyohara, Noriko Nakata, Toshitsugu Sugimoto, Shimane University Faculty of Medicine, Japan

Purpose: Patients with type 2 diabetes mellitus (T2DM) have an increased risk of vertebral fractures compared to non-T2DM controls independent of bone mineral density (BMD) (JBMR 2009), suggesting that poor bone quality causes increased bone fragility. It has been reported that the predictive power of vertebral fractures (VFs) in postmenopausal women by quantitative computed tomography-based nonlinear finite element method (QCT/FEM) was superior to that by BMD. However, availability of QCT/FEM for assessment of the bone fragility of the patients with T2DM remains unknown. The aim of this study is to investigate whether vertebral strength evaluated by QCT/FEM in the patients with T2DM is useful for assessment of bone fragility.

Methods: Vertebral strength index (VSI) of second lumbar spine calculated by QCT/FEM in the same method as the previous report (slice thickness: 2 mm, a pixel width: 0.35 mm, element: 2-mm tetrahedron and 2-mm triangular plates, Young's modulus and yield stress of each element: values calculated from the equations

obtained from non-diabetic patients reported by Keyak et al., and Poisson's ratio: 0.4). We compared parameters of bone metabolic markers including lumbar spine BMD and VSI between Japanese T2DM patients with and without vertebral fractures [54 postmenopausal women and 92 men over 50 years old].

Results: One or more vertebral fractures assessed by X-ray were observed in 20 women and 39 men whose mean ages were 65.6 and 63.4, respectively. VSI of men group was significantly higher than that of women (6.0 ± 2.1 vs. 4.3 ± 2.4 kN, respectively). Multiple regression analysis including independent variables of age, urinary NTX and spine BMD selected by simple regression analysis showed that VSI were significantly and inversely correlated with spine BMD and positively related with age in both genders. In contrast to the previous report, there was no significant difference in VSI between the subjects with and without VFs, even if multiple regression analysis was performed after adjusting for age, BMI, HbA1c, duration of T2DM and spine BMD.

Conclusion: The estimation of the bone strength of T2DM patients by established QCT/FEM using material properties obtained from non-diabetic subjects may be unable to reflect real bone fragility. This observation suggested that the poor bone quality of T2DM patients, in part, may be caused by inferior bone material strength compared with non-diabetic subjects.

A Method to Assess Bone Mineral in the Mandible Using the Norland DXA System. Jingmei Wang*¹, MinMin An², Fan Yang², Shao Yang Guan², Lei Liu², Wei Zhang², Tom Victor Sanchez³. ¹Bone Health Division, Norland at Swissray, China, ²Wuhu Second People's Hospital in Anhui Province, Wannan Medical College, China, ³Bone Health Division, Norland at Swissray, USA

The mandible is known to have high bone turnover, increased vascularity and greater susceptibility to osteoclast and osteoblast and has long been pursued by DXA as a site from which to monitor early change in response to treatment or disease. We evaluate a method developed to directly assess bone mineral in both the Body and Ramus of the mandible.

A Norland XR-800 was used to develop a procedure to evaluate bone mineral content in the Body and Ramus of the mandible. Patients were positioned on the scanner laying on their side with the head supported by a positioning platform so that the upper and lower mandibles were well superimposed on each other. A scan region width of 12cm centered over the mandible was set to start at the level of the eyebrow and end below the level of the chin. Scans were done with a resolution of 1.0x1.0mm and typically completed in a couple of minutes. The study of the mandible examined six dentate subjects—each undergoing four examinations with totally repeated positioning—to assess repeatability of the study. The studies were evaluated to assess the distribution of bone mineral content in the entire Body and Ramus of the evaluated mandibles and to assess repeatability of selected regions within the Body and Ramus of the mandibles.

Examining mandibular mineral distribution over 5x5mm regions demonstrated greater ranges of contents in the Body of the mandible—from lows of 0.141 gm to highs of 0.7gm—than seen in the Ramus—from lows of 0.141gm to highs of 0.42gm. The results point to considerable differences in how material is distributed and may indicate that both regions should be independently monitored to locate changes over time. Repeatability studies of an operator defined 10mmx10mm region showed average repeatability of 2.14% in the Body of the mandible—allowing an assessment of significant change with changes of 6.14%.

The study demonstrates that the Norland XR-800 when using specific positioners is able to document the distribution of bone mineral content in the Body and Ramus regions of the mandibles and can reflect relatively small changes in bone mineral in the Body of the mandible. Given that the mandible is reportedly able to undergo swift changes in bone, the documented repeatability of the study should allow swifter identification of changes in bone mineral content in subjects with changing bone density.

Correlation of albumin/globulin ratio (A/G ratio) with forearm bone mineral density in women above 50 years of age. Kayoko Furukawa*, Kunitaka Menuki, Yukichi Zenke, Yoshiaki Yamanaka, Hideyuki Hirasawa, Takafumi Tajima, Akinori Sakai. Department of Orthopaedic Surgery, University of Occupational & Environmental Health, Japan

[Objective] We aimed to determine whether blood test values correlates with bone mineral density by body part.[Subjects and Methods] We included data on 78

forearms of 78 women age 50 or older treated for distal radius fracture at our hospital from October 2007 to October 2012. All underwent DXA (dual-energy x-ray absorptiometry) scan of the 2nd-4th lumbar vertebrae, femoral neck, and forearm bone (divided into 3 parts: ultra distal [UD], mid distal [MD], and shaft [1/3]). The following blood test values were determined: ALB, A/G ratio, AST, ALT, LDH, ALP, GTP, Ca, P, BUN, Crea, eGFR, WBC, Hb, Hct, and PT-INR.[Statistical analysis] Using Pearson product-moment correlation coefficients, we analyzed the DXA scan results (lumbar vertebrae, femur, and 3 forearm parts) for correlations with age, height, weight, BMI, and blood test values.[Results] ALB, the A/G ratio, LDH, Hb, and PT-INR correlated positively with bone mineral densities of the forearm (UD, MD, and 1/3) and femur (neck), but not with those of the lumbar vertebrae. TP, AST, ALT, ?GTP, P, BUN, Crea, eGFR, WBC, Hb, and Hct did not correlate with any bone mineral density values. [Discussion] The A/G ratio had a stronger correlation with the bone mineral density of the proximal 1/3 (0.39), which has a high percentage of cortical bone, than with those of MD (0.38) and UD (0.26). The A/G ratio also correlated with femoral neck bone mineral density (0.23), but not with those of the lumbar vertebrae. Our results thus suggest a correlation between cortical bone amount and albumin metabolism.[Conclusions] Our statistical analyses identified correlations between blood test values and bone mineral density by body part in middle-aged and elderly females with distal radius fracture. Serum albumin and the A/G ratio correlated positively with forearm and femoral neck bone mineral densities, but not with lumbar vertebral bone mineral densities.

Clinical Applicability of TBS in Individuals with Small Bone Sizes and Low Bone Mineral Density by DXA: A Case Report. Bruno Camargos¹, Nathalia Gomes², Pedro Alvarenga*³, Caroline Silva³, Milena Leite³, Barbara Silva⁴, Angelica Tiburcio⁵. ¹Mater Dei Hospital, Brazil, ²Santa Casa de Belo Horizonte, Brazil, ³UNI-BH, Brazil, ⁴Uni-BH, Santa Casa de Belo Horizonte & Felicio Rocho Hospital, Brazil, Brazil, ⁵Santa Casa Hospital, Brazil

Measurement of areal bone mineral density (aBMD) by dual X-ray absorptiometry (DXA) is considered the gold standard for diagnosis of osteoporosis and fracture risk assessment. Nevertheless, DXA has a number of limitations. aBMD is influenced by bone size such that true BMD is underestimated in those with smaller bones and overestimated in those with larger bones. Accordingly, we have recently reported a case of a 50-yr-old man, with very short stature, with low BMD by DXA, but normal volumetric BMD (vBMD) by quantitative computed tomography (QCT). Trabecular bone score (TBS), a textural index of trabecular microarchitecture evaluated by pixel gray-level variations in the lumbar spine (LS) DXA image, appears to be independent of bone size. To this end, we aimed to assess TBS in this very short man, considering that TBS may also offer advantages over DXA in patients whose lower aBMD does not reflect bone strength.

Case report: A 50-yr-old man with SHORT syndrome (an acronym for Short stature, Hyperextensibility of joints and/or inguinal Hernia, Ocular depression, Rieger anomaly, and Teething delay) was referred to our Bone Unit for evaluation of osteoporosis. Further history revealed type 2 diabetes, hypertension, and glaucoma. His medications included insulin, enalapril, amlodipine, aspirin, simvastatin, and calcium supplements. Physical examination was remarkable for his short stature, 129 cm in height, distinctive facial features (facial gestalt), and low visual acuity. His BMI was normal at 21.9 Kg/m². Extensive evaluation ruled out secondary causes of osteoporosis. Lateral spine radiographs did not show vertebral fractures, and his medical history was negative for fragility fractures. BMD by DXA showed T-scores of -3.5 at the LS, -3.9 at the femoral neck, -2.9 at the total hip, and -3.1 at the 1/3 radius. QCT (QCT Pro 5.1, Mindways, Austin, TX) showed normal vBMD at the LS (L1-L2: 148 mg/cm³) and low, but not indicative of osteoporosis, vBMD at the femur (total hip: 112 mg/cm³; femoral neck: 117 mg/cm³). Site-matched LS TBS was then performed using TBS iNsite software (version 2.1; Medimaps, Switzerland). Remarkably, LS TBS was normal at 1.392.

We report a case of a man, with extremely short stature, with low BMD by DXA, but normal vBMD by QCT and normal TBS. These findings suggest that TBS may be helpful in selecting individuals whose lower aBMD seems to reflect their smaller bone geometry rather than reduced bone strength and fracture risk.

Disclosures: Pedro Alvarenga, None.

Distal radius cortical microstructure and calculated strength predict incident fractures independently of FRAX in postmenopausal women. Emmanuel Biver*¹, Claire Durosier¹, Andrea Trombetti¹, Thierry Chevalley¹, Bert van Rietbergen², René Rizzoli¹, Serge Ferrari¹. ¹Division of Bone Diseases, Geneva University Hospitals & Faculty of Medicine, Switzerland, ²Department of Biomedical Engineering, Eindhoven University of Technology, Netherlands

The contribution of bone microstructure determination to fracture risk prediction, in addition to prior fractures, clinical risk factors and areal bone mineral density (aBMD), all integrated in FRAX tool, remains unknown. We investigated the independent contribution of bone microstructure alterations to fracture risk assessment in postmenopausal women. Seven hundred thirty seven women (age 65.0 ± 1.4 years), enrolled in the Geneva Retirees Cohort (GERICO) study, were prospectively followed for fracture occurrence over 3.4 ± 0.9 years. At baseline, cortical (Ct) and trabecular (Tb) bone density (vBMD) and microstructure at distal radius and tibia were assessed by HR-pQCT (Xtreme CT, Scanco Medical, Bassersdorf, Switzerland), in addition to aBMD by dual X-ray absorptiometry. Prior fragility fractures (FF) were defined as clinical fractures occurring after 45 yrs of age. Sixty one incident clinical fractures (excluding fingers, toes and skull) occurred in 58 women. Wrist (n = 15), ankle (n = 10), humerus (n=7), vertebrae (n=5) and rib (n = 5) were the most common sites. At baseline, the prevalence of FF and osteoporosis (OP) was higher in women with incident fracture than without incident fracture (FF 53% vs 27%, p<0.001, OP 33% vs 19%, p=0.012), whereas their FRAX probability of major fractures was 15.5% vs 11.8% (p<0.001). Radius and tibia Ct and Tb vBMD and most microstructure parameters were associated with incident fractures: hazard ratios [HR] for one standard deviation decrease of each parameter from 1.30 to 1.59, p<0.05 to 0.001. After adjustment for age and distal radius total aBMD, radius density and microstructure remained significantly associated with fracture risk: adjusted HR (95%CI) of 1.59 (1.09-2.27) for total vBMD, 1.69 (1.14-2.56) for Ct area, 1.39 (1.01-1.89) for Tb number (p<0.05 for all), and 1.96 (1.28-2.94, p=0.002) for stiffness. After adjustment for prior FF and OP status, radius Ct area [1.37 (1-1.89), p=0.047] and stiffness [1.37 (1-1.85), p=0.049] remained significantly associated with fracture risk. After adjustment for FRAX, radius Ct area [1.39 (1.04-1.85), p=0.028], Ct thickness [1.33 (1-1.79), p=0.047] or stiffness [1.37 (1.04-1.82), p=0.027] remained significantly associated with fracture risk. In conclusion, cortical variables predict incident fractures independently of prior FF and OP status, or FRAX, indicating the major role of cortical bone microstructure analysis in identifying women at increased risk of fracture.

High Rates of Prevalent Fracture in Bone Phenotypes Identified by Cluster Analysis of High Resolution Peripheral Quantitative Computed Tomography Parameters. Mark Edwards*¹, Danielle Robinson², Camille Parsons², Kate Ward³, Cyrus Cooper², Elaine Dennison². ¹MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, ²MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, ³MRC Human Nutrition Research, United Kingdom

High resolution peripheral quantitative computed tomography (HRpQCT) has been used to differentiate fracture from non-fracture cases. Studies have demonstrated specific components of bone structure to be deficient in fracture cases. However, these components are significantly correlated and so it may be more appropriate to explore different overall bone phenotypes and their relationships to fracture. The aim of this study was to identify clusters of bone microarchitecture in older men and women and relate them to fracture prevalence and areal BMD (aBMD). We studied 177 men and 159 women, aged 72.1-80.9 years, with HRpQCT (XtremeCT) images (voxel 82µm) of the distal radius. Standard image analyses were performed for assessment of macrostructure, regional densitometry, cortical porosity and trabecular microarchitecture. K-means partitioning cluster analysis was used to identify clusters in men and women separately. Prevalent fracture rates and femoral neck aBMD were determined for each cluster and the clusters were numbered in order of fracture prevalence. Forty four (24.9%) men and 48 (30.2%) women had fractures. Women with fractures were on average 1.7 years older and 3.1 years further from menopause than women who had not fractured (p<0.05). Although analyses were carried out separately in each sex, two morphologically-similar, high risk clusters were identified in each sex. "Cluster 1" contained 26 women (50.0% fractured) and 30 men (50.0% fractured) and denoted a phenotype with mean cortical thickness and cortical volumetric BMD around 1SD below and, in men, mean total and trabecular area more than 1SD above, the sex-specific cohort mean. "Cluster 2" contained 20 women (50.0% fractured) and 14 men (35.7% fractured) and showed a phenotype with mean trabecular density and trabecular number both more than 1 SD below the sex-specific cohort mean. Logistic regression showed fracture rates in these clusters to be significantly higher than the lowest fracture risk cluster (5) (p<0.05). Mean femoral neck aBMD was significantly lower than cluster 5 in women in cluster 1 and 2 (p<0.001 for both), and in men, in cluster 2 (p<0.001) but not 1 (p=0.220). We have identified a cluster (1) that describes a bone phenotype which differs from the conventional view of osteoporosis but with a

high proportion of fractures. In men, this phenotype was not associated with lower aBMD measured by DXA and therefore could be missed by current clinical assessments of osteoporosis.

Influence of vertebral fractures severity and pelvic parameters on global spinal balance in osteoporotic patients. Jacques Fechtenbaum¹, Adrien Etchet¹, Sami Kolta¹, Antoine Feydy², Christian Roux³, Karine Briot*³. ¹Cochin Hospital, rheumatology Department, France, ²Cochin Hospital, radiology Department, France, ³Paris Descartes University, Cochin hospital, Rheumatology Hospital, France

Purpose: Thoracic kyphosis and other postural parameters related to the postural adjustment strategy affect the biomechanical environment of the spine. These parameters can be influenced by vertebral fractures in elderly osteoporotic patients. This study aims to compare the spine curvatures, the pelvic parameters and the global spinal balance of patients aged above 50 years with and without osteoporotic vertebral fractures. Methods: Two hundred patients (95% women) aged 66.5 ± 13.6 years underwent a standardised lateral and antero-posterior full skeleton radiographs in the standing position, by EOS® (a low dose biplanar imaging system) in an upright weight-bearing position. VFs were evaluated according to Genant's classification and the spinal deformity index (SDI). Spinal (thoracic and lumbar Cobb's indices, thoracic tilt (T9 tilt) and lumbar tilt (L1 tilt)) and pelvic (pelvic tilt, sacral slope, and pelvic incidence) parameters were measured. Sagittal global spinal balance was measured using 2 parameters: the C7 plumb line (mm), and the spinosacral angle (SSA in degrees). We compared these parameters in patients with and without vertebral fracture, according to the location and the severity of VFs (SDI). We assessed the discriminative value of the global spinal parameters in patients with at least one vertebral fracture using Area Under the Curve (AUC). We also assessed the variables associated with abnormal SSA. Results: Sixty-nine patients had at least 1 VF, with a mean number of VF of 2.3 ± 1.7 and a mean SDI of 4.2 ± 4.5. In patients with only lumbar VFs (n=11), only lumbar parameters (lower lumbar Cobb's angle and sacral slope and higher lumbar tilt) were modified. In contrast, in patients having only thoracic VFs (N=34), both thoracic, lumbar and pelvic parameters were different than those in patients without VFs. The greater the SDI, the greater were the thoracic Cobb's angle and pelvic tilt and the lesser the lumbar Cobb's angle. Thoracic and lumbar tilts and sacral slope were not affected by SDI increase. The global spine balance assessed by C7 plumbline and SSA was significantly altered in patients with at least one VF, and there was a dose effect of the number and severity of VFs on global spinal balance, significant for all parameters for a SDI value >2. Discriminative value for identification of patients with at least one VF, as assessed by AUCs was 0.652 and 0.706 for C7 plumbline and SSA respectively. SSA has a higher discriminative value than C7 plumb line. For a SSA of 121.8°, sensitivity and specificity were 0.67 and 0.28. Using multivariate analysis, the variables significantly associated with abnormal SSA were: age (OR=0.933 [0.897 - 0.971], p=0.0006), SDI>0 (OR= 0.202 [0.099 - 0.410], p<0.0001) and pelvic incidence (OR= 1.075 [1.040 - 1.112], p<0.0001) with an AUC of the model of 0.8175. Conclusion: Global spinal balance is significantly altered in patients with at least one vertebral fracture with a dose-effect of the number and severities of VFs. Pelvic parameters are relevant in the assessment of global spinal balance.

Nano-CT Analysis of Osteocyte Anomalies in Klotho-deficient Mice. Tomoko Minamizaki*¹, Kaoru Sakurai², Hirohisa Yoshioka³, Yuichiro Takei³, Katsuyuki Kozai⁴, Yuji Yoshiko³. ¹Hiroshima University Institute of Biomedical & Health Sciences, Japan, ²Department of Pediatric Dentistry, Hiroshima University Graduate School of Biomedical Sciences, Japan, ³Department of Calcified Tissue Biology, Hiroshima University Institute of Biomedical & Health Sciences, Japan, ⁴Department of Pediatric Dentistry, Hiroshima University Institute of Biomedical & Health Sciences, Japan

Osteocyte is the most abundant cell type in bone and plays a fundamental role in bone turnover. Morphological changes in osteocytes and osteocyte lacunae are closely related to bone loss and fragility associated with skeletal disorders. Mice homozygous for *Klotho* gene deletion (*kl/kl*) exhibit some aspects resembling human aging, including osteoporosis, and abnormal findings on osteocytes were described in *kl/kl* mice. Computed tomography (CT) is a non-destructive approach to provide three-dimensional x-ray images of the internal structure of an object. µCT for a small scale with increased resolution is often driven by the bone research field, allowing considerable success for bone morphometry in mouse models. However, conventional µCT is limited to cover the entire hierarchical assembly in some case, such as osteocyte parameters. Nano-CT achieves an isotropic voxel size of as low as 100 nanometers and is suitable for investigating the microstructure of bone. We then used nano-CT to determine multiple osteocyte parameters and mineralized bone in *kl/kl* mice versus wild type (WT) mice. Femurs were collected from 6-week-old male mice, fixed in 4% PFA and stored in 70% ethanol. The mid-portion of the diaphysis in the range of 2.4

mm thickness was scanned using SkyScan 1176 or SkyScan 2211 (Bruker), and imaging parameters were optimized to maximize spatial resolution. Reconstruction of raw data was performed using InstaRecon[®], and anisotropy in mineralized components and osteocyte parameters were determined by CT-Analyzer. Regardless of whether *Klotho* is deficient, the 3D orientation of mineralized components was mostly aligned transversely. Osteocyte lacunae were widely but not evenly distributed in *kl/kl* and WT bone. Total number of osteocyte lacunae in total bone volume was higher in WT mice, whereas the number of lacunae per mm³ was higher in *kl/kl* mice. Osteocyte lacunae less than 100 μm³ were distributed in *kl/kl* bone (12.5% of total lacunae) but not in WT bone. Osteocyte lacunar surface density in *kl/kl* mice was higher than that in WT mice. Thus, our data indicate morphological anomalies of osteocyte in *kl/kl* mice can be detected by nano-CT at the 3D microarchitecture level.

Racial and Ethnic Differences in Bone Structure in Young Adult Women and Men. Kristy Nicks^{*1}, Joshua N. Farr², Elizabeth J. Atkinson², Louise K. McCready², Sundeep Khosla². ¹Mayo Clinic, Us, ²Mayo Clinic, USA

Osteoporotic fractures are a major world-wide problem, and it is now well-established that significant geographic variability exists in fracture rates among racial and ethnic groups. A better understanding of factors that contribute to this variability might substantially influence our ability to provide new avenues for prevention and treatment. Primary determinants of fracture risk include bone mineral density (BMD) and bone structure. While several studies have examined racial and ethnic disparities in areal BMD (aBMD) by DXA, bone structural parameters have received insufficient attention. Thus, the purpose of this cross-sectional study was to utilize DXA and HRpQCT to examine aBMD as well as bone macro- and microstructure among healthy young African American (n = 45), Hispanic (n = 44), and Caucasian (n = 145) women and men, age 20-44 years, from Olmsted County, MN, USA. African American women had significantly higher DXA-derived total body aBMD than both Caucasian (by +3.2%) and Hispanic (by +4.8%) women, whereas total body aBMD did not differ between Caucasian and Hispanic women. Further, while no differences were observed in total body aBMD between African American and Caucasian men, Hispanic men had significantly lower total body aBMD than both African American (by -7.5%) and Caucasian (by -4.0%) men. HRpQCT analysis at the distal radius revealed that trabecular bone parameters were similar among the three groups of women, although African American women had significantly thicker trabeculae (by +6.4%) than Caucasian women. There were also no differences in radial cortical volumetric BMD among the three groups of women. By contrast, Hispanic women had significantly thinner radial cortices than both African American (by -12.3%) and Caucasian (by -11.7%) women. Interestingly, sex differences in HRpQCT-derived bone structural parameters were also observed among ethnic/racial groups. In particular, African American men had significantly thicker cortices at both the distal radius and tibia as compared to Caucasian (radius by +10.1%; tibia by 15.1%) and Hispanic (radius by +22.6%; tibia by +17.8%) men. In summary, these data suggest that trabecular and cortical bone structure may vary significantly by both sex and race/ethnicity, which likely contributes to differential fracture rates among these groups both in the United States and globally. Future studies in larger samples of racial/ethnically diverse populations are needed to extend these observations.

VITamin D and Omega-3 Trial (VITAL) bone health study: Clinical factors associated with Trabecular Bone Score in women and men. Anna Ross^{*1}, Amy Yue¹, Nancy Cook², JoAnn Manson², Julie Buring², Trisha Copeland³, Cindy Yu¹, Meryl LeBoff⁴. ¹Brigham & Women's Hospital, Endocrinology, Diabetes & Hypertension Division, USA, ²Brigham & Women's Hospital, Division of Preventive Medicine, Professor of Medicine, Harvard Medical School, USA, ³Brigham & Women's Hospital, Division of Preventive Medicine, USA, ⁴Brigham & Women's Hospital Professor of Medicine, Harvard Medical School, USA

The Trabecular Bone Score (TBS) is derived from textural analyses of spinal dual-energy X-ray absorptiometry (DXA) and is associated with bone microarchitecture and fracture risk. The aim of this study was to test whether baseline TBS differs by sex, race/ethnicity, body mass index (BMI) and other clinical variables.

Methods: The VITamin D and Omega-3 Trial (VITAL) is a double-blind, placebo-controlled trial assessing the role of vitamin D₃ (2000 IU/d) and/or omega-3 fatty acids (FA; 1 g/d) supplements in reducing risks of cancer and cardiovascular disease among 25,874 U.S. participants (men age ≥50 and women age ≥55). VITAL: Effects on Bone Structure and Architecture, an ancillary study among a VITAL subcohort, is determining effects of the interventions on bone with bone health phenotyping and clinical assessments at baseline and 2 yrs post-randomization (LeBoff et al. *Contemp Clin Trials* 2015). Baseline spinal BMD using DXA (Discovery

W, Hologic Inc, Bedford, MA) and TBS using TBS iNsite software (version 2.1; Medimaps Group, Geneva, Switzerland) were determined at L1-L4. Differences between unadjusted means were analyzed using analysis of variance or tests for trend.

Results (Table 1): TBS was measured in 609 participants (324 men and 285 women aged 63.7±6.0 yrs; BMI≤37 kg/m²). Mean TBS was greater in men than women (1.34±0.10 vs 1.31±0.08, p<0.001). Younger age was associated with higher TBS (p=0.02). TBS was lower at higher BMIs and in participants who used medications linked to fractures (p=0.003). TBS was lower in participants with a history of fragility fracture (trend p=0.07). History of diabetes was associated with lower TBS (1.30±0.13 vs 1.33±0.09, p=0.04). Alcohol consumption was positively associated with higher TBS (p=0.006). Greater physical activity ≥15.0 MET-hrs/wk was associated with higher TBS (p<0.001). Knee osteoarthritis was associated with lower TBS (p=0.02). There were no significant differences in TBS when analyzed according to race/ethnicity, multivitamin use, rheumatoid arthritis history, smoking status, or caffeine intake.

Summary: Higher TBS was associated with clinical variables including younger age, male sex, BMI<30 kg/m², higher MET-hrs/wk, moderate alcohol intake, and absence of diabetes, knee osteoarthritis, or medications linked to fracture. Ongoing follow-up studies at 2 yrs post-randomization will elucidate the effects of moderately high doses of vitamin D and/or omega-3 FA on TBS and other bone health measures.

Mexican population is composed mostly of Native American, European and a minimal contribution of African population. Osteoporosis, a disease characterized by low bone mineral density (BMD), is a common health problem in Mexican population. To date, Genome-wide SNP association (GWA) studies have provided an important opportunity to discover genes with sequence variants contributing to bone density variations. However, with a few exceptions, GWA studies have been focused on populations of European descent, and these results cannot, be directly extended to other populations, as the Mexican-Mestizo population. The aim of this

Aim: Bone mineral density (BMD) can be expressed as the ratio of bone mineral content (BMC) to bone area (BA) reflecting differences in bone mass relative to size. Previously we identified several loci associated with BMD at some skeletal sites, but not at others. Our aim was to perform a follow-up study to elucidate why some BMD loci exhibit site specificity by studying how genetic effects on BMD variation are the result of processes influencing BMC and BA.

Methods: Genome-wide association (GWA) analyses were performed on 12,713 children and adolescents from 5 cohorts, using imputed genetic data in relation to site-specific DXA measures of BMD, BMC and BA [at the skull (SK), upper-limbs (UL) and lower-limbs (LL)]. Multiple linear regression models based on expected allelic dosages included sex, age, height, weight and ancestry informative principal components. Meta-analyses were conducted using an inverse variance fixed-effects method.

Results: Variants in four novel loci were associated at genome-wide significance: two with SK-BMD (*CSNK1G3*, $P=2 \times 10^{-8}$ and *KCNJ16*, $P=2 \times 10^{-8}$), one with LL-BMC (*PCDH20*, $P=5 \times 10^{-8}$) and one with LL-BA (*GDF5*, $P=7 \times 10^{-11}$). Across most loci, patterns of association with BMD were largely similar to those of BMC, suggesting that the majority of loci either influenced BMC independently of BA or that their influence on BMC is substantially larger than on BA. Variants in three loci exerted larger effects on BA when compared to BMC, resulting in complete attenuation of the association with BMD at the skull (*RPS6KA5*), upper limb (*GDF5*) and lower limb (*CPED1* and *GDF5*). Site-specific genetic associations previously observed for *CPED1* (i.e. variants associated with BMD of the skull and upper limbs, but not lower limbs), were replicated and appeared to be a consequence of variants affecting BA to a greater extent than BMC at particular skeletal sites (i.e. lower limbs), but not others (i.e. skull and upper limbs).

Conclusions: Most BMD-associated loci influence BMC to a larger degree than BA; however other loci exert equivalent or larger effects on BA relative to BMC and as such are unlikely to be detected by GWA studies of BMD. In some cases site-specific genetic effects on BMD appear to be modulated by larger effects on BA relative to BMC. Loci

study was perform an initial trial of genome-wide association study to identify genetic loci that influence bone mineral density in Mexican-Mestizo postmenopausal women. A total of 425 unrelated postmenopausal women of the state of Morelos were included in the stage 1, and 435 postmenopausal women of the state of Guadalajara, were included in stage 2. Risk factors were recorded and BMD was measured in total hip, femoral neck and lumbar spine using dual-energy X-ray absorptiometry. The stage 1 genotyping of 300,739 bi-allelic SNPs was performed using the Illumina HumanCytoSNP-12 v2.1 BeadChip. After QC steps, 225,635 SNPs and 411 Mexican mestizo women were retained for statistical analysis of stage 1. In this stage none SNPs pass the genome-wide significance level, but fifteen provided P values =5 x10-05 for Femoral Neck BMD and Lumbar Spine BMD. For stage 2, we focus on two SNPs located in the (6q25) region, because this region has been previously reported associated in European and Asiatic populations. Linear regression analyses adjusted by age, body mass index and ancestry, showed that these two SNPs were associated with Femoral Neck BMD under recessive model: rs17081341 located in the CCDC170 and the rs6904364 in the RMND1 genes, (P=0.020 and P=0.023, respectively). It is noteworthy, that the frequency of the SNP rs17081341 was lower in European and African population (MAF=0.03), that in Mexican population (MAF=0.17). In conclusion, our data replicate previous associations in the 6q25 region in European populations and suggest CCDC170 and RMND1 as a potential candidate genes for BMD variation in Mexican Mestizo postmenopausal women, however, the sample size is small for the type of study, therefore further studies in other Mexican populations and with a large sample size are needed.

Disclosures: Rafael Velazquez-Cruz, None.

Exploring the *FLJ42280* Genomic Region to Identify Genetic Variants Associated with Osteoporosis. Neus Roca-Ayats¹, Marina Gerousi¹, Nuria Martinez-Gil¹, Esteban Czwan², Roser Urreiziti¹, Natalia Garcia-Giralte³, Guillem Pascual¹, Leonardo Mellibovsky³, Xavier Nogues³, Adolfo Diez-Perez³, Daniel Grinberg¹, Susana Balcells^{*1}. ¹Dept. Genetics, Fac. Biology, University of Barcelona, CIBERER, IBUB, Spain, ²Roche Diagnostics Deutschland GmbH, Germany, ³URFOA, IMIM, RETICEF, Parc de Salut Mar, Spain

Genome-wide association studies (GWAS) have identified a number of variants associated with bone mineral density (BMD) and osteoporotic fracture. Signals emerging from GWAS are frequently located in non-coding poorly studied regions. In addition, most of these GWAS SNPs are likely to be in linkage disequilibrium with ungenotyped causal variants. Recent studies have pointed out *FLJ42280* as a susceptibility gene for osteoporosis. In the meta-analysis of Estrada *et al.* (2012), an intronic SNP (rs4727338) was significantly associated with BMD and osteoporotic fracture. Likewise, other studies demonstrated correlation of other intronic SNPs (rs7781370, rs10429035 and rs4729260). Yet, *FLJ42280* is a poorly studied gene with unknown link with bone biology.

We aimed to explore the genetic variability of the *FLJ42280* locus associated with BMD by two approaches. On the one hand, we performed an eQTL analysis to determine whether the GWAS SNPs correlated with gene expression levels. We used 210 unrelated HapMap individuals' genotypes and expression levels from the whole-genome Illumina lymphoblastoid cell line gene expression data. None of these SNPs showed influence on expression levels of cis-genes. On the other hand, targeted resequencing of the *FLJ42280* region was carried out in two groups of 50 women from the BARCOS cohort (Spanish postmenopausal) presenting either extreme low bone mass (LBM) or high bone mass (HBM). In each woman, a 28 kb region was amplified in 7 overlapping fragments by LR-PCR. All amplicons were pooled into two groups, one of HBM and another of LBM, prior to massive parallel sequencing at 3600x coverage per pool with Roche's 454 Junior technology. After quality filtering, alignment and variant calling, the number and frequency of variants were statistically compared between the two groups and their overlap with functional elements from ENCODE was analyzed. Preliminary results are shown in Table 1. The number of low frequency variants (LFVs) was balanced between the two groups. As for frequency differences of all variants between the two groups these were all below the statistical power of the experimental design although we found 2 common variants and 7 LFV showing trend. We did find an undescribed downstream VNTR, but no significant difference in allele frequency distribution was found between the two groups. To further explore the most promising variants, they are currently being genotyped in the complete BARCOS cohort.

Table 1. Number and location of single nucleotide variants found in this study

| | Raw | Filtered | Coding | Regulatory regions* | Putative osteoblast enhancer | Active osteoblast enhancer |
|------------------------|-------|----------|--------|---------------------|------------------------------|----------------------------|
| Common Variants | 96 | 52 | 0 | 12 | 3 | 1 |
| LFV | 24243 | 59 | 1 | 16 | 1 | 0 |
| Total | 24339 | 111 | 1 | 28 | 4 | 1 |

* Either present in flanking regions 5'UTR, 3'UTR or introns; LFV: low frequency variants (MAF>5%)

Decline in Vertebral Strength and Bone Mineral Density in Men and Women over the Year Post Hip Fracture. Denise Orwig^{*1}, David Kopperdahl², Tony Keaveny³, Rasheeda Johnson⁴, Jay Magaziner⁴, Marc Hochberg⁴. ¹University of Maryland, Baltimore, USA, ²O.N. Diagnostics, USA, ³University of California Berkeley, USA, ⁴University of Maryland School of Medicine, USA

Previous studies have shown the rate of decline in bone mineral density (BMD) at the femoral neck is greater than expected in older women over the year post hip fracture. Little is known, however, about changes in vertebral bone strength or BMD in men compared to women post hip fracture. The objective was to compare changes in vertebral BMD and bone strength, estimated using finite element analysis (FEA) of quantitative computed tomography (QCT) scans of the spine (T12-L1), over the year post hip fracture in men and women. QCT scans were performed at 2 and 12 months post hip fracture as part of an ancillary study of the Baltimore Hip Studies 7th cohort (BHS-7) (n=339), a prospective observational study designed to examine consequences of hip fracture in equal numbers of men and women. BHS-7 participants were =65 years, community-dwelling, and had surgical repair of a non-pathological hip fracture. This analysis includes 37 BHS-7 participants (21 men; 16 women) with 2- and 12-month QCT scans. Vertebral BMD and compressive strength were calculated using VirtuOst^U (O.N. Diagnostics, Berkeley, CA). BMD of trabecular centrum and the peripheral 2 mm of bone and their individual contributions to bone strength were also determined. Unpaired t-tests were used to compare women versus men with respect to baseline demographics and measurements of BMD and strength, and 10-month changes in BMD and strength; 95% confidence intervals of mean longitudinal changes were used to identify changes significantly different from zero. At 2 months post fracture, mean age, body mass index, and vertebral strength or any BMD measurement did not differ significantly by sex. Over the 10-month follow-up, vertebral strength and density of the whole vertebral body decreased significantly in women but not in men (Figure 1); however, the trajectory of decline did not differ significantly by sex. In men and women, for both BMD and strength, losses were predominantly due to loss of the trabecular bone rather than the peripheral (cortical) bone. In men, the heterogeneity in response was greater than in women: some men did not lose strength while others lost as much as the women, whereas all women lost strength. Data suggest that appreciable loss of vertebral strength can occur in women shortly after hip fracture, primarily due to the loss of trabecular bone; responses for women and men appear to differ, but additional study is required to further elucidate these sex effects.

Delineating the relationship between leptin, fat mass, and bone mineral density: A mediation analysis. Lan T Ho Pham^{*1}, Thai Q Lai², Tuan V Nguyen³. ¹Ton Duc Thang University, Vietnam, ²Department of Rheumatology, People's Hospital 115, Vietnam, Vietnam, ³Garvan Institute of Medical Research; School of Public Health & Community Medicine, UNSW Australia; University of Technology Sydney, Australia, Australia

Background and Aim — Leptin is a hormone synthesized and secreted by adipocytes which act centrally to control fat mass. The effect of leptin on bone mineral

density (BMD) has been reported, but the role of fat mass in this relationship is not clear. The present study sought to test the hypothesis that the relationship between leptin and BMD is mediated by fat mass by using a model of mediation analysis.

Methods — The study involved 357 men and 870 women aged between 18 and 89 years (average 45). The individuals were randomly sampled from 4 districts within Ho Chi Minh City (Vietnam). BMD at the femoral neck, lumbar spine, and whole body was measured by DXA (Hologic QDR4500). Lean mass and fat mass (FM) were derived from the whole body DXA scan. Serum leptin was measured by enzyme-linked immunosorbent assay (ELISA) on the Elecsys System (Roche Diagnostics). We tested the hypothesis of mediation by fitting a series of regression models to the data, in which (i) BMD was expressed as a function of leptin alone, and then leptin and fat mass in combination, and (ii) fat mass as a function of leptin. From the estimated parameters of these models we computed the direct and indirect effects of leptin on the variation in BMD.

Results — In women, after adjusting for age, greater serum leptin levels were associated with greater BMD at the femoral neck (P=0.006), lumbar spine (P=0.0001) and whole body (P=0.06). Serum leptin levels were also highly correlated with whole body fat mass (r=0.57; P<0.0001). In the mediation analysis, the effect of leptin on BMD was primarily mediated through fat mass (P<0.001). The direct effect of leptin on BMD was not statistically significant (P=0.89), and this was observed for all BMD sites. The proportion of lumbar spine BMD variance that was attributable to direct effect of leptin, and indirect effect of fat mass was 0.4% and 6.5%, respectively.

In men, leptin was significantly associated with lumbar spine BMD, but not with femoral neck or whole body BMD. In the mediation analysis, the effect of leptin on lumbar spine BMD was mainly mediated by fat mass (P=0.02). The proportion of lumbar spine BMD that was attributable to direct effect of leptin, and indirect effect of fat mass was 0.2% and 5.1%, respectively. **Conclusions** — These results suggest that greater serum levels of leptin are associated with greater BMD, but the association is primarily mediated by fat mass. The direct effect of leptin on BMD is not negligible.

Rural First Nations Women Over Age 60 Years Have Lower Distal Forearm Bone Density for Age in Association with Low Vitamin D Status. Hope Weiler^{*1}, Kurtis Sarafin², William Leslie³. ¹McGill University, Canada, ²Health Canada, Canada, ³College of Medicine, University of Manitoba, Canada

Native First Nations (FN) Canadian women are at much higher fracture risk than the general population. Previously we demonstrated that FN women have lower bone mass in association with low vitamin D status despite similar dietary intakes to white (W) women in a representative urban population from Manitoba, Canada. Very few assessments have been conducted in FN women living in rural regions. The objective of this study was to capture measures of bone mass and vitamin D status in FN and W women residing in rural Manitoba. Women (n=262) 25 y of age and over were recruited from two rural Manitoba communities (one southern, one northern), between September 2005 and August 2011. Distal forearm and calcaneal bone mineral density (BMD) and Z-scores were assessed on the non-dominant side using a peripheral x-ray imager (PIXI, GE Lunar). Vitamin D status was assessed using total 25-hydroxyvitamin D (25OHD) as quantified using a chemiluminescent immunoassay (Liaison, Diasorin Inc.). Proportions surveyed during the UVB exposure period between April 1st and September 30th were balanced across the study (FN 51% and W 52%). Differences among ethnic and age groups were tested using mixed model ANOVA accounting for effects of season of sampling. Body mass index was not different between ethnic groups (FN 31.4 ± 7.1 vs W 29.8 ± 6.7, kg/m²). Vitamin D status was lower in FN women without main or interaction effects across age groups (FN 44.0 ± 19.8 vs W 66.3 ± 24.4 of 25OHD nmol/L, p<0.0001). No differences among ethnic groups were observed for BMD or Z-score of the calcaneus (data not shown), although women ≥ 60 y of age had lower BMD compared to the two younger groups (p<0.001). Forearm BMD was different across ethnic and age groups (p<0.003), and ethnicity-by-age interactions were observed for forearm BMD and Z-score (Table). FN women ≥ 60 y of age had lower BMD compared to all other age and ethnic groups and lower Z-score compared to white women of any age. These data suggest that BMD of the forearm is not different in First Nations and white women at younger ages, but factors associated with aging including lower vitamin D status may elevate risk of fracture in older First Nations women.

Osteoporosis Prevention: Where are the barriers to improvement in patients and doctors?. Blandine Merle¹, Julie Haesebaert², Christian Dupraz³, Marie Aussedat³, Loïc Barraud³, Amélie Bedouet³, Cyril Motteau³, Virginie Simon³, Anne-Marie Schott⁴, Marie Flori³. ¹INSERM, France, ²pôle IMER, Hospices Civils de Lyon, France, ³Université Claude Bernard Lyon, France, ⁴Hospices Civils de Lyon, France

Despite numerous programs aiming at improving osteoporosis care, the prevention, diagnostic and treatment remain suboptimal. It is important to understand barriers to preventive care initiation to improve management of osteoporosis (OP). We implemented a qualitative study to explore the knowledge and representations regarding OP and its prevention of women, men and general practitioners in Region Rhône-Alpes, France. Four types of focus groups were conducted until data saturation, with women aged 50 to 85 years and men aged 60 to 85 years, with or without a history of fragility fracture or an osteoporosis diagnostic (referred to as "aware" or "unaware"). We involved 57 men, 23 aware and 34 unaware, in 7 focus-groups; and 45 women, 23 aware and 22 unaware in 9 focus groups. In parallel, semi-directed face-to face interviews were conducted with 16 general practitioners. A thematic analysis of transcripts was made with Nvivo 10 software. Results showed that osteoporosis is not considered as an illness but rather associated to old age by women and men who usually do not feel concerned, even if they had suffered a fragility fracture. No differences could be observed between aware and unaware patients. If OP was associated with bone fragility and fractures by women, for most of the men it was a women pathology which they deny. Fragility fracture was usually not linked to OP but to the fall. Men and women agreed with a healthy lifestyle although the benefits of dairy products, sun exposure and sport practicing were discussed. Pharmacological treatments were only mentioned by women, and always with suspicion due to their side effects. Women and men thought that their general practitioner is the right person to inform them about OP although it is rarely done, but women were more likely to be active in their health. For general practitioners, OP was associated with fragility fractures, women, menopause and old age but rarely with men. Bone mineral density measurement was regarded as the referent diagnostic test, but with questions as to when to prescribe, and difficulties to interpret the results. Biphosphonates were the reference treatment. Above all, they were waiting for clear and pragmatic guidelines to better manage this disease, and a better education of patients about OP. In conclusion, understanding barriers to osteoporosis care in patients and general practitioners will help to set up effective strategies to improve prevention and treatment.

Longitudinal assessment of health-related quality of life in osteoporosis – data from the Canadian Multicentre Osteoporosis Study (CaMos). Claudie Berger¹, Wilma M. Hopman², Lisa Langsetmo³, Lawrence Joseph⁴, Suzanne N Morin⁴, Tanveer Towheed², Tassos Anastassiades², Jonathan D. Adachi⁵, David A. Hanley⁶, Jerilynn C. Prior⁷, Goltzman David⁴. ¹CaMos, McGill, Canada, ²Queen’s University, Canada, ³MUHC-RI, McGill University, Canada, ⁴McGill University, Canada, ⁵McMaster University, Canada, ⁶University of Calgary, Canada, ⁷University of British Columbia, Canada

There is evidence that osteoporosis is associated with lower health-related quality of life (HRQOL), even in the absence of fractures. However, little is known about the impact of osteoporosis on changes in HRQOL over time in women and men. Our objectives were to determine the associations between self-reported diagnosis of osteoporosis (with/without fracture) and HRQOL (SF-36 at baseline and 10-year longitudinal change) in a population-based cohort of women and men. Study population: CaMos participants age 50+. We stratified the cohort based on sex, reported diagnosis of osteoporosis, and presence of fragility fracture at baseline. Age-adjusted linear regressions were used to compare groups in terms of HRQOL. In longitudinal analysis (with further adjustment for baseline scores), we considered three diagnoses groups: never diagnosed, diagnosed at baseline, diagnosed during the 10-year follow-up. At baseline, there were 736 women and 42 men with osteoporosis and 4695 women and 2126 men without. Of those with osteoporosis, 266 (36.1%) women and 11 (26.2%) men had a prevalent fragility fracture. For women, baseline age-adjusted HRQOL differences between those with and without osteoporosis were substantial (Figure 1), with the osteoporosis group scoring lower on all 8 domains and both component summaries; in addition, most were clinically relevant. Men showed a similar pattern, although only 2 domains exceeded the threshold for clinical relevance. In women with osteoporosis, those who reported prevalent fractures had age-adjusted differences lower than those without a fracture, with 3 physically oriented scores attaining clinical relevance. For men, results suggest a lower HRQOL in those who reported prevalent fractures, but the sample size was too small to draw conclusions. For the changes over 10 years (Figure 2), those with osteoporosis were more likely to have greater declines in scores than those who were never diagnosed with osteoporosis; some differences in women were clinically relevant. A similar pattern was seen for those who developed osteoporosis over the follow-up, although the differences were smaller. Osteoporosis diagnosis appears to be associated with poorer HRQOL in women, which is compounded by the presence of fractures. In addition, having the disease, or developing it, is also associated with greater 10-year declines in HRQOL when compared to those who do not have it. Results appear similar for men, although the sample sizes were small.

A Prospective Study of Diuretic Use and Risk of Vertebral Fractures in Women. Julie M Paik^{*1}, Harold N Rosen², Catherine M Gordon³, Gary C Curhan¹. ¹Brigham & Women's Hospital, Harvard Medical School, USA, ²Beth Israel Deaconess Medical Center, USA, ³Hasbro Children's Hospital, Alpert Medical School of Brown University, USA

Purpose: Vertebral fractures are the most common type of osteoporotic fracture and are associated with significant disability and morbidity. Loop diuretics increase urinary calcium excretion, thereby affecting calcium balance. Although thiazide diuretics decrease urinary calcium excretion and preserve bone mineral density, they may also induce hyponatremia and several recent studies suggest hyponatremia to be associated with an increased fracture risk. The few studies to date examining the relation between loop diuretics, thiazides, and vertebral fracture risk have shown inconsistent results, which could be related to the assessment of vertebral fractures by self-report or administrative codes.

Methods: We conducted a prospective study of the relation between loop diuretic use, thiazide use, and vertebral fracture risk in a cohort of 56,974 women, 51-78 years of age in 1998, with no history of vertebral fracture, who were participating in the Nurses' Health Study. Use of furosemide or thiazides was assessed by questionnaire every four years. Dietary intake and vitamin supplement use were assessed from semi-quantitative food frequency questionnaires in the same years. All cases of self-reported vertebral fracture were confirmed by medical record review.

Results: In 1998, there were 5,362 women (9.4%) receiving thiazides and 1,070 women (1.9%) taking furosemide. Between 1998 and 2014, 343 incident vertebral fracture cases were documented. After adjustment for other potential risk factors, including intakes of calcium, vitamin D, protein, caffeine and alcohol, body mass index, physical activity, smoking status, and history of hypertension, diabetes, and osteoporosis, the relative risk of vertebral fracture for those women taking furosemide was 1.66 (95% confidence interval 1.14 to 2.43) compared with women who were not taking furosemide. After multivariate adjustment, the relative risk of vertebral fracture for women taking thiazides was 1.40 (95% confidence interval 1.07 to 1.83) compared with women who were not taking thiazides.

Conclusion: Diuretic use, both loop diuretics and thiazides, is associated with an increased risk of vertebral fractures in women. While the increased risk associated with loop diuretics could be related to increased calciuria, thiazides could potentially increase vertebral fracture risk by a mechanism other than urinary calcium handling such as thiazide-induced hyponatremia.

SA0273

Can FRAX Predict Falls in Older Women?. Shreyasee Amin^{*}, Elizabeth Atkinson, Sara Achenbach, Jeremy Crenshaw, Kenton Kaufman, Sundeeep Khosla, L. Joseph Melton. Mayo Clinic, USA

Falls in the elderly can lead to fragility fractures. Fall prevention targeted at those with high fall risk could help reduce fractures. Although the fracture risk assessment tool, FRAX, does not directly incorporate fall risk, it does include some risk factors for falling. We examined whether FRAX scores could predict fall risk in older ambulatory women.

We studied 125 community-dwelling women, age ≥ 65 yrs, in whom 124 had femoral neck bone mineral density (FN BMD, g/cm²) and US-FRAX scores (% 10-yr risk for major osteoporotic fractures [FRAX-OP] and hip fractures [FRAX-Hip]) reliably determined. Falls were longitudinally tracked every two weeks for 1 yr by self-reported questionnaire. We divided subjects into 4 groups, using FRAX score cutoffs for osteoporosis [OP] treatment ($\geq 20\%$ for FRAX-OP and $\geq 3\%$ for FRAX-Hip) as the initial basis for groupings. We then examined whether FRAX scores (by groups and as a continuous variable) predicted falls using an Andersen-Gill model, adjusted for age and prior fall history.

The median (range) age, FN BMD and FRAX scores of women were 77 (65-92 yrs), 0.81 (0.54-1.20 g/cm²), 14.2 (3.3-56.9%, FRAX-OP) and 3.5 (0.1-45.8%, FRAX-Hip), respectively. There were 28 women (23%) with FRAX-OP $\geq 20\%$ and 67 (53%) with FRAX-Hip $\geq 3\%$. There were 47 women (38%) who reported a fall in the yr prior to their study visit. Compliance with all fall tracking questionnaires was 97.5%. Over follow-up, 73 women fell, 38 of whom had more than one fall, for a total of 157 falls over 125 person-yrs of follow-up [p-y] (1.3 falls/p-y). There was a trend for higher fall risk with greater FRAX score [see Table]. But the association appeared non-linear when using FRAX as a continuous variable in analyses, with decreasing fall risk in women having the very highest ($>25\%$, FRAX-OP and $>10\%$, FRAX-Hip) scores [data not shown]. Women with high FRAX scores were more likely to have a parent with hip fracture, increasing the FRAX score, but which may not necessarily have influenced fall risk. They also reported being less active, which may have reduced their likelihood for falling over follow-up.

We found a higher risk of future falls in older women with greater FRAX scores, including at scores below the recommendations for OP treatment. That said, the non-linear association we observed at the highest FRAX scores suggests that information beyond FRAX would still be necessary to distinguish those at high vs. low risk for falls.

Decreased serum albumin level and renal function are the risk for mortality after newly diagnosed vertebral fracture (Vfx) in Japanese subjects. Akiko Kuwabara^{*1}, Kiyoshi Tanaka², Tetsuo Nakano³. ¹Department of Health & Nutrition, Osaka Shoin Women's University, Japan, ²Kyoto Women's University, Japan, ³Department of Orthopaedic Surgery, Tamana Central Hospital, Japan

Purpose: It is well established that the prevalence of Vfx is higher, whereas that of hip fracture is lower in Japan than that in Europe or America. Recently, some reports described the higher mortality in subjects with Vfx in Japan. Few papers have been available, however, on the factors contributing the mortality after Vfx. In addition, mortality after recently occurred Vfx has not been reported in Japan. Thus we have studied the survival rate after freshly diagnosed Vfx. Methods. 774 subjects aged 78.8 \pm 8.6 years old with back or lumbar pain, and diagnosed as fresh Vfx by magnetic resonance imaging (MRI) were studied for their age, gender, number of prevalent Vfx, survival or the date of death, circulating levels of hemoglobin (Hb), albumin (Alb), C reactive protein, and estimated glomerular filtration rate (eGFR). The subjects who died within 30 days from baseline were excluded from the analyses. Cox's proportional hazard analysis was performed to assess the significant predictors for mortality. The cut-off levels of the variables for mortality were analyzed using the receiver operator characteristic (ROC) curve. Results. The median observation duration was 3.8 years. The survival rates of our Vfx patients were 91.3%, 84.6%, and 78.8% at one, 2, and 3 years after the diagnosis of fresh Vfx, respectively. Non-survivors had significantly higher age ($p<0.001$), higher serum CRP level ($p<0.001$), and lower Alb ($p<0.001$), Hb ($p=0.002$), eGFR ($p<0.001$) than survivors. Cox's proportional hazard analysis has shown that serum Alb level (hazard ratio (HR) =0.355) and eGFR (HR=0.993) were significant predictors for mortality. Based on the ROC curves, the cut-off levels were 3.6 g/dl and 60 mL/min/1.73m², respectively. Kaplan-Meier curves revealed that survival rates were significantly decreased in patients with both serum Alb level and eGFR below these cut-off levels. Conclusions. The present study has revealed that subjects with freshly diagnosed Vfx have high risk of mortality, to which hypoalbuminemia and impaired renal function have significantly contributed.

Glucose Metabolism Status Is Not Associated With a Recent History of Falls, Recurrent Falls or Fractures – The Maastricht Study. Ellis de Waard¹, Annemarie Koster², Tom Melai³, Tineke van Geel⁴, Ronald Henry⁵, Miranda Schram⁵, Pieter Dagnelie⁶, Carla van der Kallen⁵, Simone Sep⁵, Coen Stehouwer⁵, Nicolaas Schaper⁷, Hans Savelberg³, Piet Geusens⁸, Joop van den Berg⁹. ¹NUTRIM School for Nutrition & Translational Research in Metabolism, Maastricht University, Department of Internal Medicine, Subdivision of Rheumatology, Maastricht, Netherlands, ²Maastricht University, Department of Social Medicine, Maastricht, Netherlands & CAPHRI School for Public Health & Primary Care, Maastricht University, Maastricht, Netherlands, ³NUTRIM School for Nutrition & Translational Research in Metabolism, Maastricht University, Department of Human Movement Science, Maastricht, Netherlands, ⁴NUTRIM School for Nutrition & Translational Research in Metabolism/CAPHRI School for Public Health & Primary Care, Maastricht University, Department of Family Medicine, Maastricht, Netherlands, ⁵Maastricht University Medical Centre, Department of Internal Medicine, Maastricht, Netherlands & CARIM School for Cardiovascular diseases, Maastricht University, Maastricht, Netherlands, ⁶CAPHRI School for Cardiovascular diseases/CAPHRI School for Public Health & Primary Care, Maastricht University, Maastricht, Netherlands & Maastricht University, Department of Epidemiology, Maastricht, Netherlands, ⁷Maastricht University Medical Centre, Department of Internal Medicine, Maastricht, Netherlands & CARIM School for Cardiovascular diseases/CAPHRI School for Public Health & Primary Care, Maastricht University, Maastricht, Netherlands, ⁸CAPHRI School for Public Health & Primary Care, Maastricht University Medical Centre, Department of Internal Medicine, Subdivision of Rheumatology, Maastricht, Netherlands, ⁹VieCuri Medical Centre, Department of Internal Medicine, Subdivision of Endocrinology, Venlo, Netherlands & NUTRIM, Maastricht University Medical Centre, Department of Internal Medicine, Subdivision of Rheumatology, Maastricht, Netherlands

Purpose: To compare the prevalence of past falls, recurrent falls and fractures in participants with normal glucose metabolism (NGM), impaired glucose metabolism (IGM) and type 2 diabetes (T2DM). Additionally, to examine the role of glucose metabolism regulation, insulin use and T2DM duration on falls, recurrent falls and fractures.

Methods: Baseline data of all participants over the age of 50 (N=2953) from The Maastricht Study, a population based cohort study with oversampling of patients with T2DM, was used. Glucose metabolism status was based on an oral glucose tolerance test and medication use. Data about past falls or fractures was obtained by questionnaires. Falls in the past year (yes vs. no), recurrent falls (>1 fall in the past year, yes vs. no) and fractures over the age of 50 (yes vs. no) were used for analysis.

Results: In total, 1577 participants had NGM, 468 had IGM and 908 had T2DM (mean duration 8.7 ± 7.1 years, mean HbA1c 52.1 ± 11.4 mmol/mol, 21.9% insulin user). A fall in the past year was reported by 881 (33.1%), recurrent falls by 204 (6.9%) and a fracture over the age of 50 by 176 (6.0%) participants. Adjusted for age, sex, BMI and physical activity, the odds ratios in IGM and T2DM compared to NGM were not different for falls (IGM: OR 0.94, 95% CI 0.74-1.17, T2DM: OR 1.12, 95% CI 0.86-1.47), recurrent falls (IGM: OR 1.10, 95% CI 0.71-1.69; T2DM: OR 1.29, 95% CI 0.79-2.10) or fractures (IGM: OR 1.09, 95% CI 0.70-1.71; T2DM: OR 1.39, 95% CI 0.84-2.30). Within the T2DM group, falls or fractures did not significantly differ between participants with poorly regulated (HbA1c >64 mmol/mol, N=107) and well-regulated (HbA1c ≤64 mmol/mol) diabetes (falls: 31.8% vs. 33.5%, p=0.75, fractures: 10.6% vs. 6.1%, p=0.16) and between insulin (N=199) and non-insulin users (falls: 36.5% vs. 32.5%, p=0.34, fractures: 9.9% vs. 5.8%, p=0.10). The prevalence of recurrent falls was significantly higher in the poorly regulated participants (13.0% vs. 6.7%, p=0.05) and in insulin users (13.1% vs. 6.0%, p<0.01). T2DM duration (>5 vs. ≤5 year) was not associated with the prevalence of falls (32.1% vs. 36.1%, p=0.28), recurrent falls (7.8% vs. 6.6%, p=0.59) or fractures (6.7% vs. 6.3%, p=0.88).

Conclusion: Glucose metabolism status is not associated with a recent history of falls, recurrent falls or fractures. Within the T2DM group, the prevalence of recurrent falls was higher in poorly controlled participants and in insulin users.

SA0276

High subcutaneous fat measured by DXA is associated with higher fracture risk in older men - the STRAMBO study. Pawel Szulc¹, François Duboueu², Roland Chapurlat². ¹INSERM UMR 1033, University of Lyon, Hôpital E. Herriot, Pavillon F, France, ²INSERM UMR 1033, University of Lyon, Hôpital Edouard Herriot, France

Obesity is associated with higher bone fragility. However, it is not clear whether visceral and subcutaneous fat have similar impact on fracture risk. In older men, high subcutaneous, but not visceral, fat mass was associated with low grip strength and poor physical performance (Szulc, ISCD Congress, 2015). Therefore, our aim was to assess the association between fat mass and fracture risk in older men. In a cohort of 802 men aged 60-88, a HOLOGIC Discovery A device was used to assess total hip bone mineral density (BMD) and body composition (including gynoid fat and visceral and subcutaneous compartments of android fat). Incident vertebral and non-vertebral fractures were recorded prospectively. Cox proportional hazards model was adjusted for age, hip BMD, prior fractures, self-reported ischemic heart disease and serum 25-hydroxycholecalciferol. During the follow-up (median 7 yrs), 82 men sustained low trauma fragility fractures. Higher body weight and fat mass were associated with higher fracture risk (per SD increase: HR= 1.33, 95%CI: 1.06-1.66, p<0.05 and HR= 1.46, 95%CI: 1.16-1.84, p<0.005). Gynoid fat and android fat were associated with higher fracture risk (per SD increase: HR= 1.55, 95%CI: 1.23-1.94, p<0.001 and HR= 1.38, 95%CI: 1.08-1.77, p=0.01). In the stepwise model, only gynoid fat was retained. The highest quintile of gynoid fat was associated with higher fracture risk (HR= 2.04 vs. four lower quintiles combined, 95%CI: 1.20-3.48, p<0.01). By contrast, the highest quintile of android fat was not associated with fracture risk (HR= 1.66 vs. lower quintiles combined, 95%CI: 0.93-2.94, p=0.10). Higher abdominal subcutaneous fat was associated with higher fracture risk (HR= 1.47 per SD, 95%CI: 1.15-1.87, p<0.005), whereas visceral fat and fracture tended to be associated (HR= 1.28 per SD, 95%CI: 0.98-1.64, p=0.06). When both were introduced in the stepwise model, only subcutaneous fat was retained. The highest quintile of abdominal subcutaneous fat was associated with higher fracture risk (HR= 1.94 vs. lower quintiles combined, 95%CI: 1.12-3.33, p<0.05). The highest quintile of visceral fat was not associated with the fracture risk (HR= 1.47 vs. lower quintiles combined, 95%CI: 0.82-2.62, p=0.20). In conclusion, in older men, higher subcutaneous fat is associated with higher incident fracture risk after adjustment for potential confounders.

How Do Hip Fracture Rates in Long-term Care Compare with the Community?. Courtney Kennedy¹, Alexandra Papaioannou¹, George Ioannidis¹, Ruth Croxford², Cathy Cameron³, Sara Mursleen¹, Jonathan Adachi¹, Susan Jaglal³. ¹McMaster University, Canada, ²Institute for Clinical Evaluative Sciences, Canada, ³University of Toronto, Canada

Background: Individuals living in long-term care (LTC) homes are typically frailer and are at higher risk of falls than their community counterparts. In this study we compared patterns of hip fracture rates in LTC versus community-dwelling men and women. **Methods:** A retrospective cohort was defined using population-level health administrative data for all individuals aged 65 years and older living in Ontario, Canada between 2002-12. The LTC cohort was defined based on records indicating an LTC admission or a physician visit or prescription filled while residing in LTC. In Ontario, approximately 620 LTC facilities (nursing homes) are funded by the provincial health ministry and provide residential care for older adults who need access to 24-hour nursing, supervision, or higher levels of personal care assistance. Fractures were identified (ICD-10-CA diagnosis codes) from emergency department, inpatient records, and physician claims. Crude incident hip fracture rates were calculated for men and women separately, for age strata 65-74, 75-84, and 85+ years. **Results:** The LTC cohort was substantially older [n= 733,619; women=85.0 (SD 7.4); men=81.5 (SD 7.7)] than the community cohort [n= 17,419,498; women=74.8 (SD 7.0); men=73.5 (SD 6.4)]. There was a markedly higher hip fracture rate in institutionalized women in the two younger age strata (figure) compared with women residing in the community. However, by age 85+ hip fracture rates for women were similar regardless of institutionalization status. Men in LTC had higher hip fracture rates than community-dwelling men across all age strata (figure) and a similar distribution of rates as women residing in LTC. The substantial rise in fracture rates occurred by age 75 in LTC but not until age 85 in the community. During the study period, LTC residents contributed to 17% of all hip fractures in Ontario, despite being only 4% of the overall senior population age 65 years and older. **Discussion:** There was a considerable burden of hip fractures for both men and women residing in LTC. Women age 85 years and older had similar hip fracture rates irrespective of living arrangement (community versus LTC) indicating that these two groups may have a similar risk profile and degree of frailty.

Humeral fractures in south-eastern Australia: epidemiology and risk factors. Kara Holloway¹, Gosia Bucki-Smith², Amelia Morse², Sharon Brennan-Olsen², Mark Kotowicz², David Moloney², Elizabeth Timney², Amelia Dobbins², Julie Pasco². ¹Barwon Health, Australia, ²School of Medicine, Deakin University, Australia

In this study, we report the epidemiology and risk factors for humeral fractures (proximal humerus and shaft) among men and women residing in south-eastern Australia.

Incident fractures during 2006 and 2007 were identified using X-ray reports (Geelong Osteoporosis Study Fracture Grid). Risk factors were identified using data from case-control studies conducted as part of the Geelong Osteoporosis Study.

During 2006 and 2007, there were 283 and 385 humeral fractures in males and females respectively. Of these, 105 males and 218 females had proximal humerus fracture. Median age of fracture was lower in males than females for proximal humerus (33.0 95%CI 17.3-63.1 years vs 71.2 95%CI 58.4-82.0 years), but not for humeral shaft (8.9 95%CI 5.6-16.4 years vs 8.5 95%CI 5.9-59.6 years). Most fractures were the result of a fall (>75%) onto an outstretched hand/arm or shoulder. For both sexes, proximal humerus fractures occurred mainly in older age groups (70-79 and 80+ years), whereas humeral shaft fractures followed a U-shaped pattern. Total incidence (age-standardised to the Australian population) of humerus fractures in males and females (per 100,000 person-years) were 109.9 (95%CI 109.4, 110.3) and 135.3 (95%CI 133.7, 136.9), respectively. In men, increased femoral neck BMD and younger age were protective of proximal humerus fracture, whereas prior fracture and high milk consumption were risk factors. For the humeral shaft, only prior fracture was identified as a risk factor. In premenopausal women, height and falls were both risk factors for proximal humerus fractures. For postmenopausal women, protective factors for proximal humerus fractures included a higher non-milk dairy consumption. Education and prior fractures were both risk factors. We were unable to determine risk factors for humeral shaft fractures in women due to small numbers of cases.

Males sustained proximal humerus fractures at a younger age than females. Most fractures were the result of a fall. Humeral shaft fractures in both sexes were sustained mainly in childhood, while proximal humerus fractures were sustained in older adulthood. Risk factors for adult humeral fractures in both sexes were identified and may be used as an indicator of individuals at high risk of humerus fractures.

Impact of osteonecrosis of the jaw on osteoporosis treatment in Japan: results of a questionnaire-based survey by the Adequate Treatment of Osteoporosis (A-TOP) research group. Akira Taguchi¹, Masataka Shiraki², Mayumi Tsukiyama³, Teruhiko Miyazaki³, Satoshi Soen⁴, Hiroaki Ohta⁵, Toshitaka Nakamura⁶, Hajime Orimo⁷. ¹Matsumoto Dental University, Japan, ²Research Institute & Practice for Involutional Diseases, Japan, ³Public Health Research Foundation, Japan, ⁴Department of Orthopaedic Surgery & Rheumatology, Nara Hospital, Kinki University School of Medicine, Japan, ⁵Department of Clinical Medical Research Center, International University of Health & Welfare, Women's Medical Center of Sanno Medical Center, Japan, ⁶National Center for Global Health & Medicine, Japan, ⁷Japan Osteoporosis Foundation, Japan

Purpose: The status of divergence between medical professionals and dentists may largely impact on patients who need antiresorptive therapy. It is necessary to first clarify how osteonecrosis of the jaw (ONJ) problems, especially drug holidays and cooperation between medical professionals and the dentists, impact on osteoporosis treatment in the real world of current Japan. Little is known about how drug holidays

affect osteoporosis treatment and how medical professionals and dentists cooperate to deal with ONJ in osteoporosis treatment. This study aimed to clarify the impact of ONJ on osteoporosis treatment in Japan. Methods: A structured questionnaire including 14 key clinical queries was sent to 488 medical professionals as part of the Japanese Osteoporosis Intervention Trial (JOINT)-04, and 206 responses were received. Results: A total of 173 respondents had received discontinuation requests from dentists. Of these, 28 respondents reported 30 adverse events including 10 fractures and one ONJ case. The respondents who refused discontinuation requests observed no cases of ONJ. Approximately 16% of respondents had experience of patients discontinuing osteoporosis treatment after tooth extraction under a drug holiday. Dentists requested discontinuations for many medications not associated with the incidence of ONJ. Approximately 76% of respondents had never requested oral health care from dentists before osteoporosis treatment and 72% reported no cooperation between dentists and medical professionals in their region. Conclusions: Our results suggest that drug holidays do not prevent ONJ but may increase adverse events and disturb osteoporosis treatment. Currently both medical professionals and dentists in Japan still continue to push their own treatment position. A forum to share information about ONJ among medical professionals, dentists and patients is needed.

Low blood pressure cut points for fall injuries in community-dwelling elderly: the Health, Aging and Body Composition Study. Naoko Sagawa¹, Zachary A. Marcum², Robert M. Boudreau¹, Joseph T. Hanlon¹, Steven M. Albert¹, Suzanne Satterfield³, Ann V. Schwartz⁴, Aaron I. Vinik⁵, Jane A. Cauley¹, Tamara B. Harris⁶, Anne B. Newman¹, Elsa S. Strotmeyer¹. ¹University of Pittsburgh, USA, ²University of Washington, USA, ³University of Tennessee Health Science Center, USA, ⁴University of California, San Francisco, USA, ⁵Eastern Virginia Medical School, USA, ⁶National Institute on Aging, USA

Falls often result in injury and are an important cause of morbidity and mortality. Hypertension and low blood pressure (BP) are known risk factors of falls in the elderly. However, cut points for low BP vary among studies. We investigated if BP at various cut points is associated with fall injury in the Health, Aging and Body Composition Study using incident injurious falls from linked Medicare data. Injurious falls from clinic exam (7/00-6/01) to 12/31/08 were defined as any unique event from Medicare claims for N=2375 (99%) with a fall code (E880-888) plus non-fracture injury (N=161) or a fracture code (800-829) with/without (N=367) a fall code (N=458). Traumatic, intentional or pathologic injuries were excluded (N=38). We included 2,324 with BP data (52% women, 38% black). Initial injurious falls (N=609) occurred in 3.8 ± 2.4 years, with others censored at end of Medicare coverage (N=1) or last follow-up (N=12)/death (N=514)/Medicare dataset end date (N=1188) over 6.9 ± 2.1 years. Participants with injurious falls were more likely to be white (72% vs. 59%), women (65% vs. 47%), older (age 77 ± 3 vs. 76 ± 3 years), had lower BMI (26.7 ± 4.8 vs. 27.6 ± 2.8 kg/m²), and lower diastolic BP (DBP; 70.4 ± 11.1 vs. 71.9 ± 10.9 mmHg), all p < 0.01. They were more likely to have more prescription medications (3.6 ± 2.7 vs. 3.2 ± 2.5, p < 0.01) and cerebrovascular disease history (9% vs. 6%, p = 0.02); though no difference in systolic BP (SBP; 135.0 ± 20.6 vs. 135.2 ± 19.8 mmHg), pulse pressure (64.5 ± 18.3 vs. 63.3 ± 17.0 mmHg), antihypertensive medication use (56.8% vs. 59.9%), orthostatic hypotension (defined as decrease in SBP 20 mmHg or DBP 10 mmHg; 5.6% vs. 6.9%), or diabetes (21.0% vs. 21.5%) was found. Cut points for low DBP were based on literature (80, 90 mmHg) and J-curve phenomenon (60, 70 mmHg). Cox regression models for each cut point were built for fall injuries adjusted for demographics, BMI, lifestyle factors, comorbidity and medication use at baseline. Fall injury risk was higher in those with DBP ≤ 70 mmHg (HR=1.19; 95%CI: 1.01-1.40), and was attenuated by adjustment for the total number of medications (Table 1). SBP was not associated with fall injury risk. These results were consistent after stratifying for non-fracture and fracture injuries. DBP ≤ 70 mmHg identifies older adults at higher risk of fall injury. This relationship was accounted for in part by polypharmacy; however, it is unclear what aspect accounts for the risk and this will be the focus for future work.

Table 1: Cut points for diastolic blood pressure and incident fall injury.

| Cut points (Prevalence) | Model 1 | Model 2 | Model 3 | Model 4 |
|-------------------------|--|-------------------|------------------|------------------|
| | Hazard Ratio (95% Confidence Interval) | | | |
| ≤60mmHg (22%) | 1.27 (1.05-1.54)* | 1.24 (1.02-1.51)* | 1.19 (0.98-1.44) | 1.21 (0.99-1.49) |
| ≤70mmHg (57%) | 1.19 (1.01-1.40)* | 1.19 (1.01-1.40)* | 1.14 (0.97-1.34) | 1.14 (0.96-1.35) |
| ≤80mmHg (84%) | 1.00 (0.80-1.24) | 0.99 (0.80-1.24) | 0.95 (0.76-1.19) | 0.92 (0.73-1.17) |
| ≤90mmHg (97%) | 0.89 (0.56-1.43) | 0.87 (0.54-1.39) | 0.83 (0.52-1.33) | 0.80 (0.49-1.33) |

*p<0.05. Variables in Model 1 were kept in all models, additional covariates were removed at P>0.1. Model 1: adjusted for age, sex, race, site, BMI. Model 2: Model 1 + medication use (antidepressives, opioids, benzodiazepines, antipsychotics, antiepileptics, antihypertensives). Model 3: Model 1 + medication use (antidepressives, opioids, antiepileptics), total number of medications (includes antihypertensives since these were P>0.1). Model 4: Model 1 + antiepileptics, total number of medications, Modified Mini-Mental State score, 1.4-g/10-g monofilament insensitivity, Cystatin C>3.0 mg/L.

Personality, Falls and Fractures: The Women's Health Initiative Observational Study (WHI-OS). Jane Cauley*¹, Stephen Smagula², Kathleen Hovey³, Jean Wactawski-Wende^{2,3}, Carolyn Crandall⁴, Meryl LeBoff⁵, Christopher Andrews⁶, Wenjun Li⁷, Mathilda Coday⁸, Marvan Sattari⁹, Hilary Tindle¹⁰. ¹University of Pittsburgh Graduate School of Public Health, USA, ²University of Pittsburgh, USA, ³State University of NY at Buffalo, USA, ⁴University of California, USA, ⁵Brigham & Women's Hospital, USA, ⁶University of Michigan, USA, ⁷University of Massachusetts Medical School, USA, ⁸The University of Tennessee Health Science Center, USA, ⁹University of Florida, USA, ¹⁰Vanderbilt University, USA

Traits of optimism and cynical hostility are features of personality that could influence the risk of falls and fractures in several ways. Personality may influence risk taking behavior or health behaviors i.e., physical activity. Alternatively, optimism has been associated with lower levels of inflammatory markers which have been linked to a lower risk of fractures. To test the hypothesis that personality influences fall and fracture risk, we studied 87,342 women enrolled in WHI-OS. The Life Orientation Test - Revised measures optimism with scores summed across 6-items. A sample question was "If something can go wrong for me, it will". Cynical hostility was assessed by the cynicism subscale of the Cook-Medley questionnaire. A sample question, "It is safer to trust nobody" is responded to by a true/false answer. Higher scores indicate greater optimism and hostility. Optimism and hostility were correlated at $r = -0.31$, p_2 times in the past year was modeled using repeated measures logistic regression. Average follow-up for fractures was 11.4 years; falls, 7.6 years. Women with the highest optimism scores were about 15% less likely to report 2 or more falls compared to women with the lowest optimism scores, Table. Similarly, highest hostility scores were associated with a 17% higher risk of falls. These associations were independent of many risk factors for falls. Higher optimism scores were also associated with about a 10% lower risk of hip, vertebral, lower arm and all fractures but this association was attenuated in multivariate models (MV). Women with the greatest hostility had a modest increased risk of any fracture, MV adjusted hazard ratio=1.06 (95% confidence intervals, 1.02-1.09) compared to women with lowest hostility but there was no association with other specific fracture types. Personality traits may influence the risk of falls above and beyond traditional risk factors. Associations with fractures were largely explained by other risk factors supporting conceptual models of how personality traits may prospectively influence biological outcomes. Whether interventions aimed at attitudes could reduce fall risks remains to be determined.

Repeated logistic regression of falls by optimism and hostility (n=87,342)

Predictors of Imminent Fracture Risk in Women Aged 65 Years with Osteoporosis. Derek Weycker*¹, Rich Barron², Alex Kartashov³, John Edelsberg⁴, Barry Crittenden², Andreas Grauer². ¹Policy Analysis Inc. (PAI), USA, ²Amgen Inc., USA, ³Policy Analysis Inc., USA, ⁴Policy Analysis, USA

Background: Fractures are the major source of morbidity among women with osteoporosis. However, evidence on factors leading to imminent risk for hip or other

non-vertebral fracture within the next 12 months among women aged ≥ 65 years with osteoporosis is limited.

Methods: A retrospective cohort design and data from the Study of Osteoporotic Fractures (SOF)—which includes 20 years of prospectively collected data on osteoporosis care and outcomes—were employed. The study population comprised all women aged ≥ 65 years with osteoporosis (T-score ≤ -2.5 at total hip) in the Caucasian cohort. Hip and other non-vertebral fractures were ascertained over a 1-year follow-up period. Potential predictors of fracture were evaluated using multivariate regression models and included anthropometric measures, BMD, cognitive function, comorbidities, drug use, fracture/fall history, lifestyle variables, medical symptoms, physical function/performance, quality of life, and vision status.

Results: The study population included 2,499 women with osteoporosis who contributed 6,811 observations. During the 1-year follow-up, 2.2% had a hip fracture and 6.6% had any non-vertebral fracture (including hip). Independent predictors of hip and/or non-vertebral fracture included impaired cognitive function, total hip T-score, falls history, fracture history, and lower physical performance (Table).

Conclusions: Imminent fracture risk within 12 months among osteoporotic women is higher among those with a history of fracture, history of falls, lower BMD, physical dysfunction, and/or cognitive dysfunction. Careful consideration should be given to identifying this population so that those at imminent risk may be targeted for the appropriate therapy.

Table. Independent predictors of 1-year hip and non-vertebral fracture in osteoporotic women aged ≥ 65 years from multivariate regression models

| Risk Factors | Hazard Ratios* (95% CI) | |

Recurrent major osteoporotic fracture in older men: the Osteoporotic Fractures in Men Study. Carrie Nielson*¹, Elizabeth Hooker¹, Jodi Lapidus¹, Lynn Marshall¹, Peggy Cawthon², Margaret Lee Gourlay³, Doug Bauer⁴, Jane Cauley⁵, Kristine Ensrud⁶, Nancy Lane⁷, Eric Orwoll¹. ¹Oregon Health & Science University, USA, ²California Pacific Medical Center, USA, ³University of North Carolina, USA, ⁴University of California, San Francisco, USA, ⁵University of Pittsburgh, USA, ⁶University of Minnesota, USA, ⁷University of California, Davis, USA

Background: Major osteoporotic fracture (MOF) is a risk factor for recurrent fracture and mortality. We examined characteristics of men with an incident MOF and the risk factors for a subsequent MOF, considering the competing risk of mortality.

Methods: The incidence rate of MOF, which included a hip, wrist, shoulder, or clinically detected spine fracture, was calculated in men age 65 or older in the Osteoporotic Fractures in Men (MrOS) study with at least 30 days of follow-up (N=5987). In the 585 men with an initial MOF (ages 65-98), potential risk factors from the study visit preceding the first MOF were evaluated for their associations with a subsequent MOF using Cox proportional hazards regression accounting for the competing risk of mortality. All models were minimally adjusted for age, clinic site, and race; and a multivariable model included all variables with $p < 0.2$ in minimally adjusted models.

Results: The incidence of first MOF in the full cohort was 9/1000 man-years and ranged from 5/1000 in men ages 65-69 to 28/1000 in those age 85 or older. In men with a first MOF, the incidence of second MOF was at least doubled in every age group (ranging from 31/1000 in 70-74 year old men to 71/1000 in 85+ men) and was highest after an initial clinical vertebral fracture (68/1000 man-years).

In men with an initial MOF, common conditions at the most recent clinic visit were frailty (27%), self-reported mobility limitations (29%), inability to complete a 6-

m narrow walk test (26%), osteopenia (56%) and osteoporosis (10%). 9% of men used an osteoporosis medication. Low BMD was a strong independent risk factor for subsequent MOF (HR: 1.5 per SD decrease in total hip BMD, 95% CI: 1.2-1.9). Contrary to expectation, *inability* to complete a 6-m narrow-walk test was independently associated with lower risk of recurrent fracture (HR: 0.5, 95% CI: 0.3-0.96).

Conclusions: The incidence of recurrent MOF rose dramatically after a first MOF in older men, and low BMD was a potentially modifiable risk factor. Further investigation of lifestyle and functional characteristics of men with an initial MOF may elucidate mechanisms by which inability to complete a narrow walk affects subsequent fracture. This research may have implications for improving rehabilitation and long-term fracture prevention following a first MOF. Identifying safe ways for older men to be active should be a priority to aid in recovery from the initial fracture and reduce the risk of a second fracture.

Serum phosphate levels are associated with fracture risk: the Rotterdam Study. Natalia Campos¹, Nadia Koek², Bram C van der Eerden³, Fernando Rivadeneira⁴, Albert Hofman⁵, Johannes van Leeuwen³, André G Uitterlinden³, M Carola Zillikens³. ¹Erasmus MC, The Netherlands, ²Department of Internal Medicine, Erasmus Medical Center, Netherlands, ³Department of Internal Medicine Erasmus Medical Center, Netherlands, ⁴Department of Internal Medicine, Netherlands, ⁵Department of Epidemiology, Erasmus Medical Center, Netherlands

Abnormal serum phosphate levels (P) have been associated with specific bone mineral density (BMD) phenotypes, such as rickets/osteomalacia and tumoral calcinosis. Nevertheless, the nature of an association of phosphate levels with BMD and fracture risk in the general population is unknown. We tested these relations in elderly Dutch participants from the Rotterdam Study (RS). Fasting serum phosphate was measured with same technique across cohorts; BMD at the femoral neck (FN-BMD) and lumbar spine (LS-BMD) was assessed by dual X-ray absorptiometry (DXA). The association between P and BMD was tested through linear models using three cohorts (RS-I, RS-II and RS-III). We applied competing risk regression models to assess the relation between P and prospective all-type fracture risk in two RS cohorts (RS-I and RS-II). Basic adjustments included age, BMI and smoking. Betas (β (95% CI)) and hazard ratios (HR(95% CI)) were meta-analyzed applying fixed-effect model. Results are expressed per 1 mg/dL increase in P. In BMD analyses, the initial unadjusted significant association of P with BMD at both skeletal sites in women was abolished after adjustment for body mass index (LS-BMD: 0.003(-0.09 to 0.09); FN-BMD: 0.01(-0.06 to 0.07)). In men, P was inversely related only to LS-BMD (-0.13(-0.23 to -0.02)) and this association was not substantially modified after further adjustments for calcium and 25-hydroxyvitamin D levels (-0.11(-0.22 to -0.001)). We found a positive association between P and all-type fracture risk in both sexes (men: 1.54(1.20-1.97); women: 1.23(1.01-1.49); sex-combined: 1.35(1.15-1.58)). Results were similar after further adjustments for levels of calcium, 25-hydroxyvitamin D, kidney function (defined as creatinine-based estimated glomerular filtration rate) and BMD (men: 1.57(1.11-2.22); women: 1.30(1.04-1.64)), or after restricting analyses with subjects with normal kidney function (men 1.81(1.28-2.55); women: 1.25(1.01-1.55)). To conclude, P was negatively related to LS-BMD in men but not women, and no association with FN-BMD was found in either sex. P was positively related to all-type fracture risk in both sexes. Our findings suggest that increased P even within normal range might be deleterious for bone health in the normal population

Bone turnover status in older Hispanic women with type 2 diabetes: preliminary data from the Cameron County Hispanic Cohort in Texas. Nahid Rianon^{*1}, Scott Smith², Matthew Hnatow³, Susan Fisher-Hoch⁴, Joseph McCormick⁵, Catherine Ambrose⁶. ¹UTHealth The University of Texas Medical School at Houston, USA, ²NASA, USA, ³University of Texas Medical School at Houston, USA, ⁴University of Texas School of Public Health, Brownsville Regional Campus, USA, ⁵University of Texas School of Public Health Brownsville Regional Campus, USA, ⁶University of Texas Medical School at Houston, USA

Fracture risk is elevated in individuals with type 2 diabetes (T2D) although, paradoxically, bone mineral density (BMD) is similar or higher than those without diabetes. Bone turnover, which is normally higher in older osteoporosis patients, has been reported to be lower in T2D patients. Limited human studies have reported associations between higher glycated hemoglobin levels (HbA1c) and lower serum osteocalcin (a marker of bone turnover) in older T2D patients. As most of these studies were conducted among Caucasian and Asian populations, there is a gap in knowledge about bone turnover status in Hispanic populations where there is a higher than average prevalence of diabetes. Prevalence of T2D is about 30% in the Cameron County Hispanic Cohort (CCHC) in TX, mostly with high HbA1c. This homogeneous cohort provides a unique opportunity to evaluate bone turnover, monitor risk, and design prevention and treatment of fragility fracture in high risk Hispanic T2D individuals.

BMD was measured using DXA and serum samples analyzed for bone biochemical markers. We present the preliminary cross-sectional results from 23 Hispanic T2D women (≥ 65 years) from the CCHC at baseline and compared them with an age-matched cohort without diabetes from our outpatient osteoporosis clinic in Houston, TX.

Compared to the non-diabetic controls, the T2D individuals had similar femoral neck BMD ($p=0.62$) and T-scores ($p=0.59$). Serum osteocalcin, PTH, magnesium, and vitamin D levels were significantly ($p<0.05$) lower in T2D group. Serum calcium and phosphorous levels were higher in the T2D individuals (not statistically significant). These results are similar to those previously reported for Caucasian and Asian T2D cohorts, which report lower bone turnover in T2D individuals.

Anti-resorptive drugs are frequently prescribed as a first line agent for treating osteoporosis in older individuals with osteoporosis based on BMD or fragility fracture, assuming they have high bone turnover. Our results of lower bone turnover in older Hispanic T2D individuals, therefore, raises concern of even more suppressed bone turnover in this group if treated with anti-resorptive therapy, more so in those with high HbA1c. Further longitudinal research is recommended to answer such concerns. We will continue to monitor this T2D cohort to determine the trend of bone turnover, relationships between HbA1c and bone turnover markers, and risk of fracture in diabetic patients of Hispanic heritage.

Circulating Sclerostin Level in the Elderly with and without Hip Fracture: A Prospective Case-Control Study. Ji WAN Kim^{*1}, Jai Hyung Park², Seong-eun Byun³, Jae Suk Chang⁴. ¹Haeundae Paik Hospital, Inje University, South Korea, ²Orthopaedic Surgery, Kangbuk Samsung Hospital, Sungkyunkwan University, South Korea, ³Orthopaedic Surgery, CHA Bundang Medical Center, CHA university, South Korea, ⁴Orthopaedic Surgery, Asan Medical Center, University of Ulsan, South Korea

Purpose Sclerostin is a protein secreted by osteocytes, and inhibits bone formation. The aim of this study was to compare the laboratory hallmark of osteoporosis and the serum sclerostin level between hip fracture patients and non-fracture group. Methods We conducted a prospective case-control study of 103 participants who admitted to our hospital for the surgery of hip fracture or osteoarthritis from April 2011 to Mar 2014. Serum specimens were collected, and clinical data including age, gender, height, weight, and bone mineral density (BMD), were obtained. After collecting data, case and control patients with available data were precisely matched according to sex and age. The 32 patients were enrolled into each group. We compared the sclerostin levels, laboratory parameters of bone and mineral metabolism and BMD. Results In the fracture group, the sclerostin level was 0.61ng/mL and 0.17ng/mL in the fracture group and control group, and this difference was statistically significant ($p=0.004$). The mean osteocalcin level was significantly lower (15.4ng/mL) in the fracture group than in the control group (21.8ng/mL, $p=0.048$). PTH level was higher in the fracture group (40.1 vs 28.6pg/mL, $p=0.010$), but both result were normal range (10-65pg/mL). There was no significant difference in the serum level of C-telopeptide and alkaline phosphatase, 25 (OH) D, phosphorus and calcium. Bone mineral density (BMD) was lower in the fracture group ($p<0.001$), but body mass index were not different in two groups. Conclusion The serum sclerostin level was higher and the serum osteocalcin level was lower in the fracture group. We concluded that lower ability of bone formation can be in charge of hip fracture besides low BMD.

Comparison of Vertebral Density, Structure, Strength, and Fracture Rate between Hong Kong Chinese and US Caucasian Older Men. Jian Shen¹, Lynn Marshall², Carrie Nielson³, David Lee⁴, Tony Keaveny⁴, Jodi Lapidus⁵, Dennis Black⁶, Jane Cauley⁷, Anthony Kwok⁸, Timothy Kwok⁸, John Schousboe⁹, Eric Orwoll³. ¹Oregon Health & Science University, USA, ²Department of Orthopedics & Rehabilitation, Oregon Health & Science University, USA, ³Department of Medicine, Bone & Mineral Unit, Oregon Health & Science University, USA, ⁴O.N. Diagnostics, USA, ⁵Division of Biostatistics, the Department of Public Health & Preventive Medicine, Oregon Health & Science University, USA, ⁶Department of Epidemiology & Biostatistics, University of California San Francisco, USA, ⁷Department of Epidemiology, Graduate School of Public Health, University of Pittsburgh, USA, ⁸Jockey Club Centre for Osteoporosis Care & Control, & Department of Medicine & Therapeutics, Chinese University, Hong Kong, ⁹University of Minnesota, USA

Osteoporotic fracture is a major public health problem in US and has become an increasingly important concern in Asia. However, differences between these two populations in vertebral structure, volumetric density (vBMD) and vertebral fracture rates are not well understood. Quantitative computed tomography (QCT) scans of the lumbar spine (L1-L2) were acquired in 318 Hong Kong (HK) Chinese and 177 US Caucasian men ≥ 65 yr (mean age: 75y for HK; 74y for US) who were randomly selected from the Osteoporotic Fractures in Men Study (MrOS) cohorts in HK and US. QCT image processing was performed centrally and calibrated to minimize the between-clinical site variation. Finite element analysis (FEA) was used to estimate vertebral strength under compressive loading. We used body weight and height to estimate a compressive force for forward bending at the waist, and a load-to-strength ratio was calculated. Areal BMD (aBMD) was assessed with DXA. Multivariable general linear models with linear contrast were used to compare least square means of the vertebral measures between the HK and US men adjusted for age, weight, height and US enrollment sites. Incident vertebral fractures were assessed (HK: 1544; US: 3978) using semiquantitative (SQ) scoring of lateral thoracic and lumbar radiographs. Fractures were defined as a change in SQ grade ≥ 1 from baseline to follow-up (mean: 3.99 y for HK; 4.56 y for US). We calculated the annualized binomial proportion and 95% confidence interval (CI) for a new or worsening of fracture. Compared to US Caucasian men, HK men were smaller in stature and had 13% lower areal lumbar spine aBMD, 11% smaller vertebral cross-sectional area and 13% lower total compressive strength (Table). After adjustment, these parameters did not differ between groups, although vertebral body height remained higher for the US. The two populations had similar vBMD (from QCT). The load-to-strength ratio was better (21% lower) in HK Chinese than in US Caucasians. Consistent with the trends for the load-to-strength ratio, the annualized vertebral fracture incidence was lower in HK Chinese at 0.68% (0.48%-0.88%) than in US Caucasian men at 1% (0.85%-1.13%). HK Chinese and US Caucasian men had similar vBMD, but differences in vertebral structure and strength that were mainly explained by body size. HK Chinese men had more favorable load-to-strength ratio and this biomechanical advantage appears to provide an explanation for their lower risk of vertebral fractures.

Insulin Resistance and Composite Indices of Femoral Neck Strength in Asians: the Fourth Korea National Health and Nutrition Examination Survey (KNHANES IV). Seong Hee Ahn^{*}, Hyeonmok Kim, Beom-Jun Kim, Seung Hun Lee, Woo Je Lee, Jung-Min Koh, Asan Medical Center, University of Ulsan College of Medicine, South Korea

Purpose: The fracture risk in type 2 diabetes mellitus with insulin resistance increases, despite relatively conserved bone mineral density (BMD). In this present

study, we investigated the relationship between insulin resistance and composite indices of femoral neck strength in Koreans.

Methods: This was a population-based, cross-sectional study from Korea National Health and Nutrition Examination Survey, including 1,243 men and 1,433 women. Insulin resistance was evaluated using the homeostasis model assessment-estimated insulin resistance (HOMA-IR) index. Femoral neck width and axis length were measured from hip dual-energy X-ray absorptiometry scans and combined with BMD, weight, and height to calculate composite indices of femoral neck strength relative to load: compression (CSI), bending (BSI) and impact strength indices (ISI).

Results: HOMA-IR showed an inverse relationship with CSI, BSI and ISI in both genders before and after adjusting for confounders ($P < 0.001-0.029$). CSI was more strongly associated with HOMA-IR than BSI and/or ISI in both genders ($P < 0.001-0.013$). When men were stratified according to HOMA-IR quartiles, all strength indices decreased as the quartile increased after adjusting for all potential confounders (P for trend $< 0.001-0.001$), and CSI and ISI did in women (P for trend = 0.012 and 0.002, respectively). Serum fasting insulin levels, but not glucose levels, were negatively associated with all strength indices regardless of confounders ($P < 0.001-0.044$).

Conclusion: Insulin resistance is associated with low femoral neck strength, particularly against the compressive load. These findings suggest a better approach to evaluate bone health in insulin-resistant individuals.

Mortality risk following incident low-trauma osteoporotic fracture and subsequent fracture: 15-year prospective data from the Canadian Multicentre Osteoporosis Study (CaMOS). Thach Tran^{*}, Dana Bliuc¹, Dunia Alarkawi¹, Tuan Nguyen¹, John Eisman¹, Lisa Langsetmo², Jerilynn C Prior³, Robert G Josse⁴, Stephanie M Kaiser⁵, Christopher S Kovacs⁶, Claudie Berger², David Goltzman², David A Hanley⁷, Jonathan Adachi⁸, Teneke van Geel⁹, Piet Geusens⁹, Joop van den Bergh⁹, Jacqueline Center¹. ¹Garvan Institute of Medical Research, Australia, ²McGill University, Canada, ³University of British Columbia, Canada, ⁴University of Toronto, Canada, ⁵Dalhousie University, Canada, ⁶Memorial University, Canada, ⁷University of Calgary, Canada, ⁸McMaster University, Canada, ⁹Maastricht University, Netherlands

Data on long-term consequences of osteoporotic fracture other than spine and hip are scanty. This study examined the risk of premature mortality associated with different types of low-trauma fracture and subsequent fracture.

Participants in the Canadian Multicentre Osteoporosis Study, an on-going population-based cohort study of Canadians, were followed for 15 years with scheduled interviews and annual postal questionnaires. Incident fractures were identified from annual self-reports and deaths ascertained through contact with a member family or obituary review. 7687 participants (5525 women and 2162 men) aged ≥ 50 years had one or more subsequent visits. Age- and sex-specific standardized mortality ratios (SMRs) for specific fracture types were compared with the representative general Canadian population.

There were 1494 low-trauma fractures followed by 307 deaths in women, and 337 fractures followed by 97 deaths in men. Osteoporotic fractures doubled the risk of subsequent fracture (relative risk: 2.05, 95% confidence interval (CI): 1.84-2.28 in women and 2.55, 1.95-3.30 in men). Risk of death 5 years post-fracture was increased for participants sustaining low-trauma fracture (age-adjusted SMR: 2.38, 95% CI: 2.04-2.75 in women, and 2.63, 2.01-3.37 in men). The risk was increased after virtually every fracture type (see table). The SMR for most fracture types, except for hand, finger, foot and toe, were of similar effect size between women and men; but the risk of several types was not statistically significant presumably due to smaller numbers. Mortality risk was increased for a further 5 years after a subsequent fracture (SMR: 1.83, 95% CI: 1.37-2.39 in women and 2.23, 1.25-3.68 in men). SMRs were higher if fracture occurred before 75 years of age. The most parsimonious model predicting premature mortality included age, current smoking, comorbidities and fracture type. Higher education level was associated with lower risk for women, but not men. Excessive mortality for the first 5 years post fracture was found for virtually all incident low-trauma fractures. The risk was increased for an additional 5 years after subsequent fracture. This study highlights the need for early intervention to decrease subsequent fracture risk and potentially mortality.

Table: Age-adjusted standardized mortality ratios (SMR) for specific type of fracture

| Fracture types | Women | Men |
|------------------------------------|--------------------|--------------------|
| Clinical vertebral | 3.26 (2.15-4.74)* | 3.40 (1.47-6.71)* |
| Hip | 2.12 (1.52-2.88)* | 3.08 (1.80-4.94)* |
| Rib | 3.80 (2.48-5.57)* | 2.20 (1.26-3.57)* |
| Humerus | 1.88 (1.05-3.09)* | 4.09 (1.11-10.45)* |
| Forearm | 2.82 (1.98-3.91)* | 2.35 (0.64-6.02) |
| Pelvis | 1.97 (0.85-3.91) | 1.80 (0.22-6.51) |
| Upper Leg | 4.00 (1.09-10.24)* | 7.40 (0.90-26.76) |
| Lower Leg (knee, ankle, lower leg) | 2.06 (1.07-3.60)* | 1.33 (0.16-6.53) |
| Distal (hand, finger, foot, toe) | 1.29 (0.62-2.37) | 2.50 (0.91-5.44) |

Osteoporosis Treatment is Associated with Better Post-fracture Survival: A 15-Year Prospective Study from Canadian Multicentre Osteoporosis Study.

Dana Bliuc*¹, Thach Tran¹, Dunia Alarkawi¹, Tuan Nguyen¹, John Eisman¹, Claudie Berger², Lisa Langsetmo², David Hanley³, David Goltzman², Jerilynn Prior⁴, Robert Josse⁵, Stephanie Kaiser⁶, Christopher Kovacs⁷, Rick Adachi⁸, Tineke van Geel⁹, Piet Geusens¹⁰, Joop Van Den Bergh¹⁰, Jacqueline Center¹. ¹Garvan Institute of Medical Research, Australia, ²McGill University Health Center, Canada, ³University of Calgary, Canada, ⁴University of British Columbia, Canada, ⁵Toronto CaMOS Center, Canada, ⁶Halifax CaMOS Center, Canada, ⁷St John's CaMOS Center, Canada, ⁸Hamilton CaMOS Center, Canada, ⁹Maastricht University, Netherlands, ¹⁰Maastricht University Medical Center, Netherlands

Osteoporotic fractures are associated with increased risk of mortality. There is evidence that bisphosphonates not only reduce the risk of future fracture but may also reduce post-fracture mortality. This study aimed to examine the effect of osteoporosis medication on mortality risk following low trauma fracture in women and men aged 50+ years, participating in the ongoing population-based Canadian Multicentre Osteoporosis Study (CaMOS).

During 15 years of follow-up (1996-2011), 1165 incident low trauma fractures (971 and 194 in women and men, respectively) were reported. Bone mineral density, information on co-morbidities, medication, and lifestyle were obtained. Treatment groups were classified as: bisphosphonates (BP), and no treatment (NoRx). Osteoporotic fractures were classified into 4 groups: hip, clinical vertebral, proximal and distal skeleton. There were 932 participants treated with BP (841 women and 91 men), and 233 who did not receive any treatment for osteoporosis. Individuals on BP had a higher proportion of fracture risk factors, such as lower BMD, BMI and weight compared to NoRx. The proportion of vertebral fractures was also higher in BP group. There were 299 deaths (168 and 35 in women and men, respectively) over 7,126 person-years follow-up (6,077 and 1,048 in women and men, respectively). Independent predictors of mortality risk in the fracture cohort were older age, male gender, having at least one co-morbid disease, low BMD, lower weight and being inactive. Hip, clinical vertebral and proximal fractures were also independently associated with mortality risk. Notably, despite having a less favourable risk profile, BP treatment was associated with better survival compared to NoRx after adjusting for age, BMD and clinical factors in women [adjusted HR 0.35 (95% CI, 0.23-0.54)] with a similar, albeit non-significant, effect in men [adjusted HR 0.50 (95% CI, 0.39-1.46)]. The reduction in mortality rates was not due to a decrease in the risk of subsequent fracture [subsequent fracture adjusted HR 0.40 (95% CI, 0.26-0.62) and 0.73 (95% CI, 0.42-1.29) for women and men, respectively]. This study has a caveat. The proportion of people who did not receive any treatment (NoRx) is relatively small (20%). Although further analyses is required to assess whether treatment selection criteria may play a role in this outcome, these data suggest that bisphosphonates reduce the risk of post-fracture mortality, particularly in women.

Disclosures: Dana Bliuc, None.

A Multi-Sector Public-Private Partnership Working Together to Improve America's Bone Health. Debbie Zeldow¹, David Lee*². ¹National Bone Health Alliance, USA, ²NBHA, USA

The National Bone Health Alliance (NBHA, www.nbha.org) is a public-private partnership launched in late 2010 that brings together the expertise and resources of its members to collectively promote bone health and prevent disease; improve diagnosis and treatment of bone disease; and enhance bone research, surveillance and evaluation. NBHA currently includes 53 participating organizations (29 non-profit

member organizations, 18 member companies and liaisons representing CDC, CMS, FDA, NASA and NIH).

The concept for NBHA stems from the 2004 Bone Health and Osteoporosis: A Report of the Surgeon General and the June 2008 Summit for a National Action Plan for Bone Health. NBHA's "20/20 vision" is to reduce the incidence of bone breaks 20% by the year 2020.

NBHA provides a platform for its collective voice to weigh in on subjects important to bone health, particularly vitamin D, calcium, bone mineral density reimbursement and utilization and the risks and benefits of the use of bone health therapies; communication among organizations interested in bone health; shared priorities to become reality through pooled funding; and working together towards the goals and recommendations of the National Action Plan.

Fracture Prevention CENTRAL: An online resource center which provides tools to support the implementation of a FLS program including resources, case studies, best practices, business plans and over a dozen webinars - www.FracturePreventionCENTRAL.org .

FLS Pilot: This demonstration study will assess 3 hospitals' adoption and implementation of a FLS across their communities and measure improvement in performance around selected quality measures.

Bone Turnover Marker Standardization Project: NBHA is leading the effort to standardize U.S. bone marker sample collection procedures and standardize bone turnover marker assays used in clinical laboratories through a variety of related efforts, including a bisphosphonate drug holiday study, inter-laboratory and inter-method comparison studies, patient sample collection procedure standardization and development of a standardized reference database project.

2Million2Many: This national awareness campaign is educating health care professionals and the public about the 2 million bone breaks in the U.S. each year that are not accidents but signs of osteoporosis. Campaign materials for both the consumer and provider are available - www.2Million2Many.org microsite.

Awareness and Reasons for Lack of Post-Fracture Osteoporosis Therapy: A

Survey of Post-Menopausal Women. Denise Boudreau¹, Onchee Yu², Akhila Balasubramanian³, Jane Grafton², Jackie Saint-Johnson², Hiedi Wirtz³, Andreas Grauer³, Barry Crittenden³, Delia Scholes*⁴. ¹Group Health Research Institute, Wake island, ²Group Health Research Institute, USA, ³Amgen Inc., USA, ⁴Group Health Cooperative/Group Health Research Institute, USA

Purpose: Osteoporotic fractures cause patient morbidity and increase risk for future fracture. Effective drug therapies for osteoporosis (OP) are available, yet only a minority of women receives osteoporosis pharmacotherapy (OP-Rx) post-fracture. Reasons for lack of post-fracture OP-Rx are not well understood. We undertook the first large scale survey of women with recent osteoporotic fractures to characterize their beliefs about OP and their physician interactions, and to understand the factors associated with lack of post-fracture OP-Rx. Methods: A survey was mailed to 985 women, aged >55 years with an osteoporotic fracture in 2013-2014, who were enrollees of Group Health Cooperative, a large Northwest health plan. Receipt of OP-Rx in the 6 months post-fracture was determined from automated pharmacy data. The associations between factors of interest and non-receipt of post-fracture OP-Rx were assessed using age-adjusted modified Poisson regression with a robust sandwich estimator. Results: 634 women returned the survey (73% response rate, excluding 119 ineligible); mean age was 75 (SD 11.1) and 77% were white. Primary fracture sites were distal forearm (31%), hip (27%), spine (14%), and humerus (18%). 84% of women did not receive OP-Rx within 6 months post fracture. Even among the 11% of women who were on OP-Rx prior to fracture, 40% did not continue therapy following the fracture. Only 20% of all respondents believed that OP-Rx reduces risk of fracture. Women who were not concerned about OP or future fractures, did not think OP caused their fracture, did not think OP-Rx was effective in reducing fractures, or did not believe a fracture put them at risk for future fracture were at increased risk for non-receipt of OP-Rx (Table). Similarly, women who did not discuss OP management or fracture prevention with their physicians, and whose primary source of information on OP was the media or family and friends rather than their medical providers were also at higher risk for not receiving OP-Rx. Conclusions: The majority of women who suffered an OP fracture did not receive OP-Rx in the 6 months post-fracture. This study suggests that patient education about OP, the risk for future fracture after an initial fracture, and the potential benefits of therapy – through physician input or potentially other reliable sources – may help reverse the substantial under-treatment of women post-fracture.

Table. Association between patient perspectives and interactions with medical providers on non-receipt of osteoporosis pharmacotherapy (OP-Rx) within 6 months of osteoporotic fracture

| | | Relative Risk ¹ | 95% CI |
|--|-------------------------------------|----------------------------|-----------|
| Patient self-reported perspectives and beliefs on osteoporosis and fracture | | | |
| Concerned about their future risk of fractures | Not at all vs. very/somewhat | 1.13 | 1.05-1.21 |
| Concerned about osteoporosis | Not at all vs. very/somewhat | 1.21 | 1.14-1.28 |
| Believe a fracture puts them at risk for future fractures | No vs. yes | 1.17 | 1.09-1.25 |
| Believe osteoporosis caused their fracture | No vs. yes | 1.31 | 1.15-1.48 |
| Believe OP-Rx reduces risk of fracture | No vs. yes | 1.22 | 1.09-1.36 |
| Believe harms of OP-Rx outweigh benefits | Yes vs. no | 1.06 | 0.98-1.14 |
| Interactions with medical providers on osteoporosis and fractures | | | |
| Primary source of information on osteoporosis | Media vs. medical provider | 1.13 | 1.05-1.21 |

In-Hospital Assessment and Management of Falls in the Elderly. Anna O'Connor^{*1}, Monidipa Dasgupta², Lisa-Ann Fraser². ¹Schulich School of Medicine & Dentistry, University of Western Ontario, Canada, ²University of Western Ontario, Canada

Objectives: A thorough falls assessment can successfully reduce future fall events and injuries, making it an important part of fall care in the elderly presenting to hospital with a fall. However, the frequency with which patients receive such an assessment is not known. We sought to characterize the assessment and management of elderly patients presenting to hospital with a fall. **Methods:** Records from a tertiary care center between 2003-2014 were searched. A random sample of 180 charts (96 ED and 84 inpatient), describing visits for a "fall" in individuals = 65 year, were selected. Paper and electronic charts were reviewed using a detailed pre-specified data abstraction form. **Results:** Of the 180 patients studied, mean age was 80.2 years (SD=8.46), and 66.1% were women. Many (38.9%) lived at home with family, 20.6% lived alone, and 21.1% lived in nursing homes (NH) or assisted living. Fall related injuries were common with 59.5% sustaining a new fracture. Other serious consequences of falls included: need for a new assistive walking device (21%), new wheelchair dependence (6.3%), other permanent disability (1.7%), new admission to a nursing home (2.8%), and death (3.9%). In terms of falls assessment, only 1.1% of patient charts had documentation of the presumed etiology of their fall on the discharge summary. Similarly, orthostatic blood pressure was documented in 1.7% of patients, 2.2% had a visual assessment, 11.1% underwent formal assessment of cognition, and 17.8% had a medication review. Of the patients who were discharged, 19.2% had no follow-up arranged. Despite the fact that the majority of patients had new fractures, including 83 (46.1% of the cohort) lower limb fractures, only 30 (17.1%) were discharged on Vitamin D, 25 (14.3%) on calcium, and 17 (9.7%) on a bisphosphonate. **Conclusions:** Despite the serious health consequences in elderly patients who presented to the hospital with a fall, very few received a proper falls assessment or an adequate treatment plan. These results suggest a significant care gap and highlight an area of opportunity for future quality improvement.

Miami Veterans Health Administration Fracture Prevention Program. Violet Lagari^{*1}, Andreina Rojas², Silvina Levis², Zeina Hannoush², Marilu Jurado², Daisy Acevedo², Ngina Muigai². ¹University of Miami, USA, ²University of Miami School of Medicine & Miami VA Health System, USA

Introduction
 Osteoporosis is a public health problem affecting more than 200 million people worldwide. Although the general awareness about osteoporosis and its consequences has been steadily increasing, rates of osteoporosis medication use after a fracture have declined significantly from 40.2% in 2002, to 20.5% in 2011. In 2012, an expert task force encouraged the implementation of a "fracture Liaison Service" to prevent secondary fractures which, when implemented, has shown to significantly improve

treatment for osteoporosis after an initial fracture. VA Office of Inspector General 2010 report stated that only 42% of veterans with osteoporotic fractures had received recommended management.

Methods

We identified veterans 50 years of age and older with an ICD-9 of fracture in calendar year 2012 who had one or more visits to a primary care provider (PCP) at Miami VA in 2012. We excluded patients with non-osteoporotic fractures, remote fractures, those who had a DXA scan, or were already on or declined treatment. Electronic medical records were reviewed to confirm eligibility criteria and generate a list stratified by PCP. A secure email message was sent to the PCPs listing the patients who had sustained an osteoporotic fracture and offering 3 different follow up options: start medical therapy, request an endocrinology e-consult or referral to endocrinology. We will reevaluate what measures were taken to improve care 6 months after the email was sent.

Conclusion

We expect that the implementation of an outpatient secondary fracture prevention program at the Miami VA will result in increased rates of treatment of veterans with osteoporotic fractures.

Osteoporosis-Related Knowledge, Self-Efficacy and Health Beliefs Among Chinese Breast Cancer Survivors. Evelyn Hsieh^{*1}, Qin Wang², Liana Fraenkel¹, Elizabeth Bradley³, Weibo Xia⁴, Karl Inosogna¹, Jennifer Smith⁵, Youlin Qiao², Pin Zhang². ¹Yale School of Medicine, USA, ²Cancer Institute & Hospital, Chinese Academy of Medical Sciences, China, ³Yale School of Public Health, USA, ⁴Peking Union Medical College Hospital, China, ⁵UNC Gillings School of Public Health, USA

Women with breast cancer (BC) are at increased risk for fracture. Understanding behavioral factors that influence adoption of fracture prevention measures in this population is critical. Utilizing concepts from the Health Beliefs Model, we sought to evaluate osteoporosis-related knowledge, self-efficacy, and health beliefs among a cohort of breast cancer survivors in China.

From April to August 2014, BC survivors at the Cancer Institute and Hospital of the Chinese Academy of Medical Sciences were invited to participate in this cross-sectional study. Eligibility criteria: 50-70 years of age, no history of prior osteoporosis or metabolic bone disease. Measures: A mandarin-language questionnaire including sociodemographic and fracture risk assessment, the International Physical Activity Questionnaire, a calcium and vitamin D intake scale, the Osteoporosis Knowledge Test (OKT), Osteoporosis Self-Efficacy Scale (OSES), and Osteoporosis Health Beliefs Scale (OHBS).

Two hundred women were enrolled with a mean age of 57.5 ± 4.9 yrs, and BMI of 24.9 ± 3.7 kg/m². Fifty-three percent reported high levels of physical activity, and on average women reported consuming calcium/vitamin D-rich foods more than once weekly. Mean OKT score was 11.9 ± 3.8 (scale: 0 to 26). OSES scores (scales: 0 to 100) reflected greater confidence for adopting dietary intake behaviors (89.3 ± 12.8) compared with exercise-related behaviors (66.8 ± 15.2). OHBS scores (scales: 6 to 30) showed high levels of health motivation (26.7 ± 2.9), high perceived benefit to exercise and dietary calcium intake (25.9 ± 3.6 and 23.6 ± 3.3, respectively), and relatively low perceived barriers to these activities (14.0 ± 3.9 and 14.0 ± 3.5, respectively). Logistic regression adjusted for age and BMI showed that high dietary calcium/vitamin D intake was associated with fewer perceived barriers to dietary calcium intake (OR 0.84, 95%CI 0.77-0.93, p=0.001), and high physical activity level was associated with fewer perceived barriers to exercise (OR 0.92, 95%CI 0.84-0.99, p=0.04) and higher self-efficacy (1.02, 95%CI 1.01-1.05, p=0.02).

Despite high risk for fracture, women in our study demonstrated only moderate levels of knowledge regarding osteoporosis. Perceived barriers to dietary calcium intake and physical activity, as well as self-efficacy regarding physical activity may influence uptake of these behaviors. Understanding these associations can aid development of targeted fracture prevention measures.

Real-World Clinical and Economic Outcomes In Daily Teriparatide Patients in Japan. Russel Burge¹, Masayo Sato^{*2}, Tomoko Sugihara³. ¹Eli Lilly & Company, USA, ²Eli Lilly Japan K.K., Japan, ³Inventiv Health Clinical, USA

Purpose: To estimate clinical and economic outcomes for daily teriparatide (d-TPD) patients in Japan in real-world clinical practice.

Data and Methods: A large database (Medical Data Vision Co., Ltd.) with medical and pharmacy claims from 121 hospitals in Japan was used for this study. From April 2008-July 2013, 1244 patients with an index prescription of d-TPD and with 6+ months' pre- and post-index observation were identified. Administered via daily 20mcg subcutaneous injection, d-TPD is indicated for individuals at high risk of fracture. From this sample, 445 patients had 18+ months of follow up, and were the

study's focus. Descriptive analyses were conducted on clinical vertebral and nonvertebral fractures, health care resource use, and costs. D-TPD adherence was measured by medication possession ratio (MPR) (High MPR ≥ 0.8; 0.5 < Medium < 0.8, low MPR < 0.5). Adjusted analyses of Lower (low+medium) MPR vs High MPR for fracture incidence and hospital admissions were performed using Logistic and Poisson regression models with Log-link, controlling for cross-group differences in demographics and clinical characteristics. Adjusted cost analyses used Propensity Bin Bootstrapping, controlling for baseline characteristics.

Results: Baseline patient characteristics were: mean age 74.7 years (SD=8.9); 90% female; 87% aged 65+; 20% had 1+ fracture. Post-index, 249 and 196 patients had High and Lower MPR, respectively. Mean incident fractures/1000 patient years for Lower and High MPR patients were 77.4 and 57.7, respectively. Adjusted risk of fracture was greater in Lower MPR patients in Logistic (OR=1.67, 95% CI=0.791, 3.541) and Poisson models (Incidence ratio, IR=1.505, CI=0.764, 2.966), though not statistically significant. Mean hospital admissions, length of stays, and surgeries are summarized in Table 1. Adjusted risk of hospital admission was significantly greater in Lower vs. High MPR patients (Logistic model: OR=1.85, CI=1.169, 2.921; Poisson model: IR=1.47, CI=1.137, 1.904). During d-TPD use High MPR patients had numerically lower inpatient and total unadjusted costs vs. Lower MPR patients. Adjusted inpatient costs were significantly less in High MPR patients, but outpatient and pharmacy costs were greater.

Conclusions: Better adherence to daily teriparatide revealed numerically lower fracture risk, and significant reductions in hospital admissions and costs. The small sample size limited the robustness of these results, however.

Table 1: Health Care Resource Use and Costs For Daily Teriparatide Patients Per Patient Per Month, Post-Index (N=445)

| Health Care Resource Use, Unadjusted~ | Hospital Admissions | Hospital Length of Stay | Outpatient Visits | Surgeries |
|---------------------------------------|---------------------|-------------------------|-------------------|-------------------|
| 18-month MPR | Mean (SD) | Mean days (SD) | Mean (SD) | Mean (SD) |
| Lower (<=80%) (N=196) | 0.182 (0.61) | 3.321 (7.345) | 1.84 (1.551) | 0.085 (0.203) |
| High (>80%) (N=249) | 0.028 (0.07) | 0.565 (1.646) | 1.535 (0.867) | 0.054 (0.068) |
| | Inpatient Hospital | Outpatient | Pharmacy | Total |
| Costs, Unadjusted~ | Mean (SD) | Mean (SD) | Mean (SD) | Mean (SD) |
| Lower (<=80%) (N=196) | 95,790 (197,813) | 20,214 (21,272) | 60,940 (28,919) | 176,943 (201,910) |
| High (>80%) (N=249) | 21,503 (70,897) | 20,318 (24,043) | 64,780 (27,452) | 106,601 (91,133) |
| | Inpatient Hospital | Outpatient | Pharmacy | Total |
| Costs, Adjusted^ | Mean | Mean | Mean | Mean |
| Lower (<=80%) (N=196) | 35,961* | 14,404* | 27,981* | 78,345* |
| High (>80%) (N=249) | 22,064 | 20,274 | 64,119 | 106,457 |

Notes: Resource use means are per patient. All costs are in 2013 Japanese Yen. Abbreviations: SD = standard deviation. ~Unadjusted health care resource use and unadjusted costs were measured during d-TPD exposure time period. ^The adjusted costs were from Propensity Bin Bootstrapping, controlling for 6-month baseline patient demographics and clinical characteristics. All adjusted costs were measured over an 18-month post index period. *P<0.05 relative to high (MPR).

Reasons for Patient Non-Adherence to Recommended Osteoporosis Pharmacotherapy. Sylvie Hall*¹, Stephanie Edmonds², Yiyue Lou³, Peter Cram⁴, Douglas Roblin⁵, Kenneth Saag⁶, Fredrick Wolinsky⁷. ¹University of Iowa Hospitals & Clinics, USA, ²University of Iowa Carver College of Medicine, USA, ³University of Iowa College of Public Health, USA, ⁴University of Toronto, Canada, ⁵Kaiser Permanente, USA, ⁶University of Alabama at Birmingham, USA, ⁷University of Iowa College of Public Health, USA

Purpose: Half of all patients recommended for osteoporosis (OP) pharmacotherapy do not take their medications. The purpose of this study was to examine patients' reasons for not adhering to recommended OP pharmacotherapy and differences in patient characteristics among those who did and did not adhere in order to target interventions designed to increase pharmacotherapy adherence rates and improve bone health. Methods: We used participants from the Patient Activation after DXA Result Notification (PAADRN) study, a randomized controlled trial of 7,749 participants 50 years old or older presenting for DXA scans at three medical centers in the United States (site A, B, C). Participants were first interviewed at the time of their index DXA, and then 12 weeks later. For this study, we focused on the 790 participants who reported that their healthcare provider had recommended an OP medication at 12-weeks post-DXA. We compared those who reported starting the recommended medication (adherers) and those who did not (non-adherers) on a variety of factors including demographics, health habits, DXA impression, FRAX risk, and osteoporosis knowledge using Pearson Chi-squared tests for categorical variables, and two sample t-test for continuous variables. Results: Mean age was 66.8 (SD = 8.9), 87.2% were women, and 84.2% were white (Table 1). One-fourth (24.8%) reported that they did not start the recommended medication while 75.2% participants said that they did. Non-adherers had better scores on a measure of OP knowledge (p<0.05). Adherence did not differ by patient demographics. The most common

reasons for non-adherence were fear of side effects (28.3%), a dislike of taking medicine (13.7%), and the belief that the medicine would not help their condition (8.7%). Conclusions: Patients who are recommended for OP pharmacotherapy report that they decline treatment because of the fear of side effects or the belief that the medication will not help their condition; they also have better OP knowledge. These findings suggest that improved patient counseling regarding the side effects of OP treatment and the risk-benefit ratio for these medications could increase adherence rates. Providers should address these issues in discussions with their patients.

Table 1: Characteristics of PAADRN Participants Who Were Recommended to Take Medications after Baseline DXA

| Variable | Reported Not Taking the Medication (N=196; 24.8%) | Reported Taking the Medication (N= 594; 75.2%) | P-value |
|---|---|--|----------------|
| Age | | | |
| < 65, number (%) | 89 (45.4) | 229 (38.6) | 0.090 |
| ≥65, number (%) | 107 (54.6) | 365 (61.4) | |
| Gender | | | |
| Men, number (%) | 19 (9.7) | 82 (13.8) | 0.135 |

Reasons for Patient Non-Adherence to Recommended Osteoporosis Pharmacotherapy Table 1

Disclosures: Sylvie Hall, None.

SA0298

Relationship between Gastrointestinal Events and Compliance with Osteoporosis Therapy: An administrative claims analysis of US Managed Care Population. Ankita Modi*¹, Shiva Sajjan². ¹Merck & Co., Inc., USA, ²Merck & Company, USA

Background: A large proportion of women with osteoporosis (OP) do not comply with their prescribed OP therapies, which may lead to an increase in fracture risk. Occurrence of gastrointestinal (GI) events during the course of OP therapy may be one of the reasons for non-compliance.

Purpose: To estimate the rate of gastrointestinal (GI) events and their association with osteoporosis treatment compliance.

Method: A retrospective cohort study using a large US administrative claims database from 2007 through 2013 was conducted. Claims for osteoporotic women ≥65 years old continuously enrolled in a health plan for at least 2 years, a baseline year before and a follow-up year after the date of the first prescription of oral bisphosphonate (index date) were included. Women were excluded if they had a claim for any OP medication in the baseline year, or a diagnosis of Paget's disease or malignant neoplasm. Oral bisphosphonates were identified based on national drug codes and included alendronate, ibandronate, and risedronate. The medication possession ratio (MPR) was calculated as the total days supply of all OP medications received in the follow-up period divided by 365 days. Compliance was defined as MPR of ≥ 0.80. GI events were assessed using ICD-9 diagnosis or CPT procedure codes. Logistic regression analysis was used to examine the association of post-treatment GI events and compliance adjusting for baseline covariates such as age, OP fracture, GI events, use of gastro-protective agents, NSAIDs, glucocorticosteroids, estrogen and Charlson comorbidity Index.

Results: A sample of 45,031 women taking at least one oral bisphosphonate with mean (SD) age of 72 (7.4) years was identified. A total of 17,481 (38.8%) patients experienced at least one GI event during the follow-up period. Overall, only 14,071 (31.2%) patients were compliant with their oral OP therapy, compliance was even lower among those having GI event with only 27% (n=4,750) with an MPR \geq 0.80. Patients who experienced GI events after initiation of oral bisphosphonates were 24% less likely to comply with OP therapy as compared to patients who did not experience post-treatment GI events (odds ratio [95% CI], 0.76 [0.728–0.796]; $P < .001$).

Conclusions: The rate of GI events was high among elderly osteoporotic women initiating oral bisphosphonates. GI events were associated with low treatment compliance which may result in increased fracture risk among this population.

Safety concerns and treatment monitoring among senior Chinese orthopedists in the management of osteoporotic fracture: a nationwide survey in China.
Pan Wei, Li Senyuan*, Man Yi, Liu Xun. Novartis, China

Objectives: To understand the safety concerns and treatment monitoring among senior Chinese orthopedists from tertiary hospitals in the management of osteoporotic fracture.

Material and Methods: A questionnaire with multiple-choice items according to Chinese and several international osteoporosis guidelines and advice from orthopedic specialists was designed. The questionnaire was drafted in the manner of standard flow and was pre-tested, and its reliability and validity met statistical criteria. Face to face surveys were conducted and instructed by investigators among 509 orthopedists who are deputy directors and above in Mainland China. Tablet computers were used to save the questionnaire.

Results: In all, 484 effective questionnaires (95%) were confirmed, of them, 98% agreed risk of fracture recurrence would be increased if a patient has a history of fragility fracture. The most common choice for first-line treatment of osteoporosis is bisphosphonates (80%). Nearly a quarter (23%) held the opinion that using bisphosphonates has an effect on fracture healing and 29% did not. More than half (57%) knew that acute-phase response may occur after either oral or intravenous bisphosphonates administration, and more than two-thirds (73%) knew that acute-phase response rate of intravenous bisphosphonates would drop if oral bisphosphonates were administered before. Regarding long-term management of osteoporosis, most (63%) would suggest visiting department of orthopedics, while department of endocrinology and osteoporosis received same vote (17%). For bone mineral density re-evaluation: 85% would recommend it; 52% would recommend it every 12 months and 39% would recommend it every 6 months. Three-fifths of the respondents chose bone turnover markers could be monitored in their hospitals, 27% were negative about the feasibility, and 13% chose uncertain. For prescription of bisphosphonates, 68% would consider it appropriate if aminotransferase is more than 2 times the normal range.

Conclusion: This survey showed that anti-osteoporosis treatment received quite awareness among senior Chinese orthopedists, while treatment monitoring was less cared. Safety use of bisphosphonates was a major concern but it was not well understood.

Semi-Automated Radiology Report Screening to Facilitate a Fracture Liaison Service. Agnes Zak*¹, Ronilda Lacson², Sara Lee¹, Ramin Khorasani², Daniel Solomon³. ¹Brigham & Women's Hospital, USA, ²Center for Evidence-Based Imaging, USA, ³Harvard Medical School, USA

Purpose: Osteoporosis represents the major risk factor for fractures in patients over 60 years old, and associated costs are estimated to exceed \$25 billion in 2015. However, there is a large gap in identifying these patients for secondary treatment after an initial fracture. To facilitate identification of osteoporotic fractures at a large medical center, we developed a semi-automated tool that uses Natural Language Processing (NLP) to scan a hospital-wide database of radiology reports for possible osteoporotic fractures.

Methods: The NLP system uses pre-determined query terms, derived from confirmed osteoporotic fracture cases, to scan reports linked to CPT procedure and ICD-9 diagnosis codes associated with humeral, vertebral, and hip fractures. This tool was run on a weekly basis reviewing all relevant radiologic imaging reports (e.g. spine and hip imaging reports) generated in the prior week. A brief chart review (<5 minutes per fracture) was performed to confirm that fractures were likely due to osteoporosis.

Results: The system identified 2148 potential fractures over an 8-month period. After chart review, 1400 (65%) fractures were excluded, 919 for no confirmation of fracture and 419 for reasons believed to be unrelated to osteoporosis such as cancer or major trauma. The remaining 748 (35%) potential osteoporotic fractures were categorized into the 8 groups shown in the Figure. The majority of these potential fractures (56%) had actually occurred >8 weeks from radiology report date. A small

portion of the fractures (4%) were present in a population <50 years old at diagnosis. Additionally, 11% of fractures had occurred <8 weeks from report date in patients >50 years old. This group had three sub-categories including multiple anatomic fracture sites, patient mental status/native language/residency, and death indicator.

Conclusions: The use of a semi-automated NLP tool can rapidly screen for patients who may require follow-up osteoporosis care. This screening process will facilitate referral to a fracture liaison service for appropriate treatment, bridging the communicative gap between acute and primary care settings. Further modification of NLP qualifiers can enhance the accuracy of identified fractures and eliminate the need for manual, confirmatory chart review or target a specific category of fracture based on investigator interest.

SA0301

Serum calcium levels required for the increase in bone mineral density by the combination therapy of bisphosphonate and active vitamin D3 analog for the treatment of osteoporosis. Mayuko Kinoshita*¹, Muneaki Ishijima², Haruka Kaneko², Lui Liz³, Ryo Sadatsuki², Shinnosuke Hada², Anihar Yusp², Hidetoshi Nojiri⁴, Yuko Sakamoto⁵, Kazuo Kaneko². ¹Juntendo University, Japan, ²Department of Orthopaedics & Motor Organ, Juntendo University Graduate School of Medicine, Japan, ³Sportology Center, Juntendo University Graduate School of Medicine, Japan, ⁴Department of Orthopaedics, Juntendo Tokyo Koto Geriatric Medical Center, Tokyo, Japan, ⁵Department of Orthopaedics, Juntendo Nerima Hospital, Japan

Since vitamin D insufficiency is one of the risk factors for the decrease in BMD, the combination therapy of Bisphosphonates (BPs) and active vitamin D3 analog (aVD) in osteoporosis treatment has become widespread in Japan. We reported that there were the "non-responders" in this combination therapy and the risk factor for the non-responder was the 8.5-9.0 mg/ml of serum level of calcium (sCa) [reference range (8.5-10.5 mg/ml)] at baseline. The aim of this retrospective study was to find out the sCa levels to obtain the increase in BMD adequately. Since 2008 to 2013, 275 osteoporotic patients were started to use BPs. As the 166 were excluded, the remaining 99 female patients were included in this study. While BPs used in this study were alendronate, risedronate or minodronate. aVD used in this study were either alfacalcidol or eldcalcidol. In addition to age and body mass index (BMI), serum levels of 25(OH)D, Ca (sCa), Pi (sPi), intact PTH, bone turn markers including TRACP5b and BAP, lumbar spine (L2-L4) BMD (LS-BMD) and femoral neck BMD (H-BMD) were assessed for every 6 months for 2 years. Both LS-BMD ($p < 0.001$, 5.4%) and H-BMD ($p = 0.007$, 1.8%) of the patients were significantly increased by this combination therapy for 2 years. sCa level was also significantly increased within the reference range ($p < 0.001$), while intact-PTH, sBAP and TRACP5b were significantly decreased by this combination therapy for 2 years ($p < 0.001$). sCa level was peaked out about 9.5 mg/ml in 18 months. Multiple regression analysis revealed that the factor affects both the %LS-BMD ($r^2 = 0.452$, $p = 0.030$) and %H-BMD ($r^2 = 0.464$, $p = 0.030$) were the sCa level at first visit. Patients were divided into two groups in terms of sCa level for %LS-BMD and %H-BMD. The %LS-BMD after 6 month-treatment of the lower group (0.4%) was significantly different in comparison to that of the higher group (1.5%) ($p = 0.030$) and borderline sCa level was 9.0 mg/ml. Similarly for %H-BMD, the lower group (0.0%) was significantly different in comparison to that of the higher group (1.2%) ($p = 0.027$) and borderline sCa level was 9.3 mg/ml. When sCa level was 9.3 mg/ml or more, odds ratio for the increasing both %LS-BMD and %H-BMD by the combination therapy for next 6 months was 4.9 (95%CI: 1.87 to 12.71). In conclusion, the increase in BMD by the treatment of the combination therapy of BPs and aVD was associated with the sCa level before starting the treatment, even though it is within the reference range.

Hospitalizations for Osteoporosis-Related Fractures: Economic Costs and Clinical Outcomes. Derek Weycker¹, Xiaoyan Li², Rich Barron², Rebecca Bornheimer¹, Alex Kartashov¹, David Chandler^{*2}. ¹Policy Analysis Inc. (PAI), USA, ²Amgen Inc., USA

Background: Osteoporotic fractures frequently require inpatient care, and are associated with elevated risks of morbidity, mortality, and re-hospitalization. A comprehensive evaluation of healthcare costs, resource utilization, and outcomes associated with osteoporosis-related fractures treated in US hospitals was undertaken.

Methods: A retrospective design and data from the Premier Perspective Database (2010-2013) were employed. The Premier Database includes validated discharge records for all inpatient admissions from >400 geographically diverse US hospitals. The study population comprised patients aged ≥50 years who were hospitalized with a primary diagnosis of a closed or pathologic fracture commonly associated with osteoporosis; the first qualifying hospitalization was designated the “index admission”. Patients with evidence of major trauma or malignancy (or other [non-osteoporotic] conditions that may lead to pathologic fracture) during their index admission were excluded. Study measures included healthcare costs, length of stay (LOS), intensive care unit (ICU) use, and mortality during the index admission, as well as 60-day fracture-related re-hospitalization.

Results: A total of 268,477 patients were admitted to hospital (n=548 hospitals) with a primary diagnosis of an osteoporosis-related fracture; mean (SD) age was 78 (11) years, 75% were female, 69% had ≥2 comorbidities, and 82% of patients had a diagnosis code for accidental fall. For all fractures, mean (95% CI) hospital cost was \$12,839 (12,784-12,893), LOS was 5.1 (5.1-5.1) days, ICU use was 7.4% (7.3-7.5), and mortality was 1.5% (1.5-1.6); 60-day fracture-related re-hospitalization was 2.3% (2.2-2.4). Study measures for selected fracture types are presented in the Table.

Conclusions: Hospital costs associated with the treatment of osteoporosis-related fractures are high—especially among patients with fractures of the hip and femur, and those with multiple fractures—and are comparable to or exceed those for other serious conditions such as stroke, heart failure, and chronic obstructive pulmonary disease (COPD). Among patients with vertebral fractures—the second most common reason for admission—mortality and ICU use were notably high, and costs and LOS were higher than among those with non-vertebral fractures (excluding hip). Interventions that are effective in reducing fracture risk have the potential to yield substantial cost savings.

More Evidence of a Broken Post-Fracture Care Process: A Call for a Fracture Liaison Service. Daniel Solomon^{*1}, Chih-Chin Liu², Mitch Harris². ¹Harvard Medical School, USA, ²Brigham & Women’s Hospital, USA

Background/Purpose: It has been widely noted that post-fracture osteoporosis treatment rates are dismal in typical practice settings. However, a careful examination of the process of post-fracture care at a large US medical center is lacking in the literature. In preparation for developing a Fracture Liaison Service (FLS), we examined a linked dataset that includes rich information from an electronic medical record (EMR) plus claims data from Medicare. Methods: We identified patients hospitalized with an acute fracture in 2008-2011 who were older than 65 years of age. Medicare data were linked with these patients using an exact matching system through insurance identification numbers. We examined the rates and timing of osteoporosis treatments after the index acute fracture. Cox proportional hazard regression models allowed us to identify pre-fracture variables associated with lack of treatment. As well, the post-fracture process of care was analyzed to determine possible reasons for lack of treatment (lack of diagnosis or visits for osteoporosis, lack of local primary care provider). Finally, we examined the rates of subsequent fractures among patients who did and did not receive post-fracture osteoporosis treatment. Results: We identified 1,586 patients with an acute hospitalized fracture who were Medicare eligible. The distribution of fracture type was as follows: 28.9% hip, 11.1% humerus, 11.9% pelvis, 36.2% spine, and 11.9% Wrist. The mean age of patients was 80.1±7.9 years, 72.1% were female, and 15.8% had evidence of a prior fracture in their

Medicare data. During follow-up, 19.2% had a medication for osteoporosis started or re-started. For patients with prior treatment for osteoporosis, this percentage was 56.1% and for those without prior treatment 12.1%. The types of medications included: calcitonin (5.9%), hormone replacement therapy (22.0%), IV bisphosphonates (18.8%), oral bisphosphonates (49.0%), raloxifene (2.6%), and teriparatide (1.6%). The median time until the start of such medications was 407 (interquartile range 111 - 868) days (see Figure). 29 (1.8%) patients died during follow-up. Conclusions: At one large US medical center, post-fracture osteoporosis treatment rates were sub-optimal. Further data will be presented describing the process of care post-fracture and subsequent fracture rates. These data will help us design a more targeted Fracture Liaison Service that serves patients at high risk of sub-optimal care.

Differential effect of dietary calcium intake on bone mineral density according to body size in older adults. Kyoung Min Kim^{*1}, Dong Hwa Lee¹, Soo Lim¹, Sung Hee Choi¹, Jae Hoon Moon¹, Jung Hee Kim², Sang Wan Kim³, Hak Chul Jang¹, Chan Soo Shin². ¹Seoul National University Bundang Hospital, South Korea, ²Seoul National University Hospital, South Korea, ³Boramae Hospital & Seoul National University College of Medicine, South Korea

Limited information suggests that calcium requirement for bone accretion is associated with skeletal size in growing phase. The objective of this study was to investigate whether the interactions between dietary calcium intake and bone mineral density (BMD) could be different according to the height in older adults.

This was a cross-sectional study of data from the Korea National Health and Nutrition Examination Survey from 2008 to 2010. A total of 7562 older adults aged 50 years and older (3425 men and 3938 women) were included and further stratified into three groups by ± 1SD of height in each gender: short, middle and tall groups. Dietary calcium intake was classified into three groups, less than 400 mg/d, 400-799 mg/d, and 800 mg/d or greater. All the study participants underwent dual-energy X-ray absorptiometry to estimate BMD at lumbar spine (LS), femur neck (FN) and total hip (TH)

Age and body mass index (BMI) showed significant differences between the dietary calcium intake groups in each height-group both in men and women, indicating lowest dietary calcium intake group provided significantly older age and lower BMI. In men, BMDs were positively associated with dietary calcium intake for LS, FN and TH in tall and medium groups adjusting for age, BMI and 25-hydroxy vitamin D (25OHD) levels, and the associations were stronger in tall group than those of middle group (p for trends <0.05, respectively). However, no significant differences were observed in short group for all skeletal sites in men. In women, LS BMD showed no significant differences according to dietary calcium intake in all height groups after adjusting same covariates. However, FN BMD were positively associated with dietary calcium intake in all height groups (p for trends <0.05, respectively). TH BMD showed significant differences according to dietary calcium intake in tall and short groups (P=0.033 in tall and P=0.042 in short group), whereas no significant difference in medium height group (P=0.089). The results of the present study demonstrate that the positive association between BMD and dietary calcium intake was more evident in tall and medium groups than those of short height group. These findings could suggest that the calcium requirement for bone health in older adults might be associated with skeletal size.

The Low Calcium Intake in Postmenopausal Women in the Czech Republic. Vaclav Vyskocil*¹, Frantisek Senk Senk², Pavel Novosad³, Olga Ruzickova⁴, Barbora Skyvarova². ¹Center for Metabolic Bone Diseases, Czech republic, ²Osteocenter Regional Hospital, Czech republic, ³Osteology Academy, Czech republic, ⁴Institut of Reseach Revmatology, Czech republic

The optimal dosage of calcium and vitamin D is very often discussed not only in regards to its effect on the reduction of the risk of fractures but recently also in connection with cardiovascular risk versus its benefit.

Authors of the mentioned centers used detailed questionnaires to determinate the average calcium intake from food and supplementation by patients measured in osteocenters and by that they followed the European study by O. Bruyer from 2007 which didn't contain Czech and Slovakian data.

Patients were divided into two groups, non-treated – with osteopenia using only supplementation and treated – using biophosphonates and supplementation. As a part of the acquired and evaluated data was also BMD in spine, neck and whole hip joint and also risk factors monitored with FRAX and vitamin D level, resp. 25(OH)D expressed in nmol/L.

According to the questionnaire survey it was discovered that only 57 percent of patients use supplementation regularly and from food they gain only about 200-300 mg of calcium per day. From the results of the survey, which has many limitations, comes out that the consumption of milk and dairy products is very low and the recommended values can't be reached without calcium supplementation. Most of the patients (from 60 to 70 percent) present a fluid intake 1-2 liters per day, only 4-5 percent present the intake under 1 liter per day. The vitamin D supplementation paradoxically seems to be better than the calcium saturation. Authors suppose that the acquired values of vitamin D are higher than reality. Very interesting is the high percentage of risk factors – the previous osteoporotic fracture is presented in 26 percent (in treated group 49 percent), menopause before 45th year of age occurred in 20 percent (in treated group only in 15 percent). The supplementation is regularly used only by 57 percent of patients in non-treated group and 76 percent in treated group. From the point of eating habits and fluid intake there weren't discovered any differences between the urban and country population and also the education didn't have any effect on these results.

The calcium intake from food was in both observed groups insufficient and up to 85 percent of patients in the non-treated group is without supplementation containing calcium.

The survey proved that the total calcium intake from food/supplementation by Czech women is, similarly to European women, low – in the non-treated group it was under 500 mg per day.

Association of the Dietary Inflammatory Index, Bone Mineral Density and Risk of Fracture in Postmenopausal Women. Tonya Orchard*¹, Vedat Yildiz¹, Susan Steck², James Hebert², Rebecca Jackson¹. ¹Ohio State University, USA, ²University of South Carolina, USA

Objective: Evaluate the association of an anti-inflammatory diet pattern, as measured by the Dietary Inflammatory Index (DII), with changes in bone mineral density (BMD) and risk of fracture in postmenopausal women.

Methods: The inflammatory potential of the diet was estimated using DII scores calculated from the baseline food frequency questionnaire for participants of the Women's Health Initiative (WHI) Observational Study and Clinical Trials who reported no history of hip fracture at baseline (n=161,595). BMD was measured in a sub-group (n=10,290) at baseline and years 3, 6 and 9 using dual-energy X-ray absorptiometry. Fractures were reported annually; hip fractures were confirmed by medical record review. Percent changes in hip and spine BMD over 9 years of follow-up were analyzed by pair-wise comparisons by Quartile (Q1 = reference, most anti-inflammatory diet) of baseline DII scores. Cox proportional hazard models were used to compute hazard ratios for fractures adjusted for important covariates.

Results: Women with the most anti-inflammatory diet (Q1) were older, had a lower BMI, were more likely to be White, and reported higher calcium intake, more physical activity and more falls than women in Q4. Women in Q1 had a greater increase in spine BMD compared to women in Q4 at year 6 (0.85%; p=0.003), but no significant differences at years 3 or 9. Those in Q1 had lower mean hip BMD at baseline, but lost significantly less BMD at the hip (0.54%; p=0.012) over 9 years of follow-up versus Q4. Women with the most pro-inflammatory diet had a significantly higher risk of hip fracture in Cox models adjusted for age and race (Q4 HR: 1.12; 95% CI 1.02, 1.23; p for linear trend 0.01), but risk disappeared after multivariate adjustment (Q4 HR: 1.02; 95% CI 0.91 -1.15; p for linear trend 0.82). Conversely, in fully adjusted models, lower arm fracture and total fracture risk decreased by 8% (p for trend 0.02) and 5% (p for trend 0.01) respectively in women in Q4. In analyses

excluding women who reported taking hormones or bone-active medications or those in the active treatment arm of the WHI Hormone Therapy trial, the risk of hip fracture increased by 17% in women consuming the most pro-inflammatory diet although this was not statistically significant (Q4 HR: 1.17, 95% CI: 0.93-1.46; p for trend 0.35). In contrast, women in Q4 had a 14% lower risk of lower arm fractures (Q4 HR: 0.86; 95% CI 0.75, 0.99; p for trend 0.02), and a non-statistically significant lower total fracture risk (Q4 HR: 0.94; 95% CI 0.87, 1.01; p for trend 0.06).

Conclusion: An anti-inflammatory dietary pattern was associated with less loss of BMD in postmenopausal women, but this did not translate into reduced fracture risk.

Comparative Study of Net Calcium Absorption of Two Different Pharmaceutical Formulations of Calcium Carbonate in Postmenopausal Women. Silvina Mastaglia*¹, Dana Watson², Julia Somoza³, Roxana Gainotti⁴, Graciela Brito², Beatriz Oliveri⁵. ¹Laboratorio De Enfermedades Metabólicas Óseas, CONICET-UBA, Argentina, ²Laboratorio de Enfermedades Metabólicas Óseas (INIGEM), CONICET-UBA, Argentina, ³Laboratorio de Enfermedades Metabólicas Óseas (INIGEM) CONICET-UBA, Argentina, ⁴Mautalen, Salud e Investigación., Argentina, ⁵Laboratorio de Enfermedades Metabólicas Óseas (INIGEM), CONICET-UBA, Argentina

Calcium supplementation, administered alone or associated to a specific medication for osteoporosis, would reduce bone mass loss and fracture risk in postmenopause. However, the adherence rate to calcium supplements is low, mainly due to low tolerance. New formulations with the same effect but better tolerance are required. **Objective:** To compare calcium (Ca) net absorption rate, between two different pharmaceutical formulations of calcium carbonate (PFCa) in postmenopausal women. **Materials and Methods:** Population: 11 postmenopausal women aged 58.9 ± 3yrs with a body mass index (BMI) 25.1 ± 2kg/m². **Inclusion criteria:** age: 55-65yrs, Menopause: ≥5yrs. Absence of osteoporosis (defined by T-score ≤-2.5 of Lumbar spine or Total femur or a history of osteoporotic fractures). **Exclusion criteria:** any medical condition and/or medication affecting mineral metabolism or intestinal Ca absorption. **Design:** comparative, randomized, prospective, open-label exploratory crossover study of calcium mousse versus calcium pills. **Intervention:** Participants were randomized in 2 groups to receive in two periods, 2 different PFCa (500mg): pill vs. mousse, with previous vitamin D₃ supplementation and adaptation periods for each. The parathormone (PTH) inhibition test and the area-under-the-curve (AUC) of calcium were studied. Blood samples were taken at baseline (after 12hrs fasting) and 1, 2 and 3 hrs after intake of the assigned PFCa. Urine samples (2hs) were obtained at -baseline, and after 2 and 4 hrs of PFCa intake. **Biochemical Determinations:** Serum: Calcium (Atomic absorption), phosphorus (Colorimetric); albumin (colorimetric), 25-hydroxyvitamin D (RIA), and iPTH (ECLIA). In urine: calculia/creatinuria. **Statistical Analysis:** Performed with SPSS 19.0 software for Windows (Inc. Chicago, IL, USA). The trapezoid rule was applied to assess AUC in time [R Development Core Team (2008).http://www.R-project.org]. An ANOVA model with 2 error terms was used to assess the sequence effect, period and formulation. **Results:** The highest inhibition PTH rates were observed after 2 hrs of PFCa (pill 38.2% vs. mousse 36.7%; p=ns). In Table 1, the analysis of the AUC_{0-3hrs} of both PFCa is shown. **Conclusion:** In this population sample, the absorption rate with mousse administration was similar to that one with pills. This data would be useful in clinical practice as it would allow a higher adherence to calcium supplementation with a greater therapeutic efficacy.

Table 1: Comparison of AUC_{0-3hrs} between two formulations of calcium carbonate

| Calcium carbonate | AUC _{0-3hrs} (log) | 95% CI | 90% CI (log) | Double unilateral Schnirmann test |
|-------------------|-----------------------------|-------------|--------------|-----------------------------------|
| Pills | 3.35 | (3.32;3.37) | | |
| Mousse | 3.36 | (3.33;3.38) | 97.6;101.4% | p<0.0001 |

Abbreviations: AUC: area under the concentration x time curve; CI: confidence interval

Systemic trabecular bone loss following femoral fracture in mice. Armaun Emami¹, Chrisoula Skouritakis², Clare Yellowley², David Fyhrie¹, Blaine Christiansen^{*3}. ¹UC Davis Medical Center, USA, ²UC Davis, USA, ³University of California - Davis Medical Center, USA

One of the most reliable predictors of future fracture risk is a previous history of fracture at any skeletal site, even after controlling for bone mineral density. The mechanisms of this association are not known, but it is possible that a bone fracture initiates a systemic bone resorption response that *actively compromises the skeleton*. However, the systemic loss of bone following a fracture has not been quantified, and the specific mechanisms of this bone loss have not been identified. The current study investigated trabecular bone loss at the L5 vertebral body and contralateral femur following a femur fracture in mice. We hypothesized that fracture would initiate a systemic loss of bone, which would be measurable at distant skeletal sites, and would be detectable for at least 6 weeks following fracture. Female C57BL/6 mice, 12 weeks old at injury, were subjected to transverse femur fracture (n = 36), sham surgery (n = 36; surgical placement of pin in medullary cavity), or no surgical procedure (control; n = 37). Mice were sacrificed 2, 4, or 6 weeks after fracture (n ~ 10 mice/group/time point), and L5 vertebrae and contralateral femurs were analyzed with microCT. Six mice from each group were retained for Open Field testing to quantify voluntary movement over a 24 hour period at 4 days, 2, 4, and 6 weeks post-fracture. Trabecular bone structure was significantly decreased in the L5 vertebral bodies and contralateral femurs of both fractured and sham mice by 2 weeks post-injury (Fig. 1). However, by 6 weeks there were no differences between experimental groups. Open Field testing showed that mice subjected to fracture or sham surgery exhibited less voluntary movement at 4 days post-injury compared to control mice. No differences were present at later time points. Consistent with our hypothesis, we found that femur fracture resulted in bone loss at distant skeletal sites 2 weeks post-injury, suggesting a possible systemic response to fracture. However, contrary to our hypothesis, we observed a recovery of bone by 4 or 6 weeks after fracture. Differences in voluntary movement at early time points after fracture partially explain the observed changes in bone. However, we believe that the magnitude of bone changes is not fully explained by decreased mechanical loading. Ongoing studies will quantify systemic inflammation, bone turnover, and other biological processes following fracture, and will investigate systemic bone loss and recovery in older mice.

Icariin Exerts Anabolic Effects on Osteoblasts via Rapid Estrogen Receptor α Signaling Pathways. Man-Sau Wong^{*1}, Ming-Xian Ho², Ling-Ping Zhou². ¹Hong Kong Polytechnic University, Hong kong, ²The Hong Kong Polytechnic University, Hong kong

Icariin, a prenylated flavonoid glucoside isolated from Herba Epimedii, has been shown to improve bone properties in both experimental and clinical studies. Our previous study demonstrated that the estrogenic anabolic actions of icariin in osteoblast-like cells involve estrogen response element (ERE)-independent and ligand-independent activation of estrogen receptor (ER). The present study aims to delineate the mechanism by which icariin activates ER in osteoblastic cells. The anabolic effects of icariin on pre-osteoblastic MC3T3-E1 and rat osteoblastic UMR106 cells were evaluated by its effects on cell proliferation, alkaline phosphatase (ALP) activities as well as bone specific gene expression (Runx2, collagen α 1, osterix) using real time RT-PCR. UMR 106 cells are co-treated with specific blockers (ER antagonist ICI182,780, MAPK inhibitor U0126 and PI3K inhibitor LY294002) to determine if specific signaling pathways are involved in mediating the actions of icariin. Its effects on the expression of signaling proteins and their phosphorylation were studied by using immunoblotting. The results showed that icariin (10-12 to 10-6 M) dose-dependently increased proliferation and alkaline phosphatase (ALP) activities in both MC3T3-E1 and UMR106 cells. In addition, runx2, collagen α 1 and osterix mRNA expression increased in response to icariin (10-6 M) in MC3T3-E1 cells. The anabolic effects of icariin on UMR 106 cells were completely abolished by co-treatment of UMR 106 cells with ICI182,780 (10-6 M), U0126 (10-5 M) and LY294002 (10-5 M), suggesting the involvement of ER, MAPK and PI3K in its actions. Icariin at 10-7 M rapidly stimulated ERK and Akt phosphorylation in UMR 106 cells in a time-dependent manner. In addition, icariin induced ER α phosphorylation at Ser118 and Ser 167 sites and such induction were attenuated by pre-treatment of UMR 106 cells with U0126 and LY294002. The results suggest that both MAPK and PI3K/Akt signaling pathways are involved in mediating the effects of icariin on ER α activation in osteoblastic cells. Taken together, this study provides evidence that the anabolic actions of icariin in osteoblasts are mediated by ligand-independent activation of ER α via rapid MAPK and PI3K/Akt pathway.

RANKL Inhibition Reverses the Effects of Ovariectomy and IL-10 Deficiency on Bone Composition in a Mouse Animal Model. Eleftherios Paschalis^{*1}, Klaus Klaushofer², Sonja Gamsjaeger², Norbert Hassler², Hamad Alzoman³, Dimitris Tatakis⁴. ¹Ludwig Boltzmann Institute for Osteology, Austria, ²Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK & AUA Trauma Center Meidling, 1st Medical Dept., Austria, ³Division of Periodontics College of Dentistry, King Saud University, Saudi arabia, ⁴Division of Periodontology, College of Dentistry, The Ohio State University, USA

Ovariectomy and inflammatory bowel disease are risk factors for osteoporosis. Lack of interleukin-10 (IL-10) results in severe intestinal inflammation, accelerated alveolar bone loss, reduced bone mass, increased mechanical fragility, and suppressed bone formation. Osteoprotegerin (OPG) has been shown to reduce bone resorption under osteoporotic conditions caused by menopause or other conditions. In the present study, femurs from wildtype (WT), ovariectomized (OVX), IL-10 knockout (KO), ovariectomized and IL-10 deficient (OVX-KO) mice, as well as WT, OVX, KO, and OVX-KO mice treated with OPG (WT-OPG, OVX-OPG, KO-OPG, and OVX-KO-OPG, respectively) were analyzed by Raman microspectroscopy (spatial resolution ~ 1 μ m), in the area of trabecular bone. The monitored parameters were: mineral to matrix ratio (MM); glycosaminoglycan (GAG), lipids, and pyridinoline (PYD) content; mineral maturity/crystallinity (MMC). The results were expressed as a function of tissue age. Four tissue ages were examined: 3 based on the presence of fluorescent double labels (between the second label and the mineralizing front (TA1), between the two labels (TA2), and right behind the first label (TA3). Additionally, the geometrical center of the trabeculae (TA4; representative of old tissue) were analyzed. IL-10 deficiency resulted in significantly lower MM at all 4 tissue ages, with the lowest values evident in the OVX-KO animals. While lipids content was similar between WT and KO mice, OVX-KO had significantly lower values compared to KO at TA1. KO animals had significantly higher GAG content compared to WT at TA4, potentially signifying altered canaliculi network. Similarly, OVX-KO animals had a higher GAG content compared to KO animals at TA3 and TA4. OVX, KO, and OVX-KO animals had a significantly higher PYD content compared to WT at TA1, TA2, and TA3, while OVX-KO animal values were also higher compared to KO. MMC was significantly higher in OVX-KO vs OVX, and OVX-KO-OPG vs OVX-OPG animals

at TA4. No significant differences in any of the monitored parameters were evident when WT and WT-OPG animals were compared (negative control), suggesting that OPG does not induce any adverse changes to bone composition. The values for all parameters in OVX-OPG, KO-OPG, and OVX-KO-OPG animals were restored to WT ones. The results of the present study suggest that OPG treatment reverses the individual, as well as the combined effects of ovariectomy and IL-10 deficiency on bone composition.

Sexual Dimorphism in the Metabolic Response to Glucocorticoids – The Role of the Osteoblast. Sylvia Gasparini¹, Holger Henneicke², Sarah Kim², Lee Thai², Hong Zhou², Markus Seibel³. ¹ANZAC Research Institute, Australia, ²Bone Research Program, ANZAC Research Institute, The University of Sydney, Sydney, NSW, Australia, ³Department of Endocrinology & Metabolism, Concord Hospital, The University of Sydney, Sydney, NSW, Australia

We have recently demonstrated in male mice that the adverse metabolic outcomes of glucocorticoid (GC) therapy are mediated via the osteoblast-derived peptide osteocalcin (1). Since a sexual dimorphism in the response to exogenous GCs has been reported in rodents (2), the current study aims to determine if a similar mechanism applies in female mice.

We used a transgenic (tg) mouse model in which GC signaling has been selectively disrupted in osteoblasts and osteocytes via targeted overexpression of the glucocorticoid-inactivating enzyme, 11β-hydroxysteroid dehydrogenase type 2. Eight-week-old male (M) and female (F) wild-type (wt) and tg mice received either placebo (plc) or corticosterone (CS) at a dose of 50µg/ml or 75µg/ml dissolved in the drinking water for 4 weeks. Body weight and water intake were measured weekly. Body composition by DXA, insulin tolerance and osteocalcin (OCN) serum concentrations were assessed at baseline and endpoint.

Male and female mice consumed the same amount of water irrespective of treatment (~4ml/mouse/day). Wt male mice developed profound insulin resistance (IR) with both low and high dose CS while in female mice 50ug/ml CS had no effect on insulin sensitivity and 75ug/ml CS induced partial IR only (Fig 1a,c). In tg males exposed to CS, IR was attenuated while, remarkably, female tg mice were completely protected from GC-induced IR (Fig. 1a,c). Similarly, in male wt mice, GC treatment induced pronounced obesity (Fig. 1b,d), which was again attenuated in tg mice (Fat mass: M-50µg-wt +57% vs. M-50µg-tg +24%; p<0.05 & M-75µg-wt +70% vs. M-75µg-tg +35%; p<0.05). In female wt mice, only the higher dose of 75µg/ml CS invoked obesity (Fat mass: F-50µg-wt +3% vs. F-50µg-tg -0.7%; p=ns & F-75µg-wt +50% vs. F-75µg-tg +17%; p=0.1). In line with the observed metabolic differences, OCN serum concentrations were higher in CS-treated wt and tg females than in their respective male counterparts.

The metabolically protective effect of disrupted GC-signaling in osteoblasts was evident in both genders, demonstrating that the osteoblast plays a critical role in GC-induced dysmetabolism. Interestingly, however, female mice displayed a high degree of resilience to the adverse metabolic outcomes associated with GCs. This may in part be due to maintenance of higher circulating OCN levels.

Effect of angiotensin-converting enzyme inhibitor on the fracture resistance of bone in mouse model of type 1 diabetes. Amy Creecy^{*1}, Sasidhar Uppuganti¹, Clay Bunn², Gael Cockrell³, Elizabeth Wahl³, Mallikarjuna Rettiganti³, John Fowlkes², Jeffrey Nyman⁴, Kathryn Thrailkill². ¹Vanderbilt University, USA, ²University of Kentucky, USA, ³University of Arkansas for Medical Sciences, USA, ⁴Vanderbilt University Medical Center, USA

Low areal bone mineral density (BMD) does not fully explain the 10-fold increase in fracture risk among individuals with type 1 diabetes (T1D). This suggests that insulin treatment alone partially corrects the deleterious effects of T1D on the ability of bone to resist fracture. T1D patients can also be treated with captopril, an angiotensin-converting enzyme (ACE) inhibitor, to prevent the progression of diabetic nephropathy. As a drug that causes vasodilation and improves kidney function, captopril (CAP) may exert positive effects on bone. Since CAP is not bone anabolic, we hypothesized that in diabetic mice it could partially prevent a decrease in material strength and toughness of bone (fracture resistance independent of structure). Over 5 days, streptozotocin (STZ, 40 mg/kg/day) or 100 mM citrate buffer alone was injected ip once daily into 11-wk old, male, DBA/2J mice. After confirming the development of hyperglycemia (>250 mg/ml), STZ-diabetic and control mice at 14 weeks of age were given free access to drinking water containing either CAP (~50 mg/kg/day) with 5 mg/ml ascorbic acid or just the ascorbic acid for 10 weeks. Upon sacrifice, the left femur was harvested for µCT analysis (12 µm voxel size), and three-point bend testing to determine treatment effects on cortical structure (diaphysis), trabecular architecture (metaphysis), and mechanical properties (diaphysis). CAP-treatment did not affect circulating levels of glucose or the body weight loss that follows STZ-induced diabetes, but it did lower the albumin-to-creatinine ratio (Table 1). With severe hyperglycemia, there was a decrease in bone toughness. CAP-treatment did not improve toughness, irrespective of diabetes. It also did not rescue the T1D-related decrease in the structural or material strength of bone. Interestingly, within the non-diabetic mice, the moment of inertia was actually lower for CAP- than for vehicle-treated mice. As for the metaphysis, CAP-treated, T1D mice had lower trabecular number and higher trabecular spacing than vehicle-treated, T1D mice with no effect of ACE inhibition on BV/TV in diabetic or control mice. Clinical studies investigating a positive association between ACE inhibitors and BMD in non-diabetics have been equivocal. Certainly, in poorly controlled diabetes, the likelihood of such inhibition helping to maintain fracture resistance is low.

Longitudinal Cohort Study of Once Weekly Teriparatide in Glucocorticoid-Induced Osteoporosis in Japanese Patients. Ikuko Tanaka^{*1}, Mari Ushikubo², Takashi Kato³, Keisuke Izumi², Kumiko Akiya², Hisaji Oshima². ¹NAGOYA Rheumatology Clinic, Japan, ²Tokyo Medical Center, Department of connective Tissue Disease, Japan, ³National Center for Geriatrics & Gerontology, Japan

Background) Weekly teriparatide (wTPT) developed in Japan has been shown to be effective in reducing risk of new vertebral fracture and increasing bone mineral density in primary osteoporosis. In the present study we investigated effects of wTPT on vertebral fractures in glucocorticoid induced osteoporosis.

Subjects and Methods) Patients with connective tissue diseases at Tokyo Medical Center was recruited for one-year longitudinal cohort study. The number of subjects was 168 (female; 145, age; 64±/15 (mean +/- SD), prednisolone dosage at base line; 8.4±/9.9 mg/day, prednisolone dosage during 1yr; 6.7±/5.5mg/day, duration of prednisolone treatment; 10.4±/10.8yr, prevalent vertebral fracture (Genant, H. 1996); 41.4%). Lumbar bone mineral densities (IBMD) were measured as %YAM with Lunar 3030 (GE). Incident vertebral fractures were analyzed with XP of the thoracic and lumbar spines. Patients were treated with bisphosphonates (87%) or wTPT (13%).

Results) The value of IBMD (%YAM) at the base line was 82.8±/16.3%. The rate of incident fractures during the follow-up period was 15.5%. 2) Sex, age, prevalent fracture, and IBMD were not different between two treatment groups. However, prednisolone dosages at the base line were statistically increased in patients with wTPT than bisphosphonates (19.3±/4.2 vs 6.5±/0.5, p<0.01). Increases in IBMD after 1 yr were not different in these two groups. Incident vertebral fractures were seen in 16.2% in patients with bisphosphonates and 10.0% in those with wTPT.

3) A logistic regression analysis revealed that statistically significant factors for incident fractures were IBMD (1% decrease, OR; 1.74; 95%CI; 1.18-2.59, p<0.01), prednisolone dosages (1mg/day increase, 1.09, 1.03-1.15, p<0.01), prevalent fractures (3.37, 1.23-9.20, p<0.01), and wTPT treatment (vs bisphosphonates, 0.12, 0.11-0.81, p<0.01). Conclusions) Our results suggested that wTPT might be effective for prevention of osteoporotic fractures in patients treated with glucocorticoids.

Role of Trabecular Bone Structure Analysis in Glucocorticoid-Induced Osteoporosis. Ikuko Tanaka^{*1}, Mari Ushikubo², Takashi Kato³, Keisuke Izumi², Kumiko Akiya², Hisaji Oshima². ¹NAGOYA Rheumatology Clinic, Japan, ²Tokyo Medical Center, Department of connective Tissue Disease, Japan, ³National Center for Geriatrics & Gerontology, Japan

Background) Although glucocorticoid induced osteoporosis (GIO) is known as a sever secondary osteoporosis, sufficient markers for prediction of incident fracture have not been elucidated. Recently, Trabecular Bone Structure (TBS) has been developed for a novel predictor of osteoporosis. The purpose of this study was to clarify a role of TBS in GIO.

Subjects and Methods) Patients with connective tissue diseases at Tokyo Medical Center was subjected for one year longitudinal cohort study. The number of subjects was 232 (female; 204, age; 65±/15 (mean +/- SD), prednisolone (PSL) dosage at base line; 9.1±/12.8 mg/day, PSL dosage during 1y; 6.7±/5.9mg/day, prevalent vertebral fracture (Genant, H. 1996); 46.7%). Lumbar bone mineral densities (IBMD) were measured as %YAM with Lunar 3030 (GE). TBS values were calculated with TBS (medimaps). Incident vertebral fractures were analyzed with XP at thoracic and lumbar spines. Medications during this study were bisphosphonates (65%), denosmab (26%), weekly teriparatide (9%).

Results) 1) The value of IBMD (%Young Adult Mean; %YAM) at the base line was 81.5±/15.6%, and that of TBS was 1.268±/0.107. The rate of incident fractures during the follow-up period was 14.1%. 2) TBS was significantly correlated with IBMD (r=0.695, p<0.001) and the age (r=-0.603, p<0.001). 3) A logistic regression analysis revealed that incident fractures could be predicted (87.1%) with IBMD (per

5% decrease; OR; 1.32, 95%CI; 1.08-1.81; p<0.01), daily prednisolone dosages (per 5mg/day increase; 1.47; 1.20-1.81; p<0.01), and the prevalent fractures (3.63; 1.33-9.89; p<0.02). When TBS data were added to this analysis, TBS (1.78; 1.10-2.86; p<0.02) was extracted instead of IBMD.

Conclusions) TBS analysis of the lumbar spine DXA data might be useful for prediction of prevalent fractures in GIO.

Anabolism versus Antiresorption (AVA Study): A Comparison of the Mechanism of Action (MOA) of Teriparatide (TPTD) and Denosumab (DMAB) in Postmenopausal Women with Osteoporosis Using Quadruple Fluorochrome Labeled Bone Histomorphometry. David Dempster^{*1}, Hua Zhou¹, Robert Recker², Jacques Brown³, Christopher Recknor⁴, E. Michael Lewiecki⁵, Paul Miller⁶, Sudhaker Rao⁷, David Kendler⁸, John Krege⁹, Jahangir Alam⁹, Kathleen Taylor¹⁰, Boris Janos¹¹, Valerie Ruff¹⁰. ¹Regional Bone Center, Helen Hayes Hospital, USA, ²School of Medicine, Creighton University, USA, ³Groupe de Recherche en Maladies Osseuses, Laval University, Canada, ⁴United Osteoporosis Centers, USA, ⁵New Mexico Clinical Research & Osteoporosis Center, USA, ⁶Colorado Center for Bone Research, USA, ⁷Bone & Mineral Research Laboratory, Henry Ford Health System, USA, ⁸Prohealth Clinical Research, Canada, ⁹Eli Lilly & Company, USA, ¹⁰Lilly USA, LLC, USA, ¹¹Eli Lilly Canada Inc., Canada

Purpose: The reported increase in endogenous intact parathyroid hormone (iPTH) levels 1-3 months after a dose of DMAB, an antiresorptive bone agent, has led to the speculation that elevation in iPTH could result in early stimulation of bone formation. The AVA study was conducted to evaluate the effects of DMAB vs TPTD, a well-established anabolic agent. A quadruple fluorochrome labeling method was used to compare changes from baseline (BL) in bone histomorphometric indices with changes in iPTH over the same period. Methods: This study compared TPTD (20 µg/day) with DMAB (60 mg once) for 6 months in postmenopausal women with osteoporosis. Fasting bone turnover markers (BTMs) and iPTH were collected at BL, 1, 3, and 6 months. Patients underwent fluorochrome labeling at BL and during treatment before a trans-iliac bone biopsy at 3 months. The primary objective was change from BL in mineralizing surface/bone surface (MS/BS) in the cancellous envelope. Dynamic and static histomorphometric indices were assessed in cancellous, endocortical, intracortical, and periosteal envelopes. Results: In the DMAB group, iPTH increased from BL and peaked at month 1, remaining above BL at months 3 and 6 (Figure). Even so, histomorphometric indices of bone formation in the cancellous envelope were higher in the TPTD than the DMAB group at month 3 (Table). Except for mineral apposition rate (MAR), these indices increased with TPTD and decreased with DMAB treatment from BL to month 3. Similar findings were observed in other envelopes. TPTD increased BTMs from BL: procollagen type I N-terminal propeptide (PINP) starting at month 1 and carboxyterminal cross-linking telopeptide of type I collagen (CTX) starting at month 3. In the DMAB group, PINP and CTX decreased from BL at all time points. Conclusion: This study is the first to use a quadruple fluorochrome labeling method to compare longitudinal changes from BL to month 3 between an antiresorptive and anabolic drug at the tissue level. Histomorphometric data confirm and BTM data support the opposing MOA of the 2 drugs on bone remodeling. The increase in iPTH after DMAB administration was associated with marked decreases in indices of bone formation in all envelopes, inconsistent with DMAB causing early indirect anabolic action. In contrast, TPTD increased histomorphometric indices and BTMs of bone formation in all envelopes, consistent with an anabolic MOA in trabecular and cortical bone.

| | Cancellous Envelope Median (interquartile range) | | | | | |

Incidence of Clinical Fracture in Osteoporosis Patients with Daily Teriparatide in the Japan Fracture Observational Study (JFOS): Interim Report. Saeko Fujiwara¹, Ryoichi Takayanagi², Masayo Sato³, Mika Tsujimoto³, Takanori Yamamoto³, Hiroyuki Enomoto³, Satoshi Soen⁴. ¹Health Management & Promotion Center, Hiroshima Atomic Bomb Casualty Council, Japan, ²Department of Medicine & Bioregulatory Science, Graduate School of Medical Sciences, Kyushu University, Japan, ³Medicines Development Unit Japan, Eli Lilly Japan K.K., Japan, ⁴Department of Orthopaedic Surgery & Rheumatology, Nara Hospital, Kinki University Faculty of Medicine, Japan

Background: Due to the rapid growth of the elderly population, the number of patients with osteoporosis and fragility fractures has been increasing in Japan. Although teriparatide 20 $\mu\text{g/day}$ (TPTD) has been broadly approved for osteoporosis treatment, the evidence of TPTD use in a daily clinical setting is limited in Japan. Therefore, we conducted the Japan Fracture Observational Study (JFOS) to investigate the incidence of clinical fracture and safety profile in osteoporosis patients who initiated TPTD. We report an interim analysis of results of 12-month observation. **Methods:** JFOS is a 24-month, multicenter, prospective, observational study in Japan. TPTD-naive patients with osteoporosis at high risk of fracture were included. The incidence of clinical fracture, the percent changes from baseline in bone mineral density (BMD) and serum levels of procollagen type 1 aminoterminal propeptide (PINP), and treatment emergent adverse events (AEs) were observed at up to 12 months after initiating TPTD. **Results:** A total of 1810 patients (90.1%: women) were analyzed at baseline. Mean age (SD) was 76.9 (7.9) years. Two-thirds of patients had prevalent vertebral fractures and 34.3% of patients had 2 or more fractures. One-third of patients received bisphosphonates prior to TPTD. The cumulative incidences of clinical vertebral and non-vertebral fractures were 1.1% and 1.8% at 6 months, and 1.4% and 2.3% at 12 months, respectively. The mean of BMD for the lumbar spine (L2-L4) and total hip were 0.70 g/cm^2 and 0.55 g/cm^2 at baseline, and increased by 8.9% (95% confidence interval [CI]: 7.8 to 9.9) and 0.8% (95% CI: -0.8 to 2.4) at 12

months, respectively. The median PINP serum level was 43.9 $\mu\text{g/L}$ at baseline. The median percent change was increased by 159.0% at 3 months and 187.7% at 6 months. Drug related treatment emergent AEs and serious AEs were reported from 110 (6.1%) and 39 (2.2%) patients, respectively. **Conclusion:** JFOS is the first large observational study to investigate the effectiveness of TPTD as a primary objective in osteoporosis patients in Japan. The cumulative incidence of clinical fracture was not substantially increased over time after initiating TPTD. An increase in PINP was observed in 3 months. Lumbar spine BMD was increased at 12 months. These findings are consistent with the results of previous studies and can contribute to evidence-based osteoporosis management in Japan.

Time course of disassociation of bone formation signals with bone mass and bone strength in sclerostin antibody treated ovariectomized rats. Yanfei Ma*, Qianqiang Zeng, Matthew Hamang, Mary D Adrian, Jonathan Lucchesi, Sarah E Raines, Stuart A Kuhstoss, Victor Obungu, Henry U Bryant, Venkatesh Krishnan, Eli Lilly & Company, USA

Sclerostin is a glycoprotein produced by osteocytes that negatively regulates osteoblastic bone formation. Neutralizing sclerostin with a monoclonal antibody stimulates bone formation and increases bone mass in animals and humans. To understand the anti-sclerostin antibody mechanism of action, we studied the time course response of serum bone formation signals correlating with rate and extent of accrual of bone mass and bone strength in a sclerostin antibody treated skeleton. Rats were ovariectomized (OVX) at 6 months of age and permitted to lose bone for 2 months to establish osteopenia. Rats were then treated with a chimeric sclerostin-antibody (Scl-ab) at 20 mg/kg sc once weekly and sacrificed at baseline, weeks 2, 3, 4, 6, 7, and 8 post treatment. In Scl-ab treated rats, the bone formation biomarkers N-terminal procollagen type I (PINP) and osteocalcin (OCN) rapidly increased at week 1, peaked around week 3, and returned to OVX control level at week 6. Lumbar vertebral (LV) osteoblast surface increased 88% at week 2, bone formation rate/bone surface (BFR/BS) was increased by 157% at week 4 and they returned to OVX control level at week 4 and 6, respectively. Similar to lumbar vertebrae, endocortical and periosteal BFR/BS increased rapidly and peaked around week 4 to 585% and 313%, of the vehicle control, respectively. BFR/BS remained higher than OVX control on both periosteal and endocortical surfaces through week 8. Micro-CT analysis showed Scl-ab treatment completely restored OVX induced bone mineral density (BMD) loss in LV, femoral neck (FN) and mid femur between weeks 4 to 6 and BMD continued to increase at all 3 sites through week 8. Biomechanical tests showed a similar linear improvement in bone strength through 8 weeks of Scl-ab treatment in mid-femur and FN, but bone strength begins to plateau between weeks 6 and 8 for LV. These data indicate sclerostin-antibody treatment results in rapid and robust increase in bone formation, however notably, bone anabolic response in cortical bone takes longer to reach its plateau than it does in trabecular bone. Bone mineral density and bone strength continue to improve even after the majority of objective bone formation serum signals have returned to the control level in osteopenic rats. Collectively, these results suggest that treatment with anti-Sclerostin antibodies represents a rapid build-up of bone mass followed by a more sustained and continued favorable impact on bone quality.

Transdermal Delivery of Abaloparatide: Optimization of the Pharmacokinetic Profile in Cynomolgus Monkeys. Hila Bahar*, Daniel Dohmeier², Joan Moseman², Ying Zhing², Alan Harris¹, Ken Brown², Gary Hattersley¹. ¹Radius Health, USA, ²3M Drug Delivery Systems, USA

Abaloparatide (ABL) is a novel analog of hPTHrP (1-34) being developed for the treatment of postmenopausal osteoporosis. In the ACTIVE Phase 3 clinical trial, 18 months of daily subcutaneous (SC) injection of ABL reduced the incidence of new vertebral, non-vertebral and clinical fractures while significantly increasing bone mineral density (BMD) in the lumbar spine, total hip and femoral neck. Transdermal (TD) delivery provides a promising alternative to SC injection and has the potential to improve patient convenience and compliance. We are currently evaluating a novel microneedle based transdermal technology (sMTS) developed by 3M Drug Delivery Systems to deliver ABL. In a completed phase 2 clinical study ABL-TD demonstrated dose dependent and significant BMD gains at the spine and hip. However, these BMD increases were lower than those achieved with ABL-SC. The difference in the pharmacokinetic (PK) profile between ABL-TD and SC may account for the reduced efficacy seen with ABL-TD. To select an optimized TD patch we compared the PK profiles of modified patch configurations and formulations in cynomolgus monkeys. Blood samples were collected at baseline and following TD or SC dosing, after 5, 10, 20, 30, 60 and 90 minutes, and ABL analyzed by LC-MS/MS. Consistent with clinical

PK, application of the parent formulation of ABL-TD resulted in rapid ABL delivery, with a C_{max} comparable to ABL-SC, but an earlier T_{max}, shorter half-life (T_{1/2}), and lower AUC. In contrast, application of an optimized ABL-TD patch resulted in an enhanced PK profile, with longer T_{1/2}, an AUC which increased by approximately 2-fold compared to the original patch, while retaining rapid delivery and C_{max} similar to SC. Overall the PK profile was comparable to SC injection. This optimized TD patch was well tolerated as evaluated using a modified Draize scoring system. Together, these results suggest that ABL-TD patch formulation can be optimized to achieve a PK profile comparable to SC injection and may have the potential to enhance the efficacy of ABL-TD.

A Revisit to Safety Evaluation of Calcium/Phosphate Metabolism in A 12-Month, Randomized, Controlled Study on Alendronate/Vitamin D₃ versus Calcitriol in Chinese Osteoporotic Women. Zhen Lin Zhang¹, Er Yuan Liao², Wei Bo Xia³, Hua Lin⁴, Qun Cheng⁵, Li Wang⁶, Yong Qiang Hao⁷, De Cai Chen⁸, Hai Tang⁹, Yong De Peng¹⁰, Li You¹⁰, Liang He¹¹, Zhao Heng Hu¹², Chun Li Song¹³, Fang Wei¹⁴, Jue Wang¹⁴, Lei Zhang¹⁴, Arthur C Santora¹⁵. ¹Shanghai Sixth People's Hospital, Shanghai Jiaotong University, China, ²The Second Xiangya Hospital, Central South University, China, ³Peking Union Medical College Hospital, China, ⁴Nanjing Drum Tower Hospital, China, ⁵Huadong Hospital Affiliated to Fudan University, China, ⁶Tianjin Hospital, China, ⁷Shanghai Ninth People's Hospital, China, ⁸West China Hospital, West China School of Medicine, Sichuan University, China, ⁹Beijing Friendship Hospital, Capital Medical University, China, ¹⁰Shanghai First People's Hospital, China, ¹¹Beijing Jishuitan Hospital, China, ¹²Peking University People's Hospital, China, ¹³Peking University Third Hospital, China, ¹⁴Global Medical Affairs, Merck Sharp & Dohme China, China, ¹⁵Merck Research Laboratories, Rahway, NJ, USA, USA

Purpose: In a 12-month randomized study in Chinese osteoporotic women, weekly alendronate 70mg/vitamin D₃ 5600 IU (ALN/D5600) was superior on BMD increase over calcitriol 0.25µg daily, a Chinese guideline recommended therapy recognized to have a low risk of both hypercalcemia and hypercalciuria. However, very few randomized controlled studies evaluated these safety endpoints in Chinese patients. Our purpose was to summarize key safety endpoints related to calcium (Ca) and phosphate (P) in this controlled study.

Methods: All treated patients (n=215) in the original study were included in this safety reanalysis. Patients received concomitant Ca supplements 500mg daily. Specific measures including mean serum Ca, P and 24-h urine Ca were analyzed at baseline and several time points in 1 year. Changes exceeding predefined limits—hypercalcemia (serum Ca>2.60mmol/L), hyperphosphatemia (serum P>1.46 mmol/L with an increase>20% of baseline) and hypercalciuria (24-h urine Ca>7.5mmol/L with an increase>25% of baseline)—were assessed. Mixed model repeated measures were applied to compare within and between-group differences; Chi-Square test was used to compare proportions.

Results: In ALN/D5600 treated group, a decrease in mean serum Ca occurred at Month 6 (-0.04mmol/L, p<0.05 vs. baseline) but resolved at Month 12 (p=NS vs. baseline). Patients had lower Ca levels by ALN/D5600 treatment compared with calcitriol throughout the study (p-values <0.05). Mean serum P levels generally suggested a similar trend. ALN/D5600 treatment exhibited a small increase in mean 24-h urine Ca whereas a significant increase (1.1 mmol/L, 0.9mmol/L, at Month 6, 12, p<0.05) was shown in the calcitriol group. ALN/D5600 resulted in lower 24-h urine Ca levels compared with calcitriol at Month 6 (4.9 vs 6.1 mmol/L) and 12 (5.2 vs. 5.9 mmol/L) (p-values <0.05). One event of hypercalcemia (0.9%) and hyperphosphatemia (0.9%) occurred in the calcitriol group; 3 episodes of hyperphosphatemia (2.8%) were seen in the ALN/D5600 group. The incidence of hypercalciuria was higher in the calcitriol group at Month 6 with marginal insignificance (9.4 vs.18.5%, p=0.05) but was similar between groups at Month 12 (12.3 vs. 13.0%).

Conclusions: Hypercalciuria was uncommon with no sustained increases observed in either treatment. Calcitriol 0.25µg daily was favourable for Ca/P safety with a greater incidence of hypercalciuria at Month 6. Further studies are required to establish safety for calcitriol higher doses.

Bone Mineral Density Response Rates with Teriparatide, Denosumab, or Both: a Responder Analysis of the DATA Study. Paul Wallace¹, Alexander Uihlein², Sherri-Ann Burnett-Bowie¹, Robert Neer¹, Benjamin Leder¹, Joy Tsai¹. ¹Massachusetts General Hospital, USA, ²Northwestern University, USA

Background: Both antiresorptive and anabolic osteoporosis medications increase bone mineral density (BMD) but the patient response varies between them depending on the anatomic site. In this analysis, we wished to determine the differential rates of BMD response at the hip and spine among postmenopausal osteoporotic women treated with either teriparatide (TPTD), denosumab (DMAB) or both medications (COMBO).

Methods: 94 postmenopausal women (ages 51-91) at high fracture risk and without recent bisphosphonate exposure were randomized to receive TPTD (20 mcg SC daily), DMAB (60 mg SC every 6 months), or both medications for 24 months. BMD of the total hip (TH), femoral neck (FN), and lumbar spine (LS) were assessed by DXA at each visit. The 82 subjects who completed all 2 years were included in this analysis. Responders were defined as having 2-year BMD increases of >3% as this value meets or exceeds the least significant change for DXA measurements. An "excellent response" was defined a BMD increase of >6%. Between-group differences in response rates were analyzed using 2-sided Chi-square tests.

Results: Over 24 months, TH BMD increased by >3% in 36%, 53%, and 92% of women in the TPTD, DMAB, and COMBO groups, respectively (COMBO vs. TPTD p<0.001; COMBO vs. DMAB p=0.002). TH BMD increased by >6% in 11%, 17%, and 50% of women (COMBO vs. TPTD p=0.002; COMBO vs. DMAB p=0.009). FN BMD increased by >3% in 46%, 57%, and 83% of women in the TPTD, DMAB, and COMBO groups, respectively (COMBO vs. TPTD p=0.006; COMBO vs. DMAB p=0.036), and increased by >6% in 21%, 27%, and 50% of women (COMBO vs. TPTD p=0.031; COMBO vs. DMAB p=0.078). In the LS, BMD increased by >3% in 85%, 93%, and 100% of women in the TPTD, DMAB, and COMBO groups, respectively (p=NS for all comparisons), and increased by >6% in 63%, 78%, and 100% of women (COMBO vs. TPTD p=0.001, COMBO vs. DMAB p=0.016). There were no significant differences in the response rates between TPTD and DMAB groups.

Summary and Conclusions: The BMD response in subjects treated with combined DMAB/TPTD was higher than the rates in the monotherapy groups with 19/24 subjects in the COMBO group achieving >3% BMD gains at all 3 sites. Moreover, 50% of subjects in the COMBO group achieved hip BMD increases >6%, and 100% experienced LS BMD increases >6%. These results support the potential use of combined DMAB/TPTD in postmenopausal osteoporotic women, especially those at a very high risk of fracture.

Design of the Foundation for NIH Bone Quality Project: Pooled individual-level measurements of BMD, bone strength, and bone turnover as surrogates for fracture risk reduction. Douglas C. Bauer^{*1}, Jean L. Hietpas¹, Mary Bouxsein², Richard Eastell³, Charles McCulloch¹, Anne DePapp⁴, Andreas Grauer⁵, Ursula Klause⁶, Bruce H. Mitlak⁷, Bruce Schneider⁸, Sanya Fanous-Whitaker⁹, Steven R. Cummings¹⁰, Dennis M. Black¹. ¹University of California, San Francisco, USA, ²Harvard Medical School, USA, ³University of Sheffield, United Kingdom, ⁴Merck & Co., Inc., Kenilworth, NJ, USA, USA, ⁵Amgen Inc., USA, ⁶Roche Diagnostics Corporation, Indianapolis, USA, ⁷Eli Lilly & Co., USA, ⁸Food & Drug Administration, USA, ⁹Foundation for the National Institutes of Health, USA, ¹⁰San Francisco Coordinating Center, California Pacific Medical Center, USA

Development of new treatments for osteoporosis has become prohibitively expensive due to the need for increasingly large fracture endpoint studies, particularly for hip fracture. Valid surrogate outcomes that accurately predict anti-fracture treatment efficacy could greatly decrease drug development time and costs. Imaging as well as bone turnover markers, alone or in combination, might be useful as surrogate endpoints, but individual trials are too small to be conclusive. Instead, pooling individual participant data from multiple trials increases sample size, ensures a consistent approach and allows predefined subgroup analyses. This strategy would allow optimal estimation of the relationship between potential surrogates and fracture outcomes.

The FNIH Bone Quality Project is collecting and pooling data from nearly 100,000 randomized participants enrolled in osteoporosis treatment trials. This Project is led by investigators from UCSF in collaboration with academic, regulatory, and industry co-investigators. The study aims include critical evaluation of 1) Imaging-derived bone strength measurements (QCT/finite element analysis (FEA) and DXA) and 2) Bone turnover markers (BTMs) for use in drug development and patient management.

To achieve these aims, we plan to systematically collect individual data from randomized trials with fracture endpoints. Imaging-based biomarkers include DXA and hip strength estimated by FEA from baseline and follow-up QCT images analyzed centrally (ON Diagnostics, Berkeley, CA) without knowledge of treatment group. Serum biomarkers will include commercially available BTMs, such as PINP and CTX. Once assembled, we will perform a series of individual-level meta-analyses to assess change in each biomarker as a predictor of anti-fracture efficacy for hip, non-spine and vertebral fracture. Pooled measurements of short-term changes in BTMs over 3-12 months will also be analyzed to identify their value to predict long-term treatment benefit.

This project represents a novel collaboration between academic investigators, the FNIH, the FDA and multiple pharmaceutical and diagnostic companies. Successful analysis of the pooled data may help establish the utility of imaging and biochemical biomarkers for both drug development and clinical care.

Disclaimer: Dr. Schneider's contributions are an informal communication and represent his own best judgment. These comments do not bind or obligate FDA.

Determinants of Change in Bone Mineral Density during Bisphosphonate Holiday. Li Hao Richie Xu^{*1}, Beverley Adams-Huet¹, John Poindexter¹, Naim Maalouf². ¹UT Southwestern Medical Center, USA, ²University of Texas Southwestern Medical Center, Dallas, USA

Background: Due to concerns about potential side-effects related to prolonged bisphosphonate (BP) use, a drug holiday has been suggested for some BP-treated patients with osteoporosis (OP). However, there is limited information on the evolution of bone mineral density (BMD) during a BP holiday.

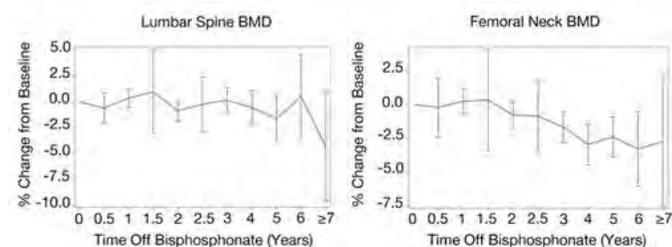

Objectives: To describe the change in BMD during a BP-holiday and assess its determinants.

Methods: A retrospective review was conducted on OP patients at a single specialty clinic who were treated with oral BP for > 2 yrs and then discontinued their BP for a drug holiday. Included were patients with at least one BMD measurement while on BP and one measurement > 1 yr after BP discontinuation. All BMD measurements were on a single DXA instrument. Excluded were patients with CKD, disuse osteoporosis, 1ry hyperparathyroidism, or concomitant glucocorticoid use. Demographic, clinical, densitometric and laboratory characteristics at the time of BP cessation were assessed as predictors of BP change in univariable and multivariable models.

Results: This analysis included 175 OP patients (13% men, 87.4% Caucasian, 7.4% Asian, 5.1% other race). At time of BP cessation, mean age was 66.5 yrs, BMI 24.5 Kg/m², T-score at L-spine (LS):-1.4 and femoral neck (FN):-1.8. Median duration on BP was 4.8 yrs. During BP holiday, patients were followed for a median of 3.1 yrs, with a median 2 follow-up DXA scans. On average, there was a significant decline in BMD at FN (-0.46%/yr; 95% CI -0.75 to -0.16; p=0.003) but not at LS (-0.28%/yr; 95% CI -0.62 to +0.05; p=0.10). FN BMD tended to drop after 1.5 yrs of BP holiday, while LS BMD was stable for 5 yrs after BP cessation (Figure). The fraction of patients whose T-score declined from >-2.5 at start of holiday to <-2.5 by the 5th yr of holiday was 8% for the LS and 11% for the FN. In univariable models, significant predictors associated with change in BMD at the FN were duration off BP therapy, BMI, Asian race, and urine DPD/Cr at time of BP discontinuation. Duration off

therapy, Asian race and BMI remained significantly associated with FN BMD decline in the multivariable model.

Conclusions: In 175 patients followed with serial DXA scans during BP holiday, FN BMD was more likely to decline over time than LS BMD. In addition to duration off BP and higher bone turnover, significant predictors of decline in BMD included lower BMI and Asian race. These data may help identify individuals who require closer BMD monitoring during BP holiday.

Effect of Denosumab on BMD Outcomes in Persistent Patients in a Prospective Observational Study. DL Kendler^{*1}, SL Silverman², E Siris³, JP Brown⁴, DT Gold⁵, EM Lewiecki⁶, C Simonelli⁷, G Quinn⁸, S Yue⁹, B Stolshek⁹, C Recknor¹⁰. ¹University of British Columbia, Canada, ²Cedars-Sinai Medical Center, UCLA School of Medicine, & OMC Clinical Research Center, USA, ³Columbia University Medical Center, USA, ⁴Laval University & CHU de Québec (CHUL) Research Centre, Canada, ⁵Duke University Medical Center, USA, ⁶New Mexico Clinical Research & Osteoporosis Center & University of New Mexico School of Medicine, USA, ⁷Health East Osteoporosis Care, USA, ⁸Sarnia Statistics Ltd, United Kingdom, ⁹Amgen Inc., USA, ¹⁰United Osteoporosis Centers, USA

Purpose

Although clinical trial data help characterize therapeutic efficacy in a very select population, understanding real-world effectiveness is of interest as patient populations may be more heterogeneous. In addition, persistence with therapy in the community may be suboptimal compared with clinical trials; studies report that up to 82% of patients prescribed osteoporosis therapy discontinue medication within a year (Cramer, 2007). The clinical efficacy of denosumab (DMAb) has been well characterized in the Fracture REduction Evaluation of Denosumab in Osteoporosis every 6 Months (FREEDOM) trial and other studies. To understand clinical outcomes in the community experience, we conducted a posthoc analysis to evaluate BMD response in postmenopausal women treated for osteoporosis in a 24-month prospective observational study.

Methods

In this 24-month, multicenter, single-arm study in the United States and Canada, 935 women were enrolled within 4 weeks of starting DMAb treatment, regardless of prior treatment. No assessments, clinical procedures, or changes in routine patient management were required. Persistence with DMAb was assessed at 12 and 24 months, defined as receiving ≥2 injections and ≥4 injections, respectively, and no 2 consecutive injections more than 6 months + 8 weeks apart. DXA assessment was not required to participate in the study and was collected as available. This analysis was conducted in patients who were persistent at 12 or 24 months and had both baseline and follow-up DXA scans at the same anatomical site (lumbar spine or femoral neck) during 12 or 24 months, respectively. DXA scans were analyzed at local study sites without central reading.

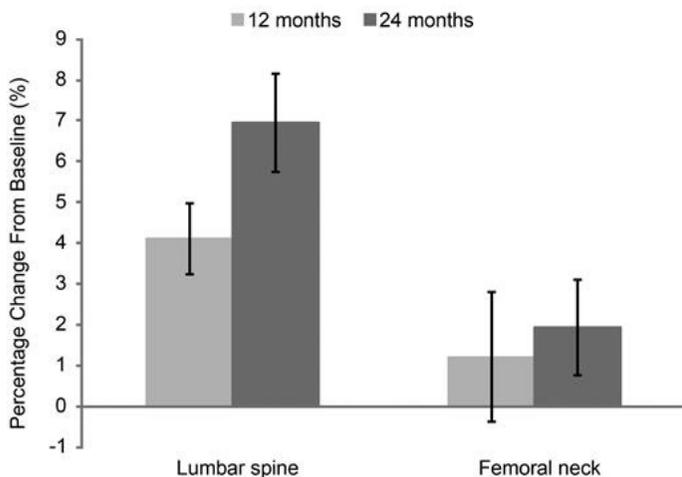

Results

Of the 374 patients with a baseline DXA and at least 1 follow-up DXA, 190 were persistent and had 12-month DXA BMD, and 154 were persistent and had 24-month DXA BMD. As expected, BMD increased over time (Figure). Mean BMD at the lumbar spine increased from baseline by 4.1% at 12 months and 7.0% at 24 months. At the femoral neck, BMD increased by 1.2% at 12 months and 1.9% at 24 months. At the 12- and 24-month time points, the percentage of patients with increased BMD was 81% and 88% at the lumbar spine and 57% and 67% at the femoral neck, respectively.

Conclusions

DMAb improved BMD in most persistent patients in a real-world setting. Moreover, the changes observed in routine clinical practice were similar to the efficacy achieved in DMAb clinical trials.

Effect of Glucocorticoid, Bisphosphonate Therapy and Disease Activity on Metacarpal Shaft Morphology: A Longitudinal pQCT Study. Inna galli-Lysak¹, Harald M Bonel², Peter M Villiger¹, Daniel Aeberli³. ¹Dept. of Rheumatology, Immunology & Allergy University of Bern, Inselspital, Switzerland, ²Institute for Diagnostic, Interventional & Paediatric Radiology, University of Bern, Inselspital, Switzerland, ³Dept. of Rheumatology, Immunology & Allergy University Hospital, Switzerland

Introduction: We established a protocol for measuring volumetric bone mineral density (vBMD) of the metacarpal shaft using peripheral quantitative computed tomography (pQCT). In a recently published cross-sectional study patients with rheumatoid arthritis (RA) had a 19% increase in cross-sectional area (CSA) at the midshaft with a reduction in cortical thickness by 10% compared to healthy controls. There was an inverse association between bone erosiveness (activity of RA) and cortical thickness. The aim of this study was to quantify the effect of glucocorticoid and bisphosphonate (BP) therapy on metacarpal shaft morphology.

Method: Consecutive postmenopausal RA patients fulfilling the American College of Rheumatology Criteria and consecutive postmenopausal healthy controls were recruited. pQCT-measurements at 50% of total metacarpal shaft of the third metacarpal bone were at baseline and follow-up. Use of BP, glucocorticoids, biologics and disease modifying anti-rheumatic drugs (DMARDs) was monitored from baseline to follow-up using patient records. Anti-CCP antibodies (ACPA) positivity, bone erosiveness (Rating Score), and disease activity (DAS28) were assessed at baseline and follow-up. Follow-up measurements were considered as valid when circumference and bone shape corresponded to baseline measurement. The following parameters were measured or calculated: total metacarpal, cortical and medullary CSA, and cortical density. To compare relative changes with muscle force, we measured muscle CSA at 60% of total radial length, and handgrip strength by sphygmomanometer. Individuals with neoplasia, anti-oestrogen or anti-testosterone therapy, HRT, osteoanabolic therapy or additional concomitant diseases or medication were excluded. For statistical analysis we used one way ANOVA or two sided Man Whitney Test.

Results: 40 consecutive postmenopausal patients with RA and 40 consecutive postmenopausal healthy controls (matched for age, height, and weight) were included. Mean follow-up was 54 months (RA patients: mean 51 months, range 24-82; controls: mean 57 months, range 23-78; p=0.122). 18 RA patients were on BP, 22 were BP-naïve. Compared to healthy controls or BP-naïve RA patients, RA patients on BP were older, had lower handgrip strength and lower forearm muscle density (p<0.01). At baseline RA patients on BP had lower cortical CSA, lower cortical thickness and bigger medullary CSA (p≤0.002). Compared to baseline BP-naïve RA patients and healthy controls showed relative increase of medullary CSA of 11% and 8%, and a reduction of cortical thickness, cortical CSA and cortical density of 6%, 4% and 1.5% (p<0.015). In RA patients on BP a relative reduction of cortical thickness was found (4%, p<0.01). Overall, glucocorticoid use ≥5mg/d had a significant negative effect on change of cortical density, cortical CSA and cortical thickness over time and a positive effect on medullary CSA. DAS28 ≥ 3.2 was positive correlated with change of cortical density. There was a trend of increased cortical CSA and cortical thickness when correlated with handgrip. ACPA positivity correlated neither with change of bone density nor geometry in a linear regression model.

Conclusion: Healthy controls, BP-naïve RA patients and RA patients on BP have an endosteal and periosteal drift at the shaft of the third metacarpal bone over time. Glucocorticoid use, disease activity and handgrip are influencing factors of metacarpal shaft morphology.

Fractures during Bisphosphonate Drug Holidays. Brittany Bindon^{*1}, Cara Clure², Neelam Balasubramanian³, William Adams³, Stephanie Kliethermes³, Jasmin Sandhu³, Pauline Camacho⁴. ¹Loyola University, USA, ²Loyola University Chicago Stritch School of Medicine, USA, ³Loyola University Medical Center, USA, ⁴Loyola University Osteoporosis & Metabolic Bone Disease Center, USA

Introduction: Atypical femoral fractures and osteonecrosis of the jaw have been associated with prolonged bisphosphonate (BP) therapy for osteoporosis. Currently, there is minimal data on safe duration of BP drug holidays. AACE guidelines (2010) recommend a holiday after 4-5 years of BP treatment for patients with moderate fracture risk and after 10 years for patients at high risk. The FDA advocates for clinicians to evaluate the need for BP therapy after 3-5 years and if a patient is at high risk, a holiday may not be "advisable". Our aim was to determine the clinical and laboratory parameters associated with increased fracture risk in patients on BP drug holiday.

Methods: A retrospective chart review was conducted of 401 patients with low bone mass and osteoporosis who began a BP drug holiday between 2004 and 2013 at Loyola University Osteoporosis and Metabolic Bone Disease Center. Collected parameters included demographics, prior therapy, bone mineral density (BMD), bone turnover markers (BTMs), PTH, calcium, Vitamin D, and clinical reports of fractures.

Results: BPs used prior included alendronate (62%), risedronate (34%), ibandronate (13%), and zoledronic acid (7%) and specific therapy did not affect fracture rates. The mean duration of treatment was 6 years ± 3.23. 62 (15.8%) patients developed a fracture during follow up. The yearly frequency of fractures ranged from 3.7-9.9%, peaking at 9.9% and 9.8% during years 4 and 5, respectively. The mean age of the fracture group was lower than the non-fracture group, almost approaching significance (69.24 years ± 12.26 vs 66.42 ± 10.18, p=0.053). Compared to the non-fracture group, the fracture group had significantly lower femoral neck BMD (0.75 gms/cm² ± 0.12 vs 0.79 ± 0.10, p = 0.02), and lumbar spine T scores (-2.13 ± 0.99 vs -1.78 ± 0.79, p = 0.01). Individuals in the fracture group had a larger increase in 25-OHD than those in the non-fractured group (9.23 ng/mL ± 21.39 vs 16.58 ± 20.61, p = 0.046). There were no significant differences when comparing changes in BMD and BTMs. Overall, there was a significant increase in bone alkaline phosphatase from the first to the last visit (p < 0.001), and more prominent with risedronate than alendronate (2.39 mcg/L ± 0.82 vs 1.27 ± 0.45).

Conclusion: Patients who begin BP drug holidays at high risk of fracture based on age and BMD warrant close follow-up. Fracture risk analysis needs to be regularly assessed during the drug holiday and treatment resumed accordingly.

Percentage of Fractures Reported

SA0344

Increased femoral cortical thickness in patients with atypical femur fractures; the Quebec Registry for Atypical Femur Fractures. Suzanne Morin^{*1}, Thomas Moser², Benoit Godbout³, Etienne Belzile⁴, Michelle Wall⁵, Laetitia Michou⁶, Louis-Georges Sainte-Marie², Jacques A de Guise⁷, Jacques P Brown⁶. ¹McGill University, Canada, ²Université de Montréal, Canada, ³Centre de Recherche du CHUM, Canada, ⁴Université Laval, Canada, ⁵McGill University Health Center Research Institute, Canada, ⁶Centre de recherche du CHU de Québec, Canada, ⁷Centre de recherche CHUM, Canada

Purpose: The 2014 American Society for Bone and Mineral Research (ASBMR) task force includes the presence of generalized increase in cortical thickness of the femoral diaphyses as a minor criterion in its case definition of atypical femur fracture (AFF). However, data on are lacking.

Methods: We determined femoral cortical thickness in 16 Caucasian women with AFF (cases) who agreed to participate in the Quebec Atypical Femur fracture registry and compared it to 16 ethnicity-, age-, height- and cumulative bisphosphonate exposure- matched women without fractures (controls). Using the EOS™ low irradiation 2D-3D X-Ray scanner, bilateral lower extremities examinations were obtained. We measured and compared differences in the cortical thickness ratio (CTR=medial + lateral cortices thickness in mm/femur diameter in mm, Niimi R et al. *JBMR* 2015; 30: 225-231) at 4 cm and 12.5 cm below the lesser trochanter, and the lateral cortical thickness every mm along the diaphysis from the lesser trochanter to the distal condyles in one non-operated femur between cases and controls.

Results: We identified 16 Caucasian women (mean age 69.1[8.7] years, height 157.4 [5.0] cm, 11 diaphyseal fractures (D) and 5 subtrochanteric fractures (ST), and a mean cumulative bisphosphonate use duration 12.4 [4.7] years) with AFF, and recruited 16 ethnicity-, sex-, age- and height-matched controls (mean age 68.8 [7.7] years, height 156.3 [7.0] cm, and mean cumulative bisphosphonate use duration 10.4 [3.3] years). CTR at 4 cm and 12.5 cm below the lesser trochanter were statistically different between cases and controls: 0.55 [0.05] and 0.60 [0.04] versus 0.49 [0.05], 0.54 [0.07] respectively, p < 0.001. (Table1). Measurements of CTR along the entire femur diaphysis revealed thicker cortices in cases with ST and D AFF versus their controls (p < 0.04) (Figure1). In those with ST fractures the location of highest thickness in the lateral cortex was at 2.5 cm below the lesser trochanter (9 mm) whereas in those with a D fracture, this was located at 11.5 cm below the less trochanter (8.2 mm) and in controls at 10 cm (7.1 mm).

Conclusion: We have documented increased cortical thickness ratio and lateral cortical thickness in patients with AFF compared to their matched controls with similar exposure to bisphosphonates. This supports inclusion of this criterion in the ASBMR task force definition of AFF.

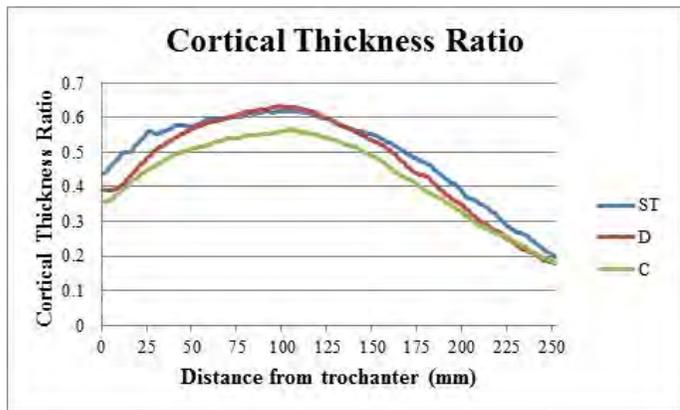

Figure Cortical Thickness Ratio distal to the lesser trochanter in participants with subtrochanteric

Molecular investigations of bone quality from osteoporotic women treated with Alendronate or Strontium Ranelate after 12 months. Guillaume Falgavrac^{*1}, Bernard Cortet², Cecile Olejnik³, Guillaume Penel³. ¹PMOI EA4490, France, ²Service de Rhumatologie, Hôpital Roger Salengro, CHRU de Lille, France, ³PMOI (Physiopathologie des Maladies Osseuses et Inflammatoires), EA4490, Faculté de Chirurgie Dentaire, University of Lille, Health & Law, France

Osteoporosis impairs the bone quality. Alendronate (ALN) and Strontium Ranelate (SrRan) are effective treatments in the field of osteoporosis. Their clinical benefits are recognized but their mechanisms at molecular level need to be elucidated. The aim of this work was to compare the effects of ALN and SrRan on bone quality at molecular level for a 12 month-period.

Paired iliac crest biopsies were harvested on postmenopausal osteoporotic women (50-84 years) at baseline (M0, n=10) and after 12 months (M12, n=10) for each treatment (ALN/SrRan). New and old bone was located by Back Scattered Electron images. Sr fixed in bone was located by elemental images. Raman microspectroscopy was done on new and old bone. The physico-chemical parameters (PCP) were assessed from Raman spectra (Olejnik et al 2014, Osteoporosis Int.): mineralization ratio, type-B carbonatation, crystallinity, collagen quality (hydroxyproline/proline and crosslinks ratio) and relative non-collagenous content (PG/AmideIII). The results were interpreted as function of the tissue age, the treatment and the nature of bone.

As the tissue age increases, the PCP showed that the mineralization, the type-B carbonatation and the crystallinity increases in cortical (ct) and trabecular (tb) bone, independently of the treatment as reported by Gamsjaeger et al (2014, JBMR).

Regarding the treatment, the mineralization increased (+9.3%, p=0.0026) in tb and PG/Amide III increased (+8.5%, p=0.0030) in ct and tb between ALN-M0 and ALN-M12 in new bone. The type-B carbonatation (-9.6%, p<0.0001) and the crystallinity (-1.8%, p=0.017) decreased in ct and tb new bone between SrRan-M0 and SrRan-M12. The PG/AmideIII (-8.3%, p=0.0047) decreased in tb new bone between SrRan-M0 and SrRan-M12. No difference was observed between M0 and M12 in old bone for both drugs.

The fact that ALN suppresses the bone remodeling and enhances the secondary mineralization process, explains the increase of the mineralization. A different mechanism may occur at the molecular level following SrRan intake, which could explain the release of carbonate and the decrease of crystallinity. Both drugs may have an opposite effect on the mineralization mechanism of collagen matrix according to PG/AmideIII. In conclusion these findings indicate that the effects of ALN and SrRan at molecular level are different. These data provide new insight in the mechanism of action of both ALN and SrRan.

Response to Denosumab in Patients attending a Specialist Bone Clinic. Triona McNicholas^{*1}, Breffni Drumm², Patrick O'Donoghue², Georgina Steen², Kevin McCarroll², JB Walsh², James Mahon², Rosaleen Lannon². ¹St James's Hospital, Dublin, Ireland, ²Bone Health Unit, St James's Hospital, Ireland

Background:

Denosumab has been available for the treatment of severe osteoporosis since October 2010. It is an anti-resorptive agent which has been shown to reduce fracture risk and increase bone mineral density (BMD). It is indicated in post-menopausal women with osteoporosis at high risk of fracture and has been shown to reduce the incidence of vertebral, non-vertebral and hip fractures.

Method:

Using an electronic database we reviewed records of subjects who were prescribed denosumab at our bone health clinic. 191 patients who had been commenced on denosumab between October 2010 and January 2013. Of these, 125 patients had a repeat DXA between the date they commenced denosumab and March 2015. We recorded the change in T-score in the AP spine and the total hip in these patients.

Results:

Looking at the 125 follow up DXAs available; mean age was 76 ± 10.54 years and mean time to follow-up DXA was 1.92 ± 1.08 years. 116 subjects had spinal results and 115 had hip results. Reasons for non-availability of spine or hip scores include vertebrae not suitable for analysis due to fracture or degenerative disease or bilateral hip replacements respectively.

Mean T-scores at baseline in spine and total hip were -2.82 and -2.42 respectively. Spinal T-scores improved in 91 subjects with an average relative improvement in T-score of 0.63SD (+/-0.42). In 18 subjects T-score deteriorated an average of 0.42SD (+/-0.41). T-score in the AP spine remained unchanged in 7 subjects. Hip T-scores improved in 70 subjects with an average relative improvement in T score of 0.34 (+/-0.23). In 24 subjects T-score deteriorated an average of 0.49SD (+/-0.87). T Score in the Hip remained unchanged in 21 subjects. Overall T-scores improved by 15% at the spine and 9% at the total hip.

Conclusion:

These results show that in 125 patients on denosumab with follow up DXA attending a tertiary clinical setting there is an improvement in T score in the AP spine in 78.45% of patients and in the hip in 60.87% of patients. Reasons for lack of response will require further analysis of factors such as duration of treatment,

previous treatment as well as bone turnover markers and vitamin D and fracture history.

Short-term functional recovery between immediate- and delayed bisphosphonate treatment in patients with femoral neck fractures: a randomized controlled trial. Aasis Unnanuntana, Panai Laohaprasitiporn*, Atthakorn Jarusriwanna, Wachirapan Narktang. Siriraj Hospital, Thailand

Objective: The objective of this study was to compare the short-term functional recovery between immediate- and delayed bisphosphonate treatment in femoral neck fractured patients who were treated with hemiarthroplasty. Methods: We conducted a randomized controlled trial study at a university hospital in Bangkok, Thailand during June 2013 – June 2015. Eighty-six patients who underwent hemiarthroplasty after femoral neck fractures were included and allocated into two groups: immediate- and delayed treatment groups. Both groups received risedronate 35 mg/week either at 2 weeks (immediate group) or 3 months (delayed group) post-operation and additional calcium and vitamin D supplementation. Functional recovery were assessed by using the de Morton Mobility Index, Barthel index, EuroQoL-5D, visual analog scale, timed get-up and go test, and 2-minute walk test (2MWT) at 2 weeks as baseline data and either at 6 weeks or 3 months after surgery. Results: Most patients were female with an average age of 77 years. The patients' demographic and baseline clinical information were similar in both groups (Table 1). At 3 months follow-up, the functional outcome of both groups improved significantly. There were no statistically significant differences in any of the functional outcomes between the two groups at both 6-week and 3-month follow-up (Table 2). Although the average distance walked within 2 minutes in the immediate treatment group was higher than that of delayed treatment group (44.8 and 40.6 meters for immediate and delayed treatment groups, respectively), the difference was not statistically significant (p-value = 0.085). Discussion and conclusion: Hip fracture in the elderly carries high morbidity and mortality and can lead to another fragility fracture. Bisphosphonate is proved to be an effective drug used to prevent osteoporotic fracture. Because there is a concern regarding bisphosphonate effect on fracture healing, most orthopaedic surgeons delayed the initiation of bisphosphonate therapy for few months after fracture fixation. Since delayed bisphosphonate treatment did not adversely affect functional recovery after hemiarthroplasty, this treatment can be postponed in femoral neck fractured patients. During the first few months after surgery, the focus of treatment should be on normalization of calcium and vitamin D levels. Once corrected, the pharmacological treatment of osteoporosis can then be initiated.

Table 1 Patients' demographics and clinical characteristics

| Clinical variables | Early BIS (N=43) | Late BIS (N=43) | p-value |
|---|------------------|-----------------|---------|
| Age (years) | 78 ± 8.43 | 76 ± 8.16 | 0.366 |

Skeletal-site Heterogeneity in the Association Between Bisphosphonate Use and Incident Non-vertebral Fracture. Lisa Langsetmo*¹, Claudie Berger², David Goltzman³, Suzanne Morin³, David Hanley⁴, Stephanie Kaiser⁵, Jerilynn Prior⁶, Brian Lentle⁶, Millan Patel⁶, Nancy Kreiger⁷, Sophie Jamal⁷, Robert Josse⁷, Jacques Brown⁸, Jonathan Adachi⁹, Alexandra Papaioannou⁹, Kenneth Davison¹⁰, Wojciech Olszynski¹¹, Christopher Kovacs¹², William Leslie¹³, Tassos Anastassiades¹⁴, Tanveer Towheed¹⁴.

¹Canadian Multicenter Osteoporosis Study, Canada, ²Canadian Multicenter Osteoporosis Study, Canada, ³McGill University, Canada, ⁴University of Calgary, Canada, ⁵Dalhousie University, Canada, ⁶University of British Columbia, Canada, ⁷University of Toronto, Canada, ⁸University of Laval, Canada, ⁹McMaster University, Canada, ¹⁰University of Victoria, Canada, ¹¹University of Saskatchewan, Canada, ¹²Memorial University, Canada, ¹³University of Manitoba, Canada, ¹⁴Queen's University, Canada

We have previously reported that the use of antiresorptives among women was associated with a decrease in all non-vertebral fractures during the period 1996-2003; this overall skeletal benefit is consistent with clinical trial results. The implications of the decline in hormone therapy and increase in bisphosphonate use since the original study are unclear. In addition, the effect of treatment may be skeletal site-specific and vary over time.

We assessed the association between bisphosphonate use (current vs none) among postmenopausal women and men age 50 years and older and incident non-vertebral fracture within the CaMos cohort from Years 5-15 (2000-12). We also considered exposure duration (≤ 5y, 6-10y, >10y) and fracture site (hip, forearm, rib, upper arm, leg, other non-vertebral fracture) in secondary analysis (women only). We used a nested case-control study design with time-varying exposure and selected 4 controls (if available) per case matched on age, prior fracture history, low BMD (binary), osteoporosis diagnosis, and time period (women only). Additional covariates included education, smoking, alcohol, BMD (continuous), and for women included hormone therapy and propensity score (probability of bisphosphonate use based on demographics/medical history). There were 641 non-vertebral fracture cases in women with 2447 matched controls, and 129 cases in men with 431 matched controls.

Current bisphosphonate use was not associated with overall fracture risk in men (OR=1.11, 95% CI: 0.61, 2.02) or in women (OR: 1.03, 95% CI: 0.82, 1.30). There was no variation by duration of use in women (55% of users had 6+ years). There was apparent heterogeneity by fracture site among women, with current use associated with a reduction in hip fracture risk (OR:0.47, 95% CI: 0.26, 0.83) and an increase in forearm fracture risk (OR=1.66, 95% CI 1.03, 2.69); associations for other fracture sites fell between these extremes. The observed associations between bisphosphonate use and site-specific fracture risk also did not differ by duration of use. Comparison of the estimates to those obtained without matching indicated substantial confounding by indication.

The present study showed possible skeletal site-specific variation in women, but failed to demonstrate an association between bisphosphonate use and all non-vertebral fracture in women or men; the hypothesized duration effects were not present. Possible residual confounding by indication precludes strong conclusions.

Surgical treatment following Atypical Femur Fractures and functional outcomes: the Quebec Atypical Femur Fracture Registry. Prism Schneider^{*1}, Edward Harvey², Michelle Wall², Etienne Belzile³, Jacques P. Brown⁴, Suzanne Morin¹. ¹McGill University, Canada, ²McGill University Health Center Research Institute, Canada, ³Université Laval, Canada, ⁴Centre de recherche CHU de Quebec, Canada

Purpose

Atypical femur fractures are rare events leading to uncertainty as to best surgical therapeutic options. We aim to describe surgical treatment following AFF and functional outcomes 6 months after fracture diagnosis.

Methods

We reviewed all X-rays from patients who agreed to participate in the Province of Quebec (Canada) Atypical Femur Fracture Registry to characterize type, location, and surgical treatment of each AFF. Functional outcomes before and 6 months following fracture were determined by an interviewer-administered questionnaire using the Level of Lower Extremity Function Scale (LEFS).

Results

To date, 51 participants have been recruited in the Registry (total of 76 AFF) with a mean age of 69 (\pm 9) years, 90% women (Table). All were exposed to bisphosphonates with an average cumulative duration of use of 10.5 [4.7] years. Incomplete subtrochanteric AFF (sAFF) were more often treated non-operatively (n = 9) compared with operatively (n = 3), similarly incomplete diaphyseal AFF (dAFF) were more often treated non-operatively (n = 18) compared to operatively (n = 12). In patients who underwent surgery, sAFF were most often treated with a long cephalomedullary nail (CMN) (n = 9 complete; n = 2 incomplete) compared to a short CMN (n = 3). Complete dAFF were treated with a long CMN (n = 10) compared to intramedullary nail (IMN) (n=9; greater trochanteric start n = 6; piriformis entry n = 3). Similarly, incomplete dAFF were treated either with CMN (n = 3) vs. IMN (n = 4; greater trochanteric start= 3). Patients with unilateral complete AFF showed greater improvement in LEFS from pre-fracture diagnosis (25.3 ± 19.9) to 6-month after (32.7 ± 7.5) with surgical fixation, when compared to patients with unilateral incomplete AFF from pre-diagnosis (43.8 ± 13.9) to 6-month follow-up (43.0 ± 17.9) without surgical fixation. Patients with bilateral AFF who underwent surgical fixation of only one side (n = 7), mean baseline LEFS was 64.9 ± 15.6 , compared to 6-month follow-up LEFS of 54.0 ± 9.8 , demonstrating a lack of return to baseline function ($p = 0.09$).

Conclusion

Treatment of AFF varied from non-operative treatment to surgical fixation for both complete and incomplete fractures using CMN or IMN implants. Clinical guidelines are needed for optimal timing of surgical fixation for incomplete AFF or for optimal implant use in complete fractures. Functional outcomes vary in patients and may be related in part to surgical treatment.

The Bone-Protective Effects of a Novel Selective Estrogen Receptor Modulator (SERM) pERD in Ovariectomized Rats. Jukka Morko^{*1}, Carsten Möller², ZhiQi Peng¹, Jukka Vääräniemi¹, Katja M Fagerlund¹, Tiina A Suutari¹, Jenni Bernoulli¹, Jukka P Rissanen¹, Andrea Wagenfeld², Arndt Schmitz², Jussi M Halleen¹. ¹Pharmatest Services Ltd, Finland, ²Bayer Pharma AG, Germany

Selective estrogen receptor modulators (SERMs) are a diverse class of compounds that bind to estrogen receptors (ERs) and agonize or antagonize estrogen action in different tissue types. Due to a broad spectrum of physiological and pathological processes contributed by ERs, SERMs provide a potential therapeutic benefit for a variety of diseases. In this study, we characterized the effects of a novel SERM pERD on bone in a rat ovariectomy (OVX) model of postmenopausal osteoporosis, and we compared the effects of pERD treatment with the effects of 17 β -estradiol (E2) and raloxifene (RAL). E2 was used as a complete agonist and RAL as a reference SERM exhibiting agonist activity on bone and being used in clinical practice. Female Sprague-Dawley rats were ovariectomized or SHAM-operated at 3 months of age. Treatment of rats was started on one day after the operations and continued once a day for 8 weeks. OVX rats were treated with pERD at 1, 3 or 10 mg/kg/d *p.o.*, E2 at 4 μ g/kg/d *s.c.*, RAL at 1 mg/kg/d *p.o.* or with vehicle, and SHAM-operated rats were treated with vehicle. Treatment effects on bone were studied by peripheral quantitative computed tomography (pQCT), bone histomorphometry and by measuring serum levels of bone turnover biomarkers. In metaphyseal trabecular bone, treatment with pERD at 1, 3 and 10 mg/kg/d prevented an OVX-induced reduction in bone mineral density (BMD), bone mineral content (BMC), bone volume fraction (BV/TV) and trabecular number (Tb.N). The effects of pERD were associated with a prevention of OVX-induced increase both in osteoclastogenesis (N.Oc/B.Pm and Oc.S/BS) and bone turnover and formation (MS/BS, MAR, BFR/BS and BFR/BV). In diaphyseal cortical bone, treatment with pERD at 1 and 3 mg/kg/d prevented an OVX-induced increase in cortical BMC, cortical bone area and periosteal perimeter. In circulation, treatment with pERD at 1, 3 or 10 mg/kg/d prevented an OVX-induced increase in serum levels of cross-linked telopeptides of type I collagen (CTX-I), N-terminal mid-fragment of osteocalcin (OC), and procollagen type I N-terminal propeptide (PINP). These effects of pERD treatment were similar with the effects of E2 and RAL indicating a bone-protective agonist activity for pERD in metaphyseal trabecular bone at 1-10 mg/kg/d and in diaphyseal cortical bone at 1-3 mg/kg/d. The maximal efficacy of pERD was lower than the efficacy of E2 presenting pERD as a novel partial agonist in bone in young adult OVX rats.

Why Do Bisphosphonates Compromise Bone Formation?. Pia Jensen^{*1}, Thomas Levin Andersen², Pascale Chavassieux³, Jean-Paul Roux³, Jean-Marie Dealisse². ¹Vejele Hospital, Denmark, ²Department of Clinical Cell Biology, Vejele Hospital, Denmark, ³INSERM Unité 1003, Université de Lyon, France

Bisphosphonates (BP) are widely used to reduce osteoclastic bone resorption in osteoporotic patients. However, BPs also reduce bone formation, an effect commonly considered as a consequence of decreased resorption. Still, direct effects of BPs on the osteoblast lineage were reported in preclinical models. Furthermore, refined analyses of remodeling sites in adult human bone recently revealed pools of osteoprogenitors in areas likely to be exposed to BPs, raising the question of an effect of BPs on osteoblast recruitment. These areas included reversal surfaces and so-called bone remodeling compartment canopies, which are not taken into account in classical bone histomorphometry. The aim of the present study was to investigate whether BPs affect these putative osteoblast recruitment sites, by re-analyzing bone sections of the initial clinical study that addressed the effect of alendronate on patients with postmenopausal osteoporosis (PMO).

Goldner trichrome-stained sections of transiliac bone biopsies of PMO patients treated with alendronate (10 mg/d, n=25) or placebo (n=64) for 24-36 months, were assessed for classical histomorphometric parameters, i.e. extent of cancellous bone surface showing erosion, osteoid, osteoclasts, and osteoblasts. Reversal surfaces, defined as eroded surfaces without osteoclasts, were also assessed. Reversal surfaces were subdivided into active and arrested, depending on whether they were leading to bone formation or not, as based on our earlier studies. All surfaces were evaluated for the presence or absence of a canopy. The activation frequency of bone formation was also determined.

BP treatment significantly decreased bone resorption and formation parameters. Of note, BPs induced an increase in the extent of arrested reversal surfaces ($p < 0.01$) and a decrease in the prevalence of canopy ($p < 0.01$), indicating an impaired delivery of osteoprogenitors at the resorption sites. This view was strengthened by the negative relation between the proportion of reversal surface that was arrested and the prevalence of canopy ($p < 0.001$), the extent of osteoid ($p < 0.0001$), the extent of osteoblast surface ($p < 0.0001$), and the activation frequency of bone formation ($p < 0.05$).

We conclude that a previously unrecognized reason why BPs compromise bone formation in PMO is that BPs induce an arrest of remodeling cycles due to deficient osteoblast recruitment. These data deserve attention when treating osteoporotic patients with BPs.

Risk of hip fracture increases with diabetes mellitus (DM): Results from the Kailun cohort in China. Shivani Sahni^{1*}, Katherine Tucker², Chunpeng Ji³, Junjuan Li³, Shouling Wu³, Xiang Gao⁴. ¹Hebrew SeniorLife, Institute for Aging Research & Harvard Medical School, USA, ²University of Massachusetts, Lowell, MA, USA, ³Kailun Hospital, China, ⁴The Pennsylvania State University, USA

Osteoporosis affects almost 70 million older Chinese and causes ~687,000 hip fractures in China each year. By the year 2050, more than 50% of all osteoporotic hip fractures will occur in Asia. Limited data from Western countries suggests that type 2 diabetes (T2D) may increase fracture risk in older adults though data on pre-diabetes is less clear. Considering the overall high prevalence of diabetes (11.6%) and pre-diabetes (50.1%) in Chinese adults, it is vital that we examine the association of diabetes and osteoporosis in Chinese populations that will aid in targeting specific risk factors of fracture in older adults with diabetes or pre-diabetes.

We examined the association of impaired fasting glucose (IFG) and T2D with the risk of hip fracture over 5 years in men and women from the Kailun cohort in China.

Men and women (n=101,510) with baseline information on IFG and T2D were followed for hip fracture from 2008-2013. After excluding those with CHD/stroke, baseline report of hip fractures and missing data, we included 95,526 participants in the analyses. Hip fracture was defined as the first fracture of the proximal femur and was confirmed by review of medical records. Participants with no medical history of diabetes treatment and fasting plasma glucose concentration <5.6 mg/dL were categorized as not having diabetes. Participants with fasting plasma glucose concentration between 5.6 and 6.9 mmol/L were categorized as having IFG. Participants who had fasting glucose concentration ≥7 mmol/L or reported active diabetes treatment during the survey were categorized as having T2D. Cox-proportional hazards regression estimated Hazard Ratios (HR) adjusting for age, smoking, height, weight, menopausal status (in women), physical activity, alcohol intake and C-reactive protein. Individuals without diabetes were considered as the reference group.

The mean age was 52 y (range: 18-98), 20% were women, 23% had IFG, and 11% had T2D. During 5.4 years of follow-up (521,782 person years), there were 183 incident hip fractures. Those with T2D had 60% greater risk of hip fracture compared to those without T2D (Table). Those with IFG appeared to have 30% greater risk of hip fracture compared to those without T2D, but this did not reach statistical significance. Further adjustment strengthened the results among those with T2D.

These findings suggest that older Chinese adults with T2D have greater risk of hip fracture than those without T2D. Future work should examine if these associations persist after adjustment for insulin use and baseline bone mineral density.

Table. Association of impaired fasting glucose and type 2 diabetes with risk of hip fracture in older men and women from the Kailun cohort in China.

| | Hazard Ratios and 95% Confidence Intervals [HR (95%CI)] by Diabetes Status | | |
|---------|--|--------------------------|-------------------|
| | Diabetes Status | | |

Serum Sclerostin Levels in Liver Transplantation Patients at Risk of New-Onset Diabetes Mellitus: Response to Oral Glucose Tolerance Test. Guillermo Martinez Diaz-Guerra^{1*}, Gonzalo Allo², Mercedes Aramendi², Sonsoles Guadalix², Soledad Librizzi², David Lora², Carlos Jiménez², Federico Hawkins². ¹University Hospital 12 Octubre, Spain, ²University Hospital 12 de Octubre, Spain

INTRODUCTION: Several studies have found that sclerostin (SCL) is increased in patients with diabetes mellitus (DM) and could have a role in the increased risk of fractures in these patients. SCL has not been investigated in new onset diabetes after transplantation (NODAT) and, particularly, the acute effect of increasing plasma glucose on SCL remains unknown. The aim of our study is to evaluate serum SCL levels in a cohort of patients with liver transplantation (LT) at risk of developing

NODAT and its response after an oral glucose overload. PATIENTS AND METHODS: 85 LT patients (50 M, 35 F) without previous DM were studied. A 75 g oral glucose tolerance test was performed (OGTT) and ADA diagnostic criteria were followed. Serum SCL (Enzyme immunoassay, TECO medical) was measured in fasting, 60 and 120-minute samples during OGTT. MANOVA test were used to evaluate the evolution of SCL levels (from baseline to 120-minute). RESULTS: Mean age was 58.6 ± 12.5 years. Minimum study time since LT was 6 months and mean time since LT was 9.7 ± 5.7 years. 48 patients (64%) showed normal glucose tolerance (NGT), 31 (36.4%) impaired glucose tolerance (IGT) and 6 NODAT (7.05%). SCL levels were significantly higher in NODAT patients at baseline compared to NGT (p<0.001) and IGT (p<0.01). Age and fasting plasma glucose were independently associated with SCL (multiple linear regression, standardized β coefficient 0.29, p=0.006; 0.24, p<0.05 respectively). After OGTT, SCL showed a significant decrease which was more pronounced in the NODAT group (% of change -0.32 ± 0.64, p=0.01), although remained higher during the test compared to the other groups. CONCLUSIONS: Our results show that serum SCL levels are positively correlated with plasma glucose and age, and higher in patients with NODAT than in patients with IGT or NGT. After an OGTT, SCL decreases particularly in patients with NODAT. More studies are necessary to evaluate the role of high SCL levels in NODAT and bone loss.

The better performance of TBS in the prediction of vertebral fractures in postmenopausal diabetic women compared to BMD or FRAX score. Yong Jun Choi^{*}, Insun Song, Yoon-Sok Chung. Ajou University School of Medicine, South Korea

Introduction Type 2 diabetes has been associated with fracture risk, but paradoxically greater bone mineral density. The trabecular bone score (TBS) derived from the dual x-ray absorptiometry (DXA) image is proposed as an index of bone microarchitecture that associated with bone quality. The aim of this study is to compare the performance of TBS, bone mineral density (BMD), Fracture Risk Assessment Tool (FRAX) score in the prediction of vertebral fractures in diabetic patients. Subjects and Methods This cross-sectional study enrolled total 187 Korean postmenopausal diabetic women. Lateral plain radiographs of the thoracolumbar spine, and BMD of lumbar spine and femur neck were obtained using DXA. TBS was obtained by TBS iNsite Software program with DXA images. The FRAX probability was computed using the algorithm available online at <http://www.shef.ac.uk/FRAX> (South Korea version). Vertebral fractures (VFs) were detected by Genant semi-quantitative method and graded according to their severity (grade 0-3). Results Among the subjects, 77 women (41.2%) had vertebral fractures and 110 women (58.8%) did not. The mean of TBS was significantly lower in subjects with VFs (1.27±0.12) than without VF (1.31±0.11), (p=.006). However, there was no significant difference in lumbar spine and femur neck BMD between the subjects with VFs and without VFs (p>.05). TBS were also significantly decreased according to the number or severity of VFs. However, lumbar spine BMD did not showed significant decrease according to the number or severity of VFs. Odds ratios (ORs) for VFs for TBS in the lowest quartile (vs. highest quartile reference) was the higher (OR 2.617, 95% CI 1.120-6.116) compared to ORs for BMD in the lowest quartile (vs. highest quartile reference) and ORs for FRAX score in the highest quartile (vs. lowest quartile reference). Conclusion TBS showed the better performance in the prediction of VFs in postmenopausal diabetic women. These results suggest that TBS could be more useful tools to predict radiographic VFs in postmenopausal diabetic women than BMD or FRAX.

Odd Ratios (95% CI) for vertebral fracture(s) with BMD or TBS or FRAX

BMD and TBS status in adult patients suffering from Polio. D Grados Canovas¹, Silvana Di Gregorio², Luis Del Rio*², E Bonel², Manuel Garcia², Renaud Winzenrieth³. ¹Departament of Rheumatology, Hospital San Rafael, Spain, ²Cetir Grup Mèdic, Spain, ³R&D department, Med-Imaps, France

Objective: Assess TBS to categorize skeletal status in adult subjects with history limbs Poliomyelitis sequelae.

Method: We scan total body, lumbar spine (LS) and both hips in 59 patients with history of poliomyelitis infection and limb. Differences between affected extremities and opposites were assessed in terms of BMD and TBS (TBS® Insight v2.1; Medimaps). Subjects were stratified using BMD T-score (minimum T-score of the scanned sites). TBS results were categorized as normal (TBS-N, >1.350); partially deteriorated (TBS-PD, [1.250 -1.350]), and significantly deteriorated (TBS-SD, ≤1.250).

Results: The left limb was the extremity most affected in this group (32 vs 21). 6 patients had both extremities affected. 15% of patients had normal BMD at femur, 49% had normal LS BMD while only 36% had TBS-N. After stratifications, osteopenic patients (47% at the femur and 42% at LS) or TBS-PD (39%) were detected similarly. In osteoporotic patients, lowest BMD T-score was found at the femur (37%, mainly at the affected limb) while only 8% were osteoporotic at LS. TBS-SD was found in 25% of these patients. Spondyloarthritis and scoliosis signs were found in 25 patients. Among them, 16.7% were osteoporotic at affected femoral side although a normal BMD at L1-L4 and at the opposite femur. All of them had a deteriorated TBS (TBS-PD and TBS-SD). TBS value is associated negatively with the fat mass ($r=-0.36$, $p<0.005$) and with the legs lean mass ($r=-0.44$, $p<0.001$) while Spine BMD was neither associated with lean nor fat mass. A positive borderline association between lean mass and BMD at Femur was observed ($r=0.26$, $p=0.049$). No correlations were obtained between TBS and BMD at all sites. Polio subjects had a significant lower TBS value (TBS Z-score=-0.6 SD; $p<0.001$) when compared with normal values for age and thus independently of the gender. It seems that TBS alteration is more pronounced in mean than in women as reported by a lower TBS z-score (-0.83 vs -0.44 SD).

Conclusion: TBS seems to be more sensitive than BMD to identify patients suffering from Polio. Postural instability could increase irregular mechanical charges to lumbar spine and unaffected femur that may decrease the BMD sensitivity to classify patients. Interestingly, TBS was negatively associated with the fat and lean mass while BMD at femur was associated positively with lean mass. This differentiating associations have to be investigated in further study.

Risk Factors For The Development Of Osteoporosis After Spinal Cord Injury. A 12-Month Follow-up Study. Laia Gifre*¹, Joan Vidal², Josep Lluís Carrasco³, Africa Muxi⁴, Enric Portell², Ana Monegal⁵, Núria Guanabens⁵, Pilar Peris⁵. ¹Hospital Clinic Barcelona, Spain, ²Guttmann Neurorehabilitation Institute. Universitat Autònoma de Barcelona, Spain, ³Public Health Department, University of Barcelona, Spain, ⁴Nuclear Medicine Department. Hospital Clínic of Barcelona, Spain, ⁵Rheumatology Department, Hospital Clinic of Barcelona, Spain

Introduction: Spinal cord injury (SCI) has been associated with a marked bone loss after injury and a consequent increased risk of osteoporosis and fractures. The aim of this study was to analyze the factors associated with osteoporosis development short-term after SCI. Methods: We included patients with complete recent SCI (<6 months) evaluating bone turnover markers (PINP, bone ALP and sCTX), 25-OH-vitamin D (25OHD) levels and lumbar and femoral BMD (Lunar, Prodigy) at baseline, and 6 and 12 months after SCI. The risk factors for osteoporosis analyzed included: age, gender, BMI, toxic habits, bone turnover markers, 25OHD levels, lumbar and femoral BMD, level, severity and type of SCI and days-since-injury. Osteoporosis was defined according to WHO criteria. Covariates at baseline were used as markers of osteoporosis at 12 months, with their diagnostic and prediction ability being assessed by computing their sensitivity, specificity and predictive values. The area under ROC curves (AUC) was analyzed, and relative risk ratios (RR) to evaluate the increase of risk of osteoporosis development at 12 months were calculated. Results: Thirty-five patients aged 35-16 years were included, and 52% developed osteoporosis during the 12-month follow-up. These latter patients had lower BMD values at femur and lumbar spine and higher bone turnover markers at baseline. Total femur BMD showed an excellent diagnostic ability (AUC=0.92; 95%CI, 0.81-1), and lumbar BMD (AUC=0.78; 95%CI, 0.6-0.97), bone ALP (AUC=0.77; 95%CI 0.57-0.96) and PINP (AUC=0.75; 95%CI, 0.54-0.95) had good diagnostic ability. On multivariate analysis the principal factors related to osteoporosis development were: baseline total femur BMD (<1gr/cm2 (RR, 3.86; 95%CI, 2.74-4.22, $p<0.0001$) and lumbar BMD <1.2gr/cm2 (RR, 2.32; 95%CI, 1.53-2.59, $p=0.0002$), with a high probability for osteoporosis development when both parameters were below these cut-off values (0.97 probability of osteoporosis). Increased risk for osteoporosis was also associated with increased baseline values of bone ALP (>14 ng/mL) (RR, 2.40; 95%CI, 1.10-5.23, $p=0.041$) and PINP (>140 ng/mL) (RR, 3.08; 95%CI, 1.10-8.57, $p=0.017$). Conclusions: Evaluation of BMD at the lumbar spine and femur short-term after SCI is a simple, effective method for predicting the development of osteoporosis during the first year after SCI.

Our results also indicate the need to evaluate and treat these patients shortly after injury.

Compromised Trabecular Microstructure in Young Adults with Cystic Fibrosis. Melissa Putman¹, Logan Greenblatt*², Padrig Tuck², Ahmet Uluer³, Leonard Sicilian⁴, Allen Lapey⁵, Catherine M. Gordon⁶, Mary Bouxsein⁷, Joel Finkelstein². ¹Massachusetts General Hospital/Children's Hospital Boston, USA, ²Massachusetts General Hospital, Endocrine Unit, USA, ³Boston Children's Hospital, Division of Respiratory Diseases, USA, ⁴Massachusetts General Hospital, Pulmonary Division, USA, ⁵Massachusetts General Hospital, Pediatric Pulmonary Division, USA, ⁶Hasbro Children's Hospital, Divisions of Adolescent Medicine & Endocrinology, USA, ⁷Massachusetts General Hospital, USA

Purpose: The risk of fracture is increased in patients with cystic fibrosis (CF). Although areal bone mineral density (aBMD) by DXA and bone microarchitecture by high-resolution peripheral quantitative computed tomography (HR-pQCT) are often compromised, these factors do not seem to account for all of the increase in fracture risk in these patients. Individual trabecular segmentation (ITS)-based morphological analysis of HR-pQCT images segments trabecular bone into individual plates and rods of different alignment and connectivity, which are important determinants of trabecular bone strength. We sought to determine whether alterations in ITS are present in patients with CF and may help explain some of their increased fracture risk.

Methods: 30 patients with CF (18 women, 12 men), ages 18-40 years (mean 25 ± 5) underwent DXA of the hip and HR-pQCT scans of the radius and tibia with further assessment of trabecular microstructure by ITS. They were compared with 60 healthy controls matched for age (+2 yrs), gender, and race using generalized linear models. Multivariable linear regression was performed adjusting for BMI and BMI plus total hip aBMD.

Results: As expected, BMI was lower in patients with CF than in controls (20.8 vs 25.2 kg/m², $p<0.01$). Plate volume fraction, thickness, and density as well as plate-plate and plate-rod connectivity were reduced and axial alignment of trabeculae was lower in CF subjects at both the radius and the tibia ($p<0.05$ for all). At the radius, adjustment for BMI eliminated most of these differences. At the tibia, however, reductions in plate volume fraction and number, axially aligned trabeculae, and plate-plate connectivity remained significant after adjustment for BMI alone and for BMI and aBMD ($p<0.05$ for all).

Conclusions: Young adults with CF have compromised plate-like and axially aligned trabecular morphology with less connectivity between trabeculae. Although the lower BMI in patients with CF may account these differences at the radius, neither differences in BMI nor in aBMD fully account for trabecular microstructural deficits at the tibia. These findings indicate that ITS provides unique information about bone integrity and thus it may help explain a portion of fracture risk in CF patients not accounted for by BMD and/or bone microarchitecture.

Table 1: ITS Results (mean ± SE)

| ITS Parameter | Radius | | Tibia | |
|--|------------------------------|--------------------|--------------------------------|--------------------|
| | CF Subjects | Healthy Volunteers | CF Subjects | Healthy Volunteers |
| Plate bone volume fraction (pBV/TV) | 0.104 ± 0.008 ^a | 0.127 ± 0.006 | 0.136 ± 0.008 ^{a,b,c} | 0.173 ± 0.006 |

Inflammatory focal bone destruction in femoral heads with end-stage hemophilic arthropathy: A study on clinic samples with micro-CT and histologic analyses. Shanxing Zhang^{*1}, Hongting Jin², Peijian Tong³.
¹Zhejiang Chinese Medical University, Peoples republic of china, ²Institute of Orthopaedics & Traumatology of Zhejiang Province, China, ³Department of Orthopaedics Surgery, the First Affiliated Hospital of Zhejiang Chinese Medical University, China

Abstract Introduction In addition to systematic bone loss, focal bone destruction has a high prevalence in hemophilic arthropathy (HA) affected joints, but the mechanism remains unclear. Purpose We performed this study on clinic samples to explore the focal bone destruction in femoral heads suffered with end-stage HA. Methods 21 femoral heads from HA patients and 19 femoral heads from rheumatoid arthritis (RA) patients were collected when they underwent total hip replacement. Micro-CT scanning and histologic analysis, including tartrate-resistant acid phosphatase (TRAP) staining of subchondral bone were performed to evaluate the bone destruction and osteoclasts activity by counting osteoclasts in each random field (magnification 5 ×). RANKL, OPG as well as pro-inflammatory cytokines, such as TNF-α and IL-1β in subchondral bone were detected by immunohistochemistry (IHC) method. The IHC photos were quantitative analyzed with software by detecting the integral optical density (IOD) of the tissue around the subchondral bone. Results Severe focal bone lesions were observed in all of the HA and RA femoral heads by micro-CT imaging and histologic analysis. The mean percentage of lesion volume to total volume of the femoral heads from HA patients was significantly higher than those from RA patients (8.2 ± 3.0% versus 6.0 ± 2.6%, P=0.019). There was no significant difference in osteoclasts numbers in subchondral bone between HA and RA groups. By IHC analysis, high expression of RANKL, TNF-α, IL-1β and low expression of OPG were observed in subchondral bone in femoral heads derived from HA and RA patients, and there were no significant differences in the expression of RANKL, OPG, TNF-α and IL-1β in femoral heads derived from HA and RA patients. Conclusion Our findings demonstrated the focal bone destruction coupled with inflammatory osteoclastogenesis at subchondral bone in femoral heads from patients with end-stage HA, and that was similar to the changes in the femoral heads of RA patients, so maybe proper therapeutic interventions are required. Microarchitectural and Biomechanical Effects of PTH Excess due to Primary or Renal Secondary Hyperparathyroidism. Emily Stein^{*}, Thomas Nickolas¹, Kyle Nishiyama¹, Donald McMahon¹, Nientara Anderson¹, Anna Kepley¹, X. Edward Guo², Shonni Silverberg¹, Elizabeth Shane¹.
¹Columbia University College of Physicians & Surgeons, USA, ²Columbia University, USA

Whether the skeletal effects of parathyroid hormone (PTH) excess differ according to etiology of hyperparathyroidism (HPT) is not known. We compared postmenopausal women (PM) with primary (PHPT) and secondary (SHPT) hyperparathyroid-

ism to determine whether primary and secondary elevations in PTH have similar effects on bone mass, microarchitecture and strength. We hypothesized that women with PHPT and SHPT from chronic kidney disease would have similar skeletal abnormalities, with greatest deficits in cortical (Ct) bone.

PM women with PHPT (n=50), SHPT (n=28), and controls (C; n=55; normal PTH and renal function) had calciotropic hormones, bone turnover markers, and areal BMD (aBMD) of lumbar spine (LS), total hip (TH), femoral neck (FN), and 1/3 radius (1/3R) by DXA. Trabecular (Tb) and Ct volumetric BMD (vBMD) and microarchitecture were measured by high resolution peripheral computed tomography (HRpQCT) of the distal radius and tibia. Whole bone stiffness was estimated by finite element analysis.

Subjects were 69 ± 8 yrs, had BMI 27 ± 6 kg/m², 76% were Caucasian. Women with SHPT had higher BMI, were older and more likely to be Latina (52% vs 8% PHPT and 15% C; p<0.01). Intact and whole PTH levels were highest in SHPT (Table 1). All groups were 25OHD sufficient. DXA and HRpQCT were compared after adjusting for age, race and BMI. aBMD was similar at the LS and 1/3R, but tended to be lower in SHPT at the TH (p=0.08) and FN (p=0.09). In contrast with the DXA findings, women with PHPT had the most abnormalities by HRpQCT (Table 2). At the radius, Ct deficits were most pronounced, with lower Ct area, thickness and density compared to controls. Total density was lower and Tb density tended to be lower in PHPT, although Tb microarchitecture did not differ. Whole bone stiffness was lower in both HPT groups compared to controls. There were no significant findings at the tibia.

In summary, women with PHPT and SHPT had similar bone stiffness that was decreased compared to controls. Despite higher PTH levels in SHPT, skeletal abnormalities were greatest in PHPT, with cortical deficits predominating. That biomechanical impairment was similar in both HPT groups despite better vBMD in SHPT suggests the importance of factors other than elevated PTH in determining fragility in patients with SHPT and CKD.

Prevalence of low bone mineral density, osteopenia, osteoporosis and its associated risk factors in female ballet dancers. Tânia Amorim^{*1}, Lygeri Dimitriou², George Metsios³, Matthew Wyon³, Alan Nevill³, Andreas Flouris⁴, José Maia⁵, José Carlos Machado⁵, Franklim Marques⁵, Nuno Adubeiro⁶, Luísa Nogueira⁶, Kerry Matthews³, Yiannis Koutedakis⁷.

¹University of Wolverhampton, UK; ²University of Porto, Portugal, United Kingdom, ³University of Middlesex, United Kingdom, ⁴University of Wolverhampton, United Kingdom, ⁵University of Thessaly, Greece, ⁶University of Porto, Portugal, ⁷Polytechnic Institute of Porto, Portugal, ⁷University of Thessaly; University of Wolverhampton, Greece

PurposeConcerns have been voiced over the possible deleterious effects of professional dance training environment on dancers' bone health. The aim of the present study was to determine low bone mineral density (BMD) prevalence,

osteopenia and osteoporosis and its associated risk factors in female ballet dancers. MethodsDancers were recruited from professional ballet companies and vocational ballet dance schools in Portugal and England. Aged and sex-matched controls (non-dancers) were also drafted from both countries. All participants provided written informed consent and were subsequently scanned at the lumbar spine (LS) and non-dominant arm using Dual-Energy X-Ray Absorptiometry. Osteopenia and osteoporosis were diagnosed in professionals and matched controls based on the American College of Sports Medicine criteria for athletes, and low BMD was diagnosed in vocational dancers (and respective controls) according to the International Society of Clinical Densitometry criteria for children. Participants were also asked to complete a menstrual history questionnaire. ResultsOne hundred and twenty-nine professional dancers (28.2[±]9.5yrs), 99 matched controls (28.9[±]10.9yrs), 109 vocational dancers (13.4[±]2.4yrs) and 56 student controls (13.7[±]2.2yrs) volunteered. Compared with their controls, professional dancers revealed a significantly higher prevalence of osteopenia and osteoporosis at the arm (36.7% vs. 16.2%, p<0.001 and 24.2% vs. 1%, p<0.001, respectively). Although not significant, a higher prevalence of osteopenia at the LS (12.4% vs. 9.1%, p>0.05) was also found. A significantly higher prevalence of low BMD at the arm (9.2% vs. 0%, p<0.01) and LS (16.4% vs. 5.5%, p<0.01) was found in the vocational dancers compared to controls. Logistic regression analysis revealed that vocational dancers are more likely to develop low BMD at the LS (OR=0.2; 95% CI: 0.08-0.73) and arm (OR= 0.1; 95% CI: 0.02-0.98) than controls. In both vocational and professional dancers, neither body weight (Kg) nor menstrual disturbances (oligo-amenorrhea) were predictors of low BMD/osteoporosis (p>0.05). ConclusionElements of low BMD and osteoporosis are present in female vocational and professional dancers at both impact (LS) and non-impact sites (arm). It seems that known associated factors for low BMD and osteoporosis do not explain the aforementioned results.

Prevalence of Morphometric Vertebral Fracture in Brazilian Women with Human Immunodeficiency Virus (HIV) Infection. Érico Carvalho¹, Francisco Bandeira^{*2}, Zoraya Barros¹, Demócrito Filho³, Heloisa Melo⁴, Maria de Fátima Albuquerque⁵, Ulisses Montarroyos⁶, Ricardo Ximenes⁷. ¹Serviço de Infectologia, Universidade de Pernambuco, Recife, Pernambuco, Brasil., Brazil, ²University of Pernambuco, Brazil, ³Departamento de Medicina Clínica, Universidade de Pernambuco, Recife, Pernambuco, Brasil., Brazil, ⁴Departamento de Medicina Clínica, Universidade de Pernambuco, Recife, Pernambuco, Brasil., Brazil, ⁵Serviço de Endocrinologia, Hospital Agamenon Magalhães, Recife, Pernambuco, Brasil, Brazil, ⁶Departamento de Medicina Tropical, Universidade Federal de Pernambuco, Recife, Pernambuco, Brasil., Brazil, ⁷Departamento de Medicina Clínica, Universidade de Pernambuco, Recife, Pernambuco, Brasil., Brazil, ⁷Departamento de Medicina Tropical, Universidade Federal de Pernambuco, Recife, Pernambuco, Brasil, Brazil

Introduction: Some studies have suggested that adults with HIV infection have a high prevalence of low bone mass (LBM), as well as increased risk for clinical fractures but few data are available regarding morphometric vertebral fractures (MVf) and its associated factors particularly in women. The aim of this study was to determine the prevalence of MVf by the semi-quantitative (SQ) and by the algorithm-based qualitative (ABQ) methods in Brazilian women living with HIV. Subjects, Methods and Results: We studied 386 women (63.1 % premenopausal) aged 44 ± 9.3 years, with a mean time of 7 years with HIV infection, of whom 90% were using highly active anti-retroviral therapy (HAART) for more than 6 years. Spine X-rays were reviewed by two observers. The inter-observer agreement (IOA) for each method was calculated by Kappa. The association with bone mineral density (BMD) as well as clinical and laboratory factors were evaluated. The prevalence of MVf was 10.1% for the SQ method and 8.8% for the ABQ method (IOA SQ: $\kappa = 0.338$, 95% CI 0.243 to 0.432; p<0.001; ABQ: $\kappa = 0.211$, 95% CI 0.113 to 0.31; p<0.001) and there was a sharp increase after the age of 50 (Figure 1). In univariate analysis MVf was associated with LBM but this did not remain significant after adjustment for age, and no association was found with factors related to HIV or HAART. Conclusions: We found a high prevalence MVf in women with HIV infection using both SQ and ABQ methods and age was the most important associated factor. Keywords: Vertebral fractures, low bone mass, osteoporosis, HIV.

B Cells Contribute to Bone Erosion in Rheumatoid Arthritis by Directly Inhibiting Osteoblast Differentiation. Wen Sun*, Nida Meednu, Hengwei Zhang, Xing Li, Teresa Owen, Alex Rosenberg, Brendan Boyce, Jennifer Anolik, Lianping Xing. University of Rochester Medical Center, USA

Rheumatoid arthritis (RA) is an autoimmune inflammatory disorder characterized by increased osteoclast-mediated joint bone erosion accompanied by decreased osteoblast (OB)-mediated bone formation. B cell depletion therapy (BCDT) effectively attenuates joint tissue damage in many RA patients. B cells promote osteoclast formation by secreting RANKL and activating other immune cells such as T cells. However, the effects of B cells on OB function in RA have not been studied. Here we investigated the effects of B cells on OB differentiation and bone erosion using TNF transgenic (TNF-Tg) mice, a mouse model of RA. Immunofluorescent staining of knee joint sections from TNF-Tg mice showed B220+ B cell aggregates at sites of joint erosion and in the subchondral bone area, and some of these localized adjacent to osteocalcin+ OBs. We co-cultured bone marrow (BM)-derived CD19+ B cells from TNF-Tg or WT littermate control (Ctl) mice with WT bone-derived mesenchymal progenitor cells (MPCs) in OB-inducing medium and found that TNF-Tg B cell cultures had significantly decreased alkaline phosphatase+ (ALP+) areas and Runx2 expression (Runx2/actin: 0.3 ± 0.03 vs. 1.1 ± 0.14 in Ctl). RNA sequencing pathway analyses of CD19+ B cells from WT BM, TNF-Tg BM and synovium revealed that 225 pathways were dysregulated in TNF-Tg BM B cells vs. WT BM B cells and 377 pathways were dysregulated in TNF-Tg synovial B cells vs. TNF-Tg BM B cells. Among these, the expression of inflammatory cytokines (TNF, Oncostatin M and IL6) and chemokines (CCL3), known to inhibit MPC-OB differentiation were markedly elevated. qPCR confirmed increased TNF expression by TNF-Tg B cells (TNF/actin: 4.6 ± 1.2 in TNF-Tg synovium vs. 0.7 ± 0.4 in TNF-Tg BM and 0.3 ± 0.1 in WT BM). TNF neutralizing antibody blocked OB inhibition induced by TNF-Tg B cells (ALP+ area: 17.3 ± 2.9 vs. 9.3 ± 1.5 mm² in IgG). TNF-Tg mice given BCDT (murine anti-CD20) had decreased joint erosion (patellar bone volume: 0.7 ± 0.05 vs. 0.6 ± 0.01 mm³ in IgG, $p < 0.05$) and increased numbers of osteocalcin+ OBs (OB#/mm bone surface: 26 ± 4.6 vs. 16.4 ± 3.1 in IgG, $p < 0.05$). BM cells from BCDT-treated TNF-Tg mice had increased OB differentiation (CFU-ALP#: 53.2 ± 8.9 vs. 20.5 ± 5.2 in IgG). We conclude that B cells inhibit OB differentiation in RA by secreting TNF and perhaps other OB inhibitors and thus contribute to bone loss in affected patients. BCDT therefore should preserve bone mass in RA patients by inhibiting bone resorption and stimulating bone formation.

Essential Role of RANKL Expressed in Chondrocytes in Endochondral Ossification. Patrick Aghajanian*, Shaohong Cheng, Weirong Xing, Heather Watt, Catrina Alarcon, Sheila Pourteymoor, Subburaman Mohan. Jerry L. Pettis Memorial VA Medical Center, USA

The long bones of the skeleton are formed by endochondral ossification, a process in which bones are first formed as cartilage templates, which are replaced subsequently by bone. RANKL and OPG are known to be expressed in hypertrophic chondrocytes and have been predicted to be involved in regulating expression of proteases involved in the dissolution of cartilage. Since thyroid hormone (TH) is essential for normal skeletal growth and development, we evaluated if the RANKL/OPG axis is involved in TH regulation of endochondral ossification. A two day treatment of TH deficient Tshr-/- mice with T3/T4 increased the RANKL mRNA level by 390% ($P < 0.001$) and decreased OPG expression by 40% ($P < 0.01$) compared to vehicle treatment at day 7. Accordingly, treatment of serum-free cultures of metatarsal-derived cells from 3-day old mice treated with T3 increased RANKL expression by 2.5-fold but decreased OPG expression by 50% ($P < 0.01$). Furthermore, T3 treatment increased RANKL expression and decreased OPG expression in both primary chondrocytes and the established ATDC5 chondrocyte cell line. To evaluate the role of a TH-induced increase in RANKL action in chondrocytes in regulating endochondral ossification, we conditionally disrupted RANKL expression in chondrocytes of Col2-Cre-ERT2 mice carrying RANKL floxed alleles by administration of a single dose of tamoxifen (Tam, 100 μ g) at day 5 when TH levels start to increase. Trabecular (Tb.) BMD was reduced by 21% ($P < 0.05$, $n = 7$) in the tibial epiphysis of Tam treated Cre+ve RANKL floxed mice compared to the Cre-ve RANKL floxed control mice that was caused by reduced Tb. number and increased Tb. separation. We next determined the mechanism for the TH effect on RANKL expression. Since T3 increased osterix (SP7) expression in chondrocytes and since the RANKL promoter contains a perfect SP7 response element but not a TRE, we evaluated if the TH effect on RANKL expression in chondrocytes was mediated via osterix. We found that knockdown of osterix expression by lentiviral shRNA decreased osterix expression by 70% and RANKL expression by 60%. Furthermore, the T3-induced increase in RANKL expression failed to occur in the osterix knockdown ATDC5 cells. By contrast, overexpression of osterix increased RANKL expression by 3-fold ($P < 0.01$). Based on these data, we conclude that RANKL expressed in chondrocytes is critically involved in mediating the TH effects on endochondral bone formation and that the TH effect on RANKL expression is mediated via osterix.

Mutations preventing regulated exon skipping of a receptor tyrosine kinase cause a developmental disorder of osteogenesis. Peter Kannu*¹, Ben Alman², Stephen Robertson³, Carol Wise⁴, Haemish Crawford⁵, Lori Karol⁶, Mary Gray³, Rebekah Jobling², Linda Vi², Heather Whetstone², Raymond Poon², Angela Weng², Gino Sommers², Christian Marshall², Lucie Dupuis², Andrew Howard². ¹Hospital for Sick Children Toronto, Canada, ²Hospital for Sick Children, Canada, ³University of Otago, New Zealand, ⁴Texas Scottish Rite Hospital for Child, USA, ⁵Starship Children's Hospital, New Zealand, ⁶Texas Scottish Rite Hospital for Children, USA

Osteofibrous dysplasia (OFD) is a proliferative fibro-osseous condition affecting bone with an onset in early childhood. Typically, affected individuals develop tibial bowing and spontaneous non-healing fractures. Radiolucent lesions centered on the periosteal surface of the shafts of the tibia and fibula are visualized radiographically. We identified mutations in a gene encoding a receptor tyrosine kinase, in three families segregating an autosomal dominant form of OFD and in a fourth sporadic case. All mutations abolished the splice inclusion of an exon in transcripts resulting in receptors lacking a juxtamembrane cytoplasmic domain. Our mouse data indicate that

exclusion of this domain is a physiologically regulated event in the periosteum which is spatially partitioned during development. Forced induction of this exon skipping event in vitro retarded osteoblastic differentiation in vitro and inhibited matrix mineralisation. To further characterize the mutation effect, comprehensive immunohistological analysis on human samples was undertaken. Histology demonstrated alkaline phosphatase positive fibroblast-like cells in the stromal tissue, which may be due to an increased number of osteoblast progenitor cells. To confirm the mutation effect on osteoblast differentiation, proliferation and function, cells derived from affected patient bone samples obtained at surgery were cultured and differentiated in osteogenic media. Abnormal fibro-osseous bone cells from the tibial fracture site were compared to the cells obtained from unaffected proximal tibial bone. When cultured in osteogenic differentiation media, fracture site-derived osteoblasts displayed considerably higher levels of mineralization compared to the cells from the unaffected tibial bone. Moreover, the fracture site osteoblasts proliferated more rapidly compared to the control cells. To examine the effect of the receptor tyrosine kinase mutation on osteoclast differentiation and function in vitro, osteoclasts were differentiated from patient peripheral blood mononuclear cells and an age and gender matched control. Mutant osteoclasts showed decreased bone resorption. Together these data indicate that the production of this mutant receptor isoform is a developmentally regulated event during mammalian embryonic development and mutations which render this alternative splice event constitutional subvert core functions of this receptor that regulate osteogenic functions within the periosteum.

A Longitudinal, Prospective, Long-Term Registry of Patients with Hypophosphatasia. Lothar Seefried¹, Wolfgang Högler², Craig Langman³, Agnès Linglart⁴, Etienne Mornet⁵, Keiichi Ozono⁶, Cheryl Rockman-Greenberg⁷, Camille Bedrosian⁸, Kenji P Fujita⁸, Alex Cole⁸, Priya Kishnani⁹.
¹University of Würzburg, Germany, ²Birmingham Children's Hospital, United Kingdom, ³Northwestern University & Lurie Children's Hospital, USA, ⁴Paris-Sud University, APHP & INSERM U1169, France, ⁵Centre Hospitalier de Versailles, France, ⁶Osaka University, Graduate School of Medicine, Japan, ⁷University of Manitoba, Canada, ⁸Alexion Pharmaceuticals, USA, ⁹Duke University Medical Center, USA

Hypophosphatasia (HPP) is a rare, inherited metabolic disease characterized by bone mineralization defects and osteomalacia, as well as systemic manifestations including seizures, respiratory insufficiency, muscle weakness, nephrocalcinosis, and pain. The biochemical hallmark of HPP is low serum alkaline phosphatase activity, resulting from loss-of-function mutations in the gene encoding tissue non-specific alkaline phosphatase. HPP presents a broad spectrum of disease severity classically defined by age at onset of symptoms (perinatal/infantile, juvenile, adult, odontohypophosphatasia [isolated dental symptoms only], and "benign" prenatal), with recognized overlap between, and range of severity within, these forms. The rarity of HPP combined with its variable expressivity presents considerable challenges in the diagnosis and understanding of the disease. Here we describe the design of an HPP Registry, which will enable better characterization and understanding of the epidemiology and clinical course of HPP through collection of demographic and longitudinal clinical data.

This multinational, observational, prospective, long-term registry will enroll ≥ 500 patients. Patients of any age with HPP will be included, except for those participating in Alexion-sponsored clinical trials. Sites will conduct the study in accordance with local regulations. Available patient data will be collected retrospectively via chart review at baseline and thereafter at intervals ≤ 6 months in the course of routine clinical care. Performance of new clinical procedures is not required. Data collected will include patient demographics; method of diagnosis; HPP disease history including dates of onset and diagnosis; family history; clinical manifestations; and genotype. Data from medical and laboratory assessments specific to HPP will be recorded. Standardized questionnaire instruments will be used to quantify patient-reported burden of disease, functional status/disability, and quality of life.

The HPP Registry will provide a detailed longitudinal profile of patients with HPP including demographics, diagnosis patterns, genotype-phenotype correlations, country-specific findings, and impact of HPP on activities of daily living and quality of life.

A novel frameshift mutation c.1362_1399del38 (p.Gly456Alafs330) in exon 12 of the ALPL gene in two siblings and their previously undiagnosed mother with hypophosphatasia: a case report. Cedric Ng^{*}, Pisit Pitukcheewanont. Children's Hospital, Los Angeles, USA

Background: Hypophosphatasia (HPP) is a rare disorder characterized by low serum alkaline phosphatase (alk phos) and elevated pyridoxal-5'-phosphate (PLP) levels causing defective mineralization of the bone. There are at least 285 reported mutations in the ALPL (alkaline phosphatase, liver/bone/kidney) gene. **Clinical Case:** A: is the 4 year old Japanese-Caucasian male with premature loss of his primary teeth, a low serum alk phos of 99 U/L, an elevated PLP level >100 ug/L, no history of skeletal demineralization, fractures, or bone pain. A diagnosis of HPP was made. B: is the fetal sibling of A aborted at 23 weeks gestation and had clinical signs of HPP, with severe skeletal abnormalities on fetal ultrasound. Both siblings have compound heterozygous mutations of the ALPL gene and share a missense mutation in exon 5 (c.407G>A amino acid change with p.R136H or R119H genotype) from their father previously reported in the literature as pathogenic in a 3 year old compound heterozygote with bone affected HPP. They also share a previously unreported heterozygous frameshift mutation in exon 12 of the ALPL gene (c.1362_1399 del38) from their mother resulting in a premature stop codon, p.Gly456Alafs330. The father has no clinical or biochemical evidence of HPP, a normal serum alk phos of 41 U/L and a normal serum PLP level (46.6 ug/L). He is heterozygous for the missense mutation in exon 5 of the ALPL gene and given that he is unaffected, this suggests that the mutation he shares with his children is non-pathogenic. The mother has both clinical and biochemical evidence of HPP, a low serum alk phos level of 29 U/L, an elevated serum PLP level (>100 ug/L), and is heterozygous for a frameshift mutation in exon 12 of the ALPL gene. Because the two siblings and their mother all have characteristics of HPP, this suggests that the frameshift mutation they share is pathogenic. **Conclusion:** We report a novel frameshift mutation in exon 12 of the ALPL gene (c.1362_1399 del38 - p.Gly456Alafs330) in two siblings and their previously undiagnosed mother with HPP. This result suggests an autosomal dominant inheritance pattern. Genetic testing and counseling should be considered for additional siblings in the future.

Hypophosphatasia: Natural History Study Of 101 Children From Inpatient Investigations Over 25 Years At A Single Research Center. Michael P Whyte¹, Deborah Wenkert¹, William H McAlister², Karen E Mack¹, Fan Zhang¹. ¹Center for Metabolic Bone Disease & Molecular Research Shriners Hospitals for Children - St Louis, USA, ²Department of Pediatric Radiology, Mallinckrodt Institute of Radiology at St. Louis Children's Hospital, Washington University School of Medicine, USA

Hypophosphatasia (HPP) is the inborn-error-of-metabolism that features deficient activity of the "tissue-nonspecific" isoenzyme of alkaline phosphatase (TNSALP). Clinical hallmarks are tooth loss and rickets or osteomalacia caused by extracellular accumulation of inorganic pyrophosphate, an inhibitor of mineralization. Dominant versus recessive transmission of nearly 300 typically missense mutations in the TNSALP gene underlies the disorder's remarkably broad-ranging expressivity. In 2015, cross-sectional data from our inpatient investigations, spanning 25 years, of 173 affected children validated and expanded the nosology for HPP in pediatric patients (Bone 75:229-39).

Here, we investigated longitudinally the natural history of HPP in children by assessing several key parameters in this cohort: z-scores for height, weight, grip-strength, and spine and hip DXA BMD. Weight and BMD z-scores were further analyzed after adjusting for stature using the equations we published in 2012 to calculate "height-age" for the preteenage patients (JCD 15:267-74).

At least one study readmission (407 total) had occurred for 101 patients (Table). They had been classified by increasing HPP severity, determined by age at presentation. There were 28 odonto HPP, 28 mild childhood HPP, 37 severe childhood HPP, and 8 survivors of infantile HPP with mean follow-up (first-last admissions) of 5.9, 6.1, 7.0, and 8.2 years, respectively. Eighteen patients had been studied "across" puberty. Cohort and group mean height z-scores, that reflected the HPP nosology, did not change with patient aging (including across puberty) ($ps > 0.1$). Mean weight z-scores for chronologic-age and after height-adjustment increased for the pre-teenage patients in all four groups, in keeping with pediatric trends for healthy children. After stature adjustment, mean weight z-scores were in the normal range for all patient groups. Mean grip-strength z-scores were not changed by aging. Spine and hip BMD z-scores calculated routinely for chronologic age did not change with patient aging, whereas the height-corrected BMD z-scores for the pre-teenage patients showed improvements in the spine, but not hip.

We found that mean z-scores for height, grip-strength, and hip BMD remained stable, whereas mean weight and spine BMD z-scores increased, in children with HPP. Our observations should aid prognostication and help assess treatment for children with HPP.

Pseudohypophosphatasia: Mutation Identification And 46-Year Follow-Up Of The Original Patient. Katherine L. Madson^{*1}, Sabrina S Gill², Steven Mumm³, Michael P. Whyte¹. ¹Center for Metabolic Bone Disease & Molecular Research, Shriners Hospitals for Children - St Louis, USA, ²Division of Endocrinology, University of British Columbia, Canada, ³Division of Bone & Mineral Diseases, Washington University School of Medicine, USA

We present a 46-year follow-up of the patient with pseudohypophosphatasia (pseudoHPP) reported by Scriver and Cameron in 1969 (NEJM 281: 604-06). She presented at 3 mos-of-age with hypotonia, broadened cranial sutures, metaphyseal changes, and elevated urinary phosphoethanolamine (PEA), all consistent with HPP. However, her serum alkaline phosphatase (ALP) activity was not low, but normal; hence, "pseudoHPP". Hypercalcemia persisted for the first 4 months-of-life, but then remitted. Rickets was reported to have nearly resolved by four years-of-age. Subsequently, most serum phosphorus levels were slightly elevated consistent with HPP. PEA was still elevated at age 18 and 19 years. As a young adult, iliac crest biopsy showed osteomalacia and normal osteoblast ALP staining. In 1986, Cole et al documented that her urinary inorganic pyrophosphate and plasma pyridoxal 5'-phosphate levels, both ALP substrates, were elevated (NEJM 314: 992-3). Serum creatinine and estimated GFR have been normal despite medically-controlled hypertension and unilateral renal calcification since age 27 yrs. Meneire's disease developed in 2005. Her low-trauma long bone fractures heal slowly, or become non-unions. The right humerus and all lower extremity long bones are rodged. Spinal stenosis, with seemingly paradoxical calcification of dura throughout the lumbar spine, has developed. Pelvic "non-union" fractures cause pain, and one extends through the left sacral ala causing L5 weakness and foot drop. She reports that teriparatide therapy from 2009-2011 was ineffective for healing fractures. This disabled former clinical dietician has been wheelchair bound since 2013. At age 51 years, her height is 141 cm (Z=-3.4) and weight 42 kg (Z=-2.4).

Serum ALP activity remains normal for age, varying from 67-102 U/L at ages 19-50 years using different laboratory assays.

In 2008, we found she carried a common American *TNSALP* mutation (c.1250A>G). Further analysis showed an additional and unique mutation (c.1355 A>G), not reported in two databases. She also has an intron polymorphism, a SNP, and a homologous alanine substitution.

Apparently, this novel combination of *TNSALP* changes in relatively close proximity within the homodimer creates an enzyme with normal in-vitro catalytic activity, under the artificial conditions of the laboratory assay, yet poor enzymatic activity in-vivo toward natural substrates resulting in a distinct and life-long form of HPP.

Accumulation of osteopontin in the absence of PHEX decreases *NaPT2A* expression. Nilana Barros^{*1}, Gabrielly Chiarantin², Raquel Neves², Adriana K Carmona², Marc McKee³. ¹Federal University of Sao Paulo, Brazil, ²UNIFESP, Brazil, ³McGill University, Canada

X-linked hypophosphatemia (XLH/HYP) is the most prevalent form of inherited rickets in humans, characterized by hypophosphatemia related to defective renal phosphate reabsorption associated with growth retardation, osteomalacia and dental abscesses. XLH occurs as consequence of inactivating mutations in the *PHEX* gene (phosphate-regulating gene with homologies to endopeptidases on the X chromosome). In vivo mouse studies have shown that the absence of *PHEX* leads to the release of a circulating factor(s) that decreases mineralization and inhibits sodium/phosphate co-transporter *NaPT2A*, which mediates reabsorption of phosphate in the kidneys. Recently we demonstrated that the mineral-binding bone extracellular matrix protein osteopontin (OPN) is a physiologically relevant substrate for *PHEX*, whose inactivation by *PHEX* normally promotes bone mineralization. In the present study,

we have extended these observations to show that OPN and a derived OPN fragment (ASARM peptide; acidic serine- and aspartate-rich motif) modulate *NaPT2A* expression.

Using a constructed *PHEX*-deficient human osteoblast cell line (MG-63 osteoblasts treated with shRNAi-*PHEX*) we show that, in the absence of *PHEX*, OPN accumulates and decreases *NaPT2A* mRNA and protein expression when conditioned media or extract were applied to human kidney (HK-2) proximal tubule epithelial cell cultures. In addition, we postulated that the absence of *PHEX* could influence FGF-23 expression via the indirect effect of OPN accumulation. We demonstrate that although FGF-23 is not inactivated by *PHEX*, OPN and FGF-23 are both increased in the shRNAi-*PHEX* osteoblasts, as similarly observed in the murine model of XLH, the Hyp mouse. In conclusion, these results provide new insight into circulating humoral factors that might influence phosphate handling in the kidney whose alterations contribute to the osteomalacic XLH phenotype, and they suggest that OPN and its fragments may be involved in this process and influence FGF-23 expression. Supported by FAPESP and CNPq.

Osteogenesis Imperfecta in Sweden - Genetic Epidemiology, Prevalence and Genotype-phenotype Correlations. Katarina Lindahl^{*1}, Eva Åström², Carl-Johan Rubin³, Giedre Grigelioniene⁴, Barbro Malmgren⁵, Östen Ljunggren⁶, Andreas Kindmark⁶. ¹Dept. of Medical Sciences, Uppsala University, Sweden, ²Department of Women's & Children's Health Karolinska Institutet & Neuropediatric Unit Astrid Lindgren's Children's Hospital at Karolinska University Hospital Stockholm Sweden, Sweden, ³Department of Medical Biochemistry & Microbiology, Uppsala University, Sweden, ⁴Department of Molecular Medicine & Surgery, Karolinska Institutet, Stockholm, Sweden, Sweden, ⁵Department of Clinical Science, Intervention & Technology, Division of Paediatrics, Karolinska University Hospital, Huddinge, Sweden & Department of Dental Medicine, Division of Pediatric Dentistry, Karolinska Institutet, Huddinge, Sweden, Sweden, ⁶Department of Medical Sciences, Uppsala University, Sweden

Background: Osteogenesis imperfecta (OI) is a rare connective tissue disorder leading to bone fragility, spanning from mild to intrauterine lethality in severity. Collagen I mutations are causative in 90%, and recently several non-collagen genes have been reported to account for the remaining 10%. There are no population-based studies determining the genetic epidemiology of OI, and no extensive genotype-phenotype studies on >100 families outside of North America.

Subjects and methods: Here, detailed clinical phenotypes were recorded, and the *COL1A1* and *COL1A2* genes were Sanger-sequenced in 164 Swedish OI-families (223 individuals). Collagen I negative families were also analyzed by MLPA-technique. Averages for bone mineral density (BMD Z-score), height (Z-score) and yearly fracture rate were calculated and related to OI- and mutation type. Furthermore, gender and age correlations were studied. Population and diagnosis data were retrieved from official Swedish national databases.

Results: Individuals were classified according to Sillence: type I n=151 (101 families), type II n=1, type III n=29 (26 families), and type IV n=42 (37 families). A typical OI-causing collagen I mutation was found in 132 families (75 qualitative and 57 quantitative). Noteworthy mutations included: five mutations located in the *COL1A1* C-propeptide, four mutations located in lethal clusters of *COL1A2* described by Marini et. al., two mutations causing OI-EDS, and one *COL1A1* C-terminal cleavage site mutation causing a high bone mass phenotype.

C-terminal helical mutations in both the $\alpha 1$ - and $\alpha 2$ -chains were associated with dentinogenesis imperfecta (DI) (p<0.0001 vs. 0.0049), while only N-terminal $\alpha 1$ -chain mutations were associated with blue sclera (p=0.0110). DI was strongly associated with classical dominant OI, as none of the 32 collagen I mutation negative families had this phenotype clinically (p<0.0001). When comparing individuals with OI types III and IV, blue sclera was associated with collagen I mutations (p=0.0094). Comparing the most frequent amino-acid substitution glycine to serine, $\alpha 2$ -alterations were associated with a milder phenotype (p=0.0031); these individuals were taller, had a higher BMD, fewer fractures, and a lower frequency of intramedullary rodding. Patients with OI type I caused by qualitative vs. quantitative mutations were shorter (p<0.0001), but did not differ considering fracture rate or BMD. Males with OI type I had a lower BMD (p=0.0482), but were taller (p=0.0265), and had a lower frequency of DI (p=0.0258).

The children in this cohort were estimated to represent >95% of the entire Swedish pediatric OI-population. The prevalence of OI type I, III and IV was 5.16, 0.89 and 1.35/100 000 respectively (7.40/100 000 overall), which extrapolated corresponds to approximately 9.50/100 000 affected pregnancies. This corresponds to what has been estimated, but not unequivocally proven in any population. Collagen I sequencing was performed in the family of 97% of known pediatric cases, with causative mutations found in 87%. OI type I was caused by qualitative mutations in 32% out of which 91% were glycine substitutions.

Conclusion: Here, the genetic epidemiology in >95% of an entire OI-population is described for the first time, and data presented may be helpful in genotype-phenotype predictions. The prevalence of OI types I, III and IV in Swedish children was 7.40/100 000.

Raloxifene reduces skeletal fractures in homozygous OIM male mice. Alycia Berman^{*1}, Drew Brown², Zachary Bart³, Erin McNerny³, Jason Organ², Chris Newman², Matthew Allen², Joseph Wallace³. ¹Indiana University - Purdue University Indianapolis, USA, ²Indiana University School of Medicine, USA, ³Indiana University Purdue University Indianapolis, USA

Osteogenesis imperfecta (OI) is a genetic disease of Type I collagen that results in brittle bone behavior that is characterized by reduced toughness. Based on previous work in our laboratory showing that raloxifene can significantly improve bone toughness through non-cellular mechanisms, we hypothesized that raloxifene would improve the mechanical properties of OI bone. In experiment 1, eight-week old WT and homozygous OIM male mice were treated for eight weeks with subcutaneous saline vehicle (VEH) or raloxifene (RAL) injections. Endpoint measures included DXA, microcomputed tomography (uCT), and fracture toughness. In vivo skeletal fractures, assessed by projection CT images of the right and left femora (fig. 1), were significantly reduced ($p = 0.014$) in OI-RAL (17%) compared to OI-VEH (46%). There were no fractures in either WT treatment group. RAL significantly increased both DXA-based BMD ($p < 0.01$) and CT-based trabecular BV/TV in WT (+10% and +11%) and OI (+13% and +43%). Fracture toughness, assessed at crack initiation, maximum load, and crack instability, was lower in OI mice compared to WT (43%, 49%, and 46%, respectively), and tended to be higher in both genotypes in response to RAL treatment. In experiment 2, tibiae from a different cohort of wild type (WT) and homozygous OIM mice were soaked in raloxifene (RAL, 2uM) for 14 days at which time mechanical properties were assessed by 4 point bending and compared to non-soaked bones. RAL significantly increased post-yield displacement (75% in WT, 472% in OI; $p < 0.004$ for both) and post-yield work (79% in WT, 451% in OI; $p < 0.002$ for both), with no effect on ultimate load or stiffness, in both WT and OIM animals. The results of these studies show that raloxifene reduces the incidence of fracture in this mouse model of OI. Furthermore, they show that raloxifene's effects are likely the result of both cellular (increased bone mass) and non-cellular (presumably changes in hydration) mechanisms, raising the possibility of new approaches to treating bone fragility associated with OI.

The Effectiveness of Bisphosphonate Treatment in Osteogenesis Imperfecta on Bone Biomarkers and Fracture Rates. Jay Shapiro^{*1}, Evelise Brizola², Adutu Kantipuly³. ¹Kennedy Krieger Institute, Johns Hopkins, USA, ²Kennedy Krieger Institute, USA, ³Johns Hopkins School of Public Health, USA

Problem Statement: Bisphosphonate (BP) therapy for Osteogenesis Imperfecta (OI) is accepted as the "standard" for both children and adults. However, questions exist regarding the long term effectiveness of BP in decreasing fractures. **Method and Results:** We have assessed the effect of BP treatment on bone biomarkers and fracture

rates in children and adults with OI. This includes 19 children, ages birth to 18 years, treated with IV pamidronate. They are divided into two groups: treatment responders with < 2 fractures/year during treatment (n=5) and non-responders with > 2 fractures/year during treatment (n=14). Only type I patients were found in the responder group. The non-responder group included Types I, III, IV. No significant difference was found between groups for mean values of vitamin D, serum total alkaline phosphatase, C-telopeptides, or osteocalcin. However, there was a difference between the responder and non-responders in mean duration of treatment ($p = .02$): responder 42.6 ± 8.1 months, vs. non-responder 72.7 ± 10.97 months. 34 adult patients who received a minimum of 3 years of BP treatment experienced 41 fractures 10 years prior to treatment and 57 fractures in the 10 years following treatment ($p > 0.05$). Treatment responses for metabolic and bone related biomarkers did not show a significant difference over a 5 year period of observation between 34 adults treated with BP and 12 non-treated controls. **Discussion:** Two meta-analyses (Dwan, 2014, Hald, 2014) conclude that BPs effect on decreasing fracture incidence is "unclear" or "inconclusive". Meta-analysis by Shi (2015) concluded that BP decrease fracture rate in children but not in adults as previously reported. Bishop et al. reported risdrionate to decrease fracture rate in children after one year of treatment but that incidence rose to non-treatment rates during a 2-3 year extended treatment period. Rauch et al. (2006) observed marked histologic effects of BP treatment on bone tissue in the first 2-4 years of pamidronate treatment but no significant effect afterwards. **Conclusion:** Conflicting data exists on the effectiveness of oral and IV BP in OI. Certain children and adults do not decrease fracture incidence in response to BP. Response of bone biomarkers does not differentiate responders from non-responders in children or adults. Current evidence questions whether prolonged treatment with IV BP is associated with a sustained decrease in fracture rate.

An overview of the etiology, clinical manifestations, management strategies and complications of hypoparathyroidism. Tayyab Khan^{*1}, Hamid Syed², Aliya Khan². ¹Department of Medicine, Western University, Canada, ²McMaster University, Canada

Hypoparathyroidism is an uncommon endocrine disease characterized by absent or inappropriately low levels of Parathyroid hormone (PTH), with low serum calcium and elevated phosphate levels, and presents unique therapeutic challenges. While evidence gathered over the last decade has led to an increased understanding of this condition, data regarding disease manifestations in the Canadian population are lacking.

We established a Canadian registry of patients with hypoparathyroidism and reviewed baseline data with respect to etiology, presenting symptoms, current treatment and complications of this condition. The study was approved by the Research Ethics Board at McMaster University and all patients provided informed consent.

Most patients (47/65; 72.3%) had postsurgical hypoparathyroidism, followed by idiopathic/autoimmune disease (12/65; 18.5%), pseudohypoparathyroidism (4/65; 6.1%) and congenital hypoparathyroidism (2/65; 3.1%). The mean age of onset was 46 years (Range: 10 years – 75 years). Paresthesias in the upper and lower extremities were the most common presenting symptom and experienced by approximately 50% of patients. Approximately 16% of patients reported tetany and 14% had seizures. 42% of patients required hospitalization at the time of presentation. Current treatment options were reviewed and almost all patients were receiving calcium supplements (90.1%) with calcitriol being used by 92.3%; 22 patients (33.8%) were on hydrochlorothiazide and 4 patients (6.1%) were receiving parathyroid hormone. Complications were reviewed and 10 patients had brain imaging completed with 8 having evidence of basal ganglia calcification. 11 of 28 (39.3%) patients who received an abdominal ultrasound showed evidence of nephrolithiasis or nephrocalcinosis. Renal impairment was present in 68.4% who had chronic kidney disease Stage II or higher, over an average disease duration of 10 years. Based on bone densitometry by dual energy xray absorptiometry in the men and women over the age of 50 years evaluating BMD at either the lumbar spine, femoral neck, total hip or one third radial site 25% of the patients had low bone density while another 25% had osteoporosis. Amongst these patients 8% had experienced fragility fractures. Our findings provide interesting insights into the etiology, symptomatology, treatment strategies and complications of hypoparathyroidism in a Canadian population. Skeletal health does require further evaluation and assessment of bone strength would be of value in this patient population.

Appendicular Lean Mass and Anxiety Disorders: A Potential Regulatory Role for Skeletal Muscle on Brain Function. Julie Pasco^{*1}, Mark Kotowicz², Sharon Brennan-Olsen¹, Kara Holloway¹, Felice Jacka¹, Michael Berk¹, Shae Quirk¹, Amanda Stuart¹, Lana Williams¹. ¹Deakin University, Australia, ²Deakin University & Barwon Health, Australia

Purpose: Skeletal muscle contraction produces neurotrophic factors that have a critical role in the pathophysiology of common mental disorders. Furthermore, skeletal muscle activity modulates immune function and redox status that impact neurological pathways. We aimed to examine the relationship between appendicular lean mass (ALM, lean mass of arms and legs combined) and the likelihood for incident anxiety disorders.

Methods: This nested case-control study utilises data from the 10-year and 15-year follow-up phases of the Geelong Osteoporosis Study (GOS). Cases were women with incident anxiety disorders, identified using the Structured Clinical Interview for DSM-IV-TR (SCID-I/NP). Controls were women who had no history of anxiety and remained anxiety-free during the five-year period of follow-up. The exposure of interest was ALM (expressed in SD units), measured by dual energy x-ray absorptiometry at the 10-year follow-up, together with socioeconomic status and health behaviours. Clinical and psychiatric data were available for 745 participants. Those with prostheses (n=26) or pre-existing anxiety at 10-year follow-up (n=100) were excluded; thus, 619 women (age 21-84 years) were included in the analysis.

Results: There were 71 cases. Cases were younger than controls (median age (IQR): 40 (27-55) vs 50 (37-64) years, $p<0.001$) and were more likely to be sedentary (24% vs 13%, $p=0.02$), otherwise no other differences were detected between the groups. Mean ALM (SD) for cases was 7.05 compared with 7.17 for controls and this difference was not significant. However, after adjusting for age, greater ALM was protective against anxiety (OR 0.75, 95%CI 0.57-0.99, $p=0.04$). This relationship was attenuated by accounting for physical inactivity (adjusted OR 0.77, 95%CI 0.58-1.01, $p=0.06$) but remained unaffected by further adjustment for height, smoking, alcohol use and socioeconomic status. No effect modifiers were identified.

Conclusions: These data suggest that lower ALM may increase the risk of subsequent anxiety disorders in women and that the relationship is explained, at least in part, by a sedentary lifestyle. This finding warrants further investigation into muscle wasting as a risk factor for the common mental disorders.

Body compositions differently affect bone mineral density in men and women throughout the lifespan : the Korean National Health and Nutrition Examination Survey (KNHANES) 2008-2011. Yoo Mee Kim^{*}, Se Hwa Kim, Jung Sun Yoo, Eun Yeong Choe, Young Jun Won. Department of Internal Medicine, Catholic Kwandong University College of Medicine, International St. Mary's Hospital, South Korea

Body mass index (BMI) is an important bone modulating factor in postmenopausal women. BMI is the best way of determining obesity, however, it has limits discriminating lean mass and fat mass. As aging proceeds, BMI changes little but muscle mass decreases and fat mass increases. Thus, BMI alone is not enough to evaluate body composition. Moreover, it is uncertain which component of body compositions mostly affects bone mineral density (BMD) in men and women throughout the lifespan. We therefore evaluated the relationship between body composition and BMD from age 10 to 97 years (y) old. This population-based, cross-sectional study is from the Korea National Health and Nutrition Examination Surveys (KNHANES) 2008-2011. The subjects who performed both body composition analysis and BMD by dual energy X-ray absorptiometry were enrolled. The total number of subjects were 20,704. The mean age was 45.3 ± 19.0 y (M, n=9,077, 10-93 y) and 46.7 ± 18.5 y (F, n=11,627, 10-97 y). The subjects were divided into 2 age groups by 50 y. Anthropometric data, lean mass (LM), appendicular skeletal muscle mass (ASM), fat mass (FM), fat percentage (FP), lumbar spine (LS) BMD, and total hip (TH) BMD were compared between 2 age groups by gender. Blood pressure, smoking, alcohol, and exercise history were compared as well. All body compositions were evaluated for correlations with LS or TH BMD. LM or ASM, and FM or FP were included in multivariate analysis for LS or TH BMD controlling for age and height in

each age group by gender. BMI and waist were higher in older men and women than younger subjects. Lower LM, ASM, and FM but similar FP were observed in older men. In older women, LM and ASM were lower, while FM and FP were higher than younger women. Anthropometric data or body composition parameters significantly correlated with both LS and TH BMD in all age groups of both gender. After adjusting for age and height, LM and ASM strongly affected LS and TH BMD in both age groups of men and women. FM and FP significantly affected LS and TH BMD in both young and old women and also in old men, but it negatively affected LS and TH BMD only in young men group. In conclusion, considering different contribution of age, height, and gender to BMD, LM and ASM are important positive independent predictors of LS and TH BMD in both men and women across the lifespan. However, FM and FP negatively affect BMD in young men but they positively affect BMD of old men and also women throughout the lifespan.

Characteristics of Regional Bone Mineral Density and Soft Tissue Composition in Japanese Elderly Women with Sarcopenia. Shinjiro Takata^{*}. Tokushima National Hospital, National Hospital Organization, Japan

The term sarcopenia was proposed by Irwin Rosenberg to describe an age-related decrease of muscle mass (Am J Clin Nutr 1989; 59:1231-3). The European Working Group on Sarcopenia in Older People (EWGSOP) recommends using the presence of both low muscle mass and low muscle function (strength or performance) to make a diagnosis of sarcopenia (Age and Ageing 2010; 39:412-423). The purpose of this study was to clarify the characteristics of regional bone mineral density (BMD) and soft tissue composition in Japanese elderly women with sarcopenia.

One hundred and thirty-three Japanese elderly women aged 65 years or more were divided into two groups, sarcopenia group (n=54) and control group (n=79). No significant differences were found between these two groups with regard to age, body height, body weight, and body mass index. The mean BMD of the second to fourth lumbar vertebrae (L2-4BMD), total body BMD, and soft tissue composition were measured by DXA using Hologic Discovery W (Waltham, MA, USA). Regional BMD (g/cm^2) was measured in the head, arms, legs, ribs, thoracic vertebrae, lumbar vertebrae, and pelvis. Lean mass (g) and fat mass (g) of the head, arms, legs, and trunk were measured. Skeletal mass index (SMI) is the appendicular skeletal mass in kilograms measured by dual energy X-ray absorptiometry divided by the square of the height in meters (kg/m^2). SMI of the sarcopenia group was less than 5.4 (kg/m^2).

The BMDs of the arms, legs, and femoral neck as well as the L2-4BMD of the sarcopenia group were significantly lower than those of the control group ($p<0.05$). The lean masses of the arms, trunk, and legs of the sarcopenia group were significantly lower than those of the control group ($p<0.05$), whereas the fat masses of the arms and legs of the sarcopenia group were significantly greater than those of the control group ($p<0.05$).

The major findings of this study were that the BMDs and skeletal muscle masses of the arms and legs were significantly lower than those of the control group, whereas the fat masses of the arms and legs of the sarcopenia group were significantly greater than those of the control group. These results show that sarcopenia in Japanese women aged 65 years or more is associated with osteopenia or osteoporosis in addition to low muscle function.

Physical exercise may prevent sarcopenia in elderly women. Samu Sjölöblom^{*}, Juha Suuronen, Toni Rikkinen, Risto Honkanen, Heikki Kröger, Joonas Sirola. University of Eastern Finland, Finland

Purpose: The aim of the study was to examine the relationship between physical exercise and sarcopenia and the components of sarcopenia in Finnish postmenopausal women. This is a cross-sectional study.

Material and Methods Study sample: a population-based cohort of 591 Finnish postmenopausal women (mean age 67.9; range 65-72) from the Osteoporosis Fracture Prevention (OSTPRE-FPS) study. Outcome measures: Relative skeletal muscle index (RSMI) and fat percent were measured by dual X-ray absorptiometry (DXA). Moreover, grip strength, quadriceps strength and 10 m walking test were measured. The study sample was divided into sarcopenic and non-sarcopenic groups according to quartiles of relative skeletal muscle mass index (RSMI) (appendicular muscle mass ($\text{kg}/\text{height}(\text{m})^2$), hand grip strength (kPa) and walking speed. The amount of physical exercise was asked by exercise diary. The number of women who walked was 489, skied 191, cycled 268, did gym 178 and swam 267. The analyses were adjusted for: strenuousness of exercise, age, height, weight, the level of serum vitamin D and hormone therapy (HT), consumption of alcohol and smoking.

Results: The logistic regression analysis revealed that the amount of cycling was negatively associated with sarcopenia in non-adjusted model ($p=0.007$, OR=0.807, Confidence interval 0.692-0.942) and in adjusted model ($p=0.035$, OR=0.817, CI=0.677-0.986). Moreover, the amount of swimming had a negative association with

sarcopenia in non-adjusted model ($p=0.018$ OR=0.841, CI 0.729-0.971) but not in adjusted model ($p=0.071$). In linear regression cycling was positively associated with RSMI in non-adjusted model ($p=0.002$) and in adjusted model ($p=0.001$). Moreover, walking had a positive association with grip strength in non-adjusted model ($p=0.006$) and in adjusted model ($p=0.008$). Cycling was positively associated with quadriceps strength in non-adjusted model ($p=0.023$) but not in adjusted model. The amount of walking and skiing was positively associated with walking speed in non-adjusted model ($p=0.036$ and 0.049 , respectively) but not in adjusted model. Finally, cycling and skiing was negatively associated with fat percent ($p=0.028$ and $p=0.001$, respectively) and in adjusted model the p -values were 0.033 and 0.277.

Conclusion Physical exercise may prevent sarcopenia and decrease fat mass. Cycling might be the most suitable form of exercise in elderly women to prevent sarcopenia.

Vitamin D Status and Muscle Strength among Ethnic Minorities Residing in Northeast Scotland. Nor Aini Jamil¹, Stuart Gray², William Fraser³, Helen Macdonald^{*2}. ¹University of Aberdeen & Universiti Kebangsaan Malaysia, United Kingdom, ²University of Aberdeen, United Kingdom, ³University of East Anglia, United Kingdom

Vitamin D may play a role in muscle strength, yet little is known about how this is affected by emigrating from low to high latitudes. The aims of this longitudinal study were (1) to examine vitamin D status and muscle strength changes among ethnic minorities from sunnier climates after arriving in Northeast Scotland (Aberdeen, 57°N) and (2) to investigate the relationship between vitamin D status on muscle strength. A total of 66 healthy adults (73% Asians (96% Southeast Asians), 15% Africans and 12% Middle Easterners) aged 19-41 years took part with 58% seen within 3 months of arriving in Scotland. Participants attended visits every 3 months for fifteen months. At each visit, fasted blood samples were collected for analysis of serum total 25-hydroxyvitamin D (25(OH)D) by dual tandem-mass spectrometry. Maximal voluntary contraction (MVC) was measured using a Takei digital grip dynamometer (both arms) and a Biodex dynamometer (right knee extension). Skin type (I-VI) was determined using a CM-2600d spectrophotometer (inner arm). Dietary vitamin D intake and sunlight exposure were assessed by questionnaires. Mean(SD) baseline 25(OH)D was lower in Middle Easterners (16.9(6.8)) nmol/L, $p=0.010$ compared to Asians (31.1(13.1)) nmol/L and Africans (32.4(10.9)) nmol/L. Mixed model analysis showed that ethnicity, longer duration in Scotland, increasing age and lighter skin colour were associated with lower 25(OH)D concentrations. Recent holiday, greater body surface exposure area and total dietary vitamin D intake (including supplements) were significant positive predictors of 25(OH)D. There was no association between vitamin D status and grip strength ($p=0.23$), although grip strength increased over time possibly due to improved technique. For knee strength, there was a trend for a positive association between 25(OH)D and knee isometric strength. The model predicted that for each 1 nmol/L increase in 25(OH)D, peak torque increased by 1 Nm ($p=0.06$). Whilst vitamin D status was associated with lower limb muscle strength among ethnic minorities residing in northeast Scotland, the study design does not prove causality.

Fracture Repair and Effects of Aging on Macrophages at the Fracture Callus. Mary Nakamura^{*1}, Erene Niemi², Yang Frank³, Ted Mclau³, Ralph Marcucio³. ¹University of California, San Francisco/San Francisco VA Medical Center, USA, ²UCSF/SFVAMC, USA, ³Orthopaedic Trauma Institute, SFGH, UCSF, USA

Delayed healing and non-union during fracture healing is common in the elderly. We propose that age-related changes in myeloid cells promote dysfunctional bone regeneration during fracture repair. We isolated fracture callus cells from aged or young animals for flow cytometric and gene expression analysis. Aged (24 months) or young (10-12 weeks) mice undergo closed non-stable tibial fracture. At indicated time points a defined area around the fracture callus is removed, skin/muscle eliminated and bone marrow discarded. The remainder of the fracture callus is minced and digested with collagenase. Isolated cells are washed, and stained for flow cytometry. Samples from aged and young animals are analyzed simultaneously, 5 animals/group/time point. Days 1, 3, 5, 7 and 10 were examined using multicolor analysis to examine F4/80 positive cells (macrophages) using lineage markers to gate out T cells, B cells, NK cells, and granulocytes. Tissue macrophages are identified as Lin^{neg}, CD11b⁺, F4/80^{hi}, Ly-6C^{lo/hi} and stained for additional markers. Live hematopoietic cell gates use CD45 and sytox blue (or dead red) staining.

Day 1 cellular analysis demonstrates similar distribution of immune cells in the aged and young fracture callus including T cells, B cells, NK cells, macrophages and granulocytes. Initial macrophages in aged and young fracture callus were phenotypically similar. F480/CD11b⁺ cells are predominantly Ly6C⁺ and MHC Class II negative. Macrophage number increases about 4-8 fold at Day 3 in the aged and young fracture callus. By Day 3, numerical and phenotypic differences between the aged and young macrophages in the fracture callus emerge. In the young fracture callus, 2 fold more F480⁺ cells particularly Ly6C⁺/MHC Class II⁻ cells are found in the young compared with aged callus, with other cells in both the aged or young, Ly6C⁺ MHC Class II⁺. At Day 7, total macrophage number decreases in both the aged and young fracture callus. At Day 10, macrophage number again rises with a marked change in Ly6C⁺ and MHC Class II⁺ cells number, with a greater increase in the young compared with the aged fracture callus. RNAseq analysis of Isolated fracture callus macrophages comparing cells from aged and young fracture calluses is in progress. Our data suggests that decreased recruitment and/or proliferation of inflammatory macrophages in addition to changes in macrophage phenotype with aging likely contribute to abnormalities in fracture healing seen with aging.

Restraining mitochondrial H₂O₂ generation in cells of the mesenchymal lineage abrogates the adverse effects of aging on the murine skeleton. Maria Almeida^{*1}, Serra Semahat Ucer¹, Srividhya Iyer², Ha-Neui Kim¹, Li Han¹, Christine Rutlen¹, Shoshana Bartell¹, Aaron Warren¹, Julie Crawford¹, Robert Jilka¹, Stavros Manolagas¹. ¹Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA, USA, ²Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA

Generation of reactive oxygen species (ROS) is an inevitable consequence of aerobic metabolism and it occurs mainly in the mitochondria from the escape of electrons passing through the electron transport chain. Of the ROS species, H₂O₂ has the highest oxidative activity and intracellular concentration. An increase in ROS has been associated with the decreased bone formation caused by old age as well as the increased resorption caused by sex steroid deficiency in mice. Increased ROS in osteoblasts and osteocytes decreases bone formation. On the other hand, H₂O₂ generation is a critical requirement for osteoclastogenesis and bone resorption. We have generated mice in which a transgene for human catalase - a potent H₂O₂ inactivating enzyme - has been targeted to the mitochondria (MitoCat) of cells of the mesenchymal lineage using Prx1-Cre (MitoCat;Prx1-Cre). Bone marrow derived osteoblasts from MitoCat;Prx1-Cre mice had 2-fold higher catalase activity as compared to wild-type, Prx1-Cre, or MitoCat-flox stop (FS) control mice. Catalase activity in kidney, liver, spleen, or cultured macrophages was, however, indistinguishable from littermate controls. Femoral cancellous and cortical bone volume in young adult males or females (3 and 6 month of age, respectively) was indistinguishable from littermate controls as determined by micro-CT. MitoCat-FS control mice aged to 22 months exhibited the expected age-related decline in cortical thickness and cortical bone volume as compared to 6 month-old mice of the same genotype. In contrast, the cortical thickness of 22 month old MitoCat;Prx1-Cre mice was indistinguishable from young adults. Elsewhere in this meeting, we report that mice in which MitoCat has been targeted to cells of the osteoclast lineage (MitoCat;LysM-Cre) are protected from the increase in osteoclast number at the endocortical surface as well as the loss of cortical bone mass caused by loss of sex steroids in females or males. The MitoCat;LysM-Cre mice, however, are not protected from the adverse effects of old age. This genetic evidence indicates that increased H₂O₂ generation with old age in cells of the mesenchymal lineage is a seminal culprit of the loss of cortical bone. In contrast, increased H₂O₂ generation in cells of the osteoclast lineage is the culprit of the loss of cortical bone caused by acute sex steroid deficiency, but not old age. Hence, the mechanisms of cortical bone loss in the two conditions are distinct.

Synergistic Effects of Metformin and Sitagliptin on Mesenchymal Stem Cells Maintenance and Differentiation During Aging. Sudharsan Periyasamy-Thandavan^{*1}, Sadanand Fulzele², Alexandra Aguilar-Pérez³, Maribeth Johnson⁴, Mark Hamrick³, Carlos Isales⁵, William Hill³. ¹Georgia Regents University & Charlie Norwood VAMC, USA, ²Department of Orthopaedic Surgery, Georgia Regents University, USA, ³Department of Cellular Biology & Anatomy, Georgia Regents University, USA, ⁴Department of Biostatistics, Georgia Regents University, USA, ⁵Department of Neuroscience & Regenerative Medicine, Georgia Regents University, USA

An imbalance between bone resorption and bone formation leads to osteoporosis, one of the most ubiquitous diseases affecting over 45 million elderly Americans. Several studies suggest that the age-related osteoporosis is mostly initiated by decline in the regenerative capacity of its resident stem cells. Mesenchymal Stem Cells (MSCs) are multipotent stem cells that can differentiate into osteoblasts. MSCs secrete SDF-1, which is required for CXCR4 regulated activation of BMP2 receptors driving osteogenic differentiation. SDF-1 is also critical in MSC survival within the bone marrow (BM) microenvironment by increasing autophagy. However, BM SDF-1 levels are altered with age, and are linked to an age-associated reduction of autophagy and bone loss. AMP-activated protein kinase (AMPK) has emerged as a key sensing mechanism in the regulation of cellular energy homeostasis by mediating autophagy, and plays a major role in bone physiology by regulating the differentiation of osteoblasts. The combination of metformin and sitagliptin, two FDA-approved antihyperglycaemic drugs, has been shown to possess enhanced therapeutic efficacy in patients over either alone. In the present study, we explored the potential connection between defective AMPK and the SDF-1 mediated autophagic signaling pathways on BM MSC maintenance, survival and osteogenic differentiation during aging. We used Sca1+ Lin- MSCs isolated from 6 and 24 month old male C57BL/6J mice (n=6; passage 3). qPCR analysis showed a significant reduction in critical osteogenic and autophagic genes with age. We examined the effect of metformin treatment, with, or without, sitagliptin, in 24 month MSCs on SDF-1 and autophagy induction at different time points. Metformin in combination with sitagliptin synergistically induced SDF-1 expression via the AMPK-autophagic signaling pathway in a time dependent manner. It also regulated the ability of MSCs to migrate. Likewise, the metformin-sitagliptin combination treatment significantly increased the osteogenic matrix deposition and its mineralization. Collectively, these data suggested that the pAMPK signaling pathway regulates SDF-1 expression, MSC survival and osteogenic potential thereby enhancing the regenerative and osteogenic capacity of aged MSCs. Our novel findings are significant in that they open new therapeutic avenues to potentially reduce osteoporotic bone loss through regulation of the SDF-1 and AMPK pathways.

Measurement of Fluoride in Rat and Monkey Urine. Florence Poitout-Belissent, Luc Huard, Rana Samadfam, Melanie Felix, Jeffrey McCartney, Smith Susan Y.^{*}. Charles River Laboratories, Canada

Exposure to compounds with fluoride results in fluoride incorporation in bones and tooth enamel, and excretion in urine. Assessment of fluoride concentration is important after administration of fluoride compounds as an excess of sodium fluoride may lead to proximal renal tubular injury. An excessive concentration of fluoride in urine has been correlated with dental fluorosis in humans. Urine fluoride evaluation is challenging because it is present only in trace amounts, and its transformation into ionic form is necessary for measurement. Common methods of analysis are high performance liquid chromatography and ion specific electrode after acid extraction.

We validated a method for the determination of fluoride concentration using a buffer extraction of the fluoride and an ion specific electrode perfectION[®], in urine of rats and cynomolgus monkeys.

Method: Urine was collected overnight at room temperature from animals deprived of food and water. 1 mL of urine was diluted 1:1 with a 5% sodium EDTA in buffer deionized water/Total Ionic Strength Adjustment Buffer, placed in a water bath at 95°C for 15 minutes, cooled at room temperature, and measured with the ion selective electrode.

Results: measurement range was 0.01 to 10.0 mg/L.

Precision intra-assay coefficient of variation (CV) was 0.1 to 0.3% in rats, 0.4 to 0.6% in monkeys. Inter-assay CV was 3.6 to 5.9% in rats, 1.5% in monkeys.

Accuracy was determined using a commercial Sodium Fluoride (NaF) control solution: CV was 0.3 to 4.9% rats, 3.6 to 4.0% monkeys.

Linearity of dilution range was 0.0164 to 5.92 mg/L in rats, 0.0163-5.33 mg/L in monkeys.

Extraction efficiency was evaluated by calculation of the recovery in five individual samples spiked at two different concentrations of NaF. Recovery ranged between 89.5 and 121% in monkeys, 97.6 and 115% in rats.

Samples were stable up to 3 months at -20°C for both species.

Reference range was 1.25-6.39 mg/L rats, 0.598-5.41 mg/L monkeys for an overnight collection.

In conclusion: The fluoride buffer extraction and ion specific electrode measurement method is simple, rapid, and suitable for the determination of trace amounts of fluoride in urine in rats and monkeys.

Diet Derived Phenolic Acid Regulates Bone Accretion and Senescence Signaling. Jin-Ran Chen^{*1}, Oxana P. Lazarenko², Michael L. Blackburn², Thomas M. Badger². ¹University of Arkansas for Medical Science, Arkansas Children's Nutrition Center, USA, ²University of Arkansas for Medical Sciences & Arkansas Children's Nutrition Center, USA

A blueberry (BB) supplemented diet has been previously shown to significantly stimulate bone formation in rapidly growing male and female rodents. Phenolic acids (PAs) are metabolites derived from polyphenols found in fruits and vegetables as a result of the actions of gut bacteria, and the levels of these PAs were found significantly higher in the serum of rats fed a BB-containing diet. We have characterized the effect on stimulating osteoblastogenesis of one such BB-associated serum PA, 3-(3-hydroxyphenyl) propionic acid (PPA). To more fully understand the mechanistic actions of PPA on bone formation, we administered four different doses of PPA (0.1, 0.5, 1 and 5 mg/kg/d) to one-month-old female C57Bl mice for thirty days. We found that stimulation of osteoblast differentiation and proliferation occurred in PPA treated osteoblastic cells. Using peripheral quantitative CT scan (pQCT) analysis, we demonstrated differences in bone phenotypes between control and PPA-treated animals, i.e., trabecular bone mineral densities were significantly higher in 0.5 to 5 mg/kg/d PPA-treated animals compared to their controls. Furthermore, static and dynamic histomorphometric analyses showed that osteoblast number and mineralizing surface per bone surface (Ms/Bs) were significantly increased in 1 and 5 mg/kg/d PPA-treated animals compared to un-treated controls. Bone formation rate was significantly increased in 0.5, 1 and 5 mg/kg/d PPA-treated animals compared to un-treated controls. After aspiration of bone marrow, femur bone protein and RNA were isolated for Western blot and real-time PCR analysis of signaling transduction. We found that PPA was able to suppress bone senescence signaling as evaluated by measuring senescence associated beta-galactosidase activity, p53 and p21 expression in bone. Suppression of PPAR γ expression in bone by PPA was associated with increased bone mass dose-dependently. In conclusion, PPA is capable of altering the mesenchymal stem cell differentiation program and merits investigation as a potential dietary therapeutic alternative to drugs for degenerative bone disorders. *Supported in part by ARS CRIS #6251-51000-005-03S (JRC).*

Bone Deficits in Chronic Kidney Disease and the Effect of Renal Transplantation on Mechanical Competence. Chamith Rajapakse*¹, Wenli Sun², Michelle Slinger¹, Elizabeth Kobe¹, Rhiannon Miller¹, Felix Wehrli¹, Mary Leonard³. ¹University of Pennsylvania School of Medicine, USA, ²University of Pennsylvania, USA, ³Stanford School of Medicine, USA

Abnormal vitamin D and mineral metabolism are a universal complication of advanced chronic kidney disease (CKD). Secondary hyperparathyroidism results in abnormal trabecular microarchitecture and cortical thinning. Renal transplantation (RTxp) corrects many of the risk factors for bone deficits; however, glucocorticoid therapy and persistently elevated PTH levels may further compromise strength. The objective of this study was to use MRI-based finite-element analysis to assess bone mechanical competence at the time of RTxp, compared with controls, and to examine changes after RTxp.

Sixty RTxp recipients (52% male, 32% preemptive), ages 20-60 years, were enrolled at transplantation and compared with 104 healthy controls (49% male), ages 19-60 years. MRI of the distal tibia was performed on a 1.5 Tesla scanner (Siemens Tim Trio, Erlangen, Germany) using a 2-channel surface coil at 0.137 mm x 0.137 mm x 0.410 mm voxel size. Trabecular bone parameters and stiffness of the whole section were computed on the basis of these images using digital topological and finite element analysis, respectively.

Within controls, bone volume fraction (BV/TV) was inversely associated with age ($p=0.001$) and greater in males ($p<0.001$). At baseline, RTxp recipients had lower BV/TV, Tb.N, higher Tb.Sp, and lower stiffness, adjusted for age and sex ($p < 0.05$) (Figure 1). In CKD patients, from baseline to 6 months following renal transplantation, stiffness significantly decreased by 3% ($p=0.01$). During 6-12 and 12-24 months, stiffness increased by 4% and 1%, respectively, however these changes were not statistically significant.

Further analysis is needed to determine if trabecular and cortical bone compartments are differentially affected by CKD and renal transplantation.

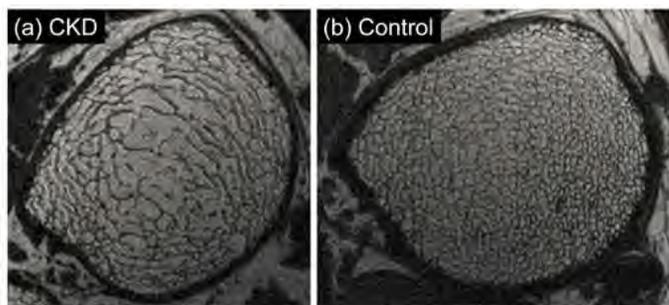

Figure 1: (a) Baseline MR image of the distal tibia metaphysis obtained from a 26-year old Caucasian female CKD patient and (b) a healthy control subject with the same age, race, and sex. Compared to the control, the CKD patient shows decreased Tb.N, increased Tb.Sp, and thinned cortex, which contribute to decreased stiffness, consistent with the overall baseline results from the study.

Specific microRNA signatures in CKD patients focusing on the risks of calcifications and ROD. Barbara Obermayer-Pietsch*¹, Matthias Ulbing¹, Alexander Kirsch², Schweighofer Natascha³, Bettina Leber⁴, Sandra Lemesch⁵, Alexander Rosenkranz⁶, Helmut Müller⁴, Kathrin Eller⁶, Vanessa Stadlbauer⁵. ¹Medical University Graz, Austria, ²Medical University Graz, Dept. Internal Medicine, Division of Nephrology, Austria, ³Medical University Graz, Dept. Internal Medicine, Div. Endocrinology & Metabolism, Austria, ⁴Medical University Graz, Dept. Surgery, Div. of Transplant Surgery, Austria, ⁵Medical University Graz, Dept. Internal Medicine, Div. Gastroenterology, Austria, ⁶Medical University Graz, Dept. Internal Medicine, Div. Nephrology, Austria

Introduction:

Calcification of vessels - mainly in the tunica media - with additional demineralisation of bone is typical for patients suffering from chronic kidney disease (CKD). In this project, we analyse samples from CKD patients with a focus on microRNAs (miRNAs) as new biomarkers for vascular calcification. Our aim is to find a pattern of miRNAs indicating vascular calcification and/or mineralisation changes in the course of the disease and after kidney transplantation.

Methods:

Serum and plasma samples of 73 patients in CKD stages 3 – 5; 67 post RT (renal transplantation) patients as well as 36 healthy controls are analysed in the study. Additional 25 patients in CKD stage 5 were prospectively followed before, and already some of them during and after RT. Known biomarkers for calcification have been measured using ELISA techniques. A miRNA profile of CKD patients

compared to healthy controls has been established using a nCounter® miRNA Expression Assay. Deregulated miRNAs were further analysed in qPCR experiments.

Results:

PTH, FGF23 and osteocalcin were significantly increased in late stage CKD patients. When analysing more than 800 miRNAs, significant differences were found in 37 of them when comparing CKD patients of stage 5 and healthy controls. These miRNAs were related to vascular smooth muscle cell (VSMC) biology and bone metabolism. 12 miRNAs of them were followed for further analysis. In subsequent experiments especially 4 miRNAs emerged showing a different expression level comparing the patient and control groups.

Discussion:

miRNAs have been shown to have a biological association to vascular calcification, bone metabolism or differentiation of VSMCs to osteoblast-like cells. They are deregulated to a considerable extent in CKD patients. These pathways may be important during the development of calcified and vascular tissue in the course of kidney disease. miRNA signatures could become early diagnostic markers indicating the risk of vascular calcification or bone demineralisation in this high risk group.

The Effect of Kidney Disease on Bone Metabolism in Mice may be Modulated by the Initial Bone Characteristics. Ryan Clark*¹, Chelsea Heveran², William Schroeder¹, Moshe Levi¹, Virginia Ferguson², Karen King¹. ¹University of Colorado School of Medicine, USA, ²University of Colorado Boulder, USA

Patients with kidney disease have altered bone metabolism including high or low resorption and/or formation. The combination and degree of alterations cannot easily be predicted based on the type or severity of kidney dysfunction. To test our hypothesis that genetic variation contributes to variation in metabolic bone disorders we induced kidney dysfunction in two different mouse strains.

We created moderate chronic kidney disease (CKD) in 10 week old male C57Bl/6 and FVB mice by first removing one kidney and then 2/3 of the other one week later (5/6 nephrectomy). Additional mice received sham surgeries. Mice were euthanized 11 weeks later (N = 12/group). From each mouse, mRNA was extracted from one femur for qRT-PCR, protein from one tibia for Western blot analysis, while the remaining femur was imaged with micro computed tomography (μ CT) and then subjected to 3-point bending.

The Wnt pathway was upregulated with CKD in the C57Bl/6 strain. Gene expression increased significantly ($P<0.05$) for low-density lipoprotein receptor-related protein 5 (LRP5), secreted frizzled-related protein-4 (sFRP4, a Wnt inhibitor), and receptor for advanced glycation end products (RAGE, a downstream target). Conversely, sFRP4 protein appeared to increase in (Fig. 1, N=2/group). The Wnt pathway was unchanged or down-regulated with CKD in the FVB strain. Dickkopf-related protein 1 (DKK1, a Wnt inhibitor) and RAGE mRNA significantly decreased and sFRP4 protein appeared to decrease (Fig. 1).

Femur mechanical and structural properties were diminished with CKD but more severely for the FVB. Three-point bending strength at maximum load decreased (-10.6%; $P=0.03$) and fracture load at the femoral neck decreased (-10.0%; $P=0.01$) for the FVB but not for the C57Bl/6. Femur cortical diaphysis thickness decreased (-10.0%; $P=0.01$) for the FVB but not for the C57Bl/6 despite an equivalent loss of bone mineral density (both strains: -1.9%; $P<0.05$). Our data indicate that these two genetically different strains exhibit opposite reactions in response to decreased kidney function. Therefore, we propose the hypothesis that the initial bone traits may modulate the effect of CKD on subsequent bone metabolism. Our data are consistent with an osteocyte response to CKD in which FVB osteocytes more efficiently suppress the Wnt pathway resulting in more severely affected bone. Our study is limited in that the data do not show whether bone loss is due to increased resorption and/or decrease formation.

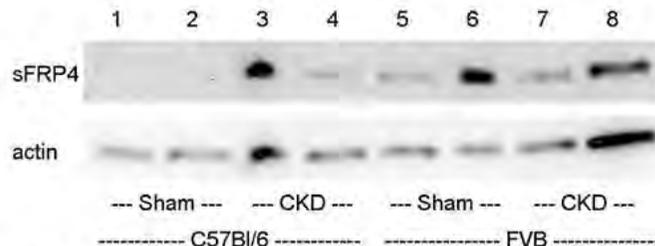

Fig. 1: Western blot analysis of protein - 10 μ g each lane - from C57Bl/6 (lanes 1-4) and FVB (lanes 5-8) mice. Mice were either sham operated (lanes 1, 2, 5, and 6) or operated to create moderate CKD (5/6 nephrectomy; lanes 3, 4, 7, and 8). Note: We believe that a calcium impurity caused lane 3 to run poorly.

The Impact of Arteriovenous Fistula on Bone Density and Structure assessed by HR-pQCT. Stephanie Boutroy*¹, Justine Bacchetta², Solenne Pelletier³, Cyrille Confavreux⁴, Denis Fouque⁵, Roland Chapurlat⁴. ¹INSERM UMR1033 & Université de Lyon, France, ²INSERM UMR1033, Service de Néphrologie et Rhumatologie Pédiatrique, Hôpital Femme Mère Enfant, Université de Lyon, France, ³INSERM UMR1033, Département de Néphrologie, Hôpital Edouard Herriot, Université de Lyon, France, ⁴INSERM UMR1033, Département de Rhumatologie, Hôpital Edouard Herriot, Université de Lyon, France, ⁵Département de Néphrologie, Hôpital Edouard Herriot, Université de Lyon, France

Objectives

Maintenance hemodialysis is usually performed through an arteriovenous fistula (AVF). However, the impact of AVF on the underlying bone is largely unknown with only one study having reported decreased forearm aBMD assessed by DXA on the AVF side in 30 hemodialysis patients. Our aim was to evaluate the impact of AVF on volumetric BMD and bone microstructure assessed by High Resolution peripheral QCT (HR-pQCT).

Patients and methods

Fifty four patients (51 ± 16yrs, 20 women, 34 men) undergoing hemodialysis with a functioning AVF were included in this study. They underwent HR-pQCT (XtremeCT, Scanco Medical, Switzerland) of both radius.

Results

Total and cortical volumetric densities were significantly decreased by 3% and 2% (p<0.05) on the AVF radius side compared to the non-AVF radius. Cortical area and thickness were also decreased by 6% (p<0.05) while no difference was observed for the trabecular bone.

When comparing patients with radiolarial (distal) AVF (n=32) to those with humero-cephalic (proximal) AVF (n=22), the magnitude of the difference between the AVF and non AVF radius were similar in the two fistula localizations groups although patients with a humero-cephalic AVF were significantly older (57 ± 15 vs. 46 ± 16 yrs) with an increased dialysis duration (42 ± 32 vs. 25 ± 33 months).

Conclusions

This study shows a cortical impairment by HR-pQCT on the AVF radius side in patients undergoing maintenance hemodialysis with a functioning AVF, but the presence of an AVF seems to have no consequence on trabecular BMD and microstructure.

Vertebral Fractures in Patients with End-Stage Renal Disease Undergoing Dialysis. Jerzy Przedlacki*¹, Paweł Żebrowski², Ewa Wojtaszek², Mariusz Mieczkowski², Agnieszka Grzejszczak³, Paweł Kulicki⁴, Małgorzata Koscielska⁴, Maria Kaszyńska², Joanna Matuszkiewicz-Rowińska². ¹Medical University of Warsaw, Poland, ²Chair & Department of Nephrology, Dialysis & Internal Diseases, Medical University of Warsaw, Poland, ³Chair & Department of Nephrology, Dialysis, & Internal Diseases, Medical University of Warsaw, Poland, ⁴Chair & Department of Nephrology, Dialysis & Internal Medicine, Medical University of Warsaw, Poland

Patients with end-stage renal failure treated with dialysis are in a high risk of bone fracture. In our everyday practice the clinically overt vertebral fractures (VFr) are recognized only, with the spine X-ray. There are no reports on the real frequency of VFr in this group of patients. The aim of the study was to assess the frequency of the low-energy VFr in dialysis patients. One hundred eight patients from our one dialysis center (62 males and 46 females; 74 hemodialysis and 34 peritoneal dialysis patients) aged 59.7 ± 13.7 years were examined. The observation was carried out during 2010-2013. Densitometric Vertebral Fracture Assessment (VFA) was done with the use of Discovery A, Hologic machine in 74 patients in 2010, and in 34 next years. Control tests were repeated every one or second year in all patients. Genant method of VFr assessment was used. In the case of the new VFr, X-ray was done to confirm it. The whole examined spine (T4-L4) was visible in 28 patients (25.9%). All but 2 lumbar vertebrae in 1 patient were visible. Altogether, 15 VFr (5 thoracic and 10 lumbar) were recognized in 9 patients (8.3%; 8 HD and 1 CAPD patients; 6 males and 3 females). In 1 male patient only VFr was diagnosed before the study with X-ray. There were wedge deformity in 4 thoracic vertebrae (2 of grade 1 and 2 of grade 2) and in 2 lumbar vertebrae (grade 1) and biconcave deformity in 1 thoracic vertebra (grade 1) and in 8 lumbar vertebrae (4 of grade 1 and 4 of grade 2). There was no statistically significant difference between fractured and not-fractured patients depending on the method of dialysis, gender and age. There were only 3 fractured patients with DXA spine and 2 with DXA hip osteoporotic result (in accordance to WHO criterion, T-score ≤ -2.5). Vertebral fractures seems to be frequent in dialysis patients but it is not possible to relate these results to general Polish population (data not available) and other dialysis patients. Most of them were not clinically overt and none of them was of grade 3. Densitometric VFA was useful in diagnosis of VFr. It is reasonable to perform VFA assessment in dialysis patients as the routine procedure because the new VFr gives information on the increased further fracture risk.

Radiation And Hypoxia Cooperatively Suppress Orofacial Mesenchymal Stem Cell Survival. Pinky Salat¹, Weihua Li¹, Sunday Akintoye*². ¹University of Pennsylvania, USA, ²University of Pennsylvania School of Dental Medicine, USA

BACKGROUND: Combination of radiotherapy and surgery is the standard of care for management of head and neck cancers. However, radiotherapy often leads to the complication of osteoradionecrosis (ORN) that further undermines the quality of life of cancer survivors. ORN pathogenesis is associated with development of a hypoxic-hypovascular-hypocellular tissue condition as tissue oxygen tension plays a vital role in critical cellular processes such as proliferation, growth factor expression and differentiation. Bone mesenchymal stem cells (MSCs) modulate bone healing and homeostasis and also display site-dependent disparity in responsiveness to irradiation. This study tested the hypothesis that radiation cooperates with hypoxia to suppress survival of orofacial (jaw) MSCs (OFMSCs) with consequent depletion of osteoprogenitor cell populations essential for post-irradiation healing and recovery. **METHODS:** Early passage human OFMSCs were subjected to two external stress modalities: 5 Gy irradiation followed by severe hypoxia (0.1% oxygen tension) for 6 hours in a modular hypoxic chamber (Billups-Rothenburg MIC-101). Appropriate control groups +/- radiation and/or +/- hypoxia were included in the experimental plan. Cell survival was assessed using WST-1 proliferation assay and western blotting was used to assess survival markers pAKT/TotalAKT and pERK1/2/TotalERK1/2, apoptotic markers p21 and MDM2 and hypoxic marker HIF-1α. **RESULTS:** Exposure to radiation, hypoxia or combination of both suppressed OFMSC survival and upregulated HIF-1α level but phosphorylation of AKT and ERK1/2 were unchanged. While p21 level was unaffected by hypoxia alone, radiation combined with or without hypoxia promoted p21 expression levels. MDM2 was upregulated only by radiation. **CONCLUSIONS:** Hypoxia apparently cooperates with radiation to suppress OFMSCs survival, a factor that may relate to ORN pathogenesis.

Association between Vitamin D deficiency and low HDL levels in Type 2 diabetics with Acute Coronary Syndrome. Fernando Gondin¹, Maria do Socorro Azevedo¹, Luiz Henrique Griz², Arianna Chacon¹, Breno Coimbra¹, Nathália Brito¹, Mirna de Sá*¹, Francisco Bandeira¹. ¹Division of Endocrinology & Diabetes, Agamenon Magalhães Hospital, University of Pernambuco Medical School, Recife, Brazil, ²Aluisio Borba Griz & Argentina Maciel Griz, Brazil

Epidemiological studies have suggested an association between vitamin D deficiency and the risk of cardiovascular disease but few data are available in patients with acute coronary syndrome, particularly in women with type 2 diabetes (T2DM).

This was a cross-sectional study comprising 321 diabetic women, stratified into two groups according to the presence or not of acute coronary syndrome (ACS) with the following characteristics: age (66.81 ± 11.38 yr x 63.62 ± 7.92 yr), duration of diabetes (mean ± SD: 9.03 ± 8.16 x 10.21 ± 8.08 yr), Body mass index (BMI): 27.16 ± 4.69 x 29.43 ± 5.87 kg/m², Waist circumference (WC): 93.05 ± 13.23 x 98.03 ± 11.57 cm, total serum cholesterol (93.05 ± 13.23 x 197.24 ± 49.07 mg/dl), LDLC (98.99 ± 32.11 x 113.43 ± 42.75 mg/dl), HDLC (40.84 ± 9.68 x 50.44 ± 13.82 mg/dl), triglycerides (196.78 ± 91.44 x 164.83 ± 82.31 mg/dl), 25OHD (7.56 ± 19.92 x 25.60 ± 8.51 ng/ml, p < 0.001) and PTH levels (42.25 x 49.20 ± 45.98 ± 28.28 pg/ml). No significant differences were found between the groups with respect to age (p = 0.106), diagnosis of hypertension (p = 0.554), duration of diabetes (p = 0.405) and PTH levels (p = 0.543). There was a statistically significant difference between BMI (p = 0.024) and WC (p = 0.016), with lower values among patients with ACS. Despite having lower BMI and WC values, ACS patients had lower serum 25OHD levels (p < 0.001) and serum HDLC cholesterol (p < 0.001). The other component of serum lipid profile also showed significant differences with the ACS group with lower total cholesterol (p < 0.001) and LDLC (p = 0.048). Only serum triglycerides were higher in the ACS group (p = 0.029).

Our data demonstrates an independent association between vitamin D deficiency and reduced HDLC in women with type 2 diabetes with ACS

Determination of Severe Suppression of Bone Turnover in Women with Atypical Femoral Fracture after Long-term Bisphosphonate Treatment. Shijing Qiu*¹, George Divine, Saroj Palnitkar, Mahalakshi Honasoge, Sudhaker D Rao, Henry Ford Hospital, USA

Inhibition of bone turnover is an effective therapeutic for osteoporosis. However, severe suppression of bone turnover (SSBT) by antiresorptive drugs, especially bisphosphonates (BP), is likely to cause accumulation of aged bone with increased fragility. Until now, there is still no clear definition or diagnostic criteria for SSBT. Most authors defined SSBT as absence of tetracycline labeling in cancellous bone.

Since bone remodeling occurs not only on cancellous but also on intracortical and endosteal surfaces, it seems improper to define SSBT solely based on the examination of cancellous bone. The purpose of this study was an attempt to provide a novel criterion for the determination of SSBT.

Iliac bone biopsies from 43 healthy premenopausal white women and 12 white women with either complete (n = 5) or incomplete (n = 7) atypical femoral fracture (AFF) after long-term (>5 years) BP treatment were examined. The different bone surfaces (cancellous, intracortical and endosteal) were combined as one, and the parameters of erosion surface (ES/BS, %), osteoid surface (OS/BS, %), osteoid thickness (O.Th, μm), mineralizing surface (MS/BS, %), mineral apposition rate (MAR, $\mu\text{m}/\text{day}$) and bone formation rate (BFR/BS, $\mu\text{m}^3/\mu\text{m}^2/\text{year}$) were obtained on the combined bone surface. Compared to the healthy premenopausal women, all parameters were significantly reduced in AFF patients ($p < 0.05-0.001$; Table 1). The reference range for each parameter is shown in Table 1 and the lower limit of BFR/BS was 0.736. In 12 patients with AFF, 8 (67%) had BFR/BS < 0.736 , in which 3 patients had no tetracycline labeling in the whole biopsy. In the other 4 patients, BFR/BS remained at lower levels of the reference range.

The current study provided a threshold value of BFR/BS (~ 0.74) on the combined bone surface for the determination of SSBT. In this study, 2/3rd of the patients had BFR/BS below this threshold. Because the value of BFR/BS obtained from the combined bone surface appears to show the remodeling status in whole bone, it may be reasonable to use this variable for the definition of SSBT.

Table 1. The changes in bone turnover on the combined bone surface in AFF patients

| | AFF | Normal | p | Reference Range | Below Range |
|--------|--------------|--------------|--------|-----------------|-------------|
| ES/BS | 3.50(2.95) | 6.28(2.63) | 0.003 | 2.49-11.0 | 5/12 |
| OS/BS | 2.60(2.37) | 13.6(6.75) | <0.001 | 4.80-29.6 | 11/12 |
| O.Th | 5.06(1.44) | 9.32(1.74) | <0.001 | 6.77-13.8 | 11/12 |
| MS/BS | 1.21(1.73) | 6.59(3.17) | <0.001 | 1.41-12.5 | 7/12 |
| MAR | 0.123(0.108) | 0.553(0.174) | <0.001 | 0.146-0.829 | 7/12 |
| BFR/BS | 0.972(1.71) | 14.1(7.77) | <0.001 | 0.736-27.5 | 8/12 |

Effects of Eldecalcitol on Inflammatory Markers in Patients with Rheumatoid Arthritis. Hayato Kinoshita¹, Naohisa Miyakoshi¹, Seiya Miyamoto², Yuji Kasukawa¹, Yusuke Sugimura³, Yoichi Shimada¹. ¹Department of Orthopedic Surgery, Akita University Graduate School of Medicine, Japan, ²Division of Orthopedic Surgery, Nakadori General Hospital, Jarvis island, ³Division of Orthopedics, Minamiakita Orthopedic Clinic, Japan

Rheumatoid arthritis (RA) is caused by upregulation of proinflammatory cytokines such as interleukin (IL)-2, IL-6 and tumor necrosis factor (TNF)- α . Furthermore, the rheumatic synovial membrane overexpresses receptor activator of nuclear factor kappa-B ligand (RANKL), which promotes differentiation of osteoclast precursors into osteoclasts, thus increasing bone resorption. Conversely, long term treatment with activated vitamin D3 is reported to suppress RANKL production, thus decreasing bone resorption. This study aimed to investigate whether activated vitamin D3 could prevent inflammation caused by excessive bone resorption in RA patients. From 490 RA patients registered to our Akita Orthopedic Group on Rheumatoid Arthritis (AORA) database, those treated with biological agents or who changed medication during observation period were excluded. Twenty-eight patients (4 male; 24 female; average age 67 years) were enrolled in this study. Patients were classified into the following groups: 1) control group (n=11), no activated vitamin D3 administration; 2) E group (n=9), treatment with eldecalcitol (0.75 $\mu\text{g}/\text{day}$); and 3) switch group (n=8), treatment with alfacalcidol (1.0 $\mu\text{g}/\text{day}$) then eldecalcitol (0.75 $\mu\text{g}/\text{day}$). White blood cells (WBC), C-reactive protein (CRP) and matrix metalloproteinase 3 (MMP-3) were measured pre-treatment, and at first (113rd days post-treatment) and second (216th days post-treatment) time points post-treatment with activated vitamin D3. Percentage (%) changes were determined for each parameter between pre- and post- (first and second) treatment time points. Although the WBC % changes in the control group at first (2.0th24%) and second (12th40%) time points were higher than those of the E group at first (-5.0th9.0%) and second (5.0th26%) and switch group at first (2.0th21%) and second (8.6th17%) time points, these were not significantly different. Additionally, there were no significant differences in CRP % changes at first and second time points between the control (180th312% and 191th336%, respectively), E (36th119% and -7.1th75%, respectively), and switch (33th157% and 3.7th29%, respectively) groups. Finally, there were no significant differences in MMP-3 % changes at first and second time points between the control (6.3th20% and 16th21%, respectively), E (11th18% and 25th33%, respectively), and switch (-19th30% and -3.6th7.6%, respectively) groups. In this study, activated vitamin D3 did not decrease inflammatory markers in RA patients.

Indole sulfate as a metabolite in CKD patients regulates low turnover of bone metabolisms through OAT-3 transporter. Michiko Hirata, Tsukasa Tominari, Masaki Inada, Chisato Miyaura*. Tokyo University of Agriculture & Technology, Japan

Kidney is sole organ that regulates calcium and phosphorus level in blood to maintain body homeostasis. In CKD patients, the mineral levels in blood are altered in many cases of symptom that is resulted in low turnover bone remodeling. One of major toxic metabolites in blood of CKD patients is indoxyl sulfate (IS), a uremic toxins, which causes uremia such as vertigo, loss of appetite, and muscle atrophy. However, the regulations of bone metabolism by IS is still not known. In this study, we investigated the effects of IS on bone metabolism including bone resorption and formation that underlies the mechanisms on CKD patients. IS suppressed osteoclast differentiation in cocultures of primary osteoblast (POB) and bone marrow cells in dose dependent manner. To investigate the direct effect of IS on macrophage lineage cells, we used Raw264.7 and bone marrow macrophages (BMM) with soluble RANKL. IS inhibited RANKL induced osteoclast differentiation from Raw264.7 and BMM. To analyze mRNA expression in osteoclasts, real time PCR was performed. IS significantly suppressed the expression of NFATc1, TRAP and RANK in osteoclasts. In osteoblasts, the expression of RANKL was suppressed by IS treatment. The expression of OAT-3, a possible receptor of IS, was detected in both osteoclasts and osteoblasts, suggesting IS suppressed osteoclast differentiation in macrophage lineage cells directly and osteoblast lineage cells indirectly. These data suggest that IS may be incorporated into these cells via OAT, and inhibits osteoclast differentiation. We next examined the effects of IS on bone formation. IS significantly suppressed the bone formation in cultures of POBs, and the mRNA expression of bmp2, colla1, osterix and osteocalcin was down-regulated in osteoblasts. In conclusion, we showed that IS is incorporated into cells via OAT-3, resulting in inhibition of osteoclast differentiation and survival through down-regulation of NFATc1 gene expression and osteoclastic bone resorption. IS also suppressed bone formation through down-regulation of osterix and osteocalcin. Since, IS inhibited both bone resorption and bone formation. IS might be involved in the abnormality of bone remodeling with low bone turnover in CKD patients. Neutralization of uremic toxin IS may apply a possible approach to prevent low-turnover bone loss in CKD patients.

Exploration of associations between air pollutants and Paget's disease of bone. Mohamed Saber Numan¹, Sonia Jean², Jeannette Dumont¹, Jacques P. Brown³, Laetitia Michou⁴. ¹CHU de Québec Research Centre, Canada, ²Institut national de santé publique du Québec & Department of Medicine, Laval University, Canada, ³CHU de Québec Research Centre; Department of Medicine, Laval University; Department of Rheumatology, CHU de Québec, Canada, ⁴Université Laval, Canada

Background: Although genetic factors play an important role in Paget's disease of bone (PDB) pathogenesis, environmental factors such as rural residency have also been reported. We have previously shown an association between PDB and tobacco exposure in French families, and wood heating exposure in French-Canadians.

Purpose: To explore the associations between outdoor and indoor air pollutants and PDB.

Methods: We recruited 141 patients with PDB and 114 healthy controls from our French-Canadian cohort. Exposure was estimated using a questionnaire on the history of residence and proximity to sources of outdoor air pollutants such as highways, bus, train or airport stations, and gas stations. Regarding indoor air pollutants, questions on heating combustibles (carbon, wood, oil) used in past residences and tobacco exposure were also used. Associations between air pollutant exposures and PDB were assessed with Chi-squared, Fisher and t tests. Odds ratio (OR) and 95% confidence intervals were calculated. In a subgroup of patients (n=15 to 46) and controls (n=12 to 48), urinary concentration of 17 heavy metals and 11 polycyclic aromatic hydrocarbons were measured by mass spectrometry. A linear regression analysis with adjustment for PDB status, wood heating exposure, sex and tobacco exposure was performed.

Results: After adjustment for gender, PDB patients were less frequently exposed to outdoor air pollutants than controls during childhood: residence close to highways (32% of patients versus 80% of controls, OR=0.09 [0.04-0.19], $p < 0.0001$), residency close to bus, train or airport stations (6% versus 19%, OR=0.25 [0.09-0.72], $p = 0.01$) and residence close to gas stations (15% versus 25%, OR=0.37 [0.16-0.84], $p = 0.02$). Wood heating exposure during childhood was the only indoor air pollutant positively associated with PDB: 90% of patients versus 80% of healthy controls, OR=2.52 [1.03-6.20], $p = 0.04$). Higher levels of lead ($p = 0.0007$), zinc ($p = 0.02$), bismuth ($p = 0.03$), mercury ($p = 0.05$) and copper ($p = 0.06$) were associated with PDB, whereas higher levels of cadmium were associated with tobacco exposure ($p = 0.07$).

Conclusions: Patients with PDB were less frequently exposed to outdoor air pollutants during childhood, which is consistent with the known association with rural residency, whereas they were more frequently exposed to wood heating during childhood. Higher levels of urinary heavy metals in patients with PDB may support some role for air pollutants in PDB.

Association between normocalcemic primary hyperparathyroidism and blood pressure. Gang Chen¹, Junping Wen*². ¹Fujian Provincial Hospital, Peoples republic of china, ²Fujian Provincial Hospital, China

Objective: Primary hyperparathyroidism (PHPT) is reported to be associated with an increased frequency of hypertension, however, information in this regard is sparse in relation to normocalcemic primary hyperparathyroidism (NPHPT). The aim of this study was to determine the association between NCHPT and blood pressure. **Methods:** We retrospectively enrolled 940 patients who visited at Fujian Provincial Hospital between September 2010 and December 2013 with a measured serum parathyroid hormone (PTH) and calcium level. Among them, 11 patients were diagnosed with NPHPT, while 296 cases with normal PTH and albumin-adjusted serum calcium. Systolic blood pressure (SBP), diastolic blood pressure (DBP), intact serum PTH and serum calcium were recorded. **Results:** There were no significant differences between subjects identified with NPHPT and those with normal PTH in terms of age, sex, BMI, serum calcium, 25-Hydroxyvitamin D, serum creatinine, FPG, TG, TC, HDL and LDL. The subjects with a diagnosis of NPHPT had higher levels of SBP (141.9±20.2 vs 131.2±16.5, P = 0.041) and DBP (85.2±12.4 vs 76.8±10.3, P = 0.026) than the subjects in the cohort with normal PTH. After adjustment for all potential confounders, risks (odds ratios and 95% confidence interval) of SBP and DBP in NPHPT patients were 1.035 (1.000, 1.071) and 1.063 (1.004, 1.125), respectively (P < 0.05). **Conclusions:** The NPHPT had higher risk of high blood pressure than subjects with normal PTH. It is worth considering the necessity of more aggressive therapeutic intervention aimed to normalize PTH even if patients with NPHPT continue to be normocalcemic.

Blood pressure and obesity in healthy postmenopausal women relationship with PTH, retinol, vitamin E and vitamin D endocrine system. Cristina Navarro Valverde¹, Aura Dulcinea Herrera Martínez*², Maria Dolores Luque de Castro³, Rafael Cuenca-Acebedo⁴, María Concepción Muñoz Jiménez⁵, José Manuel Quesada Gómez⁶. ¹Unidad de Gestión Clínica de Cardiología, HU Virgen de Valme, Spain, ²Unidad de Gestión Clínica de Endocrinología y Nutrición IMIBIC . Hospital Universitario Reina Sofía, Spain, ³Departamento de Analítica Química, Annex C-3, Campus of Rabanales, University of Córdoba, Spain, ⁴Servicio de Medicina Interna Hospital Alto Guadalquivir SEIOMM RETICEF, Spain, ⁵Unidad de Gestión Clínica de Endocrinología y Nutrición. IMIBIC Hospital Universitario Reina Sofía de Córdoba., Spain, ⁶Unidad de Gestión Clínica de Endocrinología y Nutrición. IMIBIC. Hospital Universitario Reina Sofía. RETICEF, Spain

Obesity is linked to depressed 25-hydroxyvitamin D (25OHD) and elevated parathyroid hormone (PTH). Observational data also link low 25OHD to both prevalent Blood Pressure (BP) and incident hypertension. The aim of this study was to evaluate the relationship between fat soluble vitamins and obesity in healthy postmenopausal women of Cordoba who ranged from normal weight to morbid obesity as well as the effects of fat soluble vitamins on BP.

Patients and Methods: Anthropometric data, BP, fat soluble vitamins serum levels and others serum parameters which may influence fat soluble vitamins levels were analyzed in a cross-sectional study in 232 healthy postmenopausal women. Age, age of menarche, age of menopause, Body Mass Index (BMI), HDL-cholesterol, LDL-cholesterol, triglycerides, calcium, 1,25(OH)₂D, 25(OH)D, alkaline phosphatase, PTH, osteocalcin, calcium, vitamin E:lipids ratio, vitamin A and β-crosslap were modeled by a partial least squares for systolic and diastolic blood pressure multivariate logistic regression. **Results:** Prevalence of vitamin D deficiency (< 50 nmol/l) in non-obese population was 47.2%, whereas in obese people increased up to 65%. Vitamin D serum levels were significantly higher in normal weight women (BMI < 25 Kg/m²) than in obese women (BMI > 35 Kg/m²), meanwhile PTH and vitamin E:lipids ratio were significantly higher in obese than non-obese women. Partial least squares (PLS) regression model for Systolic Blood Pressure (SBP) showed that age, BMI, LDL cholesterol, alkaline phosphatase and PTH were positive correlated with SBP. However, age of menopause, HDL-cholesterol and vitamin D were negative correlated with it. Age of menopause, HDL cholesterol, vitamin D (25OHD and calcitriol) and osteocalcin showed a negative effect on Diastolic Blood Pressure (DBP). On the other hand, BMI, triglycerides, alkaline phosphatase and PTH showed a positive correlation with DBP. Our results showed that vitamin D insufficiency is highly prevalent in the population of healthy postmenopausal women. Low 25OHD levels correlated with high body fat and BP. We conclude that vitamin D deficiency is a potential risk factor for obesity and hypertension in postmenopausal women

Brown Tumor of the Femur with Changes after Parathyroidectomy. Mohammed Almohaya*¹, Mohammed Almelthel¹, Qun Yang², Stephen Robertson³, David Kendler¹. ¹University of British Columbia, Canada, ²prohealth research center, Canada, ³Prohealth clinical research, Canada

Hyperparathyroidism of longstanding duration or greater severity can result in excess osteoclast activity with increased vascularity, hemorrhage and hemosiderin deposits in bone, so-called "Brown Tumor" (BT) of bone. Rarely, such lesions can result in pathologic fracture. The response of BT to parathyroidectomy has been inadequately documented; some surgical literature recommend excising BT lesions or internal fixation to prevent later complications.

We report a 34 year-old Indian woman presenting with a spontaneous atypical right mid-shaft femoral fracture. Femoral radiographs showed cortical thinning at the mid femoral diaphysis. She underwent intramedullary nailing; curettings from the femoral medullary canal showed giant cell rich pathology with no evidence of fibrous dysplasia or malignancy. An isotope bone scan showed multiple bony lesions that involved both the axial and peripheral skeleton. Serum parathyroid hormone was markedly elevated at 160 pmol/L (normal <6.4) and calcium elevated at 3.79 mmol/L (normal 2.10-2.55). Phosphate was low at 0.72 mmol/L (normal 0.80-1.40) and 25-hydroxy vitamin D was low at 23 nmol/L (normal 75-150). She underwent surgical removal of a left inferior parathyroid adenoma with restoration of normal levels of parathyroid, calcium and phosphate. Calcium intake of 1200 mg/day with supplemental Vitamin D 2000 IU/day was recommended. Six months later, radiographs of the left femur showed multiple sclerotic lesions along the length of the femur reported by the radiologist as suspicious for metastatic malignancy. Isotope bone scan 10 months later showed stable or diminished isotope uptake in these lesions. Baseline bone density lumbar spine Z-score was -3.5, femoral neck Z-score was -2.1 and 1/3 radius Z-score was -3.6.

The figure illustrates the anticipated increases in BMD after parathyroidectomy over 24 months. Placement of a region of interest over the trochanteric BT lesion allowed us to quantitate increases over the lesion of 48.6% after 24 months.

This case and its long-term follow-up document clearly the natural evolution of BT post parathyroidectomy with recovery of BMD, densitometric and radiographic sclerotic BT change after calcium and vitamin D supplementation alone. In the absence of imminent pathologic fracture risk, no other intervention is likely required for these patients.

BMD changes after parathyroidectomy

SU0015

FGF23 in patients with hypoparathyroidism. Larissa Savi¹, Maicon Lopes², Victoria Borba², Tatiana Costa², Carolina Moreira*². ¹Serviço de Endocrinologia e Metabologia do Hospital de Clínicas da UFPR (SEMPR), Brazil, ²Serviço de Endocrinologia e Metabologia do Hospital de Clínicas da UFPR (SEMPR), Brazil, Brazil

Introduction: Parathyroid hormone (PTH) and FGF23 have some overlapping effects, both inhibit renal phosphorus reabsorption but both have potentially counter-regulating effects, above all vitamin D metabolism. PTH acts to increase 1,25-hydroxy vitamin D (actively) synthesis and FGF23 increases 24,25-hydroxy vitamin D (not actively). It is not know if the hyperphosphatemia of hypoparathyroidism is sufficient to increase the synthesis of FGF23 in the absence of PTH.

Purpose: to evaluate the clinical parameters and FGF23 levels in patients with permanent hypoparathyroidism and connect the findings to the etiology of the hypoparathyroidism.

Methods: patients were selected from the Service of Endocrinology and Metabology (SEMPR) of the Federal University of Paraná, in Brazil, who had a diagnosis of hypoparathyroidism. A detailed chart review was performed in order to confirm etiology and evaluate the follow up of the laboratory exams. Serum FGF23 was measured using a commercially available two-site immunoassay for the FGF23

intact (Immunotopics, San Clemente, CA), in which the intra-assay coefficient of variation is 4.4% and inter-assay coefficient is 6.5%.

Results: Our study population comprises 55 patients, 50 diagnosed with hypoparathyroidism and 5 patients with pseudohypoparathyroidism (resistance to PTH). The main etiology was postoperative, 75% of patients. The laboratory parameters were: median serum calcium 7.9 ± 1.0 mg/dl; serum phosphorus 5.2 ± 1.3 mg/dl; 136.5 ± 102.5 mg 24-h urine calcium; 2.0 ± 1.7 mg urinary calcium per kilogram; Vitamin D 35.8 ± 28.1 ng/ml; eGFR 36.2 ± 94 mL/min; PTH 63.2 ± 5.7 pg/ml. The median FGF23 was 29.9 ± 93.8 pg/ml.

An inverse relationship between the levels of FGF23 and eGFR, lower glomerular filtration rate, higher the levels of FGF23 ($p < 0.05$).

In general, levels of FGF23 were less than 30 pg/ml in patients with primary hypoparathyroidism ($p: 0.002$) and greater than 30 pg/ml in the cases of postoperative hypoparathyroidism. Conclusion: The overall median FGF 23 of this study was low, suggesting that hyperphosphatemia of hypoparathyroidism does not stimulate FGF23. Patients with postoperative hypoparathyroidism had higher FGF23, lower phosphorus and PTH greater than the group's primary hypoparathyroidism, suggesting that even at low levels, PTH influences the increase in FGF23.

Impaired Trabecular Bone Score (TBS) in patients with primary hyperparathyroidism. Manuel Munoz-Torres*¹, Rossana Manzanares Cordova², Beatriz Garcia Fontana³, Antonia Garcia Martin⁴, Rebeca Reyes Garcia⁴, Rafael Nieto Serrano⁵, Sonia Morales Santana³, Fernando Escobar Jimenez⁴. ¹Hospital Universitario San Cecilio, Spain, ²Endocrinology Unit, Hospital Universitario San Cecilio, Spain, ³RETICEF, Hospital Universitario San Cecilio, Spain, ⁴Endocrinology Unit, Hospital Universitario San Cecilio, Spain, ⁵Nuclear Medicine Unit, Hospital Universitario San Cecilio, Spain

Patients with primary HPT exhibit increased bone fragility which is an indication for surgical treatment. The trabecular bone score (TBS) is a grey-level texture measurement based on the use of experimental variograms acquired during a dual-energy X-ray absorptiometry (DXA) of lumbar spine (LS). Several studies show that TBS can be an independent predictor of fragility fractures. However, the usefulness of this new technique in patients with PHPT is not well established. Our study was aimed to investigate TBS in patients with PHPT. Patients and methods: We studied 86 patients with PHPT (mean age 64.9 ± 9.9 years, 82% females, 85% postmenopausal. In all patients bone mineral density by DXA and TBS indices derived from LS DXA was assessed (TBS iNsiteU software). Results: TBS in PHPT was low (1.21 ± 0.13), representing abnormal trabecular microstructure (normal = 1.35). Males showed TBS values significantly lower than the women (1.15 ± 0.14 vs 1.23 ± 0.12 ; $p = 0.028$). PHPT patients with densitometric criteria of osteoporosis T score ($= 2.5$ SD) showed lower values of TBS (1.16 ± 0.13 vs 1.24 ± 0.13 ; $p = 0.019$). However, we found no significant correlation between the values of TBS and DXA. We did not find any correlation between values of TBS and PTH levels and bone turnover markers. Patients with symptomatic and asymptomatic PHPT showed similar values of TBS. We found significant differences when comparing postmenopausal women vs. premenopausal (1.22 ± 0.11 vs 1.30 ± 0.11 ; $p = 0.028$). Conclusion: TBS measurements show that PHPT patients exhibit a degraded trabecular microstructure. If this technique can identify patients with increased bone fragility should be investigated.

Protein Expressions of GABA_B receptor 1 and Vitamin D Receptor Are Decreased in Human Parathyroid Adenoma. A Ram Hong*¹, Jiyeon Lee², Jihyun Lee³, Young A Kim⁴, Hye Sook Min⁴, Jung Hee Kim², Chan Soo Shin², Sang Wan Kim². ¹Seoul National University Hospital, South Korea, ²Department of Internal Medicine, Seoul National University College of Medicine, South Korea, ³Department of Internal Medicine, Seoul National University College of Medicine, South Korea, ⁴Department of Pathology, Seoul National University College of Medicine, South Korea

Objective: We are to examine the protein expression of GABA_BR1 in parathyroid tissue in patients with parathyroid adenoma using tissue microarray. In addition, we are to evaluate the proteins expression of various factors involved in PTH secretion, i.e., FGFR, α -klotho, CaSR, GABA B R1, VDR, CYP24A1, and CYP27B1, and we are to analyze relationship between the proteins expression and biochemical parameters in patients with parathyroid adenoma.

Methods: We retrospectively included 66 patients who underwent parathyroidectomy for PHPT and 29 control patients with normal parathyroid in Seoul National University Hospital from January 2001 to December 2011. All patients diagnosed with PHPT had parathyroid adenomas. We examined the expression of FGFR, α -klotho, VDR, CaSR, GABA_BR1, CYP24A1, and CYP27B1 in parathyroid using immunohistochemistry.

Results: Nuclear and overall VDR expressions were significantly reduced in PHPT compared with the control group ($P < 0.001$ and $P = 0.006$, respectively). In PHPT

group, GABA_BR1 expression was significantly reduced ($P < 0.001$). There were no significant differences in expressions of FGFR, α -klotho (nuclear, cytoplasmic, and overall), CaSR, CYP24A1, and CYP27B1 between the PHPT and control group. Nuclear and overall VDR expression was not correlated with serum PTH in patients with PHPT, however, there was a significantly negative correlation between α -klotho expression and serum levels of PTH ($r = -0.461$, $P < 0.001$). Both serum calcium and phosphorus levels were not correlated with protein expressions of CaSR and GABA_BR1.

Conclusion: The protein expressions of GABA_BR1 as well as VDR were decreased in patients with parathyroid adenoma. This result suggests that hypercalcemia in patients with parathyroid adenoma can affect the expression of GABA_B receptor in parathyroid gland.

Recombinant Human Parathyroid Hormone (rhPTH [1-84]) Therapy in Hypoparathyroidism and Improvement in Quality of Life. Tamara Vokes*¹, Michael Mannstadt², Michael A. Levine³, Bart L. Clarke⁴, John P. Bilezikian⁵, Hjalmar Lagast⁶, Dolores M. Shoback⁷. ¹University of Chicago, USA, ²Massachusetts General Hospital & Harvard Medical School, Boston, MA, USA, ³Children's Hospital of Philadelphia, Philadelphia, PA, USA, ⁴Mayo Clinic Division of Endocrinology, Diabetes, Metabolism, & Nutrition, Rochester, MN, USA, ⁵College of Physicians & Surgeons, Columbia University, New York, NY, USA, ⁶NPS Pharmaceuticals, Inc., Bedminster, NJ, USA, ⁷SF Department of Veterans Affairs Medical Center, University of California, San Francisco, CA, USA

Many patients (pts) with hypoparathyroidism who are treated with calcium (Ca) and active vitamin D (Vit D) experience a reduced quality of life (QoL). Previous studies of the effects of parathyroid hormone (PTH) on QoL in hypoparathyroidism have yielded inconsistent results. We examined QoL in REPLACE, a randomized, double-blind, placebo (PBO)-controlled, multicenter international study to assess efficacy of rhPTH(1-84) in hypoparathyroidism. During the optimization period (2-16 wks), oral Ca and active Vit D doses were adjusted to achieve and maintain serum Ca level of 8.0-9.0 mg/dL for 2 wks. Pts were then randomized to receive daily subcutaneous injections of PBO or rhPTH(1-84) 50 μ g, which could be increased to 75 μ g and then to 100 μ g only during a 12-wk period according to a titration algorithm. The primary endpoint was the percentage of pts whose need for oral Ca and active Vit D decreased by $\geq 50\%$ at Wk 24 while maintaining serum Ca level at or above baseline. Pts completed a QoL questionnaire (SF-36) at randomization and at Wks 4, 12, and 24. Pre-specified analysis for this exploratory endpoint compared QoL scores between baseline and Wk 24 within each group, and between the groups at Wk 24.

A total of 124 pts were randomized to rhPTH(1-84) (n=84) and PBO (n=40), with 54.8% of rhPTH(1-84) and 2.5% of PBO pts achieving the primary endpoint ($P < 0.001$). The incidence of adverse events was similar between the groups. At 24 wks, there were no differences in serum Ca levels between the rhPTH(1-84) and PBO groups despite a significantly greater reduction from baseline in the number of Ca tablets (54% vs 3%) and active Vit D tablets (74% vs 36%) taken by the rhPTH(1-84) group. There were no changes in any QoL score within the PBO-treated group at Wk 24 compared with baseline; however, pts in the rhPTH(1-84)-treated group showed improved QoL scores in 6 of 10 domains: Role-Physical ($P = 0.033$), Bodily Pain ($P = 0.014$), General Health ($P = 0.002$), Vitality ($P = 0.001$), Mental Health ($P = 0.016$), and Physical Component Score ($P = 0.004$). A comparison between the rhPTH(1-84)-treated and PBO-treated groups showed numerically higher mean QoL scores in the rhPTH(1-84) vs PBO group at Wk 24, but the differences were small and not statistically significant.

This study suggests that rhPTH(1-84) therapy for hypoparathyroidism may improve QoL.

Surgery versus no Surgery: What works best for the kidneys in Primary Hyperparathyroidism? A retrospective study on a multi-ethnic patient population. Donovan Tay*¹, Joan Khoo², Manju Chandran³. ¹Singapore General Hospital, Singapore, ²Changi General Hospital, Singapore, ³Osteoporosis & Bone Metabolism Unit Department of Endocrinology Singapore General Hospital, Singapore

Introduction: Guidelines consistently list renal impairment as an indication for surgery in asymptomatic primary hyperparathyroidism. However, studies exploring whether parathyroidectomy is superior to medical therapy or simple surveillance with respect to long term renal function in patients with primary hyperparathyroidism are scanty and conflicting. We sought to determine if treatment modalities affect renal outcomes in a multi-ethnic South East Asian population of patients with primary hyperparathyroidism.

Method: 121 patients who presented with primary hyperparathyroidism and had follow up for up to 9 years at a large teaching hospital in Singapore were

respectively evaluated. Intervention was classified as surgical (parathyroidectomy), medical (treated with bisphosphonates or cinacalcet) or observation (observed without any treatment). One-way analysis of variance (ANOVA) was used for within group comparisons. In case of statistically significant difference in ANOVA, Bonferroni post hoc adjustment was used for multiple pairwise comparisons. One-way analysis of covariance (ANCOVA) was used to adjust within group comparisons for potential confounders. Statistical tests were 2 tailed and a P<.05 was considered as significant.

Results: The study population had 68.6% Chinese, 14.9% Malays, 9.1% Indians, 3.3% Eurasians and 4.1% others. Table 1 shows the baseline characteristics of the study group. Mean duration of follow was 2.4 ± 2.4 years. At last follow up, eGFR in the surgical group (80 ± 30 ml/min) was higher as compared to the medical (52 ± 32 ml/min) or observation group (48 ± 32 ml/min) (p<0.01). Compared to those in the medical or observation group, patients in the surgical group continued to have better eGFR at last follow up after adjustments for pre-intervention eGFR levels (p = 0.010). The between group interaction by treatment modality remained significant after adjusting for age, gender, ethnicity, presence of renal stones, serum corrected calcium, serum phosphate and 24hr urinary calcium excretion (p = 0.025).

Conclusion: Our study provides compelling evidence to support the premise that surgery for primary hyperparathyroidism may be better than a non-surgical approach with respect to long term renal function. Whether parathyroidectomy halts progression of renal impairment in patients with primary hyperparathyroidism and coexisting moderate to severe renal disease needs to be studied through prospective, randomized, controlled trials.

Table 1: Comparative baseline characteristics of the study groups. (Primary hyperparathyroidism identified using ICD-9-CM diagnosis coding)

| | Surgery (n = 34) | Medical (n = 42) | Observation (n = 45) | P value |

Vitamin D Deficiency and Insufficiency in Primary Hyperparathyroidism: Effects on the Volumetric BMD and Bone Strength at the Lumbar Spine. Marcella Walker¹, Elaine Cong¹, Melissa Sum^{*1}, Isra Saeed², James Lee¹, Anna Kepley¹, Chengchen Zhang¹, Thomas Lang², Shonni Silverberg¹. ¹Columbia University, USA, ²University of California at San Francisco, USA

Data regarding the skeletal effects of vitamin D (25OHD) deficiency and insufficiency in primary hyperparathyroidism (PHPT) are limited. We have shown that lower 25OHD in PHPT is associated with higher PTH levels, which we hypothesized might affect trabecular lumbar spine (LS) volumetric BMD (vBMD) and strength (VSTR) by central quantitative computed tomography (cQCT). Participants were mostly postmenopausal women (n=53; 84.9% women; mean ± SD age 62.3 ± 0.6yrs) and had mild PHPT (calcium 10.6 ± 0.6mg/dl, PTH 82 ± 49pg/ml, 25OHD 31 ± 11ng/ml). 25OHD deficiency (18.9% <20ng/ml, mean 14 ± 2ng/ml) and insufficiency (28.3% 25OHD 20-29ng/ml, 26 ± 2ng/ml) were common, but the majority were replete (52.8% 25OHD ≥30ng/ml, 40 ± 7ng/ml) and severe deficiency was uncommon (1.9% <10ng/ml). Those with lower 25OD (<20 vs. 20-29 vs. ≥30ng/ml) were younger (59.4 ± 12.4 vs. 58.0 ± 9.6 vs. 65.7 ± 8.6yrs, p=0.03) and less likely to be taking vitamin D supplements (20 vs. 73 vs. 86%, p<0.01) but did not differ by sex, race, ethnicity, height, weight, PHPT duration, history of osteoporosis, fragility fracture, nephrolithiasis or meeting 2008 surgical criteria. Those with lower 25OHD had higher PTH (140 ± 74 vs. 78 ± 30 vs. 64 ± 28pg/ml, p<0.0001) and lower PO4 (2.7 ± 0.4 vs. 3.0 ± 0.4 vs. 3.2 ± 0.4mg/dl, p=0.003) levels but serum and urine calcium and 1,25-dihydroxyvitamin D did not differ. GFR was worse in those with 25OHD ≥30ng/ml vs. other groups (p=0.02). DXA T-scores were normal (-1.0 ± 1.7) and did not differ by vitamin D status (-1.0 ± 1.8 vs. -1.3 ± 1.3 vs. -0.8 ± 1.8, p=0.71). Neither PTH nor 25OHD levels correlated with L1&L2 trabecular vBMD (25OHD: r=-0.07, p=0.60; PTH: r=-0.04, p=0.78) or VSTR (25OHD: r=-0.06, p=0.66; PTH: r=-0.05, p=0.71). Prior to adjusting for covariates, there were no differences in trabecular or intertrabecular vBMD or strength by vitamin D status (<20 vs. 20-29 vs. ≥30ng/ml). After adjusting for age, weight and GFR, L1&L2 trabecular vBMD (0.125 ± 0.040 vs. 0.090 ± 0.041g/cm³, p=0.03) and VSTR (0.214 ± 0.112 vs. 0.135 ± 0.84, p=0.04) were higher in those with 25OHD 20-29 vs. ≥30ng/ml. There were no differences vs. those

with 25OHD <20ng/ml. Results were similar in women only. Comparing those with 25OHD <20 vs. ≥20 and <30 vs. ≥30ng/ml, there were no differences before or after adjusting for covariates. While low 25OHD levels are associated with higher PTH levels in PHPT, neither 25OHD deficiency or insufficiency appeared to adversely affect vBMD or VSTR in a cohort in whom 25OD deficiency was uncommon.

3D Atlas-based Modeling of the Spine using MDCT images for Detecting Local Density Variations in an Age-matched Cohort. Alexander Valentinitich^{*1}, Stefano Trebeschi¹, Eva Alarcón¹, Thomas Baum¹, Cristian Lorenz², Jan S. Bauer¹. ¹Klinikum rechts der Isar, Technische Universität München, Germany, ²Philips Research Hamburg, Germany

DEXA is considered the standard assessment of osteoporosis, providing a global T-score that poorly correlates with fracture risk and neglects local variations in bone density. As these local variations in density of each individual vertebra could provide more insights for fracture prediction, we present a 3D atlas of the complete spine, based on voxel density (BMD) of each individual vertebral body. The purpose of this study was to evaluate local variations of normal, age-related differences among different age groups using this 3D atlas of the complete spine. Non-contrast MDCT scans of 18 patients under the age of 40 (28yrs) without spinal pathology were used for modeling the atlas. Each vertebra ranging from T1-L5 was used individually for calculations. For comparison, we defined 4 cohorts, of 10 patients each: forties (41-50yrs), fifties (51-60yrs), sixties (61-70yrs) and seventies (71-80yrs). We used voxel-based morphometry (VBM), which allows a voxel-wise comparison of the local BMD among each vertebra and groups. The procedure included an automatic spine segmentation and detection, non-rigid registration for spatial normalized vertebral bodies and statistical parametric mapping using a standard t-test, which was corrected for multiple comparisons by the random field method. We additionally calculated a voxel-based T-score map for each of the groups to highlight local density differences in comparison to the young population. As expected, highest global T-scores were found in the forties cohort (-0.15 ± 0.16), followed by the fifties (-1.25 ± 0.27), sixties (-2.01 ± 0.37) and seventies (-2.51 ± 0.37). All global comparisons showed statistical significance (p<0.001). VBM showed no significantly different local BMD areas in the forties cohort compared to the young population. In the fifties cohort, L4 and L5 started to highlight small local changes among the BMD distribution within the vertebra. The affected (significant) lumbar regions had a fraction 4.0% and 5.4% respectively, which grew 2-5 fold in the fifties cohort. Regions in T9-L5 also had significantly different fractions, ranging 3.6-25.2%. In the seventies cohort almost all vertebrae had significant differences in the local BMD distributions in 50% of all voxels, which was more severe around T6 and L1. We demonstrated that a local T-score of the spine, assessed by a 3D VBM-based atlas, shows local variations in an aging healthy population that correspond to known areas of increased fracture incidence.

Characterization of Collagen Fiber Orientation in Bone with Chronic Kidney Disease Using FTIR Imaging. Tepei Ito^{*1}, Kyosuke Kanazawa², Yuva Kanehira¹, Hiroimi Kimura-Suda¹. ¹Chitose Institute of Science & Technology, Japan, ²Chitose Institute of Science & Technology, Japan

Secondary hyperparathyroidism (2HPT) due to chronic kidney disease (CKD) decreases both the bone mineral density (BMD) and bone quality leading to increase a risk of bone fractures. BMD is a relatively good barometer of bone strength and reflects the risk of bone fracture; however, it is difficult to identify which factors associated with bone quality affect bone fragility. In our previous works, we characterized bone quality in the femurs in rats with primary or secondary osteoporosis using Fourier transform infrared (FTIR) imaging and demonstrated that collagen fiber orientation was a good marker of bone strength. In this work, the mineral-to-collagen matrix ratio, carbonate-to-phosphate ratio, crystallinity, collagen maturity, and collagen fiber orientation in the femurs of rats with 2HPT due to CKD were characterized by FTIR imaging. Eleven-week-old male Sprague-Dawley rats underwent 5/6 subtotal nephrectomy to replicate 2HPT due to CKD or sham surgery to prepare controls and were thereafter kept for 16 weeks. After sacrifice, the femurs were removed, embedded in PMMA, and were sliced into 3- μ m longitudinal sections by a microtome in preparation for FTIR imaging. Collagen fiber orientation was assessed with IR dichroism images of the amide I band, and the other bone quality parameters were calculated based on FTIR spectra. Both the thickness and the amount of the trabecular bone were decreased in the CKD rat femurs, and these bone conditions are typical of secondary osteoporosis due to 2HPT. The carbonate-to-phosphate ratio was reduced in both the cortical and trabecular bone of the CKD rat femurs; however, there was no significant difference in the mineral-to-collagen matrix ratio, crystallinity or collagen maturity between the sham and CKD rats. Collagen fibers in the cortical bone in the sham and CKD rats were aligned longitudinally, and the degree of collagen fiber orientation was lower in metaphysis than in the diaphysis. The carbonate-to-phosphate ratio and mineral-to-collagen matrix ratio were also lower in metaphysis than in the diaphysis. Bone quality in cases of 2HPT due to CKD can be characterized as having reduced trabecular bone thickness and decrease the amount of trabecular bone, reduced carbonate-to-phosphate ratio in both the cortical and trabecular bone, and a lower degree of collagen fiber orientation, carbonate-to-phosphate ratio and mineral-to-collagen matrix ratio in metaphysis than in the diaphysis in the cortical bone.

Cortical Bone Thickness Measurements from CT in the Presence of Metalwork. Tristan Whitmarsh, Graham Treece^{*}, Andrew Gee, Kenneth Poole. University of Cambridge, United Kingdom

Purpose: Measuring bone thickness can be an important tool in assessing fracture healing and investigating other bony pathological processes after hip replacement surgery. Measurements from CT near metallic implants or fixation devices are difficult to obtain due to the high attenuation coefficient of metal. This study therefore proposes and evaluates a method for the measurement of cortical bone thickness in the presence of metal components.

Methods: Four cases with distinct metallic implants at the proximal femur were examined. These include a post-operative CT scan of a hemi-arthroplasty, a dynamic hip screw fixation, a bipolar hemi-arthroplasty and a fixation with cannulated screws. All CT scans were processed using metal artefact removal software (Boas, Radiology 2011). A previously validated technique based on the fitting of a cortical model was used to measure the cortical thickness over selected regions, which results in a colour coded cortical thickness map (Treece, Med Image Anal 2015). This method was adapted to also model metal structures when required. The measurements were compared with the corresponding sections on the un-fractured contralateral bone segment whereby point-to-point correspondences were obtained through the registration of the two cortical maps.

Results: For the proximal femoral sections of the aforementioned cases, the cortical thickness was measured with a mean absolute difference of 0.57, 0.37, 0.44 and 0.52 mm with respect to the contralateral femur. The hemi-pelvis produced thickness differences of 0.47, 0.49, 0.51 and 0.46 mm respectively. There was no noticeable structural over- or under-estimation of the thickness measurements. Cortical thickness maps indicate a reduction of noise by applying metal artefact removal software and more valid cortical measurements with a greater accuracy when modelling metal structures.

Conclusion: A method is proposed for the measurement of cortical bone thickness in the presence of metalwork, with results indicating sub-millimetre accuracy. This new technique might be helpful in assessing fracture healing near implants, and improve the evaluation of periprosthetic bone after hip replacement surgery.

Bone quality of ovariectomized rats after combination therapy with bisphosphonate and eldcalcitol. Hiroimi Kimura-Suda^{*1}, Tepei Ito¹, Hirohata Wagatsuma², Tetsuo Yano², Daisuke Inoue³. ¹Chitose Institute of Science & Technology, Japan, ²Ajinomoto Pharmaceuticals Co., Ltd., Japan, ³Teikyo University School of Medicine, Japan

Both bisphosphonate (BIS) and eldcalcitol (ELD; a vitamin D analog) act against bone loss due to osteoporosis. We have demonstrated that combination therapy with BIS and ELD improves bone mineral density (BMD) and bone structure in ovariectomized (OVX) rats, and that three kinds of BIS, risendronate (RIS), alendronate (ALN) and minodronate (MIN), have comparable effects when used in combination with ELD. In this work, we characterized the bone quality of the femur and vertebral body in OVX rats after combination therapy with BIS and ELD using FTIR imaging. Thirteen-week-old female Sprague-Dawley rats underwent ovariectomy (OVX) or sham operation (sham). The OVX group was divided into 8 subgroups treated with Vehicle, RIS (0.7 μ g/kg/day s.c.), ALN (1.4 μ g/kg/day s.c.), MIN (0.14 μ g/kg/day s.c.), ELD (0.04 μ g/kg/day p.o.), RIS+ELD, ALN+ELD or MIN+ELD. The various forms of BIS and ELD were administered to rats five times a week for 16 weeks. The rats were sacrificed at 29 weeks of age, and the femurs and vertebrae were then removed and embedded in PMMA. Sagittal sections (3 μ m) were prepared for FTIR imaging. The mineral-to-collagen matrix ratio (the degree of calcification), carbonate-to-phosphate ratio, crystallinity, and collagen maturity in the bone were assessed based on the FTIR images. The degree of calcification was reduced in both trabecular and cortical bone of the femurs as well as in the trabecular bone of the vertebral body in the vehicle group, but was improved in all the drug-treated subgroups. The degree of calcification in trabecular bone in all BIS+ELD subgroups was higher than that of the BIS or ELD subgroups. However, the increase in calcification in cortical bone of the femur was not reflected in improved mechanical properties in the three-point bending testing of the femur. Comparisons among the three forms of BIS revealed that, RIS and MIN had almost identical effects on calcification, whereas ALN was less effective than RIS and MIN. The carbonate-to-phosphate ratio in the cortical bone of the vertebral body was increased in the vehicle subgroup and was improved in all the drug-treated subgroups. However, no significant differences from the vehicle subgroup in terms of crystallinity or collagen maturity were observed for the rats undergoing combination therapy. In conclusion, combination therapy with BIS and ELD further increased calcification of the trabecular bone in OVX rats in comparison to single treatment regimens.

Development of a strongly simplified method for determination of bone quality within joint near regions of long bones. *Volker Kuhn*¹, *Spaska Kovacheva*², *Nikola Ivanovic*¹, *Wolfgang Recheis*¹. ¹Medical University Innsbruck, Austria, ²University of Applied Sciences Wiener Neustadt, Austria

According to World Health Organization (WHO) osteoporosis is defined as a disease characterized by lessening the strength of bones, especially trabecular structures and increased proclivity of fractures. There is variety of reasons for osteoporosis - hormonal, medicinal and gastroenterological. The trend shows high morbidity and mortality. It affects mostly elderly women. The probability of a fracture in Caucasian man is up to 20%, in woman - twice as much. Within Austria/EU 700.000 people, which is 45% of all women over 50, suffer from severe osteoporosis. The main diagnostic methods - Dual Energy X-ray Absorptiometry (DXA) and Quantitative Computed Tomography (QCT) have different limitations.

The purpose of this research is the development of strongly simplified method to determine bone quality within joint near regions of long bones. This method is based on analysis of CT datasets with the image processing software ImageJ, ITK Snap and VolView and setting a relation between non-bone and bone volumes. The basic achievement of this study are several equations which after setting correct input data calculates [non-bone/bone] volume ratio and [non-bone/total] volume ratio.

This project includes various types of statistical analyzes which prove that these ratios are influenced by many factors including age and gender, associate with the disease of osteoporosis. This research should be a starting point of various studies which analyze other factors related to the disease. Patient's health history may be essential in order to improve this method and might give an opportunity for an easy and quick diagnosis of osteoporosis.

Effect of Teriparatide Treatment on Trabecular Microstructure in Postmenopausal Women with Osteoporosis Assessed with High Resolution Quantitative Computed Tomography. *Daniel J Blackwell*¹, *Margaret A Paggiosi*¹, *Eugene V McCloskey*¹, *Nicola FA Peel*², *Jennifer S Walsh*¹, *Richard Eastell*¹, *Lang Yang*^{*1}. ¹University of Sheffield, United Kingdom, ²Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom

Teriparatide (TPTD) treatment given for one year has been shown to significantly improve the microstructural integrity of the vertebral trabecular bone assessed with high resolution quantitative computed tomography (HRQCT) [1]. Since the treatment is now licensed for 2 years, the aim of this study was to develop and apply a HRQCT based structural analysis tool, to analyse in vivo, the microstructural changes associated with TPTD treatment over 2 years of treatment. In an open-label single-centre study, 20 postmenopausal women (age 64.4 ± 15.4 years) with osteoporosis (BMD T score < -2.5 at spine or hip) were treated with TPTD (FORSTEO, 20 micrograms daily) for 104 weeks. HRQCT scans of vertebra T12 (resolution $0.188 \times 0.188 \times 0.625$ mm³) were acquired at baseline, 26, 52 and 104 weeks. The Mindways density calibration phantom was used to calibrate HRQCT scans to volumetric bone mineral density. The vertebral body was segmented semi-automatically slice by slice and rotated to standardise the orientation between each scan. The endplates and 1.5 mm thick cortex were excluded, leaving only trabecular volume (Figure 1). The vertebrae were matched slice by slice, allowing the analysis of a constant region from baseline to 104 weeks. A threshold of 100 and 200 mg/ml was used to separate bone from marrow for bone density and structure analysis, respectively. Microstructural variables were calculated based on a 3D adaptation of the parallel plate model [2] and the mean intercept length method. Variables studied

included apparent trabecular bone density (appTbD), bone volume fraction (appBV/TV), trabecular number (appTbN), thickness (appTbTh) and separation (appTbSp). Intra-operator precision was assessed by analysing baseline scans 3 times. Effects of treatment was examined by comparing group means at follow up against baseline. The intra-operator %CV ranged from 0.9 to 3.4% (Table 1). By the end of 104 weeks therapy, TPTD treatment resulted in significant increases in mean appBV/TV, appTb.N and appTb.Th with a non-significant trend to reduce appTbSp (Table 1). In conclusion, effects of TPTD treatment on the T12 trabecular microstructure can be measured by HRQCT. [1] Graeff et al (2007) J Bone Miner Res 22: 1426-1433. [2] Parfitt et al (1983) J Clin Invest 72: 1396-1409.

Table 1. Mean (SD) of the apparent trabecular microstructural variables

| | Baseline | Week 26 | Week 52 | Week 104 | %CV |
|----------------|-------------|-------------|-------------|--------------|-----|
| appTbD (mg/ml) | 180 (13) | 171 (20) | 179 (16) | 190 (22) | 0.9 |
| appBV/TV (%) | 15 (7) | 13 (7) | 20 (9) | 24 (12)* | 3.4 |
| appTbN (1/mm) | 2.3 (0.7) | 2.09 (0.80) | 2.69 (0.90) | 3.03 (0.90)* | 1.8 |
| appTbTh (mm) | 0.25 (0.03) | 0.25 (0.03) | 0.28 (0.50) | 0.31 (0.07)* | 1.8 |
| appTbSp (mm) | 1.65 (0.76) | 2.07 (1.27) | 1.51 (1.07) | 1.16 (0.64) | 2.5 |

Effects of Disuse and Estrogen Deficiency on the Bone Microarchitecture and Biomechanical Properties. *Melise Peres Ueno*^{*}, *Mário Jefferson Louzada*. Unesp, Brazil

Our goal was to determine whether the different causes of osteopenia have the same effects on trabecular and cortical bone structure and on the biomechanical parameters. For this study, 30 female Wistar rats of 19 weeks old, were distributed on the groups: control (CON), hindlimb unloading (HLU) and ovariectomized (OVX). The unloading of the hindlimbs was conducted by tail suspension for 21 days at 24 weeks of age and euthanasia was performed at 27 weeks of age. Femur and tibia were removed to determine the microstructure of trabecular and cortical bone by micro-computed tomography and also the mechanical properties by 3 points bending tests for the femoral and tibial diaphysis, and mechanical testing to failure to the neck of the femur. After OVX, there was a deterioration in the microstructure of the trabecular bone in the femoral neck, with a reduction in bone volume ($p = 0.034$) and an increase in porosity ($p = 0.048$) compared to CON (Table 1, Figure 1). In tibia OVX showed greater bone changes with a change in bone volume, trabecular number, connectivity density, struture model index and porosity (all $p < 0.05$) compared to group CON, and an increase in trabecular spacing compared to HLU group ($p = 0.042$). In the cortical bone of the femur diaphysis, the disuse showed a greater change in microstructure with high total porosity ($p = 0.000$). In the tibial diaphysis, there was an increase in the total area and medullary area in the OVX group compared to the HLU group ($p = 0.0137$ and $p = 0.0194$, respectively). The three point bending test of the femur diaphysis showed a lower maximum force in HLU group compared to the OVX group ($p = 0.036$) (Table 2), the absorbed energy was higher in OVX ($p = 0.001$). However, in the diaphysis of the tibia, biomechanical parameters analyzed did not obtain statistically significant differences between groups. Femoral neck, HLU showed higher stiffness compared to OVX ($p = 0.014$), and the absorbed energy was higher in OVX ($p = 0.016$). Animals suspended by the tail had the most affected femurs, with a further deterioration in the cortical region leading to a decrease in mechanical properties. Already estrogen deficiency showed higher trabecular deterioration in the tibia without mechanical properties change. Taken together, the results suggest that different stimuli, either mechanical or hormones may affect different bones in different site, besides presenting different biomechanical responses.

Fibroin particle supported cationic lipid-layers (Fibroplex) as a high efficient intracellular protein delivery system for osteoinductive treatment. Woo Jin Kim*¹, WON-JOON YOON², HYUN-MO RYOO². ¹Seoul National University, South Korea, ²Seoul National University school of dentistry, South Korea

An average cell contains thousands of proteins that participate in normal cellular functions, and most diseases are somehow related to the malfunctioning of one or more of these proteins. Protein therapy, which delivers proteins into the cell to replace the dysfunctional protein, is considered the most direct and safe approach for treating disease like bone tissue regenerations which required long-term treatment. However, the effectiveness of this method has been limited by its low delivery efficiency and poor stability against proteases in the cell, which digest or change 3D-structure of the protein. Here we report Fibroin particle supported cationic lipid-layers (Fibroplex) that synergistically combine intracellular delivery ability of cationic liposomes and bio-mechanical advantages of natural polymer particles. Fibroplex was able to load a large amount of target proteins without chemical modifications and showed stable and proper releasing profiles for more than 90 days with sheltered target proteins from environment factors such as pH, temp changes or serum factors. Furthermore, Fibroplex achieved cytosolic delivery in several cell lines (including primary MEF cells and preosteoblasts) with high efficiency represented a 32-folds improvement over comparable delivery platforms remained protein stability over 4 weeks in vitro/vivo and observed only a relatively small amount of material remained trapped inside endosome. Fibroplex mediated delivery did not noticeably affect cell viability or immune response. Also, multiple molecules could be delivered simultaneously. The scope of application of fibroplex was extended to osteogenesis control by direct introduce intracellular regulatory factor Pin1, a cis-trans isomerase which recently reported playing critical role in osteogenesis via regulation of intracellular Runx2 protein stability. Fibroplex mediated Pin1 protein delivery enable to promoted differentiation of Pin1 KO MEF driven into osteogenic lineage caused by maintained proper protein concentration within the cell for a long period, suggesting potential therapeutic strategy for bone tissue regenerative treatment.

From material to structural properties. Density, mass and size. Arne Hoiseth*¹, Knut Strømsoe². ¹Univeristy of Oslo, Akershus University Hospital, Norway, ²University of Oslo, Norway

Bone parameters were assessed by computed tomography (CT) in patients having had a proximal femoral fracture and in controls. By employing a semiautomatic approach, CT densities were used to differentiate cortical (CT values >200) from cancellous bone (CT values 60-199). The amount of cortical, cancellous and total calcified bone (g) and area (cm) were assessed in CT slices in the middle of lumbar vertebral bodies, at right angle to the femoral necks, at cross section through the trochanteric regions and the femoral condyles. Bone density (g/cm³) was assessed in cortical bone only. In the femoral necks the mechanical parameters compressive and bending strength and buckling ratio were calculated. For buckling ratios mean cortical thickness, area of cortex and calcium mass in the cortex were employed. Morphological parameters were measured manually in the necks (diameters, cortical thickness and hip axis length). 95% confidence intervals were used for testing statistical significance. We found statistically significant gender differences for all mass and area parameters and for morphological parameters except for cortical thickness. The gender differences were found for all cases combined and for separate fracture and control cases. For some parameters there were no difference between non-fractured females and fractured men. There were statistically significant differences between fractured and non-fractured cases for all cortical and integrated cortical/cancellous area and bone mass parameters, but not for morphological parameters, nor for any of the density parameters. Of the biomechanical parameters only buckling ratios, using cortical area and mass for cortical thickness, significantly differentiated between fractured non-fractured cases. Importantly, cortical densities did not differentiate between genders or between fractured and non-fractured cases. Body weight was associated to area and mass parameters and to morphological parameters, except for cortical thickness. After adjusting for weight by calculating standardized residuals, differences between genders as well as between fractured cases and controls became less, with some loss of statistical significance. Our findings suggest that, as a structural parameter, the amount of calcified bone, particularly in the cortex, is important for fracture risk prediction. Material properties, such as cortical density and porosity and trabecular bone index are essential for appreciation of bone biology.

Improving Cortical Bone Measurements through the Inclusion of an Endocortical Parameter. Rose Pearson*¹, Graham Treece*². ¹Cambridge University PhD student, United Kingdom, ²University of Cambridge, United Kingdom

Introduction: recent advances in cortical bone measurement using model based approaches have allowed the evaluation of bone strength determinates from QCT scans in studies assessing fracture risk (Poole PLoS1 12) and osteoporosis treatments (Damm ACR 14, Allison JBMR 15). All techniques capable of measuring cortical bone morphology are limited by their inability to distinguish between the trabecularised cortical bone and the endocortical extremity of the medullary cavity (Zebaze 15). To address this weakness, we propose a new model of cortical bone that incorporates an endocortical measure.

Methods: the quality of a new 'ramp' model was investigated through direct comparison with a previously validated 'rectangular' model (Treece MedIA 15). In both cases the density variation was modelled perpendicular to the cortex; the model parameters were optimised to provide the best fit to the underlying data. In contrast to the rectangular model, the ramp model includes a gradual linear transition across the endocortical edge as illustrated in Fig. 1. Both models were fit to QCT data and compared with the equivalent profile in an HR-pQCT scan. Spatial alignment was achieved by registering the same periosteal surface to both scans. Calibration between the QCT Hounsfield units (HU) and the HR-pQCT HU was achieved with a quadratic calibration curve. The evaluation used data from 70 cadaveric femurs, 18 female and 17 male with a mean age of 77, scanned using both QCT and HR-pQCT (Dall'Ara Bone 13). Measurements were made at approximately 10,000 sites per femur.

Results: the stability and quality-of-fit of each model was assessed. In each case the comparisons were grouped into thickness ranges measured over HR-pQCT data using the Full Width Half Max technique, see Table 1. The model stabilities are comparable, with each producing a valid result at more than 98% of measurement sites. The quality-of-fit of each model was assessed using the root mean square (RMS) error between the model and the corresponding HR-pQCT profiles. The ramp model provided a highly significant reduction in the RMS error across each thickness grouping as shown in Table 1.

Conclusions: the ramp model results in a better fit to the cortical bone in HR-pQCT; the physical meaning of the additional endocortical measure merits more investigation. This measure has the potential to disentangle the effects of endocortical trabecularisation and intracortical remodelling from both cortical and trabecular bone.

Table 1: The stability and RMS errors (Mean \pm SD) for the ramp and rectangular models.

| Cortical Thickness: | < 1 mm | 1 to 3 mm | > 3 mm |
|---|--------------------|--------------------|---------------------|
| Rectangular Model Stability (%)* | 99.07 \pm 0.01 | 99.36 \pm 0.01 | 98.52 \pm 0.01 |
| Ramp Model Stability (%)* | 99.09 \pm 0.01 | 99.34 \pm 0.01 | 98.59 \pm 0.01 |
| Rectangular RMS Error (QCT HU) [†] | 263.22 \pm 75.91 | 372.87 \pm 99.45 | 398.61 \pm 112.89 |

Investigation of the Effect of Fluoride Ions on the Molecular Interaction between Bone-minerals and Non-collagenous Proteins using Single Molecule Force Spectroscopy. Soma Biswas*¹, Georg Fantner*². ¹École Polytechnique Fédérale de Lausanne (EPFL), Switzerland, ²EPFL, Switzerland

The key to understanding the remarkable mechanical toughness of bone is to explore the interfacial molecular interactions between the organic and inorganic components of bone. Some non-collagenous proteins (NCPs) in bone can act as molecular shock absorbers, dissipating large amounts of energy and preventing micro-crack formation. The adhesion of the NCP molecules to the inorganic components is essential for this mechanism to function properly. It is as yet unclear how the chemical composition of the mineral affects this molecular adhesion. Related studies have also reported that Fluoride (F-) treatment of bone resulted in a disturbance of the normal protein/mineral interaction (mostly visible at the nanometer level), which might further lead to a reduction in material quality. Given this, the effect of F- on the interaction between organic and inorganic matrix of bone needs to be studied further.

We therefore aim to elucidate the molecular interactive forces and strengths between bone minerals and NCPs, both in the presence and absence of F- ions, by utilizing atomic force microscope (AFM) analysis between synthetic hydroxyapatite (HA) and adsorbed Osteopontin molecules. AFM-based single molecule force spectroscopy has become a powerful tool to study the rupture of molecular bonds, unfolding of proteins and nucleic acids; because of its very high force sensitivity in the order of piconewton. We observed that the adhesion force and energy increased significantly while taking the pulling curves on a layer of Osteopontin deposited on HA surface instead of mica, which was used before as a crude model for bone mineral. We further found that the interaction between HA and Osteopontin did not change while replacing the monovalent ions (Na+) containing buffer with the bivalent ions (Ca2+) containing buffer solution. Finally, we show that the presence of F- ions change the molecular interaction between the synthetic HA and Osteopontin by pretreating the HA with NaF solution.

We believe that the above results will contribute towards the knowledge base for treating bone related diseases by providing quantitative information that is necessary to properly understand and model the fracture toughness of bone.

Mechanical and biochemical assessment of bone quality in men with type 2 diabetes. Heather Hunt*¹, Stephen Warner*², Ashley Torres¹, Jonathan Jo², Joseph Lane², Christopher Hernandez¹, Eve Donnelly. ¹Cornell University, USA, ²Hospital for Special Surgery, USA

Patients with type 2 diabetes mellitus (T2DM) have an increased risk of fracture, despite having normal or above average bone mineral densities (BMD). This suggests that the T2DM disease state affects the quality of bone, independently of variations in the quantity of bone. One proposed mechanism for the altered bone quality in T2DM is the posttranslational modifications of collagen that take place in the presence of

sugars and culminate in the formation of advanced glycation endproducts (AGEs). Our objective was to compare the mechanical and biochemical properties of bone from T2DM and non-DM patients.

Specimens were retrieved from the femoral necks of men undergoing total hip arthroplasties. Pre-operative serum glycated hemoglobin (HbA1c) was measured to assess glycemic control (Table 1). Patients with an HbA1c ≥ 6 and a previous T2DM diagnosis were allocated to the T2DM group (n=13), and patients with an HbA1c < 6 and no T2DM diagnosis were designated as non-T2DM controls (n=13). Cancellous cores were retrieved and analyzed with micro CT to determine morphological parameters. Ten age-matched specimens (n=5 T2DM, n=5 non-DM) were designated for mechanical testing and tested in compression to 3% strain to assess mechanical properties. Sixteen age-matched specimens (n=8 T2DM, n=8 non-DM) were designated for biochemical analyses. A fluorescence assay was used to determine AGE concentration.

Study groups were similar in BMI and bone volume fraction (BV/TV) (Table 1). As expected, HbA1c levels were 24% greater in the T2DM cohort vs the non-DM cohort ($p < 0.001$, Table 1). Tissue from T2DM patients compared to non-DM controls did not differ in apparent elastic modulus, apparent elastic modulus normalized by BV/TV, yield strain, or yield stress. Also, no correlations were found between HbA1c and these mechanical properties. For the biochemical analysis, AGEs in T2DM patients were 19% greater compared to those in non-DM patients ($p > 0.05$).

Bone tissue AGEs correlated positively with HbA1c for T2DM patients ($R^2 = 0.83$, $p = 0.001$), but not for non-DM patients ($R^2 = 0.22$, $p > 0.05$) (Figure 1) suggesting a relationship between glycemic control and bone tissue AGEs in T2DM. Direct assessment of mechanical properties and AGEs within the same specimens is required to discern the functional relationships among glycemic control, AGE accumulation, and mechanical properties.

| Characteristic | Non-DM (n=13) | T2DM (n=13) | % Difference vs non-DM | p |
|--|-------------------|-------------------|------------------------|--------|
| Age (years) | 63.2 \pm 2.9 | 68.3 \pm 3.3 | 8 | 0.498 |
| Mechanical Testing Cohort (n=5/group) | 61.8 \pm 4.4 | 62.8 \pm 5.5 | 2 | 0.896 |

Microstructural and Strength Changes in Trabecular Bone in Patients with Type 2 Diabetes Mellitus. Merce Giner^{*1}, M Jose Montoya², Cristina Miranda³, M Angeles Vazquez², J Ramon Caiero⁴, David Guede⁵, Ramon Perez-Canó⁶. ¹Bone Metabolism Unit, "Virgen Macarena" University Hospital, Spain, ²University of Seville, Spain, ³Bone Metabolism Unit, Department of Internal Medicine, "Virgen Macarena" University Hospital, Spain, ⁴Department of Orthopaedic Surgery, Complejo Hospitalario Universitario de Santiago de Compostela, Spain, ⁵Trabeculae, Parque Tecnológico de Galicia, 32900 San Cibrao das Viñas, Spain, ⁶Bone Metabolism Unit, Department of Internal Medicine, "Virgen Macarena" University Hospital university os Seville, Spain

Type 2 Diabetes Mellitus (T2DM) is one of the most common chronic diseases worldwide. Bone is one of the many organs affected by T2DM, and T2DM is associated with an increased risk of osteoporosis and fragility fractures.

This study analyses trabecular microstructural and bone material strength (BMS), markers of bone turnover (BTM) and bone mineral density (BMD) in patients with T2DM with or without recent fragility fractures.

Subjects and Methods: We recruited 23 patients, aged 65-80 years: 5 patients with osteoporotic hip fracture without T2DM (OP); 7 patients with osteoporotic hip fracture with T2DM (OP-T2DM); 6 patients with hip osteoarthritis without T2DM (OA) or osteoporotic fractures during their lifetime; and 5 patients with hip osteoarthritis and T2DM (OA-T2DM). We measured serum levels of β -CrossLaps, aminoterminal propeptide of type I procollagen (PINP), parathyroid hormone (PTH) and 25-hydroxyvitamin D (25(OH)D). We also tested BMD (by dual-energy-X-ray absorptiometry), microstructural and bone material strength from femoral heads by micro-CT. We estimated the 10-year risk of major osteoporotic and hip fracture, using the FRAX[®] tool calibrated for Spain. Variables were compared using the Student's *t* test or chi-square test, depending on the type and distribution. Correlations were examined using the Spearman correlation. All hypotheses were two-tailed. *p* value < 0.05 was considered statistically significant (IBM SPSS Statistics 22.0).

Results: We found OP and OP-T2DM patients had lower BMD values at the femoral neck and total hip than the OA and OA-T2D groups. Microstructural and BMS parameters confirm a worse quality and lower strength of the trabecular bone in T2DM patients (OA-T2DM and OP-T2DM) and OP compared with OA patients. β -CrossLaps and PINP were lower in OA-T2DM patients than in the other groups. The probability of major and hip fracture (FRAX) were higher in OP and OP-T2D patients than in OA patients with or without DM ($p < 0.006$). However, there were not differences in FRAX 10-year risk of major and hip fracture between OP and OP-T2DM nor OA and OA-T2DM.

Conclusion: Our results show the negative effect of T2DM on trabecular bone structure and mechanical properties. These results emphasize the importance of evaluating diabetic bones using not only bone markers and bone mass, but also bone quality parameters.

Therefore, diabetes should be included as a risk factor for osteoporotic fracture in daily clinical practice and in the FRAX tool.

SU0034

Mineral and collagen maturity in a polygenetic murine model of type 2 diabetes point to complex effects of sustained hyperglycemia on bone tissue composition. David Diaz^{*1}, Michelle Chin¹, Dan Weinreb¹, Tarryn Tertulien¹, Ida Adjivon¹, Karen King², Eve Donnelly¹. ¹Cornell University, USA, ²University of Colorado School of Medicine, USA

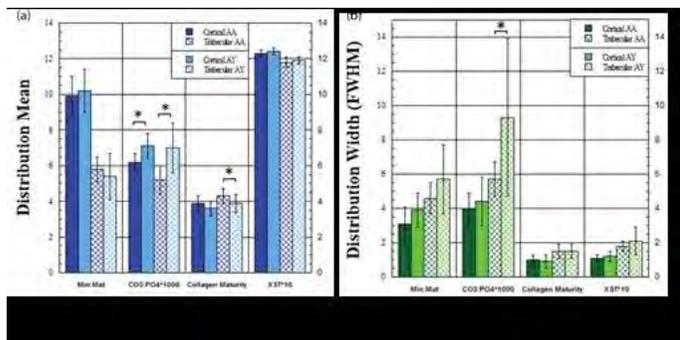

Type 2 diabetes mellitus (T2DM) increases fracture risk independently of bone mineral density. This suggests that hyperglycemia contributes to bone tissue embrittlement. However, the effects of T2DM on bone matrix properties are incompletely understood. The objective of this work is to compare bone tissue compositional properties between T2DM mice and their non-DM siblings.

With IACUC approval, proximal femora were collected after euthanasia from 20-week-old T2DM KKAy/KKAA (Ay, n=11) and non-DM KKAy/KKAA (AA, n=8) male mice. Fourier transform infrared imaging (FTIRI) was used to characterize the pixel distribution mean and full width at half maximum for 4 parameters per image: mineral:matrix ratio, carbonate:phosphate ratio (CO₃:PO₄), collagen maturity, and mineral crystallinity.

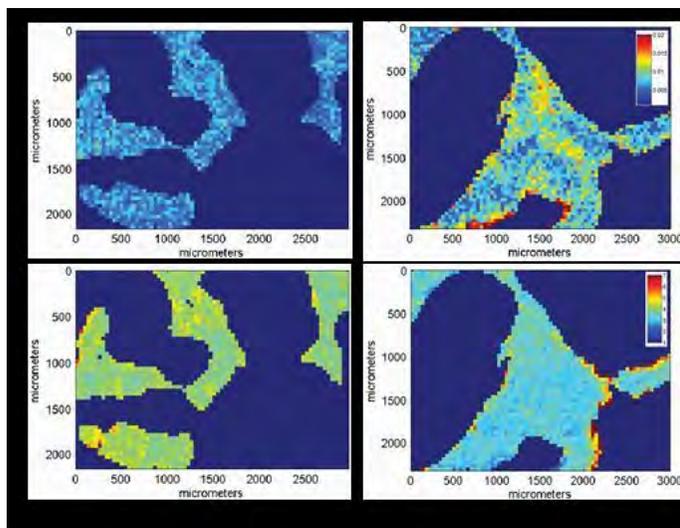

At euthanasia, T2DM mice were 8% heavier (Ay: 40 \pm 2.3 g vs. AA: 37 \pm 1.3 g, $p = 0.005$) and had 15% higher blood glucose levels than non-DM controls (Ay: 415 \pm 79 mg/dl vs. AA: 360 \pm 106 mg/dL, $p > 0.05$). The mean CO₃:PO₄ was 14% greater in T2DM cortical bone (Ay: 7.1 vs. AA: 6.2, $p = 0.011$) and 34% greater in T2DM trabecular bone (Ay: 7.0 vs. AA: 5.2, $p = 0.006$) (Fig. 1a, Fig. 2). Mean collagen maturity was 11% lower in T2DM trabecular bone than in non-DM bone (Ay: 3.9 vs. AA: 4.3, $p = 0.038$) (Fig. 1a, Fig. 2). The distribution of the CO₃:PO₄ ratio was 61% wider in T2DM trabecular bone than in non-DM bone (Ay: 9.3 vs. AA: 5.7, $p = 0.052$) (Fig. 1b).

One limitation of the study is that only end-point glucose levels were measured. Blood glucose levels in mice vary over time, and biweekly measurements would have given a clearer picture of the DM state. Because Ay male mice attain hyperglycemia

(glucose > 300 mg/dL) by ~10 weeks of age, we conclude that the observed effects on bone properties were due to sustained hyperglycemia. The greater mean CO₃:PO₄ in the Ay mice indicates increased substitution of carbonate for phosphate in the hydroxyapatite lattice with hyperglycemia. It suggests that greater mineral maturity may occur with diabetes, which is consistent with increased fracture risk. In contrast, the 11% decrease in trabecular collagen maturity would be expected to reduce fracture risk. Direct assessment of mechanical properties is required to discern the functional effects of these complex concomitant changes in mineral and collagen maturity on fracture behavior.

Removal of Proteoglycans from Bone Matrix Significantly Reduce its *In Situ* Toughness. Haoran Xu¹, Yehong Huang², Sumin Gu³, Jean Jiang³, Xiaodu Wang⁴. ¹Mechanical Engineering, University of Texas at San Antonio, Texas, USA, ²Biomedical Engineering, University of Texas at San Antonio, Texas, USA, ³Biochemistry, University of Texas Health Science Center at San Antonio, Texas, USA, ⁴Mechanical & Biomedical Engineering, University of Texas at San Antonio, Texas, USA

Introduction: Proteoglycans are present in the extracellular space between collagen fibrils. The highly negatively charged glycosaminoglycans (GAGs) in proteoglycans tend to attract water molecules for charge equilibrium. We hypothesized here that coupled with water proteoglycans play a significant role in toughening bone. To test the hypothesis, we used a novel nanoscratch test to access the effect of removal of GAGs by PNGase F on the *in situ* toughness of bone under dry/wet conditions. In addition, the efficacy of PNGase F in removing GAGs from bone matrix was verified.

Methods & Materials: 18 cubes (91mm³) were prepared from 6 middle-aged male human femurs, with 3 samples from each donor. Among the 3 samples, one served as baseline control without any treatments, one served as control with heating but without enzyme treatments, and the remaining one was heated first to unfold the proteins and then treated for 48 hours in PNGase F (8mg/mol), which cleaves N-linked oligosaccharides. After the treatments, nanoscratch tests were performed to measure the *in situ* toughness of bone. Two-factor ANOVA and Turkey *post hoc* tests were performed to analyze the experimental data. In addition, bone whole lysate extracted from mouse femurs was treated with PNGase F to confirm its efficacy in removal of GAGs in bone matrix and analyzed using SDS-PAGE gel.

Results and Discussion: The results indicated that the *in situ* toughness of bone was 2.048±0.133 GJ/m² for baseline control, 1.528±0.161 GJ/m² for control, and 1.151±0.177 GJ/m² for treated group, respectively, under wet condition. However, under dry condition the bone toughness changed to 1.418±0.059 GJ/m² for baseline control, 1.270±0.154 GJ/m² for control, and 1.142±0.260 GJ/m² for the treated group, respectively. The two-way ANOVA showed that both dehydration and partial removal of GAGs had significant effects on the *in situ* toughness of bone. In addition, a strong cross-effect was observed between the two factors (Table 1 & 2). The Turkey *post hoc* analyses indicate that removal of GAGs is significantly correlated with bone toughness only when water is present (*p*=0.02), suggesting that water functions as a plasticizer when GAGs are present. In SDS-PAGE gel profile (Fig. 1), the protein band between 70-100 kd in control (lane C) was shifted downwards after PNGase F treatment (lane D), thus suggesting that GAGs are removed.

Conclusion: The result of this study supports the hypothesis of this study.

Table 1 Nanoscratch toughness of bone

| | Wet (GJ/m ²) | Dry (GJ/m ²) |
|------------------|--------------------------|--------------------------|
| Baseline Control | 2.048±0.133 | 1.418±0.059 |

Reproduction Differentially Affects Cortical and Trabecular Bone and Alters Cortical Bone Stiffness and Trabecular Structure towards a Male Phenotype. Chantal De Bakker¹, Allison R. Altman¹, Connie Li¹, Youwen Yang¹, Chih-Chiang Chang¹, Wei-Ju Tseng¹, Yong-Hoon Jeong², Do-Gyoon Kim², X. Sherry Liu¹. ¹University of Pennsylvania, USA, ²The Ohio State University, USA

Despite significant bone loss during pregnancy and lactation, no adverse effects on future fracture risk have been reported. However, our recent study demonstrated a persistent, cumulative trabecular (Tb) bone loss in rat tibiae after 3 reproductive cycles, which resulted in 52% lower Tb bone volume than age-matched virgin rats. We hypothesized that better cortical (Ct) bone mechanical competence after reproduction may explain this paradox. Therefore we compared bone quality at multiple skeletal sites in 6-mo-old rats (n=4-6/group) euthanized at parturition (PAR), after 2 wks lactation (LAC), and 6 wks post-weaning (WEA), with virgin females (VIRG) and males (MALE) as controls.

At the femur, PAR, LAC, and WEA had 10-12% lower Ct area than VIRG. However, 3-point bending indicated that reproduction increased Young's modulus (E) by 34-61%, resulting in 21% greater bone stiffness in WEA than VIRG (Fig1A). Despite 31% lower Ct area in WEA vs. MALE, greater E in WEA (104%) compensated for the structure difference, resulting in similar whole bone stiffness in WEA and MALE.

LAC rats had 84% and 67% lower BV/TV at the tibia and vertebra (L4), respectively, than VIRG. BV/TV remained 40% and 21% lower in WEA compared to VIRG (Fig1 C,D). Conn.D was unchanged and Tb.N was 14% lower in WEA than VIRG at L4, while at the tibia, these differences were 57% and 32%, respectively. Interestingly, WEA had similar Tb structure as MALE rats, which also had inferior Tb structure (53% and 28% lower BV/TV at the tibia and L4, respectively) than VIRG. Nanoindentation of the vertebra indicated a reversible decrease in E at the inner region of the trabeculae (Fig1B). At the edges, E remained 14% lower after weaning, likely due to incomplete new bone mineralization. Results suggest that the mechanical integrity of the highly load-bearing regions of bone, such as Ct bone in the femur and Tb bone at L4, were preserved either through improved material properties (femur), or maintenance of structural integrity (L4). Skeletal calcium release during pregnancy and lactation is highly selective, resulting in an adapted skeletal composition where bone quality is optimized at the more load-bearing regions. This may account for the low fracture risk observed in parous women. Furthermore, the post-weaning Tb phenotype was more similar to male rats than virgin females, suggesting that the female skeleton may initially contain more Tb bone than needed to compensate for reproductive bone loss.

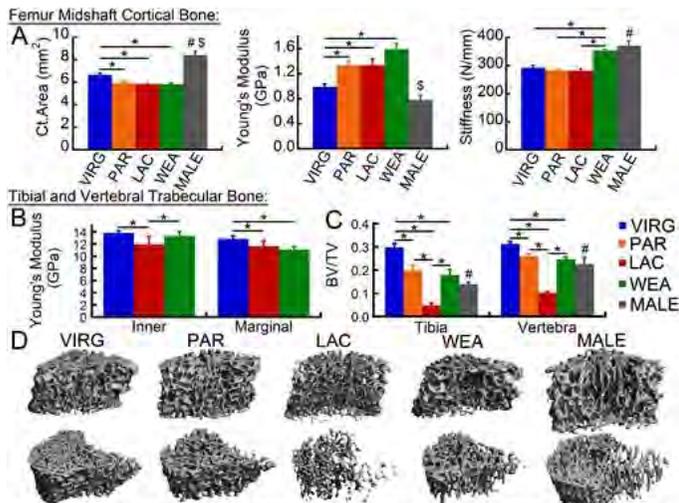

Fig 1. Effects of reproduction on (A) cortical bone at the femur, (B) material properties of vertebral trabeculae, (C) trabecular BV/TV, and (D) trabecular architecture at the vertebra (top), and tibia (bottom). *: p<0.05 among reproductive groups. In a separate analysis, MALE compared to VIRG and WEA: #MALE ≠ VIRG, \$:MALE ≠ WEA (p<0.05).

The initial slope of the variogram, foundation of the trabecular bone score, does not predict vertebral strength in three distinct biomechanical tests.

Ghislain Maquer¹, Enrico Dall'Ara², Yan Chevalier³, Yongtao Lu⁴, Lang Yang⁵, Matthias Krause⁶, Richard Eastell⁵, Kurt Lippuner⁷, Philippe Zysset¹. ¹Institute for Surgical Technology & Biomechanics, University of Bern, Switzerland, ²Department of Mechanical Engineering & INSIGNEO Institute for in silico Medicine, University of Sheffield, United Kingdom, ³Klinikum Großhadern, Orthopaedic Department, Laboratory for Biomechanics & Experimental Orthopaedics, Germany, ⁴Institute of Biomechanics, TUHH Hamburg University of Technology, Germany, ⁵Academic Unit of Bone Metabolism, Mellanby Centre for Bone Research, University of Sheffield, United Kingdom, ⁶Department of osteology & biomechanics, University Medical Center Hamburg-Eppendorf, Germany, ⁷Osteoporosis Clinic, Inselspital, University Hospital & University of Bern, Switzerland

Degradation of bone architecture characterises osteoporosis, but dual energy X-ray absorptiometry (DXA), the clinical tool to evaluate fracture risk, does not capture the 3D trabecular microstructure. Trabecular bone score (TBS) may recover the missing data via texture analysis of DXA images. Yet, in vitro biomechanical tests by Roux et al. demonstrated a lack of correlation between TBS and vertebral strength[1], leaving unclear the reasons for its discriminative power in fracture studies. Our hypothesis is that the biomechanical testing set-up could affect this surprising result. The initial slope of the variogram (ISV) was derived from the description of TBS as a purely textural index[2]. Simulated DXA, as previously used to test the robustness of TBS[3], was used to evaluate areal bone mineral density (aBMD) and ISV. HR-pQCT scans acquired for 62 vertebral samples were coarsened to DXA resolution and projected in a frontal plane. Failure loads of the samples (Fexp) were measured via three biomechanical testing set-ups. To overcome disc degeneration and distribute the load on the vertebral body, the endplates of 37 vertebral bodies (T12-L4; 7 males and 3 females; 64±12 yrs) were trimmed before compression (vertebral section). Alternatively, the endplates of 12 vertebral bodies (L1-L5; male; 66±15 yrs) were embedded in PMMA (vertebral body). Thirdly, spinous processes (except facet joints) were kept and loads were transmitted to 13 vertebrae (T12; female; 80±8 yrs) via intervertebral discs to mimic the in vivo situation (vertebra). The relation of aBMD and ISV with Fexp was assessed and their relative contribution to a multi-linear model quantified via ANOVA. On clinical DXA, ISV compared well with TBS (n=16, r²=0.745, p<0.001). Significant correlations were found between aBMD and all Fexp (0.587< r²<0.694, p<0.05). In comparison, relations of ISV with Fexp were non-significant, except in the vertebral body case (r²=0.396, p=0.028). Combined with aBMD, ISV brought no significant improvement for any of the experiments (Fig. 1). Independently of the testing set-up, ISV is not related to vertebral strength. This result brings a strong confirmation to those by Roux et al.[1] They also relaunch the question of the deterministic factors underlying the statistical relationship between TBS and vertebral fracture risk.1 Roux et al. Osteoporos Int. 2013;24(9):2455-602 Pothuaud et al. Bone. 2008; 42(4):775-7873 Winzenrieth et al. J Clin Densitom. 2013;16(3):287-296

Validation of High-Resolution Peripheral Quantitative Computed Tomography for Measurement of Bone Quality in Monkeys. Aurore Varela*, Gabrielle Boyd, Susan Y. Smith. Charles River Laboratories, Canada

Accurate quantification of bone micro-architecture is important in understanding bone mechanics and response to disease or treatment. High-resolution peripheral quantitative computed tomography (HR-pQCT) can scan extremities within a few minutes at a 30 µm voxel size, allowing for the quantification of trabecular and cortical BMD and micro-architecture. The purpose of this study was to evaluate the precision and reproducibility of the HR-pQCT (XtremeCT II, Scanco Medical AG) when scanning in vivo and ex vivo radii in Cynomolgus monkeys. Two radii were scanned ex vivo 5 times without repositioning to assess precision and reproducibility at a resolution of 30 µm. In vivo, the radius diaphysis and distal metaphysis from 7 monkeys were scanned 4 times with repositioning between each scan, at a resolution of 61 µm and 30 µm respectively.

Machine precision and reproducibility was good for all ex vivo radius diaphysis parameters (BV/TV, apparent density BMD, material density TMD and cortical thickness), with %CV between 0.04% and 0.54%. For the ex vivo metaphysis, %CV for the trabecular region (BV/TV, TMD, Tb.N and Tb.Th) were between 0.10% and 3.96%. For the cortical region, %CV, vBMD, TMD and Ct.Th, were between 0.20% and 1.32%. The cortical porosity had the highest variability, with a mean %CV of 7.16%.

For all in vivo radius diaphysis parameters: BV/TV, vBMD, vTMD and cortical thickness, %CV obtained were between 0.02% and 1.04%.

For the in vivo radius metaphysis site, %CV for the trabecular region, BV/TV, TMD, Tb.N and Tb.Th, were between 0.15% and 3.40%. %CV for the cortical region, vBMD, TMD and Ct.Th, were between 0.09% and 1.91%. The cortical porosity had the highest variability, with a mean %CV of 12.7%, consistent with the ex vivo variability.

HR-pQCT provided precise, reproducible non-invasive measurements of bone mass and micro-architecture in monkeys. HR-pQCT scans can be used for FEA as part of a comprehensive evaluation of bone quality, including bone mass, micro-architecture and estimated bone strength, and is an important translational tool in osteoporosis drug research.

Comparison of Alendronate and Zoledronate Effects on Bone Turnover and Mechanical Properties for Two Successive Periods of Simulated Microgravity Unloading. Scott Lenfest^{*1}, Harry Hogan², Susan Bloomfield³, Corinne Metzger³, Jon Elizondo², Matthew Allen⁴. ¹Texas A&M University, USA, ²Texas A&M University Department of Mechanical Engineering, USA, ³Texas A&M University Department of Health & Kinesiology, USA, ⁴Indiana University School of Medicine Department of Anatomy & Cell Biology, USA

Bisphosphonates (BP) are being tested by a limited number of International Space Station crew as part of countermeasures against bone loss. The anti-resorptive effects of BPs persist well beyond treatment withdrawal. This study used the adult hindlimb unloaded (HU) rat model to simulate two successive missions and test whether beneficial effects of BP treatment given for an initial HU period extend to a second HU period, and also to compare two BPs (Alendronate (AL) and Zoledronate (ZA)).

Adult male rats (6 mo.) were block assigned to aging control (AC) and HU groups by body weight. HU animals were exposed to 28d of HU, followed by 56d of recovery, and then a second 28d HU exposure. Subsets of HU animals were administered AL (HU+A), ZA (HU+Z), or no drug (HUC). AL (2.4 µg/kg) was given 3x/week for 5 weeks, starting the week before the first HU. ZA (60 µg/kg) was given in a single dose just prior to the first HU. Fluorochrome label injections were given 7d apart after 28d of recovery (Rec28) and after 56d of recovery (Rec56), just before the 2nd HU period. Dynamic cortical histomorphometry was performed on the tibia mid-diaphysis at these two time points. Analyses conducted at the endpoint of the study, after the 2nd HU period, included static cancellous histomorphometry (at the distal femur metaphysis), and reduced platen compression (RPC) mechanical testing (performed on a 2mm slice specimen from the proximal tibia metaphysis).

Periosteal bone formation rate (BFR) for the tibia mid-diaphysis was significantly higher ($p < 0.05$) for HUC compared to AC, HU+Z, and HU+A at Rec28, and BFR was significantly higher for HUC and HU+A compared to AC and HU+Z at Rec56. HU+Z animals had significantly lower trabecular bone osteoclast surface compared to AC (-75%) and HUC (-76%), and higher trabecular thickness compared to HU+A (+33%). Max compressive stress from RPC testing was significantly higher compared to AC (+69%), HUC (+67%), and HU+A (+66%).

Both BPs delayed recovery of BFR at Rec28, but by Rec56, BFR remained suppressed for ZA and not for AL. On balance, however, ZA proved more beneficial in giving rise to improved mechanical strength and trabecular architecture due to vastly reduced osteoclast surface. These results are consistent with the greater potency of ZA we have found for femoral neck strength and trabecular architecture from microCT, and they also provide insights into the relative effects on formation and resorption.

Associations of Fluoride Intake with Adolescents' pQCT-derived Bone Outcome Measures at Age 17. Reem Oweis^{*1}, Steven Levy², John Warren², Julie Eichenberger Gilmore², Trudy Burns², Punam Saha², Kathleen Janz², James Torner², Elena Letuchy², Barbara Broffitt². ¹University of Iowa, USA, ²The University of Iowa, USA

Purpose: To investigate associations between period-specific and cumulative fluoride (F) intakes from birth to age 17 years and pQCT bone measures. **Methods:** Subjects are members of the Iowa Bone Development Study (IBDS) that grew out of the longitudinal Iowa Fluoride Study (IFS) that investigates fluoride and dietary exposures, dental fluorosis and dental caries. IFS subjects were recruited from 8 Iowa hospital postpartum wards in 1992-95, with detailed questionnaires sent every 1.5-6 months. Data on combined F intakes from water, other beverages, selected foods, dietary supplements and dentifrice were determined from the questionnaires and F assay of the products. Subjects underwent peripheral quantitative computed tomography (pQCT) of the radius and tibia (XCT-2000/3000) at age 17. pQCT cortical and trabecular bone outcomes (bone mineral content (BMC), bone mineral density (BMD), and strength) were related to F intake in bivariate and multivariable analyses adjusted for height, weight, years since peak height velocity, average daily time in moderate-to-vigorous intensity physical activity, and daily calcium and protein intake. **Results:** Mean daily F area-under-the-curve (AUC) intake from birth to age 17 was 0.79 mg (SD = 0.32) for males and 0.70 mg (SD = 0.25) for females. Unadjusted Spearman correlations between daily F intake and bone measures were weak (females $r = -0.01$ to 0.15 for radius, -0.001 to 0.23 for tibia; males $r = 0.03$ to 0.24 for radius, -0.008 to 0.27 for tibia). From partially adjusted (for height, weight, and years since peak height velocity) linear regression models for females, there was a significant negative association ($p < 0.05$) between F AUC (birth-8.5 years) and radial bending strength ($n = 179$) and significant positive association between F AUC (14-17 years) and tibial cortical content ($n = 154$). For males ($n = 137$), there were significant positive associations ($p < 0.05$) between F AUC (14-17 years) and radial compression strength and tibial cortical content and bending strength. In fully-adjusted models (physical activity, protein and calcium added), there were significant negative associations for females ($n = 140$) between F AUC (birth-8.5 years) and radial bending strength and positive associations for males ($n = 115$) between F AUC (14-17 years) and tibial bending strength at age 17. **Conclusion:** Findings suggest that life-long F intakes from

combined sources for U.S. adolescents in fluoridated areas are weakly associated with radius and tibia pQCT measures.

Fully Automated Bone Detection, Segmentation, Axis Extraction, Trabecular Labeling, and ASBMR Morphometric Analysis in Small Animal Micro-computed Tomography. Ali Behrooz¹, Peet Kask², Jeff Meganck^{*3}, Josh Kempner³, Wael Yared³. ¹PerkinElmer, Us, ²PerkinElmer, Estonia, ³PerkinElmer, USA

In vivo micro-computed tomography (micro-CT) imaging of small animals provides 3D anatomical images that are useful for study and analysis of skeletal bone structures, formation, and diseases. Detecting the bone voxels in raw micro-CT images is necessary for enabling such studies and analyses. While micro-CT images provide contrast between bone and soft tissue components, detecting the bone voxels in micro-CT volumes can be challenging considering noise and partial volume effects which result in low voxel density in thin bones such as the pelvis. Also, automated separation of individual bones is necessary for bone analysis when manual segmentation is impractical. In this work, a fully automated optimized framework is presented for robust detection, segmentation, and analysis of bones from micro-CT images. The imaging platforms used in this work consist of stand-alone Quantum FX and GX micro-CT systems. Data from mice and rats are acquired in vivo and postmortem at different fields of view (5 to 30 mm) and voxel resolutions of 10 to 58 microns. For bone detection, after conversion to Hounsfield units, a hybrid thresholding algorithm is employed which combines the benefits of histogram-based global thresholding with local thresholding. This algorithm offers significant improvements over existing auto-thresholding techniques. After bone detection, a watershed-based algorithm is used for individual bone splitting. Despite differences in shapes of bones and partial volume effects, especially at low resolutions, the segmentation algorithm can robustly separate individual bones. The robustness in the segmentation is secured by applying splitting filters to the bone mask prior to marker-controlled watershed. Additionally, a morphological algorithm is used to separate the cortical and trabecular compartments of each bone. Results of bone segmentation and trabecular labeling for a dataset with 10 micron voxel resolution are shown in Figure 1. For shape and structural analysis of the bone, a framework is presented for obtaining the principal and 3D medial axes of each bone. Also, 3D morphometric ASBMR and structural parameters are computed for cortical and trabecular components of individual bones. In this work, we present results for various ASBMR parameters including volume, thickness, porosity, density, and anisotropy. Results of bone segmentation, axis extraction, and ASBMR thickness for a dataset with 20 micron voxel resolution are presented in Figure 2.

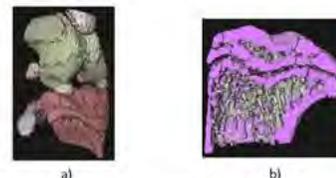

Figure 1. Bone detection, segmentation, and trabecular cortical separation for the knee joint of a mouse imaged in an in vivo micro-CT platform at 10 micron voxel resolution. a) Bones comprising the knee joint are segmented and labeled (femur, tibia, patella, and partially in-view fibula). b) The trabecular and cortical compartments of the tibia are separated and labeled.

Figure 1

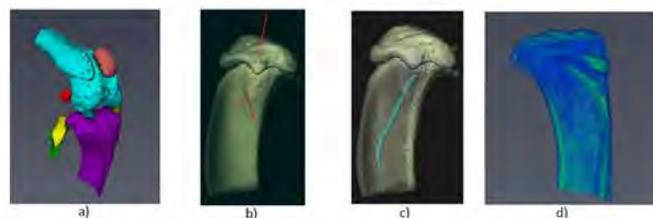

Figure 2. Bone detection, segmentation, axis extraction, and local thickness analysis for the knee joint of a mouse imaged in an in vivo micro-CT platform at 20 micron voxel resolution. a) Bones comprising the knee joint are segmented and labeled (femur, tibia, patella, and fibula). b) The principal axes of tibia are calculated and plotted overlaid with the tibia mask. c) The medial axis of tibia is extracted and visualized overlaid with the tibia mask. d) The local thickness of the cortical shell of tibia is calculated and visualized.

Intrinsic Material Property Differences in Bone Tissue from Fracturing vs Non-fracturing Women. Severine Vennin¹, Anastasia Desyatova¹, Joseph Turner¹, Robert Recker², Mohammed Akhter^{*3}. ¹University of Nebraska-Lincoln, USA, ²Creighton University, USA, ³Creighton University Osteoporosis Research Center, USA

Osteoporotic (low-trauma) fractures are a significant public health problem. Up to 50% of those over 50 yrs of age are at high risk of osteoporotic fracture. While current therapies reduce the skeletal fracture risk, additional information concerning the intrinsic material strength properties of bone tissue is needed to develop better treatments, since measurements of bone density account for no more than ~50% of fracture risk. The hypothesis is that postmenopausal women who have sustained osteoporotic fractures will have reduced bone quality as indicated by measures of intrinsic material strength properties, compared to those with who have not fractured. 120 iliac biopsies were collected from fracturing (n=60, cases) and non-fracturing postmenopausal women (n=60, matching controls) to measure intrinsic strength properties using the nano-indentation (NI) technique. Each biopsy specimen was embedded in epoxy resin, then ground and polished, and used for the NI testing. After calibration, multiple indentations were made with a target force of 6 mN (milli-newtons) at a constant loading rate of 400 µN/s (micro-newtons per second). The indentation procedure included a linear loading period of 15s, a holding period at a maximum load of 10s and a linear unloading period of 15s. In addition, dynamic testing was done using standard protocols to quantify storage and loss moduli. The load-displacement data from each indentation were used to calculate reduced indentation modulus (Er, GPa) and hardness (H, GPa) for both cortical and trabecular bone tissue. The descriptive statistics and t-tests for the NI data set are shown in Table-1. While cortical hardness was significantly greater (P=0.04), the cortical modulus showed an increased trend in controls as compared to the cases. The standard deviation (St Dev) of the measured variance in the majority of the variables, for both cortical and trabecular bone tissue (hardness/modulus, storage modulus), was reduced in controls compared to the cases. This result suggests that the cases had less heterogeneous material properties as compared to the controls, and therefore, were more prone to fracture. The higher variation in loss modulus for the cases suggests there was existing damage in bone tissue that could propagate more easily in the relatively homogenous material, and therefore, is responsible for the increased risk of fracture.

| Table-1 Variable | Cases | | Controls | | p(t) |
|-----------------------------|--------|-------|----------|-------|------|
| | Mean | Std | Mean | Std | |
| Cort Hardness-H (GPa) | 0.448 | 0.184 | 0.543 | 0.297 | 0.04 |
| St Dev Cort Hardness | 0.096 | 0.051 | 0.118 | 0.073 | 0.08 |
| Cort Modulus-Ec (GPa) | 13.572 | 4.320 | 14.974 | 4.589 | 0.10 |
| St Dev Cort Modulus | 1.638 | 0.782 | 2.075 | 0.918 | 0.00 |
| St Dev Cort Storage Modulus | 1.668 | 0.744 | 2.062 | 0.746 | 0.00 |

Osteogenesis on Nanoparticulate Mineralized Collagen Scaffolds via Auto-genous Activation of the Canonical BMP Receptor Signaling Pathway. Xiaoyan Ren^{*1}, David Bischoff², Daniel Weisgerber³, Michael Lewis⁴, Victor Tu⁵, Dean Yamaguchi⁶, Timothy Miller⁵, Brendan Harley⁷, Justine Lee⁵. ¹Division of Plastic & Reconstructive Surgery, UCLA David Geffen School of Medicine & VA Greater Los Angeles Healthcare System, USA, ²VA Greater Los Angeles Healthcare System, USA, ³Department of Chemical & Biomolecular Engineering, Institute for Genomic Biology, University of Illinois at Urbana Champaign, USA, ⁴Department of Pathology, VA Greater Los Angeles Healthcare System, USA, ⁵Division of Plastic & Reconstructive Surgery, UCLA David Geffen School of Medicine & Division of Plastic & Reconstructive Surgery, VA Greater Los Angeles Healthcare System, USA, ⁶VA Greater Los Angeles Healthcare System & UCLA David Geffen School of Medicine, USA, ⁷Department of Chemical & Biomolecular Engineering, Institute for Genomic Biology, University of Illinois at Urbana Champaign, USA

Skeletal regenerative medicine frequently incorporates deliverable growth factors to stimulate osteogenesis. However, the cost and side effects secondary to supraphysiologic dosages of growth factors warrant investigation of alternative methods of stimulating osteogenesis for clinical utilization. In this work, we describe growth factor independent

osteogenic induction of human mesenchymal stem cells (hMSCs) on a novel nanoparticulate mineralized collagen glycosaminoglycan scaffold (MC-GAG).

hMSCs were plated on scaffolds and treated with osteogenic medium for up to 12 weeks. Markers of osteogenic differentiation were assessed by real time RT-PCR. Mineralization and bone formation was followed by histology and microCT. Signal transduction was analyzed by western blot and immunohistochemistry.

hMSCs demonstrated elevated osteogenic gene expression and mineralization on MC-GAG with minimal to no effect upon addition of BMP-2 when compared to non-mineralized scaffolds (Col-GAG). To investigate the intracellular pathways responsible for the increase in osteogenesis, we examined the canonical and non-canonical pathways downstream from BMP receptor activation. Constitutive Smad1/5 phosphorylation with nuclear translocation occurred on MC-GAG independent of BMP-2, whereas Smad1/5 phosphorylation depended on BMP-2 stimulation on Col-GAG. When non-canonical BMPR signaling molecules were examined, ERK1/2 phosphorylation was found to be decreased in MC-GAG but elevated in Col-GAG. No differences in Smad2/3 or p38 activation were detected.

Collectively, these results demonstrated that MC-GAG scaffolds induce osteogenesis without exogenous BMP-2 addition via endogenous activation of the canonical BMP receptor signaling pathway.

Trabecular bone microdamage, microarchitecture and resorption in whole human vertebrae are regionally distributed and distinctly related to intervertebral disc properties. Vincent T. Carpentier^{*}, Helen Tsangari, Nicola L. Fazzalari, Julia S. Kuliwaba. Bone & Joint Research Laboratory, Anatomical Pathology, SA Pathology, Australia

Study aim: Vertebral strength is determined by bone size, shape, bone mineral density (BMD), microarchitecture, and bone material properties. Despite its importance to vertebral mechanics, no studies have reported on the variation of bone microdamage present in the human vertebra and its association with intervertebral disc (IVD) properties.

Methods: L2-L3 lumbar functional units were obtained from 15 human cadaveric spines (8 males; 7 females; 16-87 years). L2 vertebra BMD status and L2-L3 IVD thickness (IVD.Th) were respectively measured with DXA and X-rays. L2-L3 IVD degenerative grade (IVD.Gr) was determined with a phantom-based T2 weighted MRI technique. Parasagittal slices were then cut from each L2 vertebral body, en bloc-stained in basic fuchsin and resin embedded. Histomorphometric assessment of trabecular bone microarchitecture, in vivo bone microdamage, and extent of bone resorption was undertaken following the antero-posterior and cranio-caudal axes.

Results: No association was found between IVD.Th and IVD.Gr. Concerning the whole L2 vertebra, IVD.Th was negatively correlated with BMD Z-score (r=-0.55, p<0.04) and IVD.Gr was correlated with microcrack length (r=0.71, p<0.01) and surface density (r=0.66, p<0.02). No differences were found between regions following the antero-posterior axis. For the cranio-caudal axis, the bone volume fraction (BV/TV) was the highest in the cranial region (p<0.04) and negatively correlated with IVD.Th (r=-0.55, p<0.05). In this region, bone resorption was the highest (p<0.02), and microcrack length (Cr.Le) (r=0.69, p<0.01), density (Cr.Dn) (r=0.69, p<0.01) and surface density (Cr.S.Dn) (r=0.80, p<0.005) were correlated with IVD.Gr. In contrast, the mid-vertebral region had the lowest BV/TV and the highest Cr.S.Dn (p<0.04). In addition, bone resorption was the lowest (p<0.02) and correlated to IVD.Gr (r=0.59; p<0.02). The caudal region had the lowest Cr.S.Dn (p<0.04). Diffuse microdamage was minimal or absent within vertebrae.

Conclusions: For the cranio-caudal axis of the L2 human vertebra, the mid-vertebral region may be biomechanically compromised due to reduced bone volume being accompanied by an increased microcrack burden. The distinctive correlations between bone microdamage, microarchitecture and resorption with either IVD.Th or IVD.Gr suggest a heterogeneous adaptive response within the human vertebra to intervertebral disc degeneration.

Effects of Hind Limb Unloading on Wild Type and Osteocalcin Knockout Mice. Patricia Buckendahl^{*}, JAYANTH Watson, Matthew Flanagan, Aedan Hannah. Rutgers University, USA

Purpose: To evaluate the lack of osteocalcin on response to hind limb unloading (HLU). Skeletal unloading, whether due to prolonged bed rest, paralysis, or microgravity of space flight, causes physiological changes affecting not only bone, but also immune function. Male 8-week old C57Bl/6 wild type (WT) and osteocalcin null mutant (KO) mice, progeny of homozygous WT or KO mothers, were subjected to hind limb unloading or control conditions in similar cages, 6 mice per group, for 1 week. Technical difficulties forced the elimination of 2 KO controls and 2 KO HLU subjects. Weights were recorded daily. All mice tolerated the procedure well. After 1 week, mice were killed and dissected to obtain adrenals, spleen, lumbar spinal cord, lumbar vertebrae, humerus and hind limb bones. Soft tissues were quickly frozen, while tibial metaphysis and L2 were stored in RNAlater for later analysis of gene expression by RT-PCR. One femur, L3-5 vertebrae and humeri were stored in 70% ethanol for microCT analysis. The other femur was wrapped in saline soaked gauze and frozen pending breaking strength measurements. To evaluate possible stress

responses, we analyzed adrenal gene expression of tyrosine hydroxylase and NPY, which did not differ among treatment groups indicating minimal effects of the procedures. Because HLU is known to induce inflammatory responses, we examined expression of a spectrum of cytokines. There were no significant differences in gene expression among these factors in spleen. In spinal cord, NFkB and NOS2 decreased significantly with treatment, but not genotype, while BDNF was significantly lower in both KO groups relative to WT control. The involvement of BDNF with sensory transduction in the cord and the lower expression of this factor in KO mice may help explain sensory latencies that we have observed in KO mice. The lack of differences in ALP and Col1A1 in lumbar vertebrae were surprising, but may have begun to adapt to the altered loading by 1 wk. The marginal decrease in expression of OG1 (bglap1) is consistent with data from HLU and spaceflight rats. MicroCT imaging of femurs revealed lower Tb.Th. in WT HLU, but no effect of HLU on KO. This plus the marginal difference in cortical thickness between WT and KO controls is consistent with that obtained from older WT and KO mice subjected to spinal cord injury. Analyses of microCT data for humeri and vertebra are ongoing.

Moderate Elevations in Iron Stores Improves Skeletal Integrity in Mice Even During Disuse. Corinne Metzger¹, Matthew Allen², Scott Lenfest³, Harry Hogan³, Nancy D. Turner⁴, Sara Zwart⁵, Susan A. Bloomfield³, Rihana Bokhari³. ¹Texas A&M University Dept. Health & Kinesiology, USA, ²Indiana University School of Medicine, USA, ³Texas A&M University, USA, ⁴Texas A&M University Dept. Nutrition & Food Science, USA, ⁵NASA Johnson Space Center - Universities Space Research Association, USA

International Space Station crewmembers experience moderate elevations in iron stores early during flight that are associated with greater in-flight declines in bone mineral density (BMD). Preliminary data from our lab demonstrated oxidative stress induced by iron loading in adult rats was associated with high bone resorption and bone loss. The objective of this study was to test the hypothesis that increasing iron stores would aggravate bone loss during hindlimb unloading (HU). Male C57BL/6 mice (n=44; age 16 wks) were acclimated to AIN93-G purified diet with normal (45 mg Fe/kg) or high (650 mg Fe/kg, Fe) iron content for 4 wks. Mice were randomly assigned to 4 groups: weight bearing cage controls (CC), HU, CC+Fe, and HU+Fe. Liver iron in Fe groups was 28% higher than in normal diet groups after 8 weeks on the diet. PIXImus (DEXA) scans revealed HU+Fe mice did not have statistically different hindlimb and total body BMD than CC+Fe mice. Total body lean and fat mass were lower in all HU mice compared to cage controls with no dietary differences. SkyScan µ-CT of distal femurs revealed higher cancellous bone volume (BV/TV), elevated trabecular thickness and number and lower trabecular separation with high Fe. HU induced an approximately 30% lower cancellous BV/TV within both diet groups, but Fe diet led to a higher cancellous BV/TV in both groups. In all cases µCT trabecular microarchitecture measures in HU+Fe mice were equivalent to those of CC. Three-point bending to failure on mid-shaft femur demonstrated higher ultimate load values in high Fe compared to controls. Ultimate load in femoral neck axial loading to failure was greater in CC+Fe but was not different between CC, HU and HU+Fe. Contrary to our hypothesis, high dietary iron intake led to higher BMD, improved trabecular microarchitecture and bone strength in both CC and HU mice. Although most bone measures were lower in high iron mice subjected to HU compared to their diet controls, the overall bone status at the end of 4 wks of HU was equivalent to that of weight bearing mice on the control diet. These findings contrast with our previous data in adult rats and may represent a species difference in response to moderate increase in dietary iron levels. Future studies will focus on gender comparisons and the impact of constant low dose radiation-induced oxidative damage on mice during HU with elevated dietary iron intake.

Physical strenuousness of occupation is risk factor for intervertebral disc degeneration. Sami Salo^{*1}, Ville Leinonen², Toni Rikkinen³, Pauli Vainio⁴, Jarkko Marttila⁴, Risto Honkanen³, Marjo Tuppurainen⁵, Heikki Kröger⁶, Joonas Sirola⁶. ¹Kuopio Muskuloskeletal Research Unit (KMRU), University of Eastern Finland, Finland, ²Department of Neurosurgery, Kuopio University Hospital, Kuopio, Finland, Finland, ³Kuopio Muskuloskeletal Research Unit, KMRU, Surgery, Institute of Clinical Medicine, University of Eastern Finland, Kuopio, Finland, Finland, ⁴Department of Radiology, Kuopio University Hospital, Kuopio, Finland, Finland, ⁵Department of Obstetrics & Gynecology, Kuopio University Hospital, Finland, Finland, ⁶Kuopio Muskuloskeletal Research Unit, KMRU, Surgery, Institute of Clinical Medicine, University of Eastern Finland & Department of Orthopedics, Traumatology & Hand Surgery, Kuopio University Hospital, Finland

Introduction: Occupational lumbar spine load has been linked to intervertebral disc degeneration in the lumbar spine. The aim was to study the relationship between

physical strenuousness of occupation (PSO) and intervertebral disc degeneration (IDD) in postmenopausal women.

Materials and methods: The study population consisted of 160 postmenopausal women (aged 61.9 – 78.0 years, mean 70.22 years) from the OSTPRE and OSTPRE-FPS study cohorts. Information on PSO was based on self-report questionnaires and it was divided into three groups: 1) heavy, 2) moderate and 3) sedentary or light. Severity of IDD was graded from T2-weighted MRI images using 5-grade Pfirrmann classification. Five intervertebral levels (L1-L2 to L5-S1) were studied. A mean IDD grade of all five discs was calculated for each woman separately. It was categorized into three groups: slight (mean grade less than 3), moderate (mean grade 3 or more, but less than 4) and severe (mean grade 4 or more). Logistic regression was used in the analysis to calculate odds ratios (OR). Potential confounders including height, weight, age, smoking duration in years, use of postmenopausal hormone therapy, L2-L4 BMD and femoral neck BMD were used as covariates in the analysis.

Results: The heavy PSO group had higher odds for severe disc degeneration (OR = 5.07, 95% CI: 1.37-18.79, p=0.015) in comparison to slight IDD. Adjustment strengthened this association (OR = 15.31, 95% CI: 2.97-78.97, p=0.001). Age (OR = 1.33, 95% CI: 1.14-1.56, p<0.001), L2-L4 BMD (OR = 36.50, 95% CI: 1.41-947.10, p=0.030) and smoking history in years (OR = 1.08, 95% CI: 1.01-1.15, p=0.035) were statistically significant covariates in the analysis.

Conclusions: Physical strenuousness of work seems to be a significant risk factor for intervertebral disc degeneration in postmenopausal women.

Comparison of Accelerometer Processing Data for Bone-Related Physical Activity Studies: Iowa Bone Development Study. Shelby Francis, Kathleen Janz*, Elena Letuchy, Rick Paulos, Kristen Metcalf, Trudy Burns, Steven Levy. University of Iowa, USA

BACKGROUND: To more precisely understand how bone adapts to mechanical loading outside of laboratory settings, measurement methods must unobtrusively capture the dimensions of physical activity (intensity, frequency, time, intensity rate of change, and non-repetitiveness of loading). Accelerometers with their small packaging, relative stability over time, minimum user interface, good dynamic g-force ranges, and long monitoring time are well suited for this task. Currently, micro electro mechanical system (MEMS) accelerometers are the principal class of motion sensors used in epidemiologic studies of bone-related physical activity. This study used the ActiGraph GT3X+ MEMS accelerometer (Pensacola, FL) to compare new triaxial accelerometer output that includes g-force output (Hildebrand, 2014) and 1-second data summary with traditional movement count approaches.

METHODS: Three hundred and sixty-two young adults (mean age 19 y) from the Iowa Bone Development Study cohort wore the ActiGraph GT3X+ for at least 3 days and for at least 8 hours per day. Raw acceleration data (30 Hz) were processed using Freedson 1998 (F98), Freedson 2011 (F11), and Hildebrand 2014 (H14), and reduced to minutes per day in moderate-and-vigorous intensity PA (MVPA), and minutes per day in vigorous intensity PA (VPA). These variables were compared to pQCT-derived tibia bone strength outcomes (Stratec, Pforzheim, Germany; Bone Strength Index (BSI) and polar Stress Strain Index (pSSI)) in 254 (142 females) participants. Spearman correlation coefficients were estimated to investigate the associations among the PA measures and between the PA measures and bone strength outcomes.

RESULTS: Associations among the three MVPA/VPA measures were strong, consistent, and of similar magnitude (e.g., MVPA r = 0.81 to 0.96, VPA r = 0.76 to 0.96). While those between the acceleration data and bone strength indices (sex-specific, adjusted for weight and height) were low-to-moderate, consistent, and of similar magnitude (r = 0.04 to 0.39).

CONCLUSIONS: The use of different algorithms to summarize ActiGraph accelerometer outputs, including a new raw data approach, yielded comparable results for predicting bone strength based on MVPA/VPA. Therefore, general conclusions drawn from studies using different approaches to reduce accelerometer data are likely to be comparable.

Current Physical Activity Is Independently Associated with Cortical Bone Size in Older Swedish Women. Martin Nilsson*¹, Daniel Sundh², Dan Mellström², Mattias Lorentzon². ¹Centre for Bone & Arthritis Research At the Sahlgrenska Academy, Sweden, ²Geriatric Medicine, Centre for Bone & Arthritis Research, The Sahlgrenska Academy, University of Gothenburg, Sweden, Sweden

Purpose: We have previously reported that exercise during growth and young adulthood was independently associated with increased cortical bone size via periosteal expansion, whereas physical activity at old age was related to decreased endosteal bone loss in weight-bearing bone in old men (Nilsson, M. et al. JBMR. Aug, 2014).

The aim of this study was to investigate if physical activity during growth or at old age was associated with cortical geometry and trabecular microarchitecture in weight-bearing bone in older women.

Methods: In this population-based study 964 women, 78.2±1.6 (mean±SD) years old, were included. Cortical geometry and trabecular microstructure were measured at the distal (14 % level) and ultra distal tibia, respectively, using a high-resolution 3D pQCT device (XtremeCT, Scanco Medical AG). Areal bone mineral density (aBMD) was assessed using DXA (Discovery A, Hologic). A standardized questionnaire was used to collect information about previous circumference and current physical activity (Physical Activity Scale for the Elderly (PASE)).

Results: Current level of physical activity (PASE-score) was associated with cortical cross-sectional area (CSA) at the distal tibia (Fig.1). A linear regression model (including age, height, weight, calcium intake, smoking, levels of exercise during growth, and PASE-score) revealed that level of current physical activity was independently associated with CSA ($\beta=0.21$, $p<0.001$), cortical thickness ($\beta=0.17$, $p<0.001$), and bone volume fraction ($\beta=0.09$, $p=0.004$) at the distal tibia, and total hip aBMD ($\beta=0.10$, $p<0.001$). Exercise during growth and young adulthood was independently associated with periosteal circumference at the distal tibia ($\beta=0.06$, $p<0.05$) but not with any other bone measurements.

Conclusion: In this large cohort of older women, current physical activity was independently associated with cortical bone size, in terms of thicker cortex but not larger periosteal circumference, at the distal tibia. These findings indicate that physical activity at old age may decrease cortical bone loss in weight-bearing bone in older women. In contrast to our previous findings in older men, physical activity during growth and young adulthood is not the strongest determinant of cortical bone size in older women, suggesting sex-specific mechanisms.

The Use of Accelerometers to Measure Lower Limb Loading During Activity: Sampling Rate and Operating Range Considerations. Christina Ziebart*, Jenna C Gibbs, Iris Levine, Andrew Laing, James Tung, Lora Giangregorio. University of Waterloo, Canada

Background: It has been suggested that bone response to loading varies with the frequency and intensity of impact loads. While wearable accelerometers have been suggested as a tool for measuring impact loading in daily activities, it is not known how variations in sensor characteristics might affect measurement accuracy. The purpose of this study was: 1) to characterize the peak vertical acceleration achieved during a variety of activities, and 2) to compare peak acceleration values measured across three accelerometers (differing in sampling rate and operating range) during a range of activities. **Methods:** Twelve healthy young adults performed nine activities while simultaneously wearing three triaxial accelerometers. Two accelerometers designed for monitoring daily activities employed lower sampling rates and operating ranges (Actigraph GT3X: 100Hz sampling rate, ~6g range; X6-2mini: 320Hz, ~6g) were compared with a criterion standard accelerometer (Endevco 2707A: 1000Hz, ~20g) using Bland-Altman and correlation analyses. **Findings:** Box drop, vertical jump, heel drop and left single leg lateral jump resulted in the highest measured impacts. The correlation between the criterion standard accelerometer and the others was low-moderate for the majority of activities (Actigraph: R²= 0.587, X6-2mini: R²= 0.398),

but improved when the range was limited to the activity monitoring accelerometers' ~6 g operating range (Actigraph: R²= 0.831, X6-2mini: R²= 0.863). **Interpretation:** This study found that activity monitoring accelerometers under-estimated peak accelerations compared to the criterion standard accelerometer. There was variation in the magnitude of impact load detected by the different devices and studies employing these devices should take sensor characteristics into account.

Trabecular Bone Score is Related to Physical Function in Adults. Diane Krueger*¹, Ellen Fidler², Jessie Libber², Neil Binkley², Bjoern Buehring². ¹University of Wisconsin, Madison, USA, ²University of Wisconsin, USA

Background: Muscle force alters bone structure. Thus, it is not surprising that physical function and trabecular bone score (TBS; a surrogate for bone micro-structure) are related to fracture risk. It has been reported that physical performance is positively correlated with TBS in young women. This observation is plausible, as greater load application should improve bone microarchitecture. As such, we hypothesized that TBS would be positively correlated with physical function not only in young adults, but across the lifespan. This study evaluated the relationship of TBS with physical function parameters in adult men and women.

Methods: Subjects (n = 221, 90 M/131 F) from 4 studies that collected physical function measures and spine DXA were used for this analysis. The sample was limited to those with a BMI of 15-38 kg/m² to meet TBS requirements. Functional assessments included grip strength, chair rise, gait speed and relative force and power determined by jumping mechanography. Univariate and multivariate regressions were performed with each physical function test to explore the correlation of function tests with TBS and BMD using XLSTAT (New York, NY).

Results: Mean (±SD, range) age, BMI and T-score were 65.1 (±19.0, 27 to 96.5) years, 26.8 (±4.7, 15.1 to 37.3) kg/m² and +0.25 (±1.9, -4.3 to +7.0) respectively. TBS was positively correlated with all functional tests (p < 0.01) in univariate analyses. Spine and/or hip BMD was positively correlated (p < 0.01) with all functional tests except gait speed. In multivariate modeling including TBS and BMD, TBS remained independently correlated with all functional tests (p < 0.01) except grip strength. In subsequent age (< 45, < 65 and > 65 years) and sex-stratified analyses, TBS remained positively correlated with all functional parameters in men and in women younger than age 65, but not in women age > 65.

Conclusion: TBS is positively correlated with function suggesting that muscle performance affects bone microarchitecture reinforcing the paradigm that muscle is vital in fracture prevention. Loss of the relationship between TBS and function in older women may imply that estrogen depletion driven microarchitectural deterioration supersedes the role of function on bone microarchitecture. Further studies evaluating whether measures to improve physical performance alter TBS are indicated.

Bone quality and quantity in Duchenne Muscular Dystrophy patients. Renaud Winzenrieth*¹, Luis Del Rio², Silvana Di Gregorio². ¹Med-imaps, Hôpital X. Arnoz, PTIB, Pessac, France, France, ²Cetir Group Medic, Spain

It is well known that subjects with Duchenne Muscular Dystrophy (DMD) have low areal bone mineral density (aBMD) and are at higher risk for fractures. However, no data exist concerning bone microarchitecture status. The aim of the study is to evaluate bone quantity (aBMD) and bone quality as assessed by TBS in DMD subjects.

Forty three boys and girls suffering from DMD with a mean age 10.5±3.7 years and Height and Weight z-score medians of -0.67 and 0.25 SD were included in the study. Spine DXA scans were obtained using a GE Lunar Prodigy with software v13.31. Lumbar spine TBS was determined using Med-Imaps custom software to calculate raw values that were subsequently adjusted for tissue thickness based on a normative population (from birth to 19 years old) of healthy Spanish boys (n=1468) and girls (n=2659). Subjects were stratified based on tertile approach for TBS and aBMD.

Overall, the mean aBMD Z-score of the population was moderate (-1.19±1.19 SD) while TBS Z-score was normal for age (-0.08±1.32 SD). Negative associations were observed between aBMD, Height and weight Z-scores and age (r=-0.56, -0.43 and -0.51, p<0.001) whereas no association was obtained with TBS Z-score (r<0.1, p=0.9). aBMD explained 25% (r²) of TBS values. Considering subjects in the lowest tertile (LT), 14 subjects were in this tertile based on aBMD or TBS. No differences in terms of age, height and weight Z-scores, lumbar tissue thickness or fat percent (all p>0.7) were observed between these two group of subjects. The LT cut-off values were 0.582 g/cm² for aBMD (z-score=-0.84SD) and 1.188 for TBS. Subjects in the aBMD LT have a TBS value normal for age (Z-score=-0.04SD) while subjects in the TBS LT have a low aBMD for age (Z-score=-0.95SD). Interestingly, considering the minimum of TBS or aBMD LT values, 21 subjects were classified as low bone status.

As expected, low aBMD was observed in DMD subjects. Interestingly, a normal trabecular bone texture (TBS) for age was observed in those patients. aBMD and TBS identified similar number of subjects with low bone status. One striking finding concerns the cut-off value of TBS LT which is similar to that obtain for adults and

link to a high risk for fracture (1.188 vs 1.200). In addition, it seems that the combination of aBMD and TBS allows to identify more subjects with low bone status. Further researches are needed to evaluate parameters associated with a low TBS value as well as TBS changes during growth in DMD subjects.

SU0053

Evolution of bone quality and quantity in patients suffering from Duchenne Muscular Dystrophy. Luis Del Rio¹, Silvana Di Gregorio¹, Renaud Winzenrieth^{*2}. ¹Cetir Group Medic, Spain, ²R&D department, Med-Imaps, France

The aim of the study is to evaluate, across time, if a bone microarchitectural texture modification exists or not and to evaluate its associations with other bone and body composition parameters.

Sixteen Spanish boys (n=15) and girls (n=1) suffering from DMD with a mean age 9.7 ± 3.0 years and Height and Weight z-score of -0.76 and 0.16 SD were included in the study. Spine DXA scans and body composition scans were obtained using a GE Lunar iDXA (GE-Lunar, Madison) at baseline, 12 and 24 months of follow-up. Lumbar spine TBS was determined using Med-Imaps custom software to calculate raw values that were subsequently adjusted for tissue thickness based on a normative population of healthy Spanish boys and girls (n=4127). Z-score TBS were evaluated using the same normative population. Variations of mean BMD and TBS during the follow-up were expressed in SD. Z-scores variations of BMD, TBS, height and weight were also assessed.

At baseline, BMD and TBS Z-scores were -1.1SD and -0.2SD respectively. Both TBS and BMD increased significantly during the follow-up with more marked increase for TBS as expressed in SD (see figure 1). A weak correlation between TBS and BMD variations has been observed ($r=0.51$). BMD and TBS Z-score decreased along the follow-up as expressed by Z-score Changes presented figure 1. Similarly, height and weight Z-score still decreased during the follow-up. This Z-score decreases seems to be more marked on TBS (ΔZ -score=-0.78SD), Height (ΔZ -score=-1.04SD) and Weight (ΔZ -score=-1.39SD) than on Spine BMD (ΔZ -score=-0.34SD) after 24 months of follow-up. At baseline and 12 months, TBS was associated positively with total fat mass ($r^2=0.46$, $p=0.01$ and $r^2=0.64$, $p<0.001$) while lean mass, BMD at spine, age, BMI, height were excluded from the model. No association was calculated at 24 months due to a small number of patients.

As expected, both BMD and TBS increase during growth with a weak correlation between BMD and TBS changes ($r^2=26\%$). Although these physiological increases, these values remained below normal values for age. Interestingly, TBS seemed to be associated with the total fat mass while BMD was not. These results suggest that a bone texture impairment exists in DMD and that this impairment varies with growth.

Early Bone Deficits Measured by pQCT in the Mucopolysaccharidoses Despite Current Therapies. Lynda E. Polgreen^{*1}, Anna Petryk², Aaron S. Kelly², Lesley Scibora³, Bradley S. Miller², Chester B. Whitley², Ellen B. Fung⁴. ¹Los Angeles Biomedical Research Institute at Harbor-UCLA, USA, ²University of Minnesota, USA, ³St. Thomas University, USA, ⁴UCSF Benioff Children's Hospital Oakland, USA

With the development of enzyme replacement therapy (ERT) and hematopoietic cell transplantation (HCT), children with mucopolysaccharidoses (MPS) types I, II and VI are now living into adulthood and long-term disease complications need to be considered. We have previously identified deficits in areal bone mineral density (aBMD) and content measured by dual-energy x-ray absorptiometry (DXA) in children and adolescents with MPS. However, severe short stature is characteristic of these MPS diseases, which complicates interpretation of DXA measures. In addition, abnormal bone geometry has been suggested by radiographic analysis, but has never before been evaluated by peripheral quantitative computed tomography (pQCT). Therefore, we have obtained pQCT measurements to test our hypothesis that children and adolescents with MPS have bone deficits compared to healthy controls. A cross-sectional analysis was performed on 38 MPS (age 5-20 years, 29% female) and 36 healthy control (age 8-16 years, 33% female) subjects. Mean age and body mass index percentile (BMI%) were not significantly different between groups. Tibia pQCT outcomes [3% (metaphyseal) and 38% (diaphyseal) sites] were compared between groups using linear regression with adjustment for tibia length; secondary analysis evaluated the impact of age and BMI% on the group differences. At the 3% site MPS subjects had 24% lower trabecular volumetric (vBMD) ($p<0.001$). At the 38% site MPS subjects had 10-27% lower total vBMD, bone area, polar section modulus, strength strain index, periosteal circumference and cortical thickness (all $p<0.01$). There was no difference in cortical vBMD at the 38% site. These differences were unchanged with the addition of age and BMI% to our model. These results confirm our previous findings of low aBMD by DXA. In addition, with this study we were able to further show that decreased density and abnormalities in bone apposition combine leading to decreased strength measures independent of stature and despite current therapies. These abnormalities suggest that as young patients with MPS are living into adulthood they will be at risk for early osteoporosis and increased risk of fracture. Determination of underlying etiology of bone deficits is needed to direct future therapies.

A Genetic Variant in the Gamma Glutamyl Carboxylase Gene Affects Bone Quality in a Pediatric African American Cohort. Jacqueline McKesey^{*1}, Courtney Sproue², Heather Gordish-Dressman², Elizabeth Dominic³, Elizabeth Hedges³, Zachary Kendrick⁴, Michael Liu⁴, Leticia Ryan⁵, Joseph Devaney⁶, Laura Tosi⁷. ¹Georgetown University School of Medicine, USA, ²Center for Genetic Medicine Children's National Medical Center, USA, ³The School of Medicine & Health Sciences George Washington University, USA, ⁴School of Medicine & Health Sciences George Washington University, USA, ⁵John's Hopkins Children's Center, USA, ⁶Department of Laboratory Medicine Children's National Medical Center, USA, ⁷Department of Orthopaedics & Sports Medicine Children's National Medical Center, USA

Objective: To explore whether a single nucleotide polymorphism (SNP), rs699644, located in the GGX gene and recently demonstrated to be associated with bone quality, is associated with bone mineral density (BMD) and bone mineral content (BMC) in a population of African American children.

Methods: The Bone Health cohort included 142 African-American children (ages 5 to 9) previously recruited for a study on forearm fractures. Measures of bone quality were collected using Dual Energy X-ray Absorptiometry. Phenotypes included total body minus head (tBMD) and lumbar (lBMD) height and age adjusted BMD z-scores, total body minus head BMC (tBMC) and lumbar BMC (lBMC). Z-scores were obtained using the Bone Mineral Density in Childhood Study Z-score calculator. The SNP was genotyped using a TaqMan allelic discrimination assay. Statistical Analysis was performed using ANOVA on z-scores and ANCOVA on all other phenotypes with covariates of age and gender. Analyses used the dominant genetic model. The SNP was in Hardy-Weinberg equilibrium.

Results: A significant association was discovered between tBMD z-score and genotype (GA/GG[n=59]: -0.507 ± 0.120 ; AA[n=38]: -0.111 ± 0.151 ; $p=0.04$). The association approached statistical significance with tBMC (GA/GG [n=75]: $942 \pm 19g$; AA [n=43]: $999 \pm 25g$; $p=0.07$) and lumbar BMD z-score (GA/GG [n=76]: 0.013 ± 0.122 ; AA [n=44]: 0.362 ± 0.160 ; $p=0.08$). See Table 1.

Discussion: Analysis of the cohort revealed an association between variants in the GGX gene and BMD. This suggests that the SNP,rs699644, influences bone quality in children. Our results show individuals with at least one copy of the G allele display lower BMD values. Further studies with increased statistical power and ethnically diverse participants should be conducted to further determine an association between osteocalcin activity and bone quality across the lifespan.

Conclusion: This study demonstrated that a SNP in the GGX gene is associated with BMD in a pediatric African American cohort. Osteocalcin activity, whose

mineralizing properties are affected by the GGCX protein carboxylase activity, has been demonstrated to play a role in the maturation and turnover of bone as well as BMD and fracture risk in the elderly. This study demonstrated that this may also be true for the young. Literature has suggested that bone health and the achievement of peak mass is correlated with bone health in adulthood. Therefore, demonstrating the modulators of childhood BMD is essential.

| Phenotype | Genotype | | p value |
|-----------------------------------|-----------------------|-----------------------|---------|
| | GG/GA (325R) | AA (325Q) | |
| Total body (less head)BMD z-score | (N=59) -0.507 ± 0.120 | (N=38) -0.111 ± 0.151 | 0.04 |
| Lumbar BMD z-score | (N=76) 0.013 ± 0.122 | (N=44) 0.362 ± 0.160 | 0.08 |
| Total body mean BMC (g) | (N=75) 942 ± 19 | (N=43) 999 ± 25 | 0.07 |

Bone health status and associated factors in the adolescents in Taiwan. Yi-Chin Lin^{*1}, Wen-Harn Pan². ¹Chung Shan Medical University, Taiwan, ²Institute of Biomedical Sciences, Academia Sinica, Taiwan

Adolescence is critical for the development of peak bone mass, which may in turn affect the risk for osteoporosis in later life. This preliminary analysis is based on the data collected from high school subjects recruited during the Nutrition and Health Survey in Taiwan (NAHSIT) 2010-2011. A total of 1098 male and 1124 female adolescents, aged 12-19 years, have completed bone scan by DXA. The results showed that for both genders, age and body weight significantly predicted bone mineral content (BMC, in gram) at total body, lumbar spine 2-4, and femoral neck in a non-linear manner. The results of multiple regression showed that age, height and body weight explained 82.06% and 74.93% of the variation in total body BMC in adolescent boys and girls, respectively. Grip strength was significantly correlated to BMC and BMD at all sites in both genders. For girls, post-menarcheal age predicted BMC at all sites slightly better than the chronological age. In the adolescent boys, there was a significant correlation (partialled for age) between dietary intake of calcium by calories (calcium density, in mg/kcal) and bone mineral density (BMD, in g/cm³), but not BMC, at lumbar spine 2-4 ($r=0.071$). Dietary intake of protein, as the absolute amount or as percent of daily total calories, was not significant predictors for BMC or BMD at all sites. The amount of protein per kilogram of body weight (0.09 – 5.82, mean=1.62±0.82 for boys and 0.18 – 5.91, mean=1.68±0.85 for girls), however, significantly related to BMC at all site in a negative manner, although the statistical significance slightly decreased in the multivariate models. On the other hand, there was significant correlation between the stories of stairs climbed per day, the number of days per week engaged in intensive exercise and BMC at all sites, respectively, in the adolescent boys, and the significance remained in the multivariate models. The results of our current analyses showed that dietary intake and the level of physical activity may play some roles in bone health in Taiwanese adolescents.

Vitamin D levels in Swedish Children Over the Past 30 years. Diana Swolin-Eide^{*1}, Bjorn Andersson², Per Magnusson³, kerstin Albertsson-Wikland⁴. ¹Queen Silvia Children's Hospital, Sweden, ²Department of Pediatrics, The Sahlgrenska Academy at the University of Gothenburg, Sweden, ³Division of Clinical Chemistry, Linköping University, Sweden, ⁴Department of Physiology/Division of Endocrinology, The Sahlgrenska Academy at the University of Gothenburg, Sweden

Background: The importance of vitamin D for skeletal health is well established and its potential role for extraskeletal health has generated much hype in recent years, since many reports indicate that vitamin D deficiency is linked to chronic diseases. Vitamin D status is defined by serum 25-hydroxyvitamin D (25(OH)D), and although there is no consensus on optimal levels of 25(OH)D, the Institute of Medicine stated that 25(OH)D concentrations of 50 nmol/L (20 ng/mL) meet the requirements in 97.5% of the population. During infancy vitamin D supplementation is recommended in Sweden. We hypothesized that increased indoor activities and obesity would contribute to decreased vitamin D levels in children and adolescents during the three last decades. Methods: We analysed serum collected during the years 1982 to 2013 from 2048 Swedish children (mean age ± SD, 8.59 ± 3.68 years; 1197 boys). 25(OH)D was determined with the IDS-iSYS 25-Hydroxy Vitamin DS automated chemiluminescence immunoassay. Studies of decades-old sera have revealed that 25(OH)D is a stable analyte and can thus be used to explore long-term trends of vitamin D-related issues. Results: Seven hundred and four (34.4%) subjects had serum 25(OH)D levels below the recommended level of 50 nmol/L over the entire study period of 32 years. Interestingly, only 3.1% of the children had 25(OH)D levels below 25 nmol/L defined as vitamin D deficiency. We found a significant association with age, i.e., younger

children had higher levels of 25(OH)D, possibly due to the general supplementation of vitamin D recommended for Swedish children. Conclusion: We found no trend for decreased vitamin D levels over time in this study population. These results provide a unique long-term follow-up over 30 years of vitamin D levels in a large group of children. This will be of high value for future cost-benefit analyses in preventive health care.

A Subtrochanteric Femoral Stress Fracture Following Bisphosphonate Treatment in an Adolescent Girl. Alison Boyce^{*1}, Michael Collins², Laura Tosi³, Rachel Gafni⁴. ¹National Institutes of Health, USA, ²CDSB, NIDCR, NIH, USA, ³Children's National Health System, USA, ⁴CDSB, NIDCR, NIH, USA

Bisphosphonates are increasingly used to treat low bone mineral density (BMD) in children and adolescents. Long-term bisphosphonate use in adults has been associated with atypical subtrochanteric and diaphyseal femoral fractures (AFFs). Bisphosphonate-related AFFs have not been reported in children or adolescents. Case: A 16-year-old girl presented with left thigh pain. Her history was significant for idiopathic juvenile osteoporosis diagnosed at age 11 after presenting with back pain and thoracic compression fractures. A DXA scan at that time showed a lumbar spine Z-score -3.9 and total body less head -2.0. An extensive workup including vertebral biopsy and COL1A1/1A2 testing did not reveal an etiology for her low BMD. She was treated with pamidronate for a 2-year period, receiving a cumulative dose of 12 mg/kg. During treatment she had partial reconstitution of her vertebral bodies and no additional fractures. At pamidronate discontinuation (age 14), her lumbar spine Z-score improved to -1.6 and total body less head to -0.6. Just prior to the onset of thigh pain she had joined a cross-country team after several years of limited sports activity. Plain films showed diffuse cortical thickening of the bilateral femoral diaphysis, and a localized periosteal reaction at the medial cortex of the proximal left femur. A bone scan showed focal tracer uptake in this location, consistent with a stress fracture. Management: The patient was treated with relative rest and physical therapy. After a protracted 16-week course her pain improved and she was able to resume regular activities. Plain films 8-months after initial presentation with thigh pain showed resolution of the periosteal reaction. Discussion: This adolescent's presentation with a femoral stress fracture following high-dose pamidronate treatment shares several features in common with AFFs, including subtrochanteric location, localized periosteal reaction, and generalized cortical thickening of the femoral diaphysis. However unlike bisphosphonate-associated AFFs in adults, which typically develop on the lateral tensile cortical surface, this patient's stress fracture occurred at the medial cortex. Thus while suggestive, the contribution of bisphosphonates to this patient's stress fracture is not known. Nevertheless practitioners should evaluate thigh pain in children and adolescents with a history of bisphosphonate treatment, and include AFFs and other femoral stress fractures in the differential.

Arrows indicate proximal femoral stress fracture.
Stars indicate thickened femoral cortices.

Differential Behavioral and Skeletal Responses to Methylphenidate in Male and Female. Sardar Uddin¹, Lisa Robison², Melissa Vitale², Junho Lee², Michalis Michaelos², Jason Gandhi³, Soyeh Paeng³, Panayotis Thanos³, Michael Hadjiargyrou⁴, David Komatsu¹. ¹Department of Orthopaedics, Stony Brook University, USA, ²Department of Psychology, Stony Brook University, Stony Brook, NY, USA, ³Department of Psychology, Stony Brook University, USA, ⁴Department of Life Sciences, New York Institute of Technology, USA

Methylphenidate (MP) is widely used to treat Attention Deficit Hyperactivity Disorder (ADHD), the most commonly diagnosed adolescent psychological disorder with a US incidence of ~9.5%. We previously showed that MP treatment in adolescent female rats resulted in mild effects during skeletal development. The current study was conducted to examine the differential response of male and female rats to MP. Four-week old Sprague-Dawley rats were randomized to 5 groups (n=12/T_x): Water, Low-Dose MP (LD, 10mg/Kg MP), High-Dose MP (HD, 60mg/Kg MP), Water Pair-Fed to LD MP (Water LD PF), and Water Pair-Fed to HD MP (Water HD PF). Water groups received no MP. LD and HD received MP via their drinking water. Pair-fed groups had food restricted to their corresponding treatment groups' ad-lib consumption. After 13 weeks of treatment, both male and female rats showed significant decrease in body weight. HD MP treated rats were more active than water and LD MP treated rats during the dark cycle, and this was significant for both males and females (p<0.05). Within HD MP treated rats, females were more active than males during the dark cycle (p<0.001). There were no differences between any groups during the light cycle. Femora were assessed by microCT at cortical (mid-diaphysis) and trabecular (distal metaphysis) regions. No significant differences were observed during female skeletal development. Male rates showed significant decreases in trabecular thickness between LD MP vs HD MP (6%, p=0.007), Water HD-PF vs. HD MP (7%, p=0.027) and bone mineral density between LD MP vs HD MP (1%, p=0.022). Endosteal volume and surface significantly decreased in LD MP (13%) treated rats relative to water controls. Three-point bending revealed no differences in female rats but showed significant decrease energy to failure (23%), energy to ultimate force (17.5%), and ultimate force (11%) in HD MP compare to Water fed rats (Fig. 1). Overall female rats displayed hyperactivity but no effects on skeletal development while males had little behavioral difference with significant decrease in bone quality and quantity. Pair-feeding removed body weight as a confounding variable at the low dose, but not at the high dose. This is likely due to the tremendous increases in physical activity seen in the high dose rats. We speculate that increase activity in female rats protects bone from the detrimental effects of MP on skeletal development, which were apparent in less active male rats.

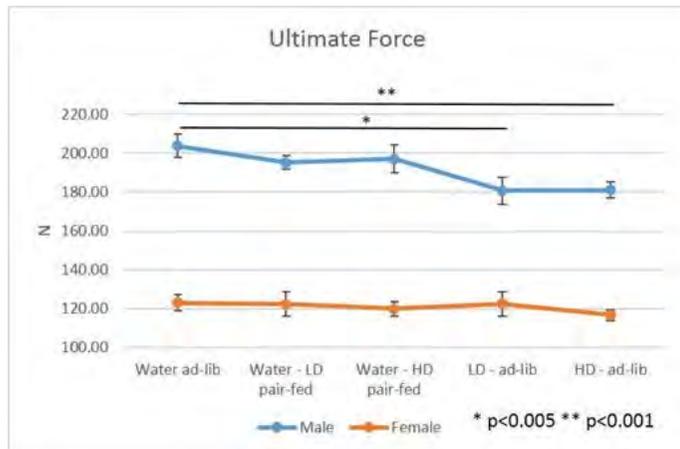

Figure 1: Three point bending Ultimate Force. No difference were observed in female rats. Male rat

Physiologic PTH Signaling in Osteocytes Restrains Long-Term Hematopoietic Stem Cells in the Niche. Benjamin Frisch¹, Alexandra Goodman¹, Olga Bromberg¹, Xiaolin Tu², Teresita Bellido³, Laura Calvi¹. ¹University of Rochester School of Medicine & Dentistry, USA, ²University of Indiana Department of Anatomy & Cell Biology, USA, ³Indiana University Department of Anatomy & Cell Biology, USA

The bone marrow microenvironment, including osteolineage cells, regulates hematopoietic stem cell (HSC) fate choices. Pharmacologic treatment of mice with parathyroid hormone, PTH (1-34), increases HSCs through their niche, as HSCs do not express the PTH receptor (PTH1R). However, it is not known if PTH plays a physiologic role in HSC regulation. Osteocytes, the most abundant osteolineage cells in bone, coordinate multiple cell types that are components of the HSC niche including osteoblasts, osteoclasts and resident macrophages. While osteocytes express the PTH1R, the role of osteocytes in HSC regulation is unclear. Therefore, we studied

the physiologic role of osteocyte-mediated PTH regulation of HSCs, using cre recombinase driven by the 8kb-DMP1 promoter to conditionally delete PTH1R in osteocytes (OCyPTH1Rko mice). Targeted deletion of PTH1R was demonstrated. OCyPTH1Rko mice were viable, fertile, and did not exhibit any significant skeletal defect as juveniles or at 6 months of age, and had no significant difference in PTH levels compared to WT mice. In juvenile OCyPTH1Rko mice there was a subtle, but significant decrease in long-term HSCs as measured by flow cytometric analysis (0.0029 ± 0.00028 vs. 0.0021 ± 0.00021 % of cells, WT vs. OCyPTH1Rko p ≤ 0.05 N ≥ 19 mice/group). OCyPTH1Rko mice had a dramatic functional loss of long-term engraftment capacity as measured by secondary competitive transplantation over 22 weeks (WT vs. OCyPTH1Rko donors, 2-way ANOVA p ≤ 0.001 , N ≥ 10 mice/group) that was evident in all hematopoietic lineages. Short-term engraftment however was increased in OCyPTH1Rko mice as measured by primary competitive transplantation (WT vs. OCyPTH1Rko donors, 2-way ANOVA p ≤ 0.01 , N ≥ 9 mice/group). These data demonstrate that physiologic PTH signaling in osteocytes regulates the balance of long-term and short-term HSC potential in juvenile, growing mice. Adult OCyPTH1Rko mice also had a dramatic decrease in long-term engraftment (WT vs. OCyPTH1Rko donors, 2-way ANOVA p ≤ 0.001 , N ≥ 15 mice/group). Our findings demonstrate a previously unrecognized physiologic role of PTH signaling in HSC regulation. Moreover, these data identify osteocytes as a critical constituent of the HSC niche that, either directly or indirectly, contribute to maintenance of the long-term repopulating HSC pool.

Erythropoietin and bone remodeling. Sukanya Suresh¹, Luis Fernandez De Castro Diaz², Soumyadeep Dey¹, Pamela Robey², Constance Noguchi¹. ¹Molecular Medicine Branch, Molecular Cell Biology Section, NIDDK, NIH, USA, ²Skeletal Biology Section, Craniofacial & Skeletal Diseases Branch, NIDCR, NIH, USA

Erythropoietin (EPO) is best known for its role as a hematopoietic hormone essential for red blood cell (RBC) production. Recombinant forms of EPO are widely used in the clinic to treat patients suffering from anemia resulting from low EPO such as chronic kidney failure, chemotherapy and antiviral treatment for Human Immunodeficiency Virus (HIV). Bone marrow is the primary site of EPO activity and EPO effects on bone remodeling have been reported to be associated with both improved bone healing as well as with bone resorption. Here we find that EPO treatment of wild type mice (1200 IU/kg daily dose of EPO for ten days) increased hematocrit (70%) and bone marrow cellularity, and resulted in decreased trabecular bone mineral density, decreased trabecular number, and increased trabecular spacing. This observed difference with EPO treatment could result from the direct or indirect EPO response of the cells that are involved in bone remodeling namely osteoblasts (bone forming) and osteoclasts (bone resorbing). Cultures of bone marrow cells for osteoclast differentiation and of osteogenic calvarial cells both express EPO receptor. However, EPO treatment did not show a change in osteoclast or osteoblast differentiation, respectively, or increased mineralization. This raises the possibility that indirect mechanisms such as the proposed EPO stimulated production of BMPs by hematopoietic stem cells may contribute to EPO induced bone resorption or that the culture conditions for wild type osteoclastic or osteogenic cells do not sufficiently mimic the in vivo microenvironment that promotes bone resorption with EPO treatment. These data provide evidence for the direct or indirect effects of EPO on bone remodeling and decreased trabecular bone mineral density associated with EPO treatment in mice in addition to the known increase in erythropoiesis and bone marrow cellularity.

Bone marrow blood vessels are further away from trabecular bone with age and short-term intermittent PTH 1-34 administration augmented bone perfusion in young Fischer-344 rats. Rhonda Prisby^{*}, Sophie Guderian, James Cirone, Shaopeng Pei, Liyun Wang, Seungyong Lee. University of Delaware, USA

Spatial closeness of bone marrow blood vessels to sites of new bone formation with intermittent parathyroid (PTH) 1-84 administration may have aided in bone accrual (Prisby et al., 2011). Under this paradigm, age-related bone loss may be partially attributed to an increased separation between blood vessels and bone. We sought to assess age- and PTH-related changes in blood vessel location and bone perfusion. Male Fischer-344 rats were divided into the following groups: 1) young control (CON; 4-6 mon; n=16), young PTH (n=16), 3) old CON (22-24 mon; n=16) and old PTH (n=16). Rats were given either PTH 1-34 (43 mg/kg/d) or a placebo (PBS; 100 μ l/d) s.c. for 5 d/wk for 2 weeks. At sacrifice, half the rats were perfused with barium sulfate and right femora analyzed by bone histomorphometry. Distances of vessels 1-29 μ m, 30-100 μ m and 101-200 μ m in diameter were analyzed in relation to quiescent trabeculae and osteoid. In the other half of rats, fluorescent microspheres were injected into the left ventricle to determine perfusion in the proximal and distal femur, marrow and femoral diaphysis. Perfusion was expressed as tissue fluorescent density (TDF [AU/g] = tissue fluorescence \div tissue mass). Left femora were scanned via μ CT. As anticipated, BV/TV was lower (p<0.05) in old ($18.48 \pm 0.01\%$) vs. young

(26.23±0.02%) CON rats via reduced Tb.N (2.7±0.5/mm² vs. 4.1±0.2/mm², respectively). BV/TV was unaltered by PTH treatment in young rats (28.89±0.02%) but tended (p=0.08) to augment BV/TV in old rats (22.41±0.01%) via thicker trabeculae. Bone static properties (i.e., OS/BS, Obs/BS and Ocs/BS) did not differ among groups. Marrow perfusion was reduced (p<0.05) in old (5769±1444AU/g) vs. young (14726±2387AU/g) CON rats. Further, perfusion in the distal (p=0.06) and proximal (p=0.08) femur tended to reduce with age. Perfusion was higher (p<0.05) in the proximal femur (6407±1020AU/g vs. 4683±406AU/g, respectively) and tended (p=0.08) to increase in the marrow (21361±4433AU/g vs. 14726±2387AU/g) in young PTH vs. CON rats. Vessels 1-29µm (110±22µm vs. 170±22µm, p=0.07) and 30-100µm (209±23µm vs. 284±23µm, p<0.05) were further away from trabeculae in old vs. young rats (main effect) and vessels 101-200µm were closer (p<0.05) to osteoid in PTH-treated (320±31µm) vs. CON (418±31µm) rats (main effect). Blood vessel distance from bone is greater and bone perfusion lower in old age and short-term (15 days), intermittent PTH 1-34 administration augmented bone perfusion in young rats.

Short-Term Intermittent PTH (1-34) Administration Augments Skeletal Blood Flow and Perfusion in Mice as Assessed with Fluorescent Microspheres. SEUNGYONG LEE*, Rhonda Prisby. University of Delaware, USA

Bone loss and fracture risk is prevalent in old age. Further, reduced bone vascular function and blood flow occur in senescence (Prisby et al., 2007). Intermittent parathyroid hormone (PTH) administration augmented bone volume and enhanced vasodilation of bone arteries in young (Prisby et al., 2013) and old (Lee et al., 2014) rats. Additionally, intermittent PTH 1-84 administration increased tibial perfusion (Roche, et al., 2014) in mice. We sought to kinetically determine the rapidity by which PTH influences bone perfusion following 5 and 10 days of intermittent PTH 1-34 administration. Secondly, we compared perfusion expressed as absolute blood flow rate vs. tissue fluorescent density (TFD). Male and female C57BL/6 mice (6-8 mon) were divided equally into three groups (CON, 5dPTH, 10dPTH) and given either PTH 1-34 (43 µg/kg/d) or PBS (50 µl) for 5 and 10 consecutive days. Under anesthesia, fluorescent microspheres (Life Technologies) were injected directly to the left ventricle. Subsequently, a left ventricular reference blood sample was collected. Following sacrifice, the vertebral column, left and right tibiae and right femora were collected, decalcified and dissolved. Blood flow rate was calculated in ml/min/100 grams of tissue by use of the reference blood sample and TFD (AU/g) was determined as tissue fluorescence ÷ tissue weight. Data were excluded if kidney flow rates differed by >20% or if there were <400 beads per tissue. Femora were sectioned into the distal and proximal ends, marrow and cortical shell. Body mass and tissue weights did not differ among conditions. Blood flow to all bones, except the left tibia, was higher (p<0.05) in the 10dPTH vs. 5dPTH and CON groups. There were tendencies for higher blood flows to the marrow (p=0.09; 10dPTH, 5.3±1.9 ml/min/100g vs. 5dPTH, 0.6±0.2 ml/min/100g and CON, 2.9±1.0 ml/min/100g, respectively) and left tibia (p=0.068; 10dPTH, 1.0±0.2 ml/min/100g vs. 5dPTH, 0.3±0.2 ml/min/100g and CON, 0.5±0.2 ml/min/100g, respectively). In contrast, left tibial TFD was higher (p<0.05) in the 5dPTH vs. 10dPTH group. Further, cortical shell TFD tended (p=0.1) to be higher in the 5dPTH vs. 10dPTH and CON groups. Short-term intermittent PTH 1-34 administration improves bone blood flow in as short as 10 days and may alleviate the age-related declines observed in skeletal perfusion. Moreover, these data suggest that blood flow rate may be a more sensitive determination of skeletal perfusion in comparison to TFD.

Inflammatory Cytokines Cause a Shift in the Haematopoietic Microenvironment Modulating the Development of Osteoclasts. Nina Ruef*, Silvia Dolder¹, Mark Siegrist¹, Deepak Balani², Daniel Aeberli³, Michael Seitz³, Willy Hofstetter¹. ¹Bone Biology, Department Clinical Research, University of Bern, Switzerland, ²Endocrine Unit, Massachusetts General Hospital & Harvard Medical School, USA, ³Department of Rheumatology, Clinical Immunology & Allergology, Bern University Hospital, Switzerland

Levels of circulating inflammatory cytokines (Tumor Necrosis Factor-α (TNFα), Interleukins (IL)-1 and -17) are increased in inflammatory diseases. TNFα and IL-17A induce the release of Granulocyte-Macrophage Colony-Stimulating Factor (GM-CSF) by murine osteoblasts (OB), leading to a change in the haematopoietic microenvironment of osteoclasts (OC) and osteoclast progenitor cells (OPC). Herein, the effects of IL-17A on OC development *in vitro* were further investigated.

OC development was investigated in co-cultures of primary calvarial OB from *DDY* or *C57BL/6J* mice and of OPC in the presence of 1,25(OH)₂D₃, w/o TNFα, and in cultures of OPC suppl. with Macrophage Colony-Stimulating Factor (M-CSF) and Receptor Activator of NF-κB Ligand (RANKL). IL-17A was added to the cultures and OC formation, as well as the release and function of cytokines and their transcript levels, were assessed.

In co-cultures with *DDY* OB, IL-17A dose dependently inhibited OC development, leading to a reduction of the number of OC by 90% at 50 ng/ml. In co-cultures with

C57BL/6J OB, IL-17A dose-dependently increased OC number. In cultures of OPC with M-CSF/ RANKL, IL-17A did not affect osteoclastogenesis. Addition of neutralizing antibodies against GM-CSF attenuated the inhibitory effect of IL-17A in co-cultures. Neutralizing antibodies against TNFα fully restored osteoclastogenesis mediated by IL-17A in co-cultures with *C57BL/6J* OB. *C57BL/6J* and *DDY* OB released GM-CSF in response to treatment with IL-17A/ 1,25(OH)₂D₃/ TNFα. *DDY* OB, however, released higher levels of GM-CSF independently of TNFα. In co-cultures, transcripts encoding RANKL, OPG, IL-6, GM-CSF and NHA2 were regulated by IL-17A, 1,25(OH)₂D₃ and TNFα. Levels of transcripts for RANKL were upregulated and those for OPG were downregulated by 1,25(OH)₂D₃/ IL-17A. Levels of transcripts encoding GM-CSF and IL-6 were upregulated by IL-17A and further increased in the presence of 1,25(OH)₂D₃ and TNFα.

In summary, OB release GM-CSF in response to an exposure to IL-17A and TNFα, generating an inflammatory microenvironment inhibiting osteoclastogenesis. The effects of IL-17A, TNFα, and 1,25(OH)₂D₃ were found to depend on the genetic background of the mice. This mechanism leads to changes in OPC pools in bone, bone marrow and blood in systemic inflammatory diseases. Upon homing to bone, with its specific inflammation driven microenvironment, the increase in OPC numbers stimulates osteoclastogenesis, causing accelerated bone resorption.

Hedgehog signaling in jawbone invasion of oral squamous cell carcinoma. Tsuyoshi Shimo*, Kenichi Matsumoto², Eriko Aoyama³, Tatsuo Okui², Naito Kurio², Akira Sasaki². ¹Okayama University Graduate School of Medicine, Dentistry & Pharmaceutical Sci, Japan, ²Department of Oral & Maxillofacial Surgery, Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sciences, Japan, ³Advanced Research Center for Oral & Craniofacial Sciences, Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sciences, Japan

INTRODUCTION: Oral squamous cell carcinoma invasion into the maxilla and the mandible is a frequent events which action is associated with a worse prognosis. Previously, we have reported that Sonic Hedgehog (SHH) stimulated the osteoclasts differentiation and activation by upregulating RANKL expression in bone stromal cells. In this study, we examined the expression of Hedgehog signaling in the oral squamous cell carcinoma at bone invasion sites, and defined the molecular changes that occur when osteoclasts are exposed to smoothened agonist. **METHODS:** From surgically resected lower gingival squamous cell carcinoma mandible samples, decalcified, immunohistochemical staining was performed. RAW264.7 cells were treated with 50 ng/ml RANKL for 3days, and then cultured with or without smoothened agonist 5 µM SAG for 24h. After the treatment of SAG, total RNAs were isolated, genome-wide gene expression analysis was performed using SuperPrint G3 Mouse GE 8x60K 2 color, and the data was analyzed by GeneSpring GX v.13. **RESULTS:** We found that SHH was highly expressed in tumor cell that had invaded bone matrix. On the other hand, Patched and Gli-2 was highly expressed in the preosteoclasts and mature osteoclasts. When comparing vehicle sample, SAG treated samples showed elevated mostly G protein-coupled receptor (GPCR) pathways. The expression of Tachykinin receptor 3 was highest upregulated in 9.8 times more than control in Non-odorant GPCRs pathways. **DISCUSSION:** Our results suggest that tumor derived SHH regulate osteoclast formation and bone resorption in the tumor bone microenvironment.

MMP13-induced type I collagen degradation plays a key role in the prostate cancer dependent bone metabolism. Kenta Watanabe, Michiko Hirata, Chisato Miyaura, Masaki Inada*. Tokyo University of Agriculture & Technology, Japan

Matrix metalloproteinases (MMPs) are involved in the degradation of extra-cellular matrix (ECM) during the invasion and the metastasis of cancer cells. When prostate cancer cells invade to bone, the cells interact with type I collagen as the major ECM in bone tissue. However, the relationship between type I collagen degradation and prostate cancer dependent bone resorption is still unclear. In this study, we first examined the mRNA expression of MMP-2, MMP-8, MMP-9, MMP-13 and MMP-14 in mouse prostate cancer cell line TRAMP. TRAMP cells expressed MMP-13 and MMP-14 mRNAs. We analyzed the invasive activity of TRAMP using type I and type IV collagen chamber migration system with or without MMP-13 specific inhibitor and general MMPs inhibitor. Both MMP inhibitors suppressed TRAMP invasive activity, and the inhibition effects was higher in MMP-13 specific inhibitor than that of general MMPs inhibitor. For the tracking precise image of the TRAMP growth, the real time culture imaging system was used during 3 days. When TRAMP cells cultured on the type I collagen coated surface, the proliferation was observed by the degradation of type I collagen by collagenases, but the growth was dramatically suppressed by the treatment of MMP-13 specific inhibitor. Next we generated MMP-13 knockdown TRAMP (TRAMP13mi) by the transfection of MMP-13 miRNA expressing vector. When TRAMP13mi cells were cultured on type I collagen surface, the collagen-induced proliferation was attenuated to compare by the control TRAMP. Finally, we cultured TRAMP on cross-linked type I collagen surface that is resistant to the

degradation by collagenase. When TRAMP cells were cultured on cross-linked type I collagen, the growth was inhibited. When TRAMP cells were cultured on mouse calvaria, we detected bone resorbing activity compared with control calvaria, and the treatment of MMP13 specific inhibitor abrogated TRAMP induced bone resorption. These results suggest that prostate cancer degrades type I collagen by MMP13 for its proliferation and bone resorption. MMP13 specific inhibitor might be a candidate for the treatment of bone metastasis of prostate cancer accompanied proliferation and bone resorption.

Novel 3D model mimics the physical properties of bone to allow for detailed studies of interactions between tumor and bone. Ushashi Dadwal¹, Ruijing Guo², Alyssa Merkel³, Shanik Fernando⁴, Denise Buenostro¹, Scott Guelcher⁵, Julie Sterling^{*6}. ¹Vanderbilt Center for Bone Biology, USA, ²Vanderbilt University, Department of Chemical & Biomolecular Engineering, USA, ³Department of Veterans Affairs (TVHS)/ Vanderbilt Center for Bone Biology, USA, ⁴Vanderbilt Department of Chemical & Biomolecular Engineering, USA, ⁵Vanderbilt University Department of Chemical & Biomolecular Engineering, USA, ⁶Department of Veterans Affairs (TVHS)/Vanderbilt University Medical Center, USA

Unique properties of the bone microenvironment influence the behavior of tumor cells. In order to study these dynamic and complex interactions, we developed novel 3D polyurethane (PUR) scaffolds that approximate the mechanical and topological characteristics of bone. Scaffolds were fabricated using 3D-printed molds with uniform pore size and pore spacing ($423 \pm 34 \mu\text{m}$ to $557 \pm 44 \mu\text{m}$) based on the average trabecular separation and thickness of a mouse tibia. Molds were filled with PUR from 10 MPa (compliant) to 2600 MPa (rigid) and coated with adhesion molecules to allow for cell attachment. Fibronectin had the highest percentage of cell attachment and gene expression compared to vitronectin, type I collagen, poly-L-lysine in tumor cells and osteoblasts. In 3D scaffolds seeded with osteoblasts, markers of differentiation (Runx2, Collagen-I and OPN) and mineralization (Alizarin Red S staining) increased significantly with increasing rigidity and decreasing pore size, suggesting that the physical bone microenvironment can alter the host cells. In scaffolds seeded with tumor cells, Gli2 and parathyroid hormone related protein (PTHrP) expression (QPCR) increased with increasing rigidity, decreasing pore size, and increasing flow rate using a perfusion based bioreactor, suggesting that gene expression and tumor cell behavior depend on tissue rigidity. Tumor seeded scaffolds implanted onto the mammary fat pad of mice demonstrated increased Gli2 (18-fold), Integrin $\beta 3$ (20-fold), and PTHrP (26-fold) expression on rigid (bone) versus compliant (tumorigenic breast) scaffolds, and contained abundant infiltrating host cells after 28 days. Flow cytometry and immunohistochemistry analyses indicated an increase in C11b+ cells (2.5-fold) and F4/80+ cells (10-fold) in the rigid scaffolds. These findings suggest that the mechanical and topological properties of the matrix regulate the response of osteoblast, inflammatory, and tumor cells, which may contribute to the uniqueness of tumors growing in the bone microenvironment. Ongoing studies are focused on investigating cellular interactions between the host and tumor cells by seeding combinations of cell types into the 3D scaffolds. Taken together, these data demonstrate the potential of this 3D model system as a unique approach for studying the dynamic and complex interactions between tumor cells and the bone microenvironment.

Anti Urokinase Receptor (uPAR) Antibody (ATN-658) Blocks Breast Cancer Growth and Skeletal Metastasis *in vitro* and *in vivo*; Effects which are Potentiated in Combination with Zometa. Shafaat Rabbani^{*1}, Ani Arakelian², Surabhi Parashar³, Haseeb Khan⁴, Imrana Tanvir⁴, Andrew P. Mazar⁵. ¹McGill University, Ca, ²McGill University Health Centre, Canada, ³McGill University, Canada, ⁴Fatima Memorial Hospital System, Pakistan, ⁵Northwestern University, USA

The proteolytic effects of urokinase (uPA) are localized within the tumor cell environment by the uPA receptor (uPAR) promoting tumor growth and metastasis resulting in the identification of uPAR as an attractive diagnostic and therapeutic target. Towards these goals we developed an anti-uPAR antibody (ATN-658) and examined its ability alone and in combination with bisphosphonate Zometa on breast cancer growth and skeletal metastasis.

Human breast cancer cells, MDA-MB-231, which express high levels of uPA and uPAR were treated with different doses of ATN-658 and Zometa alone and in combination to monitor their effect on tumor progression. In *in vitro* studies treatment with ATN-658 resulted in a dose dependent decrease in tumor cell invasion and increased apoptosis without affecting cell doubling time. Zometa decreased cell proliferation and increased apoptosis. This effect was significantly more pronounced when cells were treated in combination setting. For *in vivo* studies, MDA-MB-231 cells were inoculated via mammary fat pad (5×10^5) into female Balb c nude mice and after staging to 50 mm³ treated with control IgG or ATN-658 (10.0 mg/kg) for 5

weeks. In other studies at day three following intratibial injection of 2×10^5 of tumor cells mice were treated with vehicle alone, ATN-658 Zometa (100 $\mu\text{g}/\text{kg}$) or ATN-658 plus Zometa in combination for 4 weeks. Tumor volume and skeletal lesions were determined by calipers and X-ray using Faxitron. Treatment with ATN-658 caused a significant decrease in primary tumor volume. Both ATN-658 and Zometa were equally effective in causing a marked decrease in skeletal lesions or blocking them in >57% of experimental animals in the combination group. Following combination therapy the area of skeletal lesions was significantly smaller as compared to animals treated with either ATN-658 or Zometa alone. Results of change in the markers of tumor cell proliferation (Ki67), angiogenesis (CD31), osteoclastic activity (TRAP), intracellular signalling pathways and tumor promoting growth factors and proteases of which are regulated by uPAR signalling will be discussed. ATN-658 has now been humanized (huATN-658) and is advancing toward a phase I trial. Results from these studies provide compelling evidence for the continued development of huATN-658 as a potential therapeutic agent for the treatment of breast cancer patients as monotherapy and combined with currently available agents for blocking skeletal metastasis.

Effect of Type 1 Diabetes in Prostate Cancer Model. Sherry Abboud Werner^{*1}, Kathleen Woodruff², Diane Horn², Hanes Martha², Chung Song², Fermin Tio³, Julie Foley⁴, Robert Maronpot⁵, Bandana Chatterjee². ¹University of Texas Health Science Center at San Antonio, USA, ²University of Texas Health Science Center, USA, ³VIA Medical Center, USA, ⁴National Institute of Environmental Health Sciences, USA, ⁵Maronpot Consulting LLC, USA

Prostate cancer is a leading cause of cancer deaths worldwide. Adenocarcinomas of the prostate frequently metastasize and many patients suffer from bone metastasis. High grade tumors, extraprostatic extension and metastasis are associated with a poor prognosis. Diabetes mellitus (DM) has been linked to prostate cancer risk and high grade prostate cancer. However, the precise role of type 1 and type 2 DM in prostate cancer has not been well-defined. Studies to determine whether DM influences prostate cancer have been hampered by the lack of animal models. To examine the effect of type 1 DM in prostate cancer, we performed genetic crosses between transgenic adenocarcinoma of mouse prostate (TRAMP) mice and type 1 diabetic Akita mice. TRAMP mice show carcinoma of the prostate by 24 weeks and develop metastasis with age. At 32 weeks of age, we examined the phenotype of wild type (WT) (n=4), TRAMP (TR) (n=6), heterozygous Akita (AK) (n=3) and TRAMP/heterozygous AK mice (TR/AK) (n=7). Body weight and fasting blood glucose levels were measured. Prostate glands were excised and histologic sections of lateral, dorsal, ventral and anterior lobes were graded for epithelial-stromal/epithelial proliferation, and for the presence of carcinoma. AK and TR/AK mice showed decreased body weight and hyperglycemia compared to TR and WT controls. AK prostates showed normal glandular and stromal elements similar to WT, whereas prostates in TR and AK/TR mice showed increased epithelial proliferation in the lateral, dorsal and anterior lobes. Notably, the degree of epithelial proliferation in prostates from AK/TR mice was significantly reduced compared to that in TR prostates. Moreover, 5 of 6 TR prostates (83.3%) showed carcinoma with two tumors having anaplastic morphology, whereas only 2 of 7 AK/TR mice (28.6%) showed prostate carcinoma. These findings indicate that prolonged exposure to high glucose levels in type 1 DM may act to suppress epithelial proliferation and development of prostate cancer. Results in AK mice provide the first evidence that prostate morphology remains normal under hyperglycemic conditions. Importantly, the AK/TR mouse provides a useful preclinical model for elucidating mechanisms by which type 1 DM regulates local prostate cancer growth and metastasis. Further studies may lead to therapeutic strategies to prevent prostate cancer and improve urologic health.

Low Intensity Mechanical Signals Slow Tumor Progression and Osteolysis in a Murine Model of Multiple Myeloma. Gabriel Pagnotti^{*1}, Benjamin J. Adler¹, M. Ete Chan¹, Kenneth R. Shroyer², Janet E. Rubin³, Clinton T. Rubin¹. ¹Stony Brook University, USA, ²Stony Brook Medicine, USA, ³University of North Carolina, Chapel Hill, USA

Multiple myeloma (MM), a primary bone cancer, is associated with the rapid and extensive destruction of bone and marrow. Interventions aimed at mitigating this damage fall short due to comorbid outcomes. Mechanical stimuli have been extensively shown to have influence both bone and marrow phenotype. Here we evaluated the ability of low-intensity vibrations (LIV) to protect the quantity and quality of bone morphology and the marrow phenotype in the presence of MM. 25 7w-old immunocompromised mice (NSG, Jackson Laboratory, Bar Harbour, ME) were tail vein-injected with a human MM cell line. 8 mice (AC) were injected with saline for vehicle control. Of the MM-engrafted mice, 13 were subject to mechanical loading (LIV) (15m/d; 0.3g @ 90Hz), while 12 were sham handled (MM). At 8w post-injection, micro-CT quantification of the distal femur showed a 86% (p<0.04) decrease in trabecular bone volume fraction in MM as compared to AC, while Tb.BV/

TV of LIV femurs was only 23% less than AC and 48% greater than MM ($p < 0.05$). Cortical BV/TV of the femoral metaphysis was 16% ($p < 0.03$) lower in MM as compared to AC, as compared to 8% (NSD) lower in LIV than AC. Perforations of the cortex at the distal femur resulting from MM osteolysis, were 52% ($p < 0.002$) fewer in LIV as compared to MM. Histological examination revealed plasmacytoma infiltration throughout both MM (72%) and LIV (50%) femurs; a tumor burden that was 30% lower in LIV from that of MM. The extent of the infiltration of plasmacytoma throughout the marrow correlated to marked reductions in bone quality and integrity ($r = 0.645$; $p < 0.001$). Tartrate-resistant acid phosphatase (TRACP5b), a serum biomarker of osteoclast-mediated resorption, was significantly elevated in MM (60%; $p < 0.001$) and LIV (34%; $p < 0.05$) as compared to AC. However, TRACP5b measured from LIV was 16% ($p < 0.06$) lower than from MM serum. Quantification of skeletal and histological endpoints demonstrate the destructive capability of MM cells as they propagate, significantly and negatively impacting bone quality, and markedly elevating bone resorption of the trabecular and cortical compartments. LIV also appears to slow progression of the disease itself, perhaps reflecting some salutary benefit of mechanical signals on cell activity and/or fate. These data provide some early evidence for the introduction of mechanical signals as a means of ameliorating cancer-induced damage to bone and protecting the marrow microenvironment.

LIV Slows Resorption of Cortical Bone

Characterizing Prostate Cancer Bone Metastasis Using Tissue Engineered Matrices. Sum Ying Chiu^{*1}, Damian Genetos². ¹Anatomy, Physiology & Cell Biology, School of Veterinary Medicine, UC Davis, USA, ²Anatomy, Physiology, & Cell Biology, School of Veterinary Medicine, UC Davis, USA

Purpose:

The American Cancer Society estimates ~28,000 men will die mostly from advanced prostate cancer (PCa) bone metastasis in 2015. The preferential localization of PCa to the skeleton indicates that metastasis is enhanced by PCa cellular response to chemical cues from the bone microenvironment (bone organic matrix). The molecular mechanism of this process is unclear. We propose using tissue engineering with cell and molecular biology assays to identify novel factors critical for PCa cell migration, osteomimicry and secondary tumor formation.

Methods:

To mimic the organic matrix, we created de-cellularized matrices (DM) from human BM-MSCs and treated DM with enzymes (eDM) to abolish growth factor binding sites. The matrices were characterized with staining and protein analysis. Cell response towards DM and eDM was measured in non-osteotropic LNCaP, osteoblastic C4-2B and osteolytic PC-3 PCa cell lines. Migration to DM or eDM was measured through Boyden chamber assays, and gene expression was analyzed *via* qPCR to examine osteomimicry in PCa cells seeded on DM or eDM. DM and eDM were profiled by LC-MS/MS to identify differential matrix components.

Results:

PCa cells showed heterogeneous migration to DM or eDM (Fig. 1). Non-osteotropic LNCaP cells did not specially migrate to DM, and revealed modest migratory capacity to eDM. Osteotropic C4-2B cells revealed significant migration to DM, and this was attenuated with eDM. PC-3 cells did not reveal migration to DM or eDM. Expression of osteogenic genes *RUNX2* and *BGLAP*, and indices of Wnt, BMP and TGF- β signaling, were neither temporally nor matrix-type dependent in all PCa cells.

Coomassie Blue staining and microBCA protein assay showed no qualitative or quantitative difference in homogeneity or total protein in DM vs. eDM; Alcian Blue staining showed reduced growth factor-binding glycosaminoglycans (GAGs) in eDM compared to DM. These data suggest DM and eDM only differ in growth factor presence and not overall matrix deposition (Fig. 2).

Proteomic analysis of DM and eDM identified differential expression of potential metastasis-promoting candidates in matrix proteins associated with TGF- β /BMP/Wnt signaling, including biglycan, decorin and periostin. These continuing studies and future *in vivo* work will expose details on how PCa invades into the bone. This knowledge can lead to metastasis-inhibiting therapies that when combined with treatments targeting primary tumors will finally eradicate PCa.

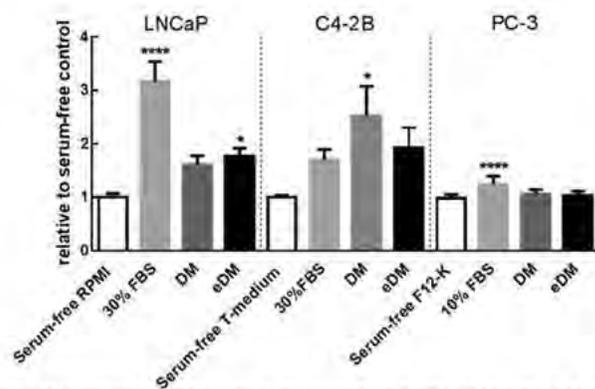

Figure 1. Comparison of DM vs. eDM as chemoattractants for PCa cell lines LNCaP, C4-2B, and PC-3. Migration of LNCaP, C4-2B and PC-3 cells towards DM and eDM were determined using Boyden chamber assay and quantified by detection of fluorescence after Calcein AM staining. All conditions were normalized to migration towards their respective serum-free media control. Bars shows mean (+SEM). The tumor suppressor miRs-30-5p family in the control of metastatic bone disease. Martine Croset^{*1}, Casina Kan¹, Edith Bonnelly², Fransecco Pantano³, Françoise Descotes⁴, Catherine Alix-Panabières⁵, Charles Lecellier⁶, Saw See Hong⁷, Philippe Clézardin¹. ¹INSERM, UMR_S1033, UFR de médecine Lyon-Est, University of Lyon, France, ²INSERM, UMR_S1033, UFR de médecine Lyon-Est university of Lyon, France, ³Medical Oncology Dept.\Translational Oncology Laboratory, Italy, ⁴Service de Biochimie Biologie Moléculaire, Hospices Civils de Lyon, France, ⁵Department of Cellular & Tissular LCCRH Biopathology of Tumors, University Medical Centre, France, ⁶Université Montpellier 1, France, ⁷Université Lyon 1, UCBL-INRA-EPHE UMR-754, France

Bone metastasis is a common complication of advanced breast cancer. Breast tumor cells that escape the primary tumor to invade the bone marrow (BM) express a

set of deregulated genes and/or microRNAs (miRs) that facilitate BM engraftment which may lead to the formation of overt osteolytic lesions. Comparative expression of miRs in human breast cancer cell lines, MDA-MB-231 (non-osteotropic), MDA-B02 (an osteotropic subpopulation of MDA-MB-231) and micrometastases from BM aspirate (BC-M1) identified the miR-30 family (miR-30s) as being down-regulated in osteotropic cell lines MDA-B02 and BC-M1. The role of miR-30s in the formation of bone micrometastases and subsequent development of overt osteolytic lesions was therefore investigated.

MDA-B02 cells were transduced with a retroviral vector containing the genomic sequences for miR-30s (MDA-B02-miR-30s) and injected in the tail artery of immunodeficient mice. X-ray and histomorphometric analyses showed that mice bearing MDA-B02-miR-30 tumors developed osteolytic lesions that were significantly smaller than those of mice bearing MDA-B02. The inhibitory effect of miR-30s on tumor-induced bone destruction was confirmed by the significant increase of bone volume/tissue volume ratio in tibias from mice injected with MDA-B02-miR-30 (14.1% \pm 1.7 vs 26.6% \pm 2.7 p<0.01). This was associated with a decrease in tumor burden/tissue volume ratio (45.2% \pm 5.4 vs 21.7% \pm 6.1 p<0.01) and a decrease of TRAP-positive osteoclast surface at the bone/tumor cell interface (77.4% \pm 8.1 vs 41.7% \pm 16.5 p<0.05). Consistent with these *in-vivo* data, conditioned medium from MDA-B02-miR-30s (CM-miR-30s) decreased the formation of TRAP-positive multinucleated osteoclasts and IL-11 and IL-8 concentration in CM. The mineralization of bone nodules induced by MC3T3-E1 osteoblastic cells was inhibited in the presence of CM from MDA-B02 cells and this inhibitory effect was repressed by miR-30s through a decreased production of the Wnt inhibitor *Dkk1* in the CM. Osteotropic and osteomimetic gene expression (*ITGbb3*, *ITGa5*, *CDH11*, *RUNX2*, *CTGF*, *CX43*) was down-regulated in MDA-B02-miR-30s cells. The invasiveness of MDA-B02-miR30s cells was also decreased *in-vitro*. In the clinic, low miR-30s expression in primary tumors from patients with breast cancer was associated with poor relapse-free survival. We conclude that miR-30s control breast cancer cell invasion in the BM and the formation of overt skeletal lesions in tumor-bearing animals.

Effects of ONO-5334, a Cathepsin K Inhibitor, on Bone Volume and Bone Turnover Markers in a Rabbit VX2 Carcinoma Induced Bone Osteolysis Model. YASUO OCHI*, YASUTOMO NAKANISHI, YASUAKI HASHIMOTO, SATOSHI NISHIKAWA, HIROYUKI YAMADA, HIROSHI MORI, SHINSEI FUJIMURA, MAKOTO TANAKA, KAZUHIITO KAWABATA, ONO Pharmaceutical Co., LTD., Japan

Osteolytic bone metastasis can cause a broad range of symptoms that could impair a quality of life in cancer patients. ONO-5334 is a small molecule and an orally-active inhibitor of cathepsin K. In this study, we evaluated the effect of ONO-5334 on bone volume and bone turnover markers in a rabbit bone osteolysis model induced by VX2 carcinoma. VX2 carcinoma cells or phosphate buffered saline (PBS) was intratibially transplanted in female New Zealand White rabbits. Seven days after the transplantation (day 7), VX2-transplanted rabbits were assigned to one of the following 5 groups (8-9 animals/group): vehicle-treated (Cont), ONO-5334 (1.2, 6 or 30 mg/kg) or zoledronic acid (ZOL, 0.06 mg/kg), based on a value of plasma tartrate-resistant acid phosphatase (TRAP) activity. ONO-5334 or vehicle was orally administered once daily from day 8 to 20, and ZOL was administered intravenously in a single dose on day 8. Osteolysis in the isolated proximal tibia was evaluated by peripheral quantitative computed tomography (total and cortical bone mineral content (BMC) at 5 and 10% of total tibia length from the proximal end) and χ CT (trabecular bone volume, number, thickness and separation, measurement area: 2.5 - 6% of total tibia length from the proximal end) on day 21, and urine helical peptide (HP) concentration and plasma TRAP activity were measured. Transplantation of VX2 carcinoma caused a significant decrease in total and cortical BMC and also caused a significant deterioration in trabecular architectures (all parameters, p<0.05 vs PBS). ONO-5334 significantly increased total and cortical BMC (1.2, 6 and 30 mg/kg), and significantly improved trabecular bone volume (1.2 and 30 mg/kg), number (30 mg/kg), thickness (1.2 and 6 mg/kg) and separation (30 mg/kg) compared to Cont (p<0.05). ZOL significantly improved all of the parameters except for the trabecular separation (p<0.05 vs Cont). In bone turnover markers, transplantation of VX2 carcinoma caused a significant increase in TRAP activity (p<0.01 vs PBS). ONO-5334 significantly decreased HP (all doses, p<0.01 vs Cont) but did not affect TRAP activity. ZOL significantly decreased both HP and TRAP activity (p<0.01 vs Cont). These results suggest that ONO-5334, unlike ZOL, inhibited a bone resorption without influence on osteoclast survival and improved both trabecular and cortical osteolysis induced by VX2 carcinoma. Thus, ONO-5334 may become a novel oral therapy for treatment of osteolytic bone metastasis.

Elevated and persistent cAMP-Creb1 pathway activation is essential for the maintenance of osteosarcoma. Mannu Walia*¹, Patricia Ho², Alvin Ng², Ankita Gupte², Alistair M. Chalk², T. John Martin², Carl Walkley². ¹St Vincents Institute of medical research, Australia, ²St Vincents Institute of Medical Research, Australia

Osteosarcoma (OS) is the most common primary tumor of bone. Several studies highlight that alterations in the cyclic AMP (cAMP)/protein kinase A (PKA) pathway are important in OS, although this has not been functionally evaluated. There are three main subtypes of osteosarcoma (OS) (osteoblastic, fibroblastic and chondroblastic). We have generated the fibroblastic subtype in mice using deletion of p53 and pRb from the osteoblast-lineage, and the osteoblastic subtype by shRNA-mediated knockdown of p53 within the lineage. All the primary and metastatic tumors from either subtype express PTHR1, and PTHrP. Elevated generation of cAMP and persistent downstream signaling through Creb1 are characteristics of these OS, with the activation pathway greater in osteoblastic OS than in fibroblastic OS. Creb1 was phosphorylated more prominently in the osteoblastic than in either the fibroblastic OS or primary osteoblasts, and the mean expression of Creb1 mRNA was 2-3 fold higher in osteoblastic OS compared to fibroblastic OS and primary osteoblasts. Greater than 95% knockdown of Creb1 using shRNAs greatly increased apoptosis and reduced OS proliferation, as did similar knockdown of PTHrP (proliferation reduced by 40-60%), revealing that OS requires sustained PTHrP-cAMP-Creb1 activity for proliferation and survival. Loss of Creb1 in fibroblastic OS cells resulted in significantly reduced proliferation. Knockdown of Creb1 in osteoblastic OS caused a profound proliferation arrest and loss of viability, thus showing the dependence of osteoblastic OS on Creb1 is greater than that of fibroblastic OS, revealing a genetic difference between the OS subtypes. In order to test for autocrine regulation via PTHrP, cyclic AMP was assayed after OS cells were incubated without agonist, in the presence of IBMX. Cyclic AMP accumulation was ablated when either PTHrP or PTHR1 were knocked down by shRNA, and was inhibited by 80% when a neutralizing antibody against PTHrP was included in incubations. Furthermore knockdown of PTHrP resulted in 50% inhibition of growth of each of two explanted fibroblastic OS cell lines, as shown previously with PTHR1 knockdown in these cells. These findings identify an autocrine/paracrine circuit of PTHrP-PTHr1-cAMP-Creb1 as a critical proliferation and survival pathway in OS, with PTHrP as the autocrine/paracrine driver. These results demonstrate that constitutively active and enhanced cAMP signaling is oncogenic in OS

Human Breast Cancer Cell Derived PTHrP Reduces Osteoblast Cell Death and Apoptosis Induced by Potential Anticancer Compounds. Sahiti Chukkappalli¹, Magesh Muthu², Arun Rishi³, Nabanita Datta^{*1}. ¹Wayne State University School of Medicine, USA, ²Karmanos Cancer Institute, USA, ³Wayne State University, USA

Breast cancers with advanced disease metastasize to the skeleton. Although osteoclasts are largely responsible for osteolytic metastatic lesions, osteoblasts themselves are negatively affected by metastatic breast cancer. Current clinical strategies are primarily focused on inhibiting the tumor-induced osteoclastic osteolysis. There is a critical need to minimize chemotherapy associated side effects in bone by restoring osteoblast function while preventing osteolysis, and reduce the risk of worsening the disease. Therefore development of new anti-cancer agents that have superior efficacy and minimal toxicity is warranted. Cell cycle and apoptosis regulatory protein (CARP)-1 (aka CCAR1) is a novel regulator of signaling by diverse agents including cell growth and differentiation factors, and chemotherapy-dependent apoptosis. The therapeutic potential of CARP-1 functional mimetics (CFMs)-4 and -5 for triple negative human breast cancer (TNBC) cells has been recently shown in vitro and in xenograft studies. Our in vitro and in vivo studies revealed that CARP-1 is present in osteoblasts and CFM-4 and -5 cause osteoblast cell death and apoptosis correlated with caspase-3 activation and cyclin D1 down-regulation. Parathyroid hormone-related peptide (PTHrP) is a secretory protein associated with many tumors including breast cancer. In this study we investigated the role of MDA-MB-231 TNBC cell-derived PTHrP on MC3T3-E1 (MC-4) osteoblast with CFM-4 and -5 treatments. MC-4 cells, either in normal differentiation media, or in condition media (CM) derived from serum starved MDA-MB-231 cells, were treated with or without 10 μ M dose of respective CFMs overnight. ApoAlert caspase profiling indicates that CFM-4 or -5 dependent caspase-3 activation was reduced by 1.6- 3-fold in the presence of CM. Neutralizing CM with anti PTHrP antibody failed to attenuate caspase-3 activation. The QPCR and/or Western blot analysis revealed a 2-4 fold down-regulation of cyclin D1, but not CARP-1 expression by CFMs in the CM with or without PTHrP neutralization. These data indicate that PTHrP from TNBC cells likely antagonizes osteoblast apoptosis by CFMs. On the other hand, regulation of cyclin D1 by CFMs maintains G1-phase arrest of mature osteoblasts that permits continued extracellular matrix production. The present study provides the first proof-of-principle evidence that PTHrP regulates signaling by potential anticancer agents to benefit osteoblast survival.

Discoidin Receptor 2 is Necessary for In Vitro TMJ Chondrocyte Differentiation While Its Absence is Associated with Aging Related TMJ Degeneration. Chunxi Ge^{*1}, Yan Li², Hanshi Sun², Sunil Kapila², Renny Franceschi². ¹Pom Univ of Michigan School of Dentistry, USA, ²University of Michigan, USA

Temporomandibular joint disorder (TMJD), a relatively common condition, is associated with development of osteoarthritis (OA)-like degenerative changes in the mandibular condyle. Discoidin Receptors 1 and 2 (DDR1/2), are associated with OA formation in hyaline cartilage and may also be similarly relevant in TMJD. As recently reported, the selective development of TMJ-OA in Ddr1 knockout mice is accompanied by compensatory up-regulation of DDR2 (Schminke et al Cell Mol Life Sci 71:1081, 2014).

To test whether DDR2 can drive OA-like hypertrophic differentiation/mineralization of TMJ fibrocartilage, DDR2 levels were modified in established TMJ chondrocyte cell lines using lentivirus-mediated shRNA knockdown of DDR1 or overexpression of DDR2. Cells were cultured in chondrogenesis medium for 15 days and differentiation was measured by Alcian Blue and Alizarin Red staining. Expression of chondrocyte differentiation marker and OA associated gene mRNAs were measured by quantitative RT/PCR. The spontaneous development of TMJ degeneration in 10 month-old smallie (slie) mice harboring a spontaneous 150 kb deletion in Ddr2 gene was analyzed by microCT.

Ddr1 shRNA was shown to knockdown DDR1 levels by more than 50%. DDR1 knockdown was associated with up-regulation of DDR2, MMP13 and VEGF mRNA. Lentivirus-mediated DDR2 overexpression in TMJ cells resulted in dramatically increased DDR2 protein levels as compared to very low levels of endogenous DDR2 in control cells. DDR2 overexpressing cells had an enlarged chondrocyte-like appearance after 5 days of chondrogenesis induction. After 15 days, these cells formed increased numbers of mineralizing nodules and expressed hypertrophic cartilage marker genes (Collagen X and MMP13) as well as RUNX2 and osteocalcin. Paradoxically, 100% of 10 month-old Ddr2(slie/slie) mice developed severe spontaneous TMJ degeneration while only 12% of wild type mice showed slight TMJ degeneration. MicroCT analysis showed dramatic bone loss in the TMJ of Ddr2(slie/slie) mice compared to wild type litter mates. Three dimensional reconstruction of the mandibular condyles of Ddr2(slie/slie) mice showed a rough, flattened bone surface and increased TMJ joint space. The bone mineral density of mandibular condyle surface was greatly decreased in Ddr2(slie/slie) mice compared to wild type littermates.

These studies indicate that appropriate expression of DDR2 is required for normal TMJ chondrocyte differentiation and maintenance of an intact TMJ.

High fat diet compromises articular cartilage thickness relative to body weight, while low intensity mechanical signals protects this relationship, building cartilage relative to body size. Tee Pamon^{*}, Vincent Bhandal, Mei Lin Chan, Patryk Krzesaj, Clinton Rubin. Stony Brook University, USA

Obesity is a risk factor for osteoarthritis, a degenerative joint disease characterized by joint pain and immobility. The elevated risk has been attributed to higher joint loading due to body weight. Since obesity has been associated with the disruption of bone formation, it is possible that cartilage formation is also impeded. Recent evidence has shown that low intensity vibration (LIV) protects mesenchymal stem cell (MSC) lineage selection towards the formation of higher order connective tissues, and we sought to determine if these signals could protect the formation of AC in spite of the obese phenotype. C57BL/6 male, 5w mice were separated into 3 groups (n=10): Regular diet (RD), High fat diet (HF), and High fat diet + LIV (HFv). 2w of high fat diet were given to HF and HFv. LIV (90Hz, 0.2g, 30 min/d, 5 d/w) was then administered to HFv for 6 wks, with all groups continuing their respective diets. The R tibias were extracted, and the AC and subchondral bone (SB) of the tibial plateau were visualized using contrast agent enhanced μ CT. AC and SB thickness were measured within a 480um ROI, centered at the midpoint of the medial condyle. Means reported, and the one-way ANOVA was used to detect differences between groups; a p-value<0.05 was considered statistically significant. After 8 wks of high fat diet, AC thickness between RD and HF animals was not statistically different. However, these similarities in thickness reflect a failure of AC to adapt to increased mechanical demands relative to the 17.2% increase in body weight in HF (p=0.006), a weight gain similar to LIV. More specifically, HF exhibited a lower thickness/weight ratio compared to RD (-27.0%, p=0.03). In contrast, LIV stimulated a 46% increase in AC thickness as compared to HF (p=0.001), as well as a 51% higher thickness/weight ratio (p=0.002), levels n.s.d. from RD. SB thickness and mineralization were not different between groups, however, the medial condyle width of the HF group increased compared to RD and LIV groups (~3%, p<0.05). Resisting loading challenges is a major function of cartilage, a goal that seemingly was not achieved in the obese controls. Introducing dynamic mechanical signals, however, appears to have 'activated' the adaptive goals of the musculoskeletal system, with LIV driving AC thickness towards a more suitable support structure.

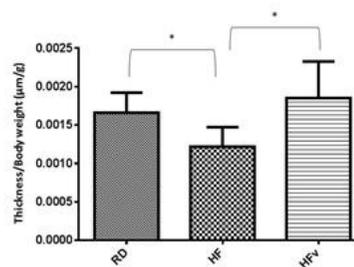

Figure 1: When AC thickness is normalized to body weight, HF has a significantly lower ratio compared to RD, and the relationship is protected with LIV.

AC Thickness normalized to body weight

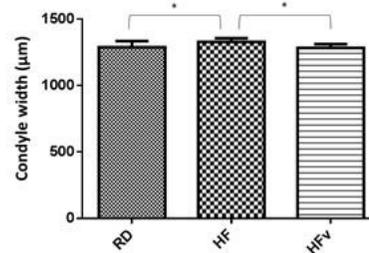

Figure 2: The medial condyle is wider in HF compared to both RD and HFv groups.

In Vivo Identification and Induction of Articular Cartilage Stem cells by Inhibiting NF- κ B Signaling in osteoarthritis. Xiaoling Zhang¹, Wenxue Tong^{*2}, Yiyun Geng². ¹Institute of Health Sciences, Peoples republic of china, ²The Key Laboratory of Stem Cell Biology, Institute of Health Sciences, Shanghai Jiao Tong University School of Medicine (SJTUSM) & Shanghai Institutes for Biological Sciences (SIBS), Chinese Academy of Sciences (CAS), Shanghai 200025, China, China

Abstract

Osteoarthritis (OA) is a highly prevalent and debilitating joint disorder characterized by the degeneration of articular cartilage. However, no effective medical therapy has been found yet for such condition. In this study, we directly confirmed the existence of articular cartilage stem cells (ACSCs) in vivo and in situ for the first time both in normal and OA articular cartilage, and explored their chondrogenesis in Interleukin-1 β induced inflammation environment and disclose whether the inhibition of NF- κ B signaling can induce ACSCs activation thus improve the progression of experimental OA. We found an interesting phenomenon that ACSCs were activated and exhibited a transient proliferative response in early OA as an initial attempt for self-repair. During the in vitro mechanism study, we discovered IL-1 β can efficiently activate the NF- κ B pathway and potently impair the responsiveness of ACSCs, whereas the NF- κ B pathway inhibitor rescued the ACSCs chondrogenesis. The final in vivo experiments further confirmed ACSCs' activation were maintained by NF- κ B pathway inhibitor, which induced cartilage regeneration, and protected articular cartilage from injury in an OA animal model. Our results provided in vivo evidence of the presence of ACSCs, and disclosed their action in the early OA stage and gradual quiet as OA process, presented a potential mechanism for both cartilage intrinsic repair and its final degradation, and demonstrated the feasibility of inducing endogenous adult tissue-specific mesenchymal stem cells for articular cartilage repair and OA therapy.

Male Estrogen Receptor Beta KO mice Develop TMJ Degeneration. Sunil Wadhwa, Jing chen, Manshan Xu*, Jennifer Robinson, Alina O'Brien, Thomas Choi. Columbia University, USA

Introduction-Temporomandibular joint diseases (TMD) are a collection of diseases that afflict over 20 million Americans. One form of chronic TMD is TMJ joint degeneration. TMJ degeneration occurs in an older age group (mean age 55) than other TMD diseases and accounts for 35-50% of the people who seek treatment. Women most often seek treatment suggesting a role of estrogen in the disease process. However, conflicting reports indicate the role of estrogen either in potentiating or inhibiting the degenerative process. It is known that WT mice develop mild age related TMJ degeneration at 12 months of age. Therefore, the goal of this project was to evaluate the effect of estrogen through estrogen receptor β (ER β) on TMJ degeneration at 12 months.

Material and Methods- TMJ condyle was dissected and sectioned from male C57Bl/6 WT and ER β KO 4-month old (n=12) and 12-month old (n=6) mice. Histomorphometry was conducted to determine cartilage thickness and cell numbers. Cell proliferation was measured by BrdU labelling and quantification. Histopathology of TMJ degeneration was conducted using OARSJ scoring.

Results- No significant difference was observed in any of the parameters comparing 4-month old ER β KO mice to age-matched WT controls. At 12 months of age, a significant increase in histopathological scoring of TMJ degeneration was observed in 12-month old male ER β KO mice (4 +/- 1) compared to male WT mice (2 +/- 1).

Conclusion- These results may suggest that ER β signaling delays TMJ degeneration in older mice.
